Requirements

- The CPU must be in the RUN mode.
- The project has been created and downloaded to the CPU.
- The technology object is disabled by your user program ("MC_Power.Enable" = FALSE).
- The axis control panel for the technology object is not used by another installation of the TIA Portal.
- The axis has been enabled for commissioning.

Procedure for SINAMICS drives with DSC configured with Startdrive

To optimize the position controller, follow these steps:

1. Configure values for the distance, duration, and dynamics of a test step in the "Measurement configuration" area.
2. Click the green arrow at "Optimize values in drive".

   You go to the optimization of the drive in Startdrive.
3. Optimize the controller automatically in Startdrive using One Button Tuning (OBT).
4. Navigate back to the optimization of the axis.

   The "Drive optimized" display is green.
5. Click the "Take values from drive" button.

   The following values are taken:

   – Gain (Kv factor): The technology object takes 50% of the value from the drive (r5276).
   – Speed control loop substitute time: The technology object adopts the value from the drive (r5277).

   The online values of the drive are applied when they are connected to the drive online in SINAMICS Startdrive. The offline values of the drive are applied when they are not connected to the drive online in SINAMICS Startdrive.
6. Click the "Forward" or "Backward" button to start a test step for optimization in the positive or negative direction.

   A setpoint is output for the specified duration according to the specified distance. The axis moves by the specified distance. A trace recording of the motion (setpoint and actual values) is created automatically in the "Trace" area.
7. Evaluate the trace recording.
8. If you are not yet satisfied with the optimization result, continue to adjust the gain (KV).
9. Apply the optimized parameters in the project.

Procedure for SINAMICS drives with DSC configured without Startdrive

Requirements: You have carried out a One Button Tuning (OBT) controller optimization in the configuration of the drive. If you use an alternative method for controller optimization in drive, then proceed as with the other drives.

To optimize the position controller, follow these steps:

1. If necessary, configure values for the distance, duration, and dynamics of a test step in the "Measurement configuration" area.
2. Configure the following values as actual values in the "Optimize position controller" area:
   - Gain (Kv factor): Apply 50% of the value from the parameter "r5276" of the drive to the technology object.

     Note that: Kv(TO) = 0.5 · 16.66666 · Kv(r5276)
   - Speed control loop substitute time: Apply the value from the parameter "r5277" of the drive to the technology object.

     Note that: vtc(TO) = 0.001 · vtc(r5277)
3. Click the "Forward" or "Backward" button to start a test step for optimization in the positive or negative direction.

   A setpoint is output for the specified duration according to the specified distance. The axis moves by the specified distance. A trace recording of the motion (setpoint and actual values) is created automatically in the "Trace" area.
4. Evaluate the trace recording.
5. If you are not yet satisfied with the optimization result, continue to adjust the gain (KV).
6. Apply the optimized parameters in the project.

Procedure for other drives

You use the procedure described here for the following drives:

- SINAMICS drives with DSC that are not optimized with OBT
- SINAMICS drives without DSC
- Third-party drives

To optimize the position controller, follow these steps:

1. In the "Master control" area, click the "Activate" button to activate master control for the technology object, and to establish an online connection to the CPU.

   A warning message is displayed.
2. In the "Axis" area, click the "Enable" button to enable the technology object.
3. Configure values for the distance and dynamics of a test step in the "Measurement configuration" area. Select a sufficiently long measurement duration to record the entire measurement with the trace. If the measurement duration is too short, you will see a warning when entering the value.

4. Configure the following values as actual values in the "Optimize position controller" area:
   - Precontrol: 0.0
   - Speed control loop substitute time: 0.0
   - Gain (Kv factor): 10.0
5. Click the "Forward" or "Backward" button to start a test step for optimization in the positive or negative direction.

   To traverse the specified distance, a trapezoid velocity profile is used. The velocity profile is calculated from the specified dynamic parameters and the distance. A trace recording of the motion (setpoint and actual values) is created automatically in the "Trace" area.

   NOTE

   Check whether the current or torque limitation is active in the drive. To get a meaningful trace recording, both limitations should not be active during optimization. To check this, record the tag "<TO>.StatusTorqueData.ActualTorque" when using telegram 750 or check the limitations directly in the drive.

6. Evaluate the trace recording.
7. If required, increase in "measurement configuration" the values you use for "acceleration" and "deceleration".
8. Configure the following values as actual values in the "Optimize position controller" area:
   - Precontrol: 100.0
   - Speed control loop substitute time: 0.0
   - Gain (Kv factor): 90% of the determined value
9. Adjust the speed control loop equivalent time until no more overshoots occur.
10. Apply the optimized parameter values as start values in the project.

Evaluating trace recordings

The trace recordings are not saved. Note the following properties of the curve:

- The curve shows a brief compensation time.
- The curve does not show any motion reversal of the actual position.
- When approaching the position setpoint, no overshoot occurs.
- The curve shows a stable overall behavior (oscillation-free curve).

The following trace recording shows a curve with a long settling time:

The following trace recording shows a curve with overshoot when approaching the setpoint:

The following trace recording shows a curve in which the gain is optimal and the overall response is steady:

Adjust gain (Kv factor)

Proceed as follows to adapt the gain (Kv factor):

1. Increase the value with each test step, e.g. by 5%. If there is no major change in the control behavior, then select larger steps.
2. Click the "Forward" or "Backward" button to start another test step for optimization in the positive or negative direction.
3. Evaluate the trace recording.
4. Repeat steps 1 to 3 until no more overshoots occur in the trace recording.

Adjust speed control loop substitute time

With velocity precontrol, a simplified speed control loop model can be generated using the speed control loop substitute time. This prevents the velocity variable being overridden by the position controller during the acceleration and deceleration phases. To accomplish this, the position setpoint of the position controller is delayed by the amount of the speed control loop substitute time in relation to the velocity precontrol. Proceed as follows to adapt the speed control loop equivalent time:

1. Increase the value with each test step, e.g. by 1 ms.
2. On "Forward" or "Backward", perform another test step.
3. Evaluate the trace recording.
4. Repeat steps 1 to 3 until no more overshoots occur in the trace recording.

Transferring the optimized parameter values of the position controller to the project

To transfer the optimized parameter values of the position controller to your project, follow these steps:

1. Click the icon next to the field of the respective parameter.

   A list of values is displayed.
2. Enter the determined value in the "Start value project" field of the value list. The value is then transferred to the configuration of the technology object in the project.
3. In the "Axis" area, click the "Disable" button to disable the technology object.
4. In the "Master control" area, click the "Deactivate" button to return master control to your user program.
5. Load your project into the CPU.

More information

For more information about axis control and axis optimization, refer to Siemens Industry Online Support in the FAQ entry 109779884 (https://support.industry.siemens.com/cs/ww/en/view/109779884).

7.8 Disable axis and hand over master control

NOTE

No automatic transfer of the parameters to the technology object

The configured parameter values are discarded after master control is returned.

Transfer the values as needed into your configuration. You can apply the values for the gain, precontrol and speed control loop equivalent time in your configuration using the "Project start value" value.

Requirement

- The axis is enabled in the axis control panel/optimization.
- The enabled technology object accepts Motion Control jobs.
- Speed control and position control are active.
- The actual values of the technology object are valid.

Procedure

Follow these steps to disable the axis and hand over the master control using the axis control panel or optimization:

1. To disable the technology object, click the "Disable" button in the "Axis" area.
2. To return master control to your user program, click the "Deactivate" button in the "Master control" area.

Diagnostics 8

The description of Motion Control diagnostics is limited to the diagnostics view of the technology objects in TIA Portal, the technology alarms and the error IDs on Motion Control instructions.

"Debug" program mode is available for testing the execution of your Interpreter program.

The following descriptions can be found in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation:

- Diagnostics concept
- Technology alarms
- Error IDs in Motion Control instructions

A comprehensive description of the system diagnostics of the S7-1500 CPU can be found in the "Diagnostics" function manual (https://support.industry.siemens.com/cs/ww/en/view/59192926).

8.1 Speed-controlled axis technology object

8.1.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Axis status

The following table shows the possible axis status values:

Status	Description
Simulation active	The axis is simulated in the CPU or used as the virtual axis. Setpoints are not output to the drive.
Enabled	The technology object has been enabled. The axis can be moved with motion jobs. (<TO>.StatusWord.X0 (Enable))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is reinitialized. (<TO>.StatusWord.X2 (RestartActive))

Status	Description
Axis control panel enabled	The axis control panel is active. The axis control panel has master control over the technology object. The axis cannot be controlled from the user program. (<TO>.StatusWord.X4 (ControlPanelActive))
Drive ready	Drive is ready to execute setpoints. (<TO>.StatusDrive.InOperation)
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Motion status

The following table shows the possible axis motion status values:

Status	Description
Done (no job running)	There is no active motion job at the technology object. (<TO>.StatusWord.X6 (Done))
Jog	The axis is being moved with a job for jog mode of Motion Control instruction "MC_MoveJog" or from the axis control panel. (<TO>.StatusWord.X9 (JogCommand))
Speed setpoint	The axis is traversed with a job with speed setpoint of the Motion Control instruction "MC_MoveVelocity" or using the axis control panel. (<TO>.StatusWord.X10 (VelocityCommand))
Constant speed	The axis is moved with constant speed or is stationary. (<TO>.StatusWord.X12 (ConstantVelocity))
Accelerating	Axis is being accelerated. (<TO>.StatusWord.X13 (Accelerating))
Decelerating	The axis is being decelerated. (<TO>.StatusWord.X14 (Decelerating))
Torque limit active	At least the threshold value (default 90%) of the preset force/torque limitation acts on the axis. (<TO>.StatusWord.X27 (InLimitation))
Active stop job	The axis is stopped and disabled by Motion Control instruction "MC_Stop". (<TO>.StatusWord2.X0 (StopCommand))

Warnings

The following table shows the possible warnings:

Warning	Description
Configuration	One or several configuration parameters are adjusted internally at a certain time. (<TO>.WarningWord.X1 (ConfigWarning))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because the necessary conditions have not been met. (<TO>.WarningWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.WarningWord.X6 (DynamicWarning))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Drive	An error occurred in the drive. (<TO>.ErrorWord.X4 (DriveFault))
Data exchange	Communication with a connected device is faulty. (<TO>.ErrorWord.X7 (CommunicationFault))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because necessary requirements have not been met (e.g. technology object not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.ErrorWord.X6 (DynamicError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

"StatusWord" tag (speed axis) (Page 403)
"ErrorWord" tag (speed axis) (Page 405)
"WarningWord" tag (speed axis) (Page 406)

8.1.2 Motion status

You use the "Technology object > Diagnostics > Motion status" diagnostic function in the TIA Portal to monitor the motion status of the axis. The diagnostics function is available in online operation.

"Setpoints" area

The following table shows the meaning of the status data:

Status	Description
Speed setpoint	Speed setpoint of the axis (<TO>.Velocity)
Speed override	Speed setpoint correction as percentage The speed setpoint specified in Motion Control instructions or set by the axis control panel is superimposed with an override signal and corrected as a percentage. Valid speed correction values range from 0.0 % to 200.0 %. (<TO>.Override.Velocity)

"Current values" area

The following table shows the meaning of the status data:

Status[1]	Description
Speed on load side	Speed of the axis on the load side (<TO>.Velocity)
Speed on motor shaft	Actual speed of the axis at the motor shaft (<TO>.ActualSpeed)

[1] At the virtual axis, only the "Speed on load side" value is displayed (<TO>.Velocity).

"Dynamic limits" area

This area displays the limit values for the dynamic parameters.

The following table shows the meaning of the status data:

Status	Description
Speed	Configured maximum speed (<TO>.DynamicLimits.MaxVelocity)
Acceleration	Configured maximum acceleration (<TO>.DynamicLimits.MaxAcceleration)
Deceleration	Configured maximum deceleration (<TO>.DynamicLimits.MaxDeceleration)
Jerk	Configured maximum jerk (<TO>.DynamicLimits.MaxJerk)

8.1.3 PROFIdrive telegram

The "Technology object > Diagnostics > PROFIdrive telegram" diagnostics function is used in the TIA Portal to monitor the PROFIdrive telegram that the drive returns to the controller. The Diagnostics function is available in online operation.

"Drive" area

This area displays the following parameters contained in the PROFIdrive telegram from the drive to the controller:

- Status words "ZSW1" and "ZSW2"
- The speed setpoint (NSET) that was output to the drive
- The actual speed that was signaled from the drive (NACT)

8.2 Positioning axis technology object

8.2.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Axis status

The following table shows the possible axis status values:

Status	Description
Simulation active	The axis is simulated in the CPU or used as the virtual axis. Setpoints are not output to the drive. (<TO>.StatusWord.X25 (AxisSimulation))
Enabled	The technology object has been enabled. You can move the axis with motion jobs. (<TO>.StatusWord.X0 (Enable))
Position-controlled mode	The axis is in position-controlled mode. (Inversion of <TO>.StatusWord.X28 (NonPositionControlled))
Homed	The technology object is homed. The relationship between the position in the technology object and the mechanical position was successfully created. (<TO>.StatusWord.X5 (HomingDone))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Axis control panel enabled	The axis control panel is active. The axis control panel has master control over the technology object. You cannot control the axis from the user program. (<TO>.StatusWord.X4 (ControlPanelActive))
Drive ready	Drive is ready to execute setpoints. (<TO>.StatusDrive.InOperation)
Encoder values valid	The actual encoder values are valid. (<TO>.StatusSensor[1].State)
Encoder values valid (S7-1500T)	The actual encoder values of encoder 1, encoder 2, encoder 3 or encoder 4 are valid. (<TO>.StatusSensor[1..4].State)
Active encoder (S7-1500T)	The encoder in effect operationally is encoder 1, encoder 2, encoder 3 or encoder 4. (<TO>.OperativeSensor)

Status	Description
Encoder homed	Encoder is homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment (<TO>.StatusSensor[1].Adjusted)
Encoder homed (S7-1500T)	Encoder 1, encoder 2, encoder 3 or encoder 4 is homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment (<TO>.StatusSensor[1..4].Adjusted)
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Status limit switch

The following table shows the possibilities for enabling the software and hardware limit switches:

Status	Description
Negative SW limit switch approached.	The negative software limit switch has been approached. (<TO>.StatusWord.X15 (SWLimitMinActive))
Positive SW limit switch approached.	The positive software limit switch has been approached. (<TO>.StatusWord.X16 (SWLimitMaxActive))
Negative HW limit switch approached	The negative hardware limit switch has been approached or overtraveled. (<TO>.StatusWord.X17 (HWLimitMinActive))
Positive HW limit switch approached.	The positive hardware limit switch has been approached or overtraveled. (<TO>.StatusWord.X18 (HWLimitMaxActive))

Motion status

The following table shows the possible axis motion status values:

Status	Description
Done (no job running)	No job active at technology object. (<TO>.StatusWord.X6 (Done))
Homing job	The technology object executes a homing job of the Motion Control instruction "MC_Home" or from the axis control panel. (<TO>.StatusWord.X11 (HomingCommand))
Jog	The axis is being moved with a job for jog mode of Motion Control instruction "MC_MoveJog". (<TO>.StatusWord.X9 (JogCommand))

Status	Description
Velocity specification	The axis is traversed with a job with velocity specification of the Motion Control instruction "MC_MoveVelocity" or from the axis control panel. (<TO>.StatusWord.X10 (VelocityCommand))
Positioning job	The axis is traversed with a positioning job of the Motion Control instruction "MC_MoveAbsolute", "MC_MoveRelative", "MC_PositionProfile" or of the axis control panel (OR logic operation). (<TO>.StatusWord.X8 (PositioningCommand); <TO>.StatusWord2.X9 (PositionProfileCommand))
Constant velocity	The axis is moved with constant velocity or is stationary. (<TO>.StatusWord.X12 (ConstantVelocity))
Standstill	The axis is at a standstill. (<TO>.StatusWord.X7 (StandStill))
Accelerating	Axis is being accelerated. (<TO>.StatusWord.X13 (Accelerating))
Decelerating	The axis is being decelerated. (<TO>.StatusWord.X14 (Decelerating))
Torque limit active	At least the threshold value (default 90%) of the preset force/torque limitation acts on the axis. (<TO>.StatusWord.X27 (InLimitation))
Active stop job	The axis is stopped and disabled by Motion Control instruction "MC_Stop". (<TO>.StatusWord2.X0 (StopCommand))
Superimposed motion	The motion of the axis is superimposed by at least one superimposing Motion Control instruction (OR logic operation). (<TO>.StatusWord.X23 (MoveSuperimposedCommand); <TO>.StatusWord2.X6 (MotionInSuperimposedCommand); <TO>.StatusWord2.X8 (MotionInSuperimposedAxesCommand); <TO>.StatusWord2.X7 (HaltSuperimposedCommand))

Warnings

The following table shows the possible warnings:

Warning	Description
Configuration	One or more configuration parameters are being internally adapted temporarily. (<TO>.WarningWord.X1 (ConfigWarning))
Job rejected	Job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled. (<TO>.WarningWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.WarningWord.X6 (DynamicWarning))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Drive	An error occurred in the drive. (<TO>.ErrorWord.X4 (DriveFault))
Encoder	An error occurred in the encoder system. (<TO>.StatusSensor[1].Error)
Encoder (S7-1500T)	An error has occurred in the encoder system of encoder 1, encoder 2, encoder 3 or encoder 4. (<TO>.StatusSensor[1..4].Error)
Data exchange	Communication with a connected device is faulty. (<TO>.ErrorWord.X7 (CommunicationFault))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))
Job rejected	A job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled (for example, technology object not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
Homing	An error occurred during a homing process. (<TO>.ErrorWord.X10 (HomingFault))
Positioning	The positioning axis was not positioned correctly at the end of a positioning motion. (<TO>.ErrorWord.X12 (PositioningFault))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.ErrorWord.X6 (DynamicError))
Following error	The maximum permitted following error has been exceeded. (<TO>.ErrorWord.X11 (FollowingErrorFault))
SW limit switch	A software limit switch has been reached. (<TO>.ErrorWord.X8 (SwLimit))
HW limit switch	A hardware limit switch has been reached or overtraveled. (<TO>.ErrorWord.X9 (HWLimit))
Adaptation	An error occurred during data adaption. (<TO>.ErrorWord.X15 (AdaptionError))
Superimposing	An error has occurred during the superimposing of the axis motion. The superimposing axis specified at the corresponding Motion Control instruction was not configured as a possible superimposing axis. (<TO>.ErrorWord.X16 (SuperimposingError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

"StatusWord" tag (positioning axis) (Page 437)
"ErrorWord" tag (positioning axis) (Page 439)
"WarningWord" tag (positioning axis) (Page 441)

8.2.2 Motion status

You use the "Technology object > Diagnostics > Motion status" diagnostic function in the TIA Portal to monitor the motion status of the axis. The Diagnostics function is available in online operation.

"Setpoints" area

The following table shows the meaning of the status data:

Status	Description
Target position	Current target position of an active positioning job The target position value is only valid during execution of a positioning job. (<TO>.StatusPositioning.TargetPosition)
Position setpoint	Setpoint position of the axis (<TO>.Position)
Velocity setpoint	Velocity setpoint of the axis (<TO>.Velocity)
Velocity override	Percentage correction of the velocity specification The velocity setpoint specified in Motion Control instructions or set by the axis control panel is superimposed with an override signal and corrected as a percentage. Permissible velocity correction values are 0.0% to 200.0%. (<TO>.Override.Velocity)

"Current values" area

The following table shows the meaning of the status data:

Status	Description
Operative encoder	Operative encoder of the axis
Actual position	Actual position of the axis If the technology object is not homed, then the value is displayed relative to the position that existed when the technology object was enabled. (<TO>.ActualPosition)
Actual velocity	Actual velocity of the axis (<TO>.ActualVelocity)
Following error	Following error of the axis (<TO>.StatusPositioning.FollowingError)

"Dynamic limits" area

This area displays the limit values for the dynamic parameters.

The following table shows the meaning of the status data:

Status	Description
Velocity	Configured maximum velocity (<TO>.DynamicLimits.MaxVelocity)
Acceleration	Configured maximum acceleration (<TO>.DynamicLimits.MaxAcceleration)
Deceleration	Configured maximum deceleration (<TO>.DynamicLimits.MaxDeceleration)
Jerk	Configured maximum jerk (<TO>.DynamicLimits.MaxJerk)

8.2.3 PROFIdrive telegram

You use the "Technology object > Diagnostics > PROFIdrive telegram" diagnostic function in the TIA Portal to monitor the PROFIdrive telegrams returned by the drive and encoder. The display of the Diagnostics function is available in online operation.

"Drive" area

This area displays the following parameters contained in the PROFIdrive telegram from the drive to the controller:

- Status words "ZSW1" and "ZSW2"
- The speed setpoint (NSET) that was output to the drive
- The actual speed that was signaled from the drive (NACT)

"Encoder" area

in the areas "Encoder" for CPU S7-1500 or "Encoder 1" to "Encoder 4" for CPU S7-1500T, the following parameters from the PROFIdrive telegram are displayed by the encoder to the controller.

- Status word "Gx_ZSW"
- The actual position value "Gx_XIST1" (cyclic actual encoder value)
- The actual position value "Gx_XIST2" (absolute encoder value)

8.3 Technology object external encoder

8.3.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Encoder status

The following table shows the possible external encoder status values:

Status	Description
Encoder enabled	The technology object has been enabled. (<TO>.StatusWord.X0 (Enable))
Homed	The technology object is homed. The relationship between the position in the technology object and the mechanical position was successfully created. (<TO>.StatusWord.X5 (HomingDone))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Encoder values valid	The actual encoder values are valid. (<TO>.StatusSensor[n].State)
Encoder homed	Encoder is homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment (<TO>.StatusSensor[n].Adjusted)
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Motion status

The following table shows the possible states of the job execution:

Status	Description
Done (no job running)	No Motion Control job is active at the technology object (enable by "MC_Power" job excepted). (<TO>.StatusWord.X6 (Done))
Homing job	The technology object executes a homing job of the Motion Control instruction "MC_Home". (<TO>.StatusWord.X11 (HomingCommand))
Standstill	The axis is at a standstill. (<TO>.StatusWord.X7 (StandStill))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 UserFault))
Encoder	An error occurred in the encoder system. (<TO>.ErrorWord.X5 (SensorFault))
Data exchange	Missing or faulty communication. (<TO>.ErrorWord.X7 (CommunicationFault))
Adaptation	An error occurred during data adaption. (<TO>.ErrorWord.X15 (AdaptionError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

See also

"StatusWord" tag (external encoder) (Page 454)
"ErrorWord" tag (external encoder) (Page 455)
"WarningWord" tag (external encoder) (Page 456)

8.3.2 Motion status

You use the "Technology object > Diagnostics > Motion status" diagnostic function in the TIA Portal to monitor the actual encoder values. The diagnostics function is available in online operation.

"Current values" area

The following table shows the meaning of the status data:

Status	Description
Actual position	Actual position of the axis If the technology object is not homed, then the value is displayed relative to the position that existed when the technology object was enabled. (<TO>.ActualPosition)
Actual velocity	Actual velocity of the axis (<TO>.ActualVelocity)

8.3.3 PROFIdrive telegram

The "Technology object > Diagnostics > PROFIdrive telegram" diagnostic function is used in the TIA Portal to monitor the PROFIdrive telegram of the encoder. The display of the diagnostics function is available in technology object online mode.

"Encoder" area

This area displays the following parameters contained in the PROFIdrive telegram that the encoder returns to the controller:

- Status word "G1_ZSW"
- The actual position value "G1_XIST1" (cyclic actual encoder value)
- The actual position value "G1_XIST2" (absolute value of the encoder)

Instructions 9

9.1 MC_Power V10

9.1.1 MC_Power: Enable, disable technology object V10

Description

With the Motion Control instruction "MC_Power", a technology object is enabled or disabled and, if necessary, a configured drive is switched on or off.

The Motion Control instruction offers you the following:

- Enabling a technology object with the Motion Control instruction "MC_Power" (Page 108)
  - Enabling a technology object at a standstill (Page 110)
  - Enabling a technology object in motion (Page 110)
  - Enabling a technology object at a standstill when encoder signal is noisy (Page 110)
  - Enabling a technology object after the alarm response "Remove enable" (Page 158)
- Switching the position control off and on (Page 242)
- Enabling a drive (Page 110)
- Disabling a technology object with the Motion Control instruction "MC_Power" (Page 149)
  - Disabling a technology object with emergency deceleration (Page 150)
  - Disabling a technology object with fast stop (Page 152)
  - Disabling a technology object with maximum dynamic values (Page 154)
  - Disabling a technology object with coast down (Page 156)
- Disabling the drive (Page 149)

NOTE

Multi-instance DBs

If you use multi-instances of the MC_Power instruction, create the multi-instances in a separate function block. This allows you to download program blocks from other sections of your user program without switching off the axes, including in "RUN" mode.

Applies to

- Speed axis
- Positioning axis
- Synchronous axis
- External encoder

Requirements

- The technology object has been configured correctly.
- The readiness of the drive is assumed for enabling the technology object. When using the SIEMENS telegram 10x, you can evaluate the bit "DriveReady" from the signal word "MELDW" of the receiving telegram "PD_TEL10x_IN".
- Cyclic bus communication is established between controller and encoder ("<TO>.StatusSensor[1..4].CommunicationOK" = TRUE).
- Cyclic bus communication is established between controller and drive ("<TO>.StatusDrive.CommunicationOK" = TRUE).
- The status of the active encoder is valid ("<TO>.StatusSensor[1..4].State" = 2).
- The optional data adaptation (Page 71) has been completed ("<TO>.StatusDrive.AdaptionState" = 2 and "<TO>.StatusSensor[1..4].AdaptionState" = 2).

The requirements that must be met before a technology object can be released via "MC_Power" can be found in the Siemens Industry Online Support in the FAQ entry 109750297 (https://support.industry.siemens.com/cs/ww/en/view/109750297).

Override response

- An "MC_Power" job cannot be aborted by any other Motion Control job.
- An "MC_Power" job with parameter "Enable" = TRUE enables a technology object but does not thereby abort any other Motion Control instructions.
- Disabling the technology object (parameter "Enable" = FALSE) aborts all Motion Control jobs on the corresponding technology object in accordance with the selected "StopMode". This process cannot be canceled by the user.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_Power":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The technology object is enabled. (Page 110) Setpoints are output to the drive. If the drive is not yet switched on, these are ignored by the drive. As soon as the drive is switched on, these setpoints take effect immediately.
				FALSE	The technology object is disabled. (Page 149) All current jobs at the technology object are canceled in accordance with the configured "StopMode". The technology object matches the setpoint to the actual value.
StartMode	INPUT	DINT	1	Position control (Page 242)	
				0	Enable positioning axis/synchronous axis not position-controlled
				1	Enable positioning axis/synchronous axis position-controlled
				The parameter initially takes effect when the positioning axis is enabled ("Enable" changes from "FALSE" to "TRUE") and when the axis is enabled after acknowledgment of an interrupt that caused the axis to be disabled. The parameter is ignored when a speed axis or an external encoder is being used.	
StopMode	INPUT	INT	0	Not applicable to the technology object external encoder If you disable a technology object with a negative edge at parameter "Enable", the axis decelerates in accordance with the selected "StopMode".	
				0	Emergency stop (Page 150)
				1	Fast stop (Page 152)
				2	Stop with maximum dynamic values (Page 154)
				3	Coast-down (Page 156)[1]
Status	OUTPUT	BOOL	FALSE	Technology object enable status	

[1] When an AUS3 ramp is active and "RemoveEnableReaction" = 16#7, this StopMode takes effect only after the AUS3 ramp and standstill of the drive.

Parameter	Declaration	Data type	Default value	Description	
Status	OUTPUT	BOOL	FALSE	FALSE	Disabled • The technology object does not accept any Motion Control jobs. • Speed control and positioning control are not active. • The actual values of the technology object are not checked for validity.
				TRUE	Enabled • The enabled technology object accepts Motion Control jobs. • Speed control and positioning control are active. • The actual values of the technology object are valid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power". The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

[1] When an AUS3 ramp is active and "RemoveEnableReaction" = 16#7, this StopMode takes effect only after the AUS3 ramp and standstill of the drive.

9.1.2 MC_Power: Function chart V10

Function chart: Enabling a technology object and example of alarm response

A technology object is enabled with "Enable_1" = TRUE. The successful enable can be read from "Status_1" at time ①. The axis will then move with an "MC_MoveVelocity" job (A2). The velocity profile of the axis can be read from "TO_1.Velocity".

At time ② an error occurs in the technology object, which results in the disabling of the technology object (alarm response: remove enable). The axis is decelerated to a standstill dependent on the configured alarm response "Remove enable" (Page 159). When the technology object is disabled, "Status_1" is reset. Since the axis was not disabled using "Enable_1" = FALSE, the selected "StopMode" does not apply. The cause of the error is corrected and the alarm is acknowledged at time ③.

Since "Enable_1" is still set, the technology object is enabled again. The successful enable can be read from "Status_1". Finally, the technology object is disabled with "Enable_1" = FALSE.

9.2 MC_Reset V10

9.2.1 MC_Reset: Acknowledge alarms, restart technology object V10

Description

With the Motion Control instruction "MC_Reset", you acknowledge all technology alarms that can be acknowledged in the user program. Acknowledgment also resets the "Error" and "Warning" bits in the technology object data block. An acknowledgment of alarms in the drive is also possible without a pending error at the technology object.

With "Restart" = TRUE, you start reinitialization (restart) of technology objects. Upon restart of the technology object, the new configuration data are applied in the technology object data block.

The Motion Control instruction offers you the following:

- Acknowledging technology alarms (Page 113)
- Reinitializing a technology object after a fatal error (Page 114)
- Applying restart-relevant value changes (Page 114)

Applies to

- All technology objects

Requirement

- The technology objects speed axis, positioning axis, synchronous axis and external encoder.

  For a restart, the technology object must be disabled.

  ("MC_Power.Status" = FALSE and "MC_Power.Busy" = FALSE)
- Cyclic BUS communication is established between controller and encoder ("<TO>.StatusSensor[1..4].CommunicationOK" = TRUE).
- Cyclic BUS communication is established between controller and drive ("<TO>.StatusDrive.CommunicationOK" = TRUE).
- With parameter "Restart" = TRUE: The "Debug" program mode cannot have master control over the Interpreter technology object.

Override response

- An "MC_Reset" job cannot be aborted by any other Motion Control job.
- A "MC_Reset" job with "Restart" = TRUE cancels all running Motion Control jobs.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_Reset":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy (S7-1500T) TO_OutputCam TO_CamTrack TO_MeasuringInput TO_Cam (S7-1500T) TO_Cam_10k (S7-1500T) TO_Cam_600Seg (S7-1500T) TO_Cam_6kSeg (S7-1500T) TO_Kinematics (S7-1500T) TO_Interpreter (S7-1500T)	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Restart	INPUT	BOOL	FALSE	TRUE	Reinitialization of the technology object and acknowledgment of pending technology alarms (Page 114) The technology object is being reinitialized with the configured start values.
				FALSE	Acknowledgment of pending technology alarms (Page 113)
Done	OUTPUT	BOOL	FALSE	TRUE	Technology alarms have been acknowledged. The restart has been executed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.3 MC_Home V10

9.3.1 MC_Home: Home technology object, set home position V10

Description

With the Motion Control instruction "MC_Home", you create the relationship between the position in the technology object and the mechanical position. The actual position value in the technology object is assigned to a homing mark at the same time. This homing mark represents a known mechanical position.

In the case of active homing (Page 188), the default values under "Technology object > Configuration > Extended parameters > Dynamic default" are used for the dynamic values acceleration, deceleration and jerk.

The Motion Control instruction offers you the following:

- Active homing (Page 195)
- Passive homing (Page 205)
- Direct homing (Page 211)
- Setting the position setpoint (Page 213)
- Adjusting the absolute encoder (Page 213)
- Adjusting the incremental encoder (Page 217)

Applies to

- Positioning axis
- Synchronous axis
- External encoder

Requirements

- The technology object has been configured correctly.
- The actual value of the active encoder is valid (<TO>.StatusSensor[1..4].State = 2).
- "Mode" = 2, 3, 5, 8, 10
  The axis is in position-controlled mode. The axis is enabled.
- "Mode" = 0, 1, 6, 7,11,12,13

  The axis is in position-controlled mode. Enabling of the technology object is not required.

Override response

The override response for "MC_Home" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_Home":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Position	INPUT	LREAL	0.0	The specified value is used according to the selected "Mode".	
Mode	INPUT	INT	0	0 to 13	Homing mode (Page 295) Homing can occur by means of an independent homing motion (active homing), the detection of a homing mark during an initiated motion (passive homing) or a direct position assignment.
Sensor	INPUT	DINT	0	S7-1500: Not relevant	
				S7-1500T: Selection of the absolute encoder ("Mode" = 6, 7) or incremental encoder ("Mode" = 13) to be calibrated	
				0	Operative encoder
				1..4	Encoders 1 to 4 (S7-1500T)
ReferenceMarkPosition	OUTPUT	LREAL	0.0	Display of the position at which the technology object was homed. With active homing, the homing mark position corresponds to the home position minus home position offset. With passive homing, the homing mark position corresponds to the home position. (valid when "Done" = TRUE)	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

See also

Homing (Page 188)

9.3.2 MC_Home: "MC_Home.Mode" parameter V10

Value	Description
0	Direct homing (absolute) (Page 211) The current position of the technology object is set to the value of parameter "Position". **Note** In the case of an axis with several encoders, the offset of the position at the sensors of all encoders is also applied with a position correction with the "Mode" parameter = 0. This prevents the sensors from diverging.
1	Direct homing (relative) (Page 211) The current position of the technology object is shifted by the value of parameter "Position". **Note** In the case of an axis with several encoders, the offset of the position at the sensors of all encoders is also applied with a position correction with the "Mode" parameter = 1. This prevents the sensors from diverging.
2	Passive homing (without reset) (Page 205)[1)] Function same as "Mode" = 8 with the difference that the "homed" status is **not** reset when the function is enabled.
3	Active homing (Page 195)[1)] The positioning axis/synchronous axis technology object performs a homing movement according to the configuration. After the completion of the motion, the axis is positioned at the value of the "Position" parameter.
4	Reserved
5	Active homing ("Position" parameter invalid) (Page 195)[1)] The positioning axis/synchronous axis technology object performs a homing movement according to the configuration. After completion of the motion, the axis is positioned at the home position configured under "Technology object > Configuration > Extended parameters > Homing > Active homing". (<TO>.Homing.HomePosition)
6	Absolute encoder adjustment (relative) (Page 213) The current position is shifted by the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<TO>.StatusSensor[1..4].AbsEncoderOffset)
7	Absolute encoder adjustment (absolute) (Page 213) The current position is set to the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<TO>.StatusSensor[1..4].AbsEncoderOffset)
8	Passive homing (Page 205)[1)] When the homing mark is detected, the actual value is set to the value of the "Position" parameter.
9	Abort passive homing (Page 205) An active job for passive homing is aborted.

1) In the case of active/passive homing with absolute encoder, if a valid absolute value offset has not yet been saved (<TO>.StatusSensor[1..4].Adjusted = 0), an absolute value offset is retentively saved via the switching on/off of the controller. If an absolute value offset has already been saved in the CPU (<TO>.StatusSensor[1..4].Adjusted = 1), it is retained after an active/passive homing. To update the absolute encoder offset, perform an absolute encoder adjustment to the current position after the active/passive homing.

Value	Description
10	Passive homing ("Position" parameter invalid) (Page 205)[1)] When the homing mark is detected, the actual value is set to the home position configured under "Technology object > Configuration > Extended parameters > Homing > Passive homing". (<TO>.Homing.HomePosition)
11	Setting of position setpoint (absolute) (Page 213) The set position of the technology object is set to the value of the "Position" parameter. The following error remains.
12	Shift the setpoint position (relative) (Page 213) The set position of the technology object is shifted by the value of the "Position" parameter. The following error remains.
13	Incremental encoder adjustment (Page 217) The current position is set to the value of parameter "Position".

1) In the case of active/passive homing with absolute encoder, if a valid absolute value offset has not yet been saved (<TO>.StatusSensor[1..4].Adjusted = 0), an absolute value offset is retentively saved via the switching on/off of the controller. If an absolute value offset has already been saved in the CPU (<TO>.StatusSensor[1..4].Adjusted = 1), it is retained after an active/passive homing. To update the absolute encoder offset, perform an absolute encoder adjustment to the current position after the active/passive homing.

9.4 MC_Halt V10

9.4.1 MC_Halt: Stop axis V10

Description

With the Motion Control instruction "MC_Halt", you brake an axis until it comes to a standstill.

You define the dynamic behavior of the braking operation with parameters "Jerk" and "Deceleration".

The Motion Control instruction offers you the following:

- Configuring dynamic values (Page 114)
- Stopping a technology object (Page 168)
- Stopping a basic motion with or without a superimposed motion (Page 168)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_Halt" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_Halt":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 114)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 114)	
				> 0.0	Constant-acceleration velocity profile; the specified jerk is used
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
AbortAcceleration	INPUT	BOOL	FALSE	FALSE	The current acceleration at the start of the job is reduced using the configured jerk. Afterwards, the deceleration builds up.
				TRUE	The acceleration is set to 0.0 at the start of the job, and the deceleration immediately builds up.
Mode	INPUT	DINT	0	Select the motion which is to be stopped (Page 168)	
				0	The basic motion and the superimposed motion are stopped.
				1	The basic motion is stopped. The superimposed motion remains active.
Done	OUTPUT	BOOL	FALSE	TRUE	When "Mode" = 0: Velocity zero has been reached.
					When "Mode" = 1: Velocity zero of the basic motion has been reached.

Parameters	Declaration	Data type	Default value	Description	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

More information

Information on the evaluation of the individual bits can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Configuring dynamic defaults (Page 115)

9.4.2 MC_Halt: Function chart V10

Function chart: Pausing an axis and the overriding job characteristics

Section A

An axis is moved with an "MC_MoveVelocity" job (A1). At time ①, the "MC_MoveVelocity" job is overridden by an "MC_Halt" job (A2). The job abort is signaled via "Abort_1". With "AbortAcc_2" = FALSE, the current acceleration is reduced with the specified jerk. Afterward, the deceleration builds up and the axis is braked to a standstill. The completion of the "MC_Halt" job is reported via "Done_2".

Section B

The axis is moved with an "MC_MoveVelocity" job (A1). At time ②, the "MC_MoveVelocity" job is overridden by an "MC_Halt" job (A2). The job abort is signaled via "Abort_1". With "AbortAcc_2" = TRUE, the current acceleration is set to zero immediately and the deceleration builds up. The axis is braked to a standstill. The completion of the "MC_Halt" job is reported via "Done_2".

Function chart: Stopping basic motion with "Mode"=1

Section A

An axis is moved with an "MC_MoveAbsolute" job (A1) with setpoint velocity 100.0. An "MC_MoveSuperimposed" job (A2) is triggered via "Exe_2" with the velocity deviation 50.0 from the running basic motion. The axis is moved with the added velocities of both jobs 100.0 + 50.0 = 150.0.

At time ①, the "MC_MoveAbsolute" job (A1) is overridden by an "MC_Halt" job (A3) with "Mode_3" = 1. The basic motion is stopped. The "MC_MoveSuperimposed" job (A2) remains active. The job abort is signaled via "Abort_1". The completion of the "MC_Halt" job is reported via "Done_3".

Section B

An axis is moved with an "MC_MoveAbsolute" job (A1) with setpoint velocity 100.0. An "MC_MoveSuperimposed" job (A2) is triggered via "Exe_2" with the velocity deviation 50.0 from the running basic motion. The axis is moved with the added velocities of both jobs 100.0 + 50.0 = 150.0.

At time ②, the "MC_MoveAbsolute" job (A1) and the "MC_MoveSuperimposed" job (A2) are overridden by an "MC_Halt" job (A3) with "Mode_3" = 0. The basic motion and the superimposed motion are stopped. The job abort is signaled via "Abort_1" and "Abort_2". The completion of the "MC_Halt" job is reported via "Done_3".

9.5 MC_MoveAbsolute V10

9.5.1 MC_MoveAbsolute: Position axis absolutely V10

Description

With the Motion Control instruction "MC_MoveAbsolute", you move an axis to an absolute position.

The Motion Control instruction offers you the following:

- Defining the dynamics of the motion (Page 140)
- Defining the absolute target position (Page 140)
- Defining the motion transition (Page 141)
- Starting the job and tracking the motion status (Page 140)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.
- The technology object is homed.

Override response

The override response for "MC_MoveAbsolute" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveAbsolute":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Position	INPUT	LREAL	0.0	Absolute target position (Page 140)	
Velocity	INPUT	LREAL	-1.0	Velocity setpoint for the positioning	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 140)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 140)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted

Parameters	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 140)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
BufferMode	INPUT	DINT	0	Motion transition (Page 141)	
				0	Abort active motion
				1	Append new motion
Direction	INPUT	INT	1	Direction of movement of the axis (Page 140) This parameter is only evaluated when the modulo function is enabled. "Technology object > Configuration > Basic parameters > Enable modulo"	
				1	Positive direction
				2	Negative direction
				3	Shortest distance
Done	OUTPUT	BOOL	FALSE	TRUE	The target position has been reached. The minimum dwell time has expired (<TO>.PositioningMonitoring.MinDwellTime).
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated. The job has control of the axis.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.5.2 MC_MoveAbsolute: Function chart V10

Function chart: Motion transition when positioning an axis absolutely

Section A

An active "MC_MoveAbsolute" job (A1) is overridden at time ① by another "MC_MoveAbsolute" job (A2). The abort is signaled via "Abort_1". The axis is braked to the changed velocity and moved to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

Section B

An axis is moved to absolute position 1000.0 with an "MC_MoveAbsolute" job (A1). An additional "MC_MoveAbsolute" job (A2) has been appended to the active motion sequence via "Exe_2". The active motion sequence is completed and the axis comes to a standstill. When the axis reaches the target position, this is signaled at time ② via "Done_1". At this

time ②, another "MC_MoveAbsolute" job (A2) with target position 1500.0 is started. When the axis reaches the target position 1500.0, this is signaled via "Done_2".

9.6 MC_MoveRelative V10

9.6.1 MC_MoveRelative: Position axis relatively V10

Description

With the Motion Control instruction "MC_MoveRelative", you move an axis relative to its actual position setpoint when execution of the job began.

The Motion Control instruction offers you the following:

- Defining the dynamics of the motion (Page 140)
- Defining the relative target position (Page 140)
- Defining the motion transition (Page 141)
- Starting the job and tracking the motion status (Page 140)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MoveRelative" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveRelative":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Distance	INPUT	LREAL	0.0	Distance for the positioning[1] (negative or positive) (Page 140)	
Velocity	INPUT	LREAL	-1.0	Velocity setpoint for the positioning (Page 140)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 140)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 140)	
				> 0.0	The specified value is used.

[1] If you have set "nm" as the unit of measurement for an axis, enter a value with magnitude greater than or equal to 1000.0 at the "MC_MoveRelative.Distance" parameter. If the amount of the value of "MC_MoveRelative.Distance" is less than 1000.0, the axis will not move during a motion task.

Parameter	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 140)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
BufferMode	INPUT	DINT	0	Motion transition (Page 141)	
				0	Abort active motion
				1	Append new motion
Done	OUTPUT	BOOL	FALSE	TRUE	The target position has been reached. The minimum dwell time has expired (<TO>.PositioningMonitoring.MinDwell-Time).
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated. The job has control of the axis.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

1) If you have set "nm" as the unit of measurement for an axis, enter a value with magnitude greater than or equal to 1000.0 at the "MC_MoveRelative.Distance" parameter. If the amount of the value of "MC_MoveRelative.Distance" is less than 1000.0, the axis will not move during a motion task.

9.6.2 MC_MoveRelative: Function chart V10

Function chart: Motion transition when positioning an axis relatively

Section A

An active "MC_MoveRelative" job (A1) is overridden by another "MC_MoveRelative" job (A2). The abort is signaled at time ① via "Abort_1". The axis is then moved at the new velocity by the distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

Section B

The axis is moved by an "MC_MoveRelative" job (A1) by the distance ("Distance") 1000.0 (the start position here is 0.0). An additional "MC_MoveRelative" job (A2) has been appended to the active motion sequence via "Exe_2". The active motion sequence is completed and the axis comes to a standstill. When the axis reaches the target position, this is signaled at time ② via "Done_1". At this time ②, another "MC_MoveRelative" job (A2) with distance 500.0 is started. When the new target position is reached, this is signaled via "Done_2".

9.7 MC_PositionProfile V10

9.7.1 MC_PositionProfile: Move axis via a time-based position profile V10

Description

You start an axis motion which follows a time-based position profile preset in the cam technology object with the Motion Control instruction "MC_PositionProfile".

The axis motion is ended when the end position of the time-based position profile of the cam is reached. The axis is at a standstill.

The Motion Control instruction offers you the following:

- Defining the relative or absolute traversing motion of the time-based position profile (Page 142)
- Defining the motion transition (Page 141)
- Defining the dynamics of the transition profile (Page 142)
- Defining the start time of the time-based position profile (Page 142)

Applies to

- Positioning axis
- Synchronous axis
- Cam

Requirement

- The technology objects positioning axis/synchronous axis and cam have been configured correctly.
- The technology object of the axis is enabled.
- The cam is interpolated with "MC_InterpolateCam".
- The technology object of the axis is homed when "ProfileReference" = 1.

Override response

The override response for "MC_PositionProfile" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When the active job is overridden by a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration or deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. If the new acceleration or deceleration deviates significantly from the acceleration or deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration or deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration or deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_PositionProfile":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Axis technology object	
TimePosition	INPUT	TO_Cam TO_Cam_10k TO_Cam_6kSeg TO_Cam_600Seg	-	Time-based position profile of the cam technology object (Page 142)	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
BufferMode	INPUT	DINT	0	Motion transition (Page 141)	
				0	Abort active motion
				1	Append new motion
StartTime	INPUT	LREAL	0.0	Start time of the time-based position profile (Page 142) The time relates to the start time of the cam from which the motion transition of the axis to the profile begins. The value must be within the definition of the cam.	
ProfileReference	INPUT	DINT	0	Traversing motion of the time-based position profile (Page 142)	
				0	Relative
				1	Absolute
Velocity	INPUT	LREAL	-1.0	Velocity (Page 142)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted

Parameter	Declaration	Data type	Default value	Description	
Velocity	INPUT	LREAL	-1.0	< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 142)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 142)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 142)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed. The target position has been reached. The minimum dwell time has expired (<TO>.PositioningMonitoring.MinDwell-Time).
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated. The job has master control over the axis.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.7.2 MC_PositionProfile: Function chart V10

Function chart: Time-based position profile with relative positioning of an axis

Using "Exe_1", an "MC_PositionProfile" job (A1) is initiated. In the range ①, the axis does not follow the cam "Cam_1". A transition profile ① is calculated by the system with required dynamics.

The "PosAxis.StatusWord2.X10 (OnProfile) = TRUE" tag indicates that the start position of the cam profile has been reached. The axis travels relative to its position according to the cam profile "Cam_1". The axis comes to a standstill when the end position of the time-based position profile of the cam is reached.

At the time ②, a further "MC_PositionProfile" job (A2) is initiated via "Exe_2". The axis travels immediately according to the cam profile "Cam_2".

Shortly afterwards, a further "MC_PositionProfile" job (A3) is initiated via "Exe_3". The "MC_PositionProfile" job (A3) waits until the end of the active cam "Cam_2".

At the time ③, the "MC_PositionProfile" job (A3) is appended to the running job (A2). The "MC_PositionProfile" job (A2) active motion sequence is completed and the axis comes briefly to a standstill. The job (A3) is then executed. The axis travels relative to its position according to the start time "StartTime = 10.0" of the cam "Cam_3".

Function chart: Time-based position profile with absolute positioning of an axis

At time ①, an "MC_PositionProfile" job (A1) with absolute traversing motion is initiated. Shortly thereafter, an "MC_PositionProfile" job (A2) is transmitted. The axis does not follow the cam "Cam_1". A transition profile ④ is calculated by the system with required dynamics. The axis moves a transition profile to the absolute time-based position profile of the "MC_PositionProfile" job (A1). The "PosAxis.StatusWord2.X10 (OnProfile) = TRUE" tag indicates that the start position of the cam profile has been reached. The axis travels absolutely according to the cam profile "Cam_1". The "MC_PositionProfile" job (A2) waits until the end of the active cam "Cam_1". The axis comes to a standstill when the absolute end position of the time-based position profile of the cam (A1) is reached.

At the time ②, the "MC_PositionProfile" job (A2) is appended to the running job (A1). The axis travels immediately according to the cam profile "Cam_2" without using a transition profile.

At the time ③, the "MC_PositionProfile" job (A2) is aborted by another "MC_PositionProfile" job (A3). The axis moves a transition profile ④ to the absolute time-based position profile of the "MC_PositionProfile" job (A3). During traversing of the transition profile, the axis has the state "PosAxis.StatusWord2.X10 (OnProfile) = FALSE". After the start position of the cam profile is reached, the axis travels absolutely according to the cam profile "Cam_3". The axis comes to a standstill when the absolute end position of the time-based position profile of the cam (A3) is reached.

9.8 MC_MoveVelocity V10

9.8.1 MC_MoveVelocity: Move axis with velocity/speed setpoint V10

Description

With the Motion Control instruction "MC_MoveVelocity", you move an axis with constant velocity/speed.

The Motion Control instruction offers you the following:

- Defining the dynamics of the motion (Page 137)
- Defining the position control (Page 137)
- Starting the job and tracking the motion status (Page 137)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MoveVelocity" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveVelocity":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Velocity	INPUT	LREAL	100.0	Velocity setpoint/speed setpoint for the motion (Page 137) ("Velocity" = 0.0 is permitted)	
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 137)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 137)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 137)	

Parameters	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
Direction	INPUT	INT	0	Direction of rotation of the axis	
				0	The sign of the velocity specified at the "Velocity" parameter defines the direction of rotation.
				1	Positive direction of rotation The value of "Velocity" is used.
				2	Negative direction of rotation The value of "Velocity" is used.
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	Disabled The values of parameters "Velocity" and "Direction" are taken into account.
				TRUE	Enabled The values at the parameters "Velocity" and "Direction" are not taken into account. The current velocity and direction at function start are retained. When the axis resumes motion at the velocity that was current at function start, the "InVelocity" parameter returns the value "TRUE".
PositionControlled	INPUT	BOOL	TRUE	FALSE	Not in position-controlled mode (Page 137)
				TRUE	Position-controlled mode (Page 137)
				The parameter applies as long as the "MC_MoveVelocity" job is being executed. After this, the setting of the following job applies. This parameter is ignored when a speed axis is used.	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity setpoint/speed setpoint has been reached. A constant velocity setpoint/speed setpoint is output (Page 137).
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameters	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

9.8.2 MC_MoveVelocity: Function chart V10

Function chart: Moving an axis with velocity specification, and the response to an overriding job

An "MC_MoveVelocity" job (A1) initiated via "Exe_1" accelerates the axis and signals at time ① via "InVel_1" that the velocity setpoint 50.0 has been reached.

At time ②, the job is overridden by another "MC_MoveVelocity" job (A2). The abort is signaled via "Abort_1". When the new velocity setpoint 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the constant velocity 15.0.

The running "MC_MoveVelocity" job (A2) is overridden by another "MC_MoveVelocity" job (A1). The abort is signaled via "Abort_2". The axis is accelerated to the new velocity setpoint

50.0. Before the velocity setpoint is reached, the current "MC_MoveVelocity" job (A1) is overridden at time ③ by another "MC_MoveVelocity" job (A2). The abort is signaled via "Abort_1". When the new velocity setpoint 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the constant velocity 15.0.

9.9 MC_MoveJog V10

9.9.1 MC_MoveJog: Move axis in jog mode V10

Description

With the Motion Control instruction "MC_MoveJog", you move an axis in jog mode.

The Motion Control instruction offers you the following:

- Defining the dynamics of the motion and the direction of movement (Page 146)
- Defining the position control (Page 146)
- Starting the job and tracking the motion status (Page 146)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MoveJog" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveJog":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
JogForward	INPUT	BOOL	FALSE	TRUE	As long as the parameter is "TRUE", the axis moves in the positive direction with the velocity specified at the "Velocity" parameter. (Page 146)
JogBackward	INPUT	BOOL	FALSE	TRUE	As long as the parameter is "TRUE", the axis moves in the negative direction with the velocity specified at the "Velocity" parameter. (Page 146)
Velocity	INPUT	LREAL	100.0	Velocity setpoint/speed setpoint for the motion (Page 146)	
				≥ 0.0	The specified value is used.
				< 0.0	The absolute value of the specified value is used.
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 146)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 146)	
				> 0.0	The specified value is used.

Parameter	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 146)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
PositionControlled	INPUT	BOOL	TRUE	FALSE	Not in position-controlled mode (Page 146)
				TRUE	Position-controlled mode (Page 146)
				The parameter applies as long as the "MC_MoveJog" job is being executed. After this, the setting of the following job applies. This parameter is ignored when a speed axis is used.	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity setpoint/speed setpoint has been reached. A constant velocity setpoint/speed setpoint is output.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

9.9.2 MC_MoveJog: Function chart V10

Function chart: Moving an axis in jog mode

The axis is moved in the negative direction in jog mode via "Jog_B". When the velocity setpoint -50.0 is reached, this is signaled via "InVel" = TRUE. After "Jog_B" is reset, the axis is braked and brought to a standstill. Then the axis is moved in the positive direction via "Jog_F". When the velocity setpoint 50.0 is reached, this is signaled via "InVel" = TRUE.

At the time ①, if "Jog_F" is set, the velocity setpoint is changed to 100.0 by means of "Vel_Input". Alternatively, you can also change the velocity setpoint using the velocity override. "InVel" is reset. Axis is being accelerated. When the new velocity setpoint 100.0 is reached, this is signaled via "InVel" = TRUE.

If "Jog_F" is set, "Jog_B" is likewise set at time ②. If both "Jog_F" and "Jog_B" are set, then the axis is braked with the last applicable deceleration. An error is indicated via "Error", and the "ErrorID" of the error 16#8007 (incorrect direction specification) is output.

This error is resolved by resetting the two inputs "Jog_F" and "Jog_B".

During the braking ramp, "Jog_F" is set at time ③. The axis is accelerated to the last configured velocity. When the velocity setpoint 100.0 is reached, this is signaled via "InVel" = TRUE.

9.10 MC_MoveSuperimposed V10

9.10.1 MC_MoveSuperimposed: Position axis overlapping V10

Description

With the Motion Control instruction "MC_MoveSuperimposed", you can start a relative positioning motion which is superimposed on a running basic motion.

The Motion Control instruction offers you the following:

- Superimposing a relative positioning motion onto a basic motion (Page 132)
  - The basic motion is a single-axis motion (Page 132)
  - The basic motion is a synchronous operation motion (Page 132)
  - The basic motion is a MotionIn motion (Page 132)
- Starting a superimposed motion (Page 132)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MoveSuperimposed" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveSuperimposed":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Distance	INPUT	LREAL	0.0	Additional distance for the superimposed positioning (negative or positive) (Page 132)	
VelocityDiff	INPUT	LREAL	-1.0	Maximum velocity difference from the running motion (Page 132)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 132)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 132)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted

Parameters	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 132)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
Done	OUTPUT	BOOL	FALSE	TRUE	Superimposed positioning complete
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.10.2 MC_MoveSuperimposed: Function chart V10

Function chart: Positioning axes overlapping

Section A

Using "Exe_1", an "MC_MoveRelative" job with a distance of 50.0 is initiated. At time ①, using "Exe_2", an "MC_MoveSuperimposed" job with a distance of 50.0 is initiated. The axis is

traversed by the distance 50.0 + 50.0 = 100.0 with the added dynamic values of both jobs. When the axis reaches the target position, this is signaled via "Done_2".

Section B

Using "Exe_1", an "MC_MoveRelative" job with a distance of 50.0 is initiated. At time ②, using "Exe_2", a "MC_MoveSuperimposed" job with a distance of -50.0 is initiated. The axis reverses and is traversed by the distance 50.0 - 50.0 = 0.0 with the added dynamic values of both jobs. When the axis reaches the target position, this is signaled via "Done_2".

9.11 MC_HaltSuperimposed V10

9.11.1 MC_HaltSuperimposed: Pause superimposed motions on axis V10

Description

With the Motion Control instruction "MC_HaltSuperimposed", you decelerate a superimposed motion on the axis generated with the "MC_MoveSuperimposed", "MC_MotionInSuperimposed", "MC_MotionInSuperimposedAxes" or "MC_HaltSuperimposed" instructions to zero velocity. This instruction has no effect on the basic motion of the axis.

The Motion Control instruction offers you the following:

- Stopping a superimposed motion (Page 134)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_HaltSuperimposed" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_HaltSuperimposed":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Deceleration	INPUT	LREAL	-1.0	Deceleration of the superimposed motion (Page 134)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk of the superimposed motion (Page 134)	
				> 0.0	Constant-acceleration velocity profile of the superimposed motion; the specified jerk is used
				= 0.0	Trapezoidal velocity profile of the superimposed motion
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
AbortAcceleration	INPUT	BOOL	FALSE	Acceleration reduction during braking (Page 134)	
				FALSE	The current acceleration of the superimposed motion at the start of the job is reduced using the configured jerk. Afterwards, the deceleration builds up.
				TRUE	The acceleration of the superimposed motion is set to 0.0 at the start of the job; the deceleration builds up immediately.
Done	OUTPUT	BOOL	FALSE	TRUE	The execution of the job is completed. The superimposed motion is stopped.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameters	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.11.2 MC_HaltSuperimposed: Function chart V10

Function chart: Pause superimposed motions on the axis

Section A

The axis is moved with an "MC_MoveRelative" job (A1) as the basic motion.

Via "Exe_2", a "MC_MoveSuperimposed" job (A2) is triggered as a superimposed motion. The <TO>.StatusWord.X23 bit is set. At time ①, the "MC_MoveSuperimposed" job is overridden by an "MC_HaltSuperimposed" job (A3). The job abort is signaled via "Abort_2". The

<TO>.StatusWord2.X7 bit is set and the <TO>.StatusWord.X23 bit is reset. With "AbortAcc_3" = FALSE, the current acceleration is reduced with the specified jerk. After that, the deceleration is built up and the superimposed motion is decelerated to velocity = 0. The completion of the "MC_HaltSuperimposed" job is reported via "Done_3". The <TO>.StatusWord2.X7 bit is reset.

Section B

The axis is moved with an "MC_MoveRelative" job (A1) as the basic motion.

Via "Exe_2", a "MC_MoveSuperimposed" job (A2) is triggered as a superimposed motion. The <TO>.StatusWord.X23 bit is set. At time ②, the "MC_MoveSuperimposed" job is overridden by an "MC_HaltSuperimposed" job (A3). The job abort is signaled via "Abort_2". The <TO>.StatusWord2.X7 bit is set and the <TO>.StatusWord.X23 bit is reset. With "AbortAcc_3" = TRUE, the current acceleration is set to zero immediately and the deceleration builds up. The superimposed motion is decelerated to velocity = 0. The completion of the "MC_HaltSuperimposed" job is reported via "Done_3". The <TO>.StatusWord2.X7 bit is reset.

9.12 MC_SetSensor V10

9.12.1 MC_SetSensor: Switch alternative encoder to operative encoder V10

Description

With the Motion Control instruction "MC_SetSensor", you switch over the encoder for closed loop position control of the axis.

The actual value of the addressed encoder can be adapted without switchover using parameter "Mode" = 2 and 3.

The Motion Control instruction offers you the following:

- Switching the encoder ("Mode" = 0, 1) (Page 67)
- Adjusting the position between the new encoder ("Sensor" parameter) and the old/active encoder ("Mode" = 0, 2) (Page 67)
- Transferring the position of the reference encoder ("ReferenceSensor" parameter) to the new encoder ("Sensor" parameter) ("Mode" = 3) (Page 67)
- Switching the encoder to an absolute encoder (Page 67)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object and the alternative encoder have been configured correctly.
- No restart job and no "MC_Home" job running.

Override response

- An "MC_SetSensor" job is not aborted by any other Motion Control job.
- A new "MC_SetSensor" job does not abort any active Motion Control jobs.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetSensor":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Sensor	INPUT	INT	1	Number of the new encoder (1 to 4) (Page 67)	
Mode	INPUT	DINT	0	The mode determines the position alignment between the old encoder and new encoder.	
				0	Switching the encoder and transferring the current actual position to the new encoder (Page 67)
				1	Switching the encoder without adjusting the actual position (Page 67) **Note** When closed loop position control is active, an additional difference of the two encoders acts as additional control deviation and can trigger a compensating motion.
				2	Transferring the actual value (Page 67)
				3	Transferring the actual value of the "reference encoder" (Page 67)
ReferenceSensor	INPUT	INT	1	Number of the reference encoder (see parameter "Mode" = 3) (Page 67)	
Done	OUTPUT	BOOL	FALSE	TRUE	Encoder for closed loop position control of the axis was switched over.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job has been aborted.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.13 MC_Stop V10

9.13.1 MC_Stop: Stop axis and prevent new motion jobs V10

Description

With the Motion Control instruction "MC_Stop", you stop all movements of an axis and prevent new motion jobs for the technology object. The axis decelerates to a standstill and remains switched on.

The Motion Control instruction offers you the following:

- Stopping a technology object (Page 170)
- Decelerating an axis with active force/torque limiting (Page 170)
- Decelerating an axis with emergency deceleration (Page 170)
- Decelerating an axis with maximum dynamic values (Page 170)
- Decelerating an axis with specified dynamics (Page 170)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirements

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

- An "MC_Stop" job is not triggered by other movements.
- An "MC_Stop" job is aborted by an "MC_Power" job with "Enable" = FALSE.
- An "MC_Stop" job does not abort any synchronous operation function in simulation.
- An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

  Significance of stop responses (descending): "Mode" = 0 > "Mode" = 2 > "Mode" = 3

You can find more detailed information on the override behavior of an "MC_Stop" job in section "Override response of Motion Control jobs V10 (Page 380)" or "Override behavior between alarm responses and "MC_Stop" (Page 171)".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_Stop":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	The motion is stopped and new motion jobs are prevented.
				FALSE	Motion jobs can be executed again.
Mode	INPUT	DINT	0	Mode for dynamic behavior (Page 170)	
				0	Emergency stop (Page 170) The technology object is braked to a standstill without jerk limitation, using the emergency stop deceleration configured in "Technology object > Configuration > Extended parameters > Emergency stop". (<TO>.DynamicDefaults.EmergencyDeceleration)
				1	Not permitted
				2	Stop with maximum dynamic values (Page 170) The technology object is braked to a standstill using the maximum deceleration configured in "Technology object > Configuration > Extended parameters > Dynamics limits". In so doing, the configured maximum jerk is taken into account. (<TO>.DynamicLimits.MaxDeceleration, <TO>.DynamicLimits.MaxJerk)
				3	Stop with specified dynamics (Page 170) The technology object is stopped with the specified values at the parameters "Deceleration" and "Jerk".
Deceleration	INPUT	LREAL	-1.0	When "Mode" = 3: Deceleration for the braking ramp (Page 115)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	When "Mode" = 3: Jerk for the braking ramp (Page 115)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation

Parameter	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic defaults" is used. (<TO>.DynamicDefaults.Jerk)
AbortAcceleration	INPUT	BOOL	FALSE	TRUE	Acceleration is set to 0.0. The configured deceleration is built up immediately.
				FALSE	The acceleration is reduced using the configured jerk. The configured deceleration then builds up.
Done	OUTPUT	BOOL	FALSE	TRUE	Standstill is reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted during execution either by "MC_Power" with "Enable" = FALSE, another "MC_Stop" job or an alarm response.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Override response V10: Homing and motion jobs (Page 380)
Emergency stop deceleration (Page 123)

9.13.2 MC_Stop: Function chart V10

Function chart: Braking an axis and the overriding job characteristics

An axis is moved with an "MC_MoveVelocity" job (A1). At time ①, the "MC_MoveVelocity" job is overridden by an "MC_Stop" job (A2). The job abort is signaled via "Abort_1". Afterwards, the configured deceleration builds up and the axis is braked to a standstill. While the axis is braking, "Busy_2" = TRUE. The completion of the "MC_Stop" job is reported via "Done_2".

At time ②, with an active "MC_Stop" job (A1), an "MC_MoveVelocity" job (A2) is executed. Because the axis is disabled by an "MC_Stop" job, the "MC_MoveVelocity" job is rejected. The error is signaled by "Error_1". "Exe_2" is then reset to "FALSE".

At time ③, the axis is moved by an "MC_MoveVelocity" job (A1) with positive edge.

9.14 MC_SetAxisSTW V10

9.14.1 MC_SetAxisSTW: Control bits of control word 1 and 2 V10

Description

With the Motion Control instruction "MC_SetAxisSTW", you control selected bits in control word 1 (STW1) and control word 2 (STW2) of the PROFIdrive telegram. This provides the possibility of directly controlling bits not used by the technology object. The bits to be controlled are specified via the parameters "STW1" and "STW2". The controlled bits remain effective until an "MC_SetAxisSTW" job is reset, the technology object is restarted or the CPU transitions from "RUN" to "STOP".

The following bits can be controlled in STW1:

- 8
- 9
- 11 to 15

Bits 0 to 11 can be controlled in STW2.

The following parameters are available:

- With the "STW1BitMask" and "STW2BitMask" parameters, you define which bit is to be written.
- With the "STW1" and "STW2" parameters, you set the value of the specified bit.

For the meaning of the controllable bits, refer to the list manuals of your drive system.

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object is interconnected with a drive telegram.
- The technology object is not in simulation.
- A permissible bit masking is set.

Override response

- A new "MC_SetAxisSTW" job does not abort any active Motion Control jobs.
- An "MC_SetAxisSTW" job is aborted by another "MC_SetAxisSTW" job.
- An "MC_SetAxisSTW" job is aborted during disabling of the technology object ("MC_Power.Enable" = FALSE, "MC_Power.Busy" = TRUE).

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetAxisSTW":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
STW1	INPUT	WORD	16#0000	Set bits for STW1: Set values of the specified bits for STW1	
STW1BitMask	INPUT	WORD	16#0000	Bit masking for STW1: Select the bits to be specified. If 1, the bit is specified with this command. If 0, the bit is not specified with this command.	
STW2	INPUT	WORD	16#0000	Set bits for STW2: Set values of the specified bits for STW2	
STW2BitMask	INPUT	WORD	16#0000	Bit masking for STW2: Select the bits to be specified. If 1, the bit is specified with this command. If 0, the bit is not specified with this command.	
Done	OUTPUT	BOOL	FALSE	TRUE	The job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

9.15 MC_WriteParameter V10

9.15.1 MC_WriteParameter: Write parameter V10

Description

With the Motion Control instruction "MC_WriteParameter", you can change selected parameters of the technology objects in runtime. The changes take effect directly or after a restart, depending on the corresponding parameter.

The values of restart-relevant parameters (RES) are retained at a "RUN → STOP → RUN" transition of the CPU and at another restart of the technology object.

In the following cases, however, the changed values are reset to the start value:

- Download of the technology object
- POWER OFF → POWER ON
- Memory reset

For parameters that take effect directly, the values are retained at a "RUN → STOP → RUN" transition of the CPU.

In the following cases, however, the changed values are reset to the start value:

- Restart of the technology object
- POWER OFF → POWER ON
- Memory reset

The Motion Control instruction offers you the following:

- Interconnecting the addresses of the Boolean variables in the technology object (Page 178)
- Writing addresses of the Boolean variables in the user program (Page 178)
- Configuring the communication times T_i, T_o, T_{DC} (Page 59)
- Configure stop mode for alarm response "Remove enable" (Page 159)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis
- External encoder

Requirement

- The technology object has been configured correctly.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_WriteParameter": An overview of the changeable parameters ("ParameterNumber" = Index) can be found in the next table:

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ParameterNumber	INPUT	DINT	0	Index of the parameter to be changed	
Value	INPUT	Variant (BOOL, INT, DINT, UDINT, LREAL)	-	Variant pointer to the value to be written (source address)	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during processing. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

Modifiable parameters

The following table shows the parameters that can be changed with the Motion Control instruction "MC_WriteParameter". You select the parameters to be changed at the "ParameterNumber" input parameter using the index:

Tag	Index	Technology object	Data type	Description		Effectiveness
PositionLimits_HW.Active	1000	Positioning axis Synchronous axis	BOOL	Enabling/disabling hardware limit switch The negative and the positive hardware limit switches (Page 211) are activated or deactivated with this parameter,		Direct
				FALSE	HW limit switch deactivated	

Tag	Index	Technology object	Data type	Description		Effectiveness
PositionLimits_HW.Active	1000	Positioning axis Synchronous axis	BOOL	TRUE	HW limit switch activated	Direct
T_i	1010	Speed axis Positioning axis Synchronous axis External encoder	LREAL	Communication time T_i (read in process values) Specify the values in seconds (s).		After restart
T_o	1011	Speed axis Positioning axis Synchronous axis External encoder	LREAL	Communication time T_o (output process values) Specify the values in seconds (s).		After restart
T_{Pn}/T_{DP}	1012	Speed axis Positioning axis Synchronous axis External encoder	LREAL	PROFINET send clock or PROFIBUS send clock Specify the values in seconds (s).		After restart
Actor.RemoveEnableReaction	1020	Speed axis Positioning axis Synchronous axis	WORD	Stop reaction on "Remove enable"		Direct
				16#1	OFF1 – Ramp stop - Braking with ramp-function generator	
				16#3	OFF2 – Coast stop - Coast down	
				16#5	OFF3 – Quick stop - Quick stop	
				16#7 Default setting	OFF3 – Quick stop (compatible configuration for technology versions up to V7)

9.16 MC_SaveAbsoluteEncoderData V10

9.16.1 MC_SaveAbsoluteEncoderData: Save absolute encoder adjustment for device replacement V10

Description

With the Motion Control instruction "MC_SaveAbsoluteEncoderData" you can save the adjustment of an absolute encoder for the device replacement.

The Motion Control instruction offers you the following:

- Saving the data of the absolute encoder adjustment on the SIMATIC Memory Card (Page 216)

Requirement

Sufficient storage space is available on the SIMATIC Memory Card.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SaveAbsoluteEncoderData":

Parameter	Declaration	Data type	Default value	Description	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Done	OUTPUT	BOOL	FALSE	TRUE	The absolute encoder adjustment for all technology objects of the CPU with an absolute encoder is saved for device replacement.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.17 MotionIn

9.17.1 MC_MotionInVelocity V10

9.17.1.1 MC_MotionInVelocity: Specify motion setpoints V10

Description

With the Motion Control instruction "MC_MotionInVelocity", you specify cyclically applicable calculated motion setpoints for velocity and acceleration as a basic motion for the axis. No velocity profile is calculated for this, the values are directly active at the technology object. The dynamic limits are not effective.

The Motion Control instruction offers you the following:

- Specifying the motion profile in the application cycle (Page 244)
- Defining the dynamics of the motion (Page 246)
- Stopping the MotionIn motion (Page 253)

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MotionInVelocity" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

For MotionIn jobs, the specification of the acceleration is only relevant for overriding the job. When the currently active acceleration is not to be slowed down via the jerk, enter the value "0.0" at the "Acceleration" parameter of the MotionIn job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MotionInVelocity":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge The specified setpoints are used as long as the parameter is set to "TRUE".
				FALSE	End of the job with negative edge If the parameter is set from "TRUE" to "FALSE", the setpoints are set to 0.0.
Velocity	INPUT	LREAL	0.0	Velocity setpoint Observe the dynamic limits.	
Acceleration	INPUT	LREAL	0.0	Setpoint acceleration Observe the dynamic limits.	
PositionControlled	INPUT	BOOL	TRUE	TRUE	Position-controlled mode
				FALSE	Controlled running
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.17.1.2 MC_MotionInVelocity: Function chart V10

Function chart: Specify motion setpoints

Section A

With "Enable_1 = TRUE", the technology object is specified cyclically in the MC_PreServo clock velocity "Vel_1" and acceleration "Acc_1". These specifications are applied directly as setpoint velocity "TO_1.Velocity" and setpoint acceleration "TO_1.Acceleration", without hereby calculating a velocity profile.

As the position monitoring "PosContr_1" is set to "FALSE", no following error "TO_1.StatusPositioning.FollowingError" is determined.

Section B

The velocity and acceleration specifications are not effective as long as "Enable_1" is set to "FALSE".

At time ①, "Enable_1" is set to "TRUE". As the position monitoring "PosContr_1" is set to "TRUE", a following error "TO_1.StatusPositioning.FollowingError" is determined.

The velocity specification "Vel_1" and the acceleration default "Acc_1" cause a setpoint jump which exceeds the maximum permissible following error. With active position lag monitoring, the technology alarm 521 is output, and the technology object is disabled. With deactivated following error monitoring, the setpoint jump is executed with maximum dynamic.

9.17.2 MC_MotionInPosition V10

9.17.2.1 MC_MotionInPosition: Specify motion setpoints V10

Description

With the Motion Control instruction "MC_MotionInPosition", you specify the cyclic, applicable motion setpoints for position, velocity and acceleration as basic motion for the axis. No velocity profile is calculated for this, the values are directly active at the technology object. The dynamic limits are not effective.

The Motion Control instruction offers you the following:

- Specifying the motion profile in the application cycle (Page 244)
- Defining the motion setpoints (Page 247)
- Stopping the MotionIn motion (Page 253)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MotionInPosition" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

For MotionIn jobs, the specification of the acceleration is only relevant for overriding the job. When the currently active acceleration is not to be slowed down via the jerk, enter the value "0.0" at the "Acceleration" parameter of the MotionIn job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MotionInPosition":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge The specified setpoints are used as long as the parameter is set to "TRUE".
				FALSE	End of the job with negative edge If the parameter is set from "TRUE" to "FALSE", the setpoints are set to 0.0. The most recently specified value remains active for the set position.
Position	INPUT	LREAL	0.0	Position setpoint	
Velocity	INPUT	LREAL	0.0	Velocity setpoint Observe the dynamic limits.	
Acceleration	INPUT	LREAL	0.0	Setpoint acceleration Observe the dynamic limits.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for the parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.17.2.2 MC_MotionInPosition: Function chart V10

Function chart: Specify motion setpoints

Section A

With "Enable_1 = TRUE", the technology object is specified cyclically in the MC_PreServo clock position "Pos_1", velocity "Vel_1" and acceleration "Acc_1". These specifications are applied directly as set position "TO_1.Position", setpoint velocity "TO_1.Velocity" and setpoint acceleration "TO_1.Acceleration", without hereby calculating a velocity profile.

Section B

The position, velocity and acceleration specifications are not active as long as "Enable_1" is set to "FALSE".

At time ①, "Enable_1" is set to TRUE. The default position setting "Pos_1" causes a setpoint jump which exceeds the maximum permissible following error. With active position lag monitoring, the technology alarm 521 is output, and the technology object is disabled. With deactivated following error monitoring, the setpoint jump is executed with maximum dynamic.

9.17.3 MC_MotionInSuperimposed V10

9.17.3.1 MC_MotionInSuperimposed: Specify superimposed motion setpoints V10

Description

With the Motion Control instruction "MC_MotionInSuperimposed", you specify the cyclic, applicable motion setpoints for position, velocity and acceleration in addition to the basic motion for the axis. No velocity profile is calculated for this, the values are directly active at the technology object. The dynamic limits are not effective.

The Motion Control instruction offers you the following:

- Specifying the motion profile in the application cycle (Page 244)
- Superimposed MotionIn motions (Page 248)
- Specifying superimposed motion setpoints with "MC_MotionInSuperimposed" (Page 250)
- Ending a superimposed motion (Page 253)
- Halting a superimposed motion (Page 252)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.

Override response

The override response for "MC_MotionInSuperimposed" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MotionInSuperimposed":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge The specified setpoints are used as long as the parameter is set to "TRUE".
				FALSE	End of the job with negative edge If the parameter is set from "TRUE" to "FALSE", the setpoints are set to 0.0. The most recently specified value remains active for the set position.
Distance	INPUT	LREAL	0.0	Additional distance of the superimposed motion (negative or positive) (Page 250)	
VelocityDiff	INPUT	LREAL	0.0	Acceleration setpoint of the superimposed motion (velocity difference) (Page 250) Observe the dynamic limits of the axis.	
AccelerationDiff	INPUT	LREAL	0.0	Acceleration setpoint of the superimposed motion (acceleration difference) (Page 250)[1)] Observe the dynamic limits of the axis.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

1) The superimposed acceleration "AccelerationDiff" is only required for overriding the superimposed or entire motion. When braking the superimposed motion with a "MC_HaltSuperImposed" job with "AbortAcceleration" = FALSE, the specified acceleration is reduced via the jerk.

9.17.3.2 MC_MotionInSuperimposed: Function chart V10

Function chart: Specifying superimposed motion setpoints

①

A "Exe_1" job is triggered via "MC_MoveRelative" with the distance 0.08 as the basic motion.

②

The "MC_MotionInSuperimposed" job is triggered. With the positive edge at "Enable_2", the setpoints "Pos_2", "Vel_2", and "Acc_2" become valid and superimpose the basic motion.

9.17.4 MC_MotionInSuperimposedAxes V10

9.17.4.1 MC_MotionInSuperimposedAxes: Specify superimposed motion setpoints from another axis V10

Description

With the Motion Control instruction "MC_MotionInSuperimposedAxes", you specify for the axis of the basic motion the superimposing axis from which the additional motion setpoint values for additional distance, velocity and acceleration are derived without cycle offset. In this case, no velocity profile is calculated. The additive values take effect directly at the technology object. The dynamic limits are not effective.

The Motion Control instruction offers you the following:

- Specifying the motion profile in the application cycle (Page 244)
- Superimposed MotionIn motions (Page 248)
- Specifying superimposed motion setpoints from another axis (Page 251)
- Ending a superimposed motion (Page 253)
- Halting a superimposed motion (Page 252)

Applies to

- Positioning axis
- Synchronous axis

Requirement

- The technology objects have been configured correctly.
- The technology objects are enabled.
- The superimposing axis "SuperimposingAxis" is configured as one of the possible superimposing axes for the superimposed axis "Axis" under "Configuration > Extended parameters > Superimposing axes".
- The technology objects are in position-controlled mode.
- No active homing job on both axes

Override response

The override response for "MC_MotionInSuperimposedAxes" jobs is described in section "Override response V10: Homing and motion jobs (Page 380)".

NOTE

Deviating dynamic settings

When overriding the active job with a new jerk-limited motion, the current acceleration or deceleration is transferred to the new acceleration/deceleration via the jerk. Depending on the dynamic settings, this may take several application cycles. When the new acceleration or deceleration deviates significantly from the acceleration/deceleration at the time of the override, the transition profile can result in an unexpected axis motion.

If such transitions cannot be excluded during acceleration/deceleration, adjust the dynamic settings of your jobs. For example, add a motion that is not jerk-limited with a direct transition to the new acceleration/deceleration. As an alternative, use high jerk values.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MotionInSuperimposedAxes":

Parameters	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Axis technology object for superimposing the basic motion (Page 251)	
SuperimposingAxis	INPUT	TO_PositioningAxis TO_SynchronousAxis	-	Technology object of the axis for the superimposed motion (Page 251)	
Enable	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge (Page 251) The specified setpoints are used as long as the parameter is set to "TRUE".
				FALSE	End of the job with negative edge If the parameter is set from "TRUE" to "FALSE", the setpoints are set to 0.0. The most recently specified value remains active for the set position.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

9.17.4.2 MC_MotionInSuperimposedAxes: Function chart V10

Function chart: Specify superimposed motion setpoints from another axis

Section A

Via "Exe_1", the TO_1 axis is traversed with a "MC_MoveAbsolute" job (A1) as basic motion with the target position 300.0 and the velocity of 100.0 ①.

At time ②, "Enable_2" from the "MC_MoveSuperimposedAxes" job (A2) is used to activate that the motion of the TO_2 axis is superimposed on the motion of the TO_1 axis. Via "Exe_3", the TO_1 axis is superimposed with the relative positioning motion (A3) with a distance of 200.0 and a velocity of 100.0. The TO_1 axis is traversed with the added dynamic values of the two positioning jobs and reaches the target position 500.0. The resulting

velocity TO_1.Velocity is composed of the velocity of the absolute motion $V_{MC_MoveAbsolute}$ and the relative motion $V_{MC_MoveRelative}$.

Section B

The "MC_MoveAbsolute" job (A1) is at a standstill. The "MC_MoveSuperimposedAxes" job (A2) is active.

At time ③, a relative positioning motion (A3) without the basic movement (A1) is triggered via "Exe_3". The TO_1 axis is traversed further by the distance 200.0 with the dynamic values of the "MC_MoveRelative" job (A3) and reaches the target position 700.0. The resulting velocity TO_1.Velocity is composed of the velocity of the absolute motion $V_{MC_MoveAbsolute}$ and the relative motion $V_{MC_MoveRelative}$.

At time ④, "Enable_2" is reset by the "MC_MoveSuperimposedAxes" job (A2). The motion of the TO_2 axis no longer superimposes the motion of the TO_1 axis.

9.18 Torque data

9.18.1 MC_TorqueAdditive V10

9.18.1.1 MC_TorqueAdditive: Specify additive torque V10

Description

With the Motion Control instruction "MC_TorqueAdditive", you specify an additive torque for the drive to which the technology object is assigned. The torque data are transferred via the telegram 750.

With a linear motor, use the "MC_TorqueAdditive" instruction to specify an additive force.

The Motion Control instruction offers you the following:

- Specifying and activating an additive setpoint torque in the drive (Page 129)

If alarms occur at the technology object while "Enable" = TRUE, the force/torque limiting or fixed stop detection remains active.

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object has been enabled.
- The drive is connected via PROFIdrive telegram.
- Telegram 750 is configured.
  Telegram 750 is available for SINAMICS drives V4.9 and higher.

Override response

- An "MC_TorqueAdditive" job is not aborted by any other Motion Control job.
- A new "MC_TorqueAdditive" job does not abort any active Motion Control jobs.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_TorqueAdditive":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The specified setpoint is used as long as the parameter is set to TRUE.
				FALSE	The additive torque transferred to the drive is zero.
Value	INPUT	LREAL	0.0	With standard motor: Additive setpoint torque With linear motor: Additive setpoint force Permissible values: -1.0E12 to 1.0E12	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Connecting force/torque data via SIEMENS additional telegram 750 (Page 74)

9.18.1.2 MC_TorqueAdditive: Function chart V10

Function chart: Activate/deactivate additive setpoint torque

Section A

With "Enable_1" = TRUE, an additive setpoint torque "Value_1" is specified for the drive assigned to the technology object. This specification is transferred to the drive parameter "p1511" (Supplementary torque 1) using telegram 750.

Section B

With "Enable_1" = TRUE, an additive setpoint torque "Value_1" is specified for the drive assigned to the technology object. This specification is transferred to the drive parameter "p1511" (Supplementary torque 1) using telegram 750. The additive setpoint torque is first built up. At time ①, "Enable_1" is already set to "FALSE", before the additive setpoint torque is reduced again. The reduction of the torque setpoint is transmitted directly to the drive.

9.18.2 MC_TorqueRange V10

9.18.2.1 MC_TorqueRange: Set high and low torque limit V10

Description

With the Motion Control instruction "MC_TorqueRange", you can specify an upper and lower torque limit to the drive assigned to the technology object. The torque data are transferred via the telegram 750.

With a linear motor, use the "MC_TorqueRange" instruction to specify an upper and lower force limit.

The Motion Control instruction offers you the following:

- Specifying an upper and lower force/torque limit in the drive (Page 130)

If alarms occur at the technology object while "Enable" = TRUE, the force/torque limiting or fixed stop detection remains active.

Applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The drive is connected via PROFIdrive telegram.
- Telegram 750 is configured.

  Telegram 750 is available for SINAMICS drives V4.9 and higher.

Override response

- An "MC_TorqueRange" job is not aborted by any other Motion Control job.
- A new "MC_TorqueRange" job does not abort any active Motion Control jobs.
- If the torque limiting is active via the "MC_TorqueLimiting" job, the "MC_TorqueRange" job is rejected with an error message and vice versa. The functions do not override one another.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_TorqueRange":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The specified values are used as long as the TRUE parameter is set.
				FALSE	No values for the high and low torque limit are transferred to the drive.
UpperLimit	INPUT	LREAL	1.0 E12	With standard motor: Upper torque limit (in the configured unit) With linear motor: Upper force limit (in the configured unit) Permitted value range: -1.0 E12 to 1.0 E12 The value of the parameter "UpperLimit" must be greater than the value of the parameter "LowerLimit".	
LowerLimit	INPUT	LREAL	-1.0 E12	With standard motor: Lower torque limit (in the configured unit) With linear motor: Lower force limit (in the configured unit) Permitted value range: -1.0 E12 to 1.0 E12 The value of the parameter "LowerLimit" must be less than the value of the parameter "UpperLimit".	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

See also

Connecting force/torque data via SIEMENS additional telegram 750 (Page 74)

9.18.2.2 MC_TorqueRange: Function chart V10

Function chart: Set high and low torque limits

With "Enable_1" = TRUE, an upper torque limit "UpperLimit_1" and a lower torque limit "LowerLimit_1" are specified to the drive assigned to the technology object. These settings are transferred directly to the drive parameters "p1522" (Torque limit upper) and "p1523" (Torque limit lower) using telegram 750. If "Enable_1" is reset to "FALSE", the upper and lower torque limits are no longer active.

9.18.3 MC_TorqueLimiting V10

9.18.3.1 MC_TorqueLimiting: Activate/deactivate force/torque limit / fixed stop detection V10

Description

With the Motion Control instruction "MC_TorqueLimiting", you activate and assign parameters for force/torque limiting and fixed stop detection. Together with a position-controlled motion job, a "Travel to fixed stop" can be realized with the fixed stop detection. In the axis configuration, you can configure whether the force/torque limiting is to relate to the drive side or the load side.

The functions of the Motion Control instruction "MC_TorqueLimiting" can be activated and deactivated before and during a motion job.

The Motion Control instruction offers you the following:

- Specifying and activating the force/torque limiting (Page 124)
- Activating and monitoring the fixed stop detection (Page 127)

NOTE

Multi-instance DBs

If you use multi-instances of the MC_TorqueLimiting instruction, create the multi-instances in a separate function block. This allows you to download program blocks from other sections of your user program without switching off the axes, including in "RUN" mode.

In case of alarms on the technology object and "Enable" = TRUE, the force/torque limits or the fixed stop detection remain active.

Force/torque limiting applies to

- Speed axis
- Positioning axis
- Synchronous axis

Requirements for force/torque limiting

- The technology object and the reference torque of the drive have been configured correctly.
- No errors that prevent enabling are pending for the technology object (the technology object must not be enabled).
- The drive must support force/torque reduction. Only PROFIdrive drives with SIEMENS telegram 10x support force/torque limiting.

- The upper and lower torque limit of the drive must be set to the reference torque of the drive. The sum of all values must be equal.

  If you want to use different torque limits, use an "MC_TorqueRange" job, for example.

  You can find more information in the "Connecting force/torque data via SIEMENS additional telegram 750 (Page 74)" section.
- The reference torque set in the "Data exchange with the drive" configuration dialog of the technology object must match the reference torque of the drive. If the automatic application of drive data is enabled, the axis automatically takes the reference torque of the drive.

Required interconnections in the SINAMICS drive

Make sure that the following interconnections required for force/torque limit are set in all drive data sets in the drive:

- P1522 = P1520 = P2003 (interconnection to the reference torque)
- P1523 = P1521 = -P2003 (interconnection to the negative reference torque)
- P1544 Torque/force reduction evaluation during travel to fixed stop to 100% (default)
- P2194 Threshold value for the parameter "InLimitation" of < 100% (default 90%)

Fixed stop detection applies to

- Synchronous axis
- Positioning axis

Requirement for fixed stop detection

- Fixed stop detection can only be applied to position-controlled axes. For fixed stop detection, the axis must be enabled as position-controlled. Motion jobs must be executed as position-controlled.
- The technology object has been configured correctly.
- When a drive and telegram that support force/torque limiting are used, the reference torque of the drive must be correctly configured for the technology object.
- No errors that prevent enabling are pending for the technology object (the technology object must be enabled).

Override response

- An "MC_TorqueLimiting" job cannot be aborted by any other Motion Control job.
- A new "MC_TorqueLimiting" job does not abort any active Motion Control jobs.
- If the high and low torque limiting is active via the "MC_TorqueRange" job, the "MC_TorqueLimiting" job is rejected with an error message and vice versa. The functions do not override one another.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_TorqueLimiting":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis TO_PositioningAxis TO_SynchronousAxis	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Activate function corresponding to input parameter "Mode"
Limit	INPUT	LREAL	-1.0	Value of force/torque limiting (in the configured unit)[1]	
				≥ 0.0	The value specified at the parameter is used.
				< 0.0	The value configured in the "Torque limiting" configuration window is used. Tag Torque Limit: <TO>.TorqueLimiting.LimitDefaults.Torque Tag Force Limit: <TO>.TorqueLimiting.LimitDefaults.Force
Mode	INPUT	DINT	0	0	Force/torque limiting (Page 124)[1]
				1	Fixed stop detection (Page 127)[1]
InClamping	OUTPUT	BOOL	FALSE	TRUE	"Mode" = 1: The drive is kept at the fixed stop (clamping[2]). The axis position is within the positioning tolerance.
InLimitation	OUTPUT	BOOL	FALSE	TRUE	"Mode" = 0 and 1: The drive operates at least at the threshold value (default 90%) of the torque limit/force limitation.

1) Changes to input parameters "Limit" and "Mode" are also applied at the cyclic call of the Motion Control instruction when "Enable" = TRUE.

2) If "InClamping" = TRUE, all motion and synchronization jobs are canceled.

Parameter	Declaration	Data type	Default value	Description	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

1) Changes to input parameters "Limit" and "Mode" are also applied at the cyclic call of the Motion Control instruction when "Enable" = TRUE.

2) If "InClamping" = TRUE, all motion and synchronization jobs are canceled.

9.18.3.2 MC_TorqueLimiting: Function chart V10

Function chart: Pausing an axis when the torque limit is reached

At time ①, an "MC_Halt" job (A2) is executed on an axis with active torque limiting "MC_TorqueLimiting" (A1). Torque limiting is still active ("MC_TorqueLimiting.Enable" = TRUE) and any accumulated following error is retained and will be reduced with the time.

When the actual velocity is "0.0" and the minimum dwell time in the standstill window has elapsed, the tag "MC_Halt.Done" shows = TRUE. When position monitoring is activated, reaching of the target position is also monitored.

Function chart: Torque limiting with fixed stop detection (mode = 1)

At time ①, a "MC_TorqueLimiting" job (A1) is initiated via "En_1". An "MC_MoveVelocity" job (A2) is executed on the axis with active torque limiting. The torque limiting is still active "MC_TorqueLimiting.Enable" = TRUE.

When the following error limit ② is reached, the "MC_MoveVelocity" job is aborted with "Abort" = TRUE. The drive is kept at the fixed stop (clamping). The actual position of the axis is within the positioning tolerance.

An "MC_MoveVelocity" job is once again called via the two tags "Execute" = TRUE and "Direction_2" = TRUE and the axis moves with constant velocity in the opposite direction. The clamping is hereby reduced when the positioning tolerance ③ is exited.

At time ④, the torque limiting is cancelled.

9.19 Override response of Motion Control jobs V10

9.19.1 Override response V10: Homing and motion jobs

The following table shows how a new Motion Control job affects active homing and motion jobs:

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 0, 1 active MC_Move-Velocity MC_MoveJog	MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_Move-Super-imposed MC_Motion-InSuper-imposed MC_Motion-InSuper-imposed-Axes MC_Halt-Super-imposed	MC_Motion-InVelocity MC_Motion-InPosition

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

NOTE

Override response with active fixed stop

With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

9.19.2 Override response V10: Synchronous operation jobs

The following table shows how a new Motion Control job affects the motion of the axis on active synchronous operation jobs:

⇒ **Active job** ⇓ **New job**	**MC_GearIn**	**MC_GearInVelocity**	**MC_GearInPos MC_CamIn waiting[2)]**	**MC_GearInPos MC_CamIn active[3)]**	**MC_PhasingAbsolute MC_PhasingRelative**	**MC_OffsetAbsolute MC_OffsetRelative**	**MC_LeadingValueAdditive**	**MC_GearOut MC_CamOut waiting[4)]**	**MC_GearOut MC_CamOut active[5)]**
MC_Home[1)] "Mode" = 3, 5	A	A	-	N	-	-	-	-	A
MC_Halt "Mode" = 0, 1 **MC_MoveAbsolute/ MC_MoveRelative** "BufferMode" = 0 Active **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog**	A	A	-	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]

MC_GearOut MC_CamOut active[5]	A[7]	N	A[7] [8]	A[7]	A	A	-	A[7]	N

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

NOTE
Override response with active fixed stop
With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

9.19.3 Override response V10: Measuring input jobs

The following table shows which new Motion Control jobs will override active measuring input jobs:

⇒ **Active job** ⇓ **New job**	**MC_MeasuringInput**	**MC_MeasuringInputCyclic**
MC_Home "Mode" = 2, 3, 5, 8, 9, 10	B	B
MC_Home "Mode" = 0, 1, 6, 7, 11, 12	-	-
MC_MeasuringInput **MC_MeasuringInputCyclic** **MC_AbortMeasuringInput**	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B The running job is aborted with "ErrorID" = 16#80A3.

- No effect. Running job continues to be executed.

9.19.4 Override response V10: Kinematics motion commands

Single axis jobs are not overridden by kinematics jobs.

The following table shows how a new Motion Control job affects active kinematics motion jobs:

⇒ **Active job** ⇓ **New job**	**MC_MoveLinearAbsolute** **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt** **MC_DefineWorkspaceZone** **MC_DefineKinematicsZone** **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive** **MC_SetOcsFrame**	**MC_GroupInterrupt**	**MC_GroupStop**
MC_Home **MC_MoveSuperimposed** **MC_GearOut** **MC_CamOut**	N	N	N
MC_Halt **MC_MoveAbsolute/** **MC_MoveRelative/** **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog** **MC_Stop** **MC_GearIn** **MC_GearInPos** **MC_GearInVelocity** **MC_CamIn** **MC_MotionInVelocity** **MC_MotionInPosition**	A	A	A
MC_GroupStop	A	A	N
MC_GroupInterrupt **MC_GroupContinue**	B	A	N
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt**	-	-	N

⇒ Active job ⇓ New job	MC_MoveLinearAbsolute MC_MoveLinearRelative MC_MoveCircularAbsolute MC_MoveCircularRelative MC_MoveDirectAbsolute MC_MoveDirectRelative MC_TrackConveyorBelt MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive MC_SetOcsFrame	MC_GroupInterrupt	MC_GroupStop
MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive			
MC_SetOcsFrame	C, -	-	N

A The running job is aborted with "CommandAborted" = TRUE.

B Running job is interrupted or resumed.

C Synchronization of the OCS with the conveyor belt is aborted with "MC_SetOcsFrame" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed. A new kinematics job is added to the job sequence.

9.19.5 Override response V10: Interpreter jobs

The following table shows how a new Motion Control job affects running Interpreter jobs:

⇒ Active job ⇓ New job	MC_LoadProgram	MC_RunProgram	MC_StopProgram
MC_LoadProgram	N	N	N
MC_RunProgram	-[1]	N	N
MC_StopProgram	A	A	A[2]
MC_Reset	-/N[3]	-/N[3]	-/N[3]

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) The new job is also executed.

2) A new "MC_StopProgram" job with "Mode" = 0 cancels a running "MC_StopProgram" job with "Mode" = 1 or 2. A new "MC_StopProgram" job with "Mode" = 1 aborts a current "MC_StopProgram" job with "Mode" = 2.

3) An "MC_Reset" job with "Restart" = TRUE is rejected. Running job continues to be executed.

Override response for technology objects controlled by the Interpreter

The following table shows how a new Motion Control job acts in relation to a technology object controlled by the Interpreter during the execution of an Interpreter program ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)):

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_Power disable/enable with technology object	✓	✓
MC_Reset with "Restart" = TRUE	✓	✓
MC_Reset with "Restart" = FALSE	✓	-
MC_Home **MC_Halt** **MC_Stop**	✓	✓
MC_MoveAbsolute **MC_MoveRelative** **MC_MoveVelocity** **MC_MoveJog**	✓	✓
MC_SetAxisSTW **MC_WriteParameter**	✓	-
MC_MoveSuperimposed **MC_MotionInSuperimposed** **MC_MotionInSuperimposedAxes** **MC_HaltSuperimposed**	-	-
MC_MotionInVelocity **MC_MotionInPosition**	✓	✓
MC_GearIn **MC_GearInPos** **MC_GearInVelocity** **MC_GearOut** **MC_CamIn** **MC_CamOut**	✓	✓[1]
MC_PhasingRelative **MC_PhasingAbsolute**	-	-
MC_LeadingValueAdditive	✓	-
MC_OffsetRelative **MC_OffsetAbsolute**	-	-
MC_TorqueAdditive **MC_TorqueRange**	✓	-
MC_TorqueLimiting	✓	-/✓[2]
MC_SynchronizedMotionSimulation	✓	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative**	-	-
MC_GroupInterrupt **MC_GroupContinue**	-	-
MC_GroupStop	✓	✓
MC_KinematicsMotionSimulation	✓	-
MC_TrackConveyorBelt	-	-
MC_DefineTool **MC_SetTool** **MC_SetOcsFrame**	-	-
MC_KinematicsTransformation **MC_InverseKinematicsTransformation**	✓	-
MC_DefineWorkspaceZone **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_DefineKinematicsZone** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive**	-	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

NOTE

MC_Power

Note that a "MC_Power" request with "Enable" = FALSE always locks the specified technology object, even if the technology object was enabled via an Interpreter program with "powerOn()".

Mixed operation of MC_Power (SCL) and powerOn() (MCL) is not permitted.

NOTE

MC_Stop

Note that when starting a motion controlled by the Interpreter no "MC_Stop" job may be active, otherwise the motion job will be aborted.

NOTE

MC_GroupStop

Note that when starting a kinematics motion controlled by the Interpreter, no "MC_GroupStop" job may be active, otherwise the motion job will be aborted.

A "MC_GroupStop" job only affects active kinematics motions or if the kinematics technology object is controlled by the Interpreter ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)).

Tags of the technology object data blocks 10

10.1 Legend

Tag	Name of the tag	
Data type	Data type of the tag	
Values	Value range of the tag - minimum value to maximum value (L - linear specification R - rotary specification) If no specific value is shown, the value range limits of the relevant data type apply or the information under "Description".	
W	Effectiveness of changes in the technology data block	
	DIR	Direct: Values are changed via direct assignment and take effect at the start of the next MC_Servo.
	CAL	At call of Motion Control instruction: Values are changed directly and take effect at the start of the next MC_Servo after the call of the corresponding Motion Control instruction in the user program.
	RES	Restart: Changes to the start value in the load memory are made using the extended instruction "WRIT_DBL" (write to DB in load memory). Changes will not take effect until after restart of the technology object.
	RON	Read only: The tag cannot and must not be changed during runtime of the user program.
Description	Description of the tag	

Access to the tags is with "<TO>.<tag name>". The placeholder <TO> represents the name of the technology object.

10.2 Tags of the speed axis technology object

10.2.1 Actual values and setpoints (speed axis)

The following tags indicate the setpoint and actual values of the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Velocity	LREAL	-	RON	Velocity setpoint/speed setpoint
ActualSpeed	LREAL	-	RON	With analog setpoint = 0.0: Actual speed of motor in 1/min
Acceleration	LREAL	-	RON	Setpoint acceleration
VelocitySetpoint	LREAL	-1.0E12 to 1.0E12	RON	Output velocity setpoint/speed setpoint

10.2.2 "Simulation" tag (speed axis)

The tag structure "<TO>.Simulation.<tag name>" contains the configuration of the simulation mode. In simulation mode, you can simulate axes without a real drive in the CPU.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Simulation.	TO_Struct_AxisSimulation				
Mode	UDINT	0, 1	RES[1]	Simulation mode	
				0	No simulation, normal operation
				1	Simulation mode

[1] Technology version V2.0: RON

10.2.3 "VirtualAxis" tag (speed axis)

The tag structure "<TO>.VirtualAxis.<tag name>" contains the configuration of the virtual operation of the axis. A virtual axis is often used as a virtual leading axis in order to generate the setpoints for several real following axes in synchronous operation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
VirtualAxis.	TO_Struct_VirtualAxis				
Mode	UDINT	0, 1	RON	Virtual axis	
				0	No virtual axis
				1	Technology version ≤ V7.0: The behavior of a virtual axis is identical to the behavior of an axis in simulation. The actual values are generated via the control loop and a simplified drive model. Technology version ≥ V8.0: In technology version V8.0, the behavior of the virtual axis has been changed. The behavior of a virtual axis is no longer identical to the behavior of an axis in simulation. The position and velocity setpoints are directly adopted as actual values with an application cycle delay. The feedback loop and the drive model are not simulated. The dynamic filter is effective. To maintain compatibility with virtual axes of technology versions ≤ V7.0 for an axis: 1. Switch on the axis in simulation (<TO>.Simulation.Mode = 1). 2. Deactivate the virtual axis (<TO>.VirtualAxisMode = 0).

10.2.4 "Actor" tag (speed axis)

The tag structure "<TO>.Actor.<tag name>" contains the controller-side configuration of the drive.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Actor.	TO_Struct_Actor				
Type	DINT	0, 1	RON	Drive connection	
				0	Analog output

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

Tag	Data type	Values	W	Description	
Type	DINT	0, 1	RON	1	PROFIdrive telegram
InverseDirection	BOOL	-	RES	Inversion of the setpoint	
				FALSE	No
				TRUE	Yes
DataAdaption	DINT	0, 1	RES	Automatic transfer of the drive values reference speed, maximum speed and reference torque in the device	
				0	No automatic transfer, manual configuration of values
				1	Automatic transfer of values configured in the drive to the configuration of the technology object
Efficiency	LREAL	0.0 to 1.0	RES	Efficiency of gear	
RemoveEnableReaction	WORD	16#0...16#7	RES[1]	Stop reaction on "Remove enable"	
				16#1	OFF1 – Ramp stop - Braking with ramp-function generator
				16#3	OFF2 – Coast stop - Coast down
				16#5	OFF3 – Quick stop - Quick stop
				16#7	OFF3 – Quick stop (compatible configuration for technology versions up to V7)
				16#0 16#2 16#4 16#6	Invalid
Interface.	TO_Struct_ActorInterface				
AddressIn	VREF	0 to 65535	RON	Input address for the PROFIdrive telegram	
AddressOut	VREF	0 to 65535	RON	Output address for the PROFIdrive telegram or the analog setpoint	
EnableDriveOutput	BOOL	-	RES	"Enable output" for analog drives	
				FALSE	Disabled
				TRUE	Enabled
EnableDriveOutput-Address	VREF	0 to 65535	RON	Address for the "Enable output" for analog setpoint	
DriveReadyInput	BOOL	-	RES	"Ready input" for analog drives The analog drive signals its readiness to receive speed set-points.	
				FALSE	Disabled
				TRUE	Enabled
DriveReadyInput-Address	VREF	0 to 65535	RON	Address for the "Enable input" for analog setpoint	
EnableTorqueData	BOOL	-	RES	Torque data	
				FALSE	Disabled
				TRUE	Enabled

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

Tag	Data type	Values	W	Description
TorqueDataAddressIn	VREF	0 to 65535	RON	Input Address of the Telegram 750
TorqueDataAddress-Out	VREF	0 to 65535	RON	Output address of the telegram 750
DriveParameter.	TO_Struct_ActorDriveParameter			
ReferenceSpeed	LREAL	0.0 to 1.0E12	RES	Reference value (100%) for the speed setpoint (N-set) of the drive The speed setpoint is transferred in the PROFIdrive telegram as a normalized value from -200% to 200% of the "ReferenceSpeed". For setpoint specification via an analog output, the analog output can be operated in the range from -117% to 117%, provided the drive permits this.
MaxSpeed	LREAL	0.0 to 1.0E12	RES	Maximum value for the speed setpoint of the drive (N-set) (PROFIdrive: MaxSpeed ≤ 2 × ReferenceSpeed Analog setpoint: MaxSpeed ≤ 1.17 × ReferenceSpeed)
ReferenceTorque	LREAL	0.0 to 1.0E12	RES	Reference torque of drive (p2003) Valid for the standard motor setting.

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

10.2.5 "TorqueLimiting" tag (speed axis)

The tag structure "<TO>.TorqueLimiting.<tag name>" contains the configuration of the torque limiting.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
TorqueLimiting.	TO_Struct_TorqueLimiting				
LimitBase	DINT	0, 1	RES	Torque limiting	
				0	Motor side
				1	Load side
PositionBasedMonitor-ings	DINT	0, 1	RES	Positioning and following error monitoring	
				0	Monitoring deactivated
				1	Monitoring activated
LimitDefaults.	TO_Struct_TorqueLimitingLimitDe-faults				
Torque	LREAL	0.0 to 1.0E12	CAL	Limiting torque	
Force	LREAL	0.0 to 1.0E12	CAL	Limiting force	

10.2.6 "LoadGear" tag (speed axis)

The tag structure "<TO>.LoadGear.<tag name>" contains the configuration of the load gear.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description
LoadGear.	TO_Struct_LoadGear			
Numerator	UDINT	1 to 4294967295	RES	Load gear numerator
Denominator	UDINT	1 to 4294967295	RES	Load gear denominator

10.2.7 "Units" tag (speed axis)

The tag structure "<TO>.Units.<tag name>" shows the set technological units.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Units.	TO_Struct_Units / TO_Struct_ExternalEncoder_Units				
VelocityUnit	UDINT	-	RON	Unit for velocity	
				1082	1/s
				1083	1/min
				1528	1/h
TimeUnit	UDINT	-	RON	Unit for time	
				1054	s
TorqueUnit	UDINT	-	RON	Unit for torque	
				1126	Nm
				1128	kNm
				1529	lbf in (pound-force-inch)
				1530	lbf ft
				1531	ozf in (ounce-force-inch)
				1532	ozf ft
				1533	pdl in (poundal-inch)
				1534	pdl ft
ForceUnit	UDINT	-	RON	Unit for force	
				1120	N
				1122	kN
				1094	lbf (pound-force)

Tag	Data type	Values	W	Description	
ForceUnit	UDINT	-	RON	1093	ozf (ounce-force)
				1535	pdl (poundals)
MassUnit	UDINT	-	RON	Unit for mass	
				1088	kg
				1089	g
				1090	mg
				1092	t
				1540	lb
IneritaUnit	UDINT	-	RON	Unit for moment of inertia	
				1118	kg·m²
				1541	lb·ft²

10.2.8 "DynamicLimits" tag (speed axis)

The tag structure "<TO>.DynamicLimits.<tag name>" contains the configuration of the dynamic limits. During Motion Control, no dynamic values greater than the dynamic limits are permitted. If you specify greater values in a Motion Control instruction, then motion is performed using the dynamic limits, and a warning is indicated (alarm 501 to 503 - Dynamic values are limited).

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
DynamicLimits.	TO_Struct_DynamicLimits			
MaxVelocity	LREAL	0.0 to 1.0E12	RES	Maximum permissible velocity of the axis
Velocity	LREAL	0.0 to 1.0E12	DIR	Current maximum velocity of the axis The minimum from "MaxVelocity" and "Velocity" is effective for motion control.
MaxAcceleration	LREAL	0.0 to 2.77777777777778E8	DIR	Maximum permissible acceleration of the axis
MaxDeceleration	LREAL	0.0 to 2.77777777777778E8	DIR	Maximum permissible deceleration of the axis
MaxJerk	LREAL	0.0 to 4629629.629	DIR	Maximum permissible jerk on the axis

10.2.9 "DynamicDefaults" tag (speed axis)

The tag structure "<TO>.DynamicDefaults.<tag name>" contains the configuration of the dynamic defaults. These settings will be used when you specify a dynamic value less than 0.0 in a Motion Control instruction (exceptions: "MC_MoveJog.Velocity", "MC_MoveVelocity.Velocity"). Changes to the default dynamic values will be applied at the next positive edge at the "Execute" parameter of a Motion Control instruction.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
DynamicDefaults.	TO_Struct_DynamicDefaults			
Velocity	LREAL	0.0 to 1.0E12	CAL	Default velocity
Acceleration	LREAL	0.0 to 2.77777777777778E8	CAL	Default acceleration
Deceleration	LREAL	0.0 to 2.77777777777778E8	CAL	Default deceleration
Jerk	LREAL	0.0 to 4629629.629	CAL	Default jerk
EmergencyDeceleration	LREAL	0.0 to 2.77777777777778E8	DIR	Emergency stop deceleration

10.2.10 "Override" tag (speed axis)

The tag structure "<TO>.Override.<tag name>" contains the configuration of override parameters. The override parameters are used to apply a correction percentage to default values. An override change takes effect immediately, and is performed with the dynamic settings in effect in the Motion Control instruction.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Override.	TO_Struct_Override			
Velocity	LREAL	0.0 to 200.0%	DIR	Velocity or speed override Percentage correction of the velocity or speed

10.2.11 "StatusDrive" tag (speed axis)

The tag structure "<TO>.StatusDrive.<tag name>" indicates the status of the drive.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
StatusDrive.	TO_Struct_StatusDrive				
InOperation	BOOL	-	RON	Operation status of the drive	
				FALSE	Drive not ready Setpoints will not be executed.
				TRUE	Drive ready Setpoints can be executed.
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and drive	
				FALSE	Cyclic communication not established. Fault ZSW1.X3 (FaultPresent) is present. Possible causes: • The CPU is in STOP. • The drive has failed. • The "ControlRequested" bit in the status word of the drive has the value "FALSE". • The drive signals an error using the status word. • For isochronous configuration, the dynamic sign of life in the telegram has failed or is not supplied by the drive.
				TRUE	Cyclic communication OK and no fault effective
Error	BOOL	-	RON	FALSE	No drive error
				TRUE	Drive error
AdaptionState	DINT	0 to 4	RON	Status of automatic data transfer of drive parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer

10.2.12 "StatusTorqueData" tag (speed axis)

The tag structure "<TO>.StatusTorqueData.<tag name>" indicates the status of the torque.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description	
StatusTorqueData.	TO_Struct_StatusTorqueData				
CommandAdditive-TorqueActive	DINT	-	RON	Additive torque setpoint function	
				0	Disabled
				1	Enabled
CommandTorqueRange-Active	DINT	-	RON	Torque range above high and low limit of the torque function	
				0	Disabled
				1	Enabled
ActualTorque	LREAL	-1.0E12 to 1.0E12	RON	Actual torque of the axis in the technological unit of the technology object for torque	

10.2.13 "StatusMotionIn" tag (speed axis)

The tag structure "<TO>.StatusMotionIn.<tag name>" indicates the motion status.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description	
StatusMotionIn.	TO_Struct_StatusMotionIn				
FunctionState	DINT	0, 1	RON	0	No "MotionIn" function active
				1	"MotionInVelocity" function active

10.2.14 "StatusInterpreterMotion" tag (speed axis)

The tag structure "<TO>.StatusInterpreterMotion.<tag name>" contains status information on motion jobs controlled by a technology object Interpreter.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusInterpreterMotion.	TO_Struct_StatusInterpreterMotion			
Interpreter	DB_ANY	0 to 65535		Controlling Interpreter technology object
StatusWord.	DWORD	-	RON	Status information

Tag			Data type	Values	W	Description
		Bit 0	-	-	-	"ControlledByInterpreter" An MCL job is processed or active or the bit is set via the MCL instruction "setControlledByInterpreter()".
		Bit 1	-	-	-	"MotionByInterpreter" An MCL motion job is in effect.
		Bit 2 to Bit 31	-	-	-	Reserved

10.2.15 "StatusWord" tag (speed axis)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 0 "Enable") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend (Page 393)

Tag		Data type	Values	W	Description
StatusWord		DWORD	-	RON	Status information of the technology object
	Bit 0	-	-	-	"Enable" Enable status The technology object has been enabled.
	Bit 1	-	-	-	"Error" An error is present.
	Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is reinitialized.
	Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
	Bit 4	-	-	-	"ControlPanelActive" The axis control panel is active.
	Bit 5	-	-	-	Reserved
	Bit 6	-	-	-	"Done" No motion job is in progress and the axis control panel is deactivated.
	Bit 7	-	-	-	Reserved
	Bit 8	-	-	-	Reserved
	Bit 9	-	-	-	"JogCommand" An "MC_MoveJog" job is running.
	Bit 10	-	-	-	"VelocityCommand" An "MC_MoveVelocity" job is running.
	Bit 11	-	-	-	Reserved

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using Mc_TorqueRange without SIEMENS telegram 10x, compare M_ACT with M_LIMIT_POS or M_LIMIT_NEG of telegram 750. InLimit = M_ACT * 0.9 > M_LIMIT_POS OR M_ACT * 0.9 < M_LIMIT_NEG. Evaluate the variable InLimit instead of StatusWord.%X27.

Tag	Data type	Values	W	Description
Bit 12	-	-	-	"ConstantVelocity" The velocity setpoint is reached. A constant velocity setpoint is output.
Bit 13	-	-	-	"Accelerating" An acceleration operation is active.
Bit 14	-	-	-	"Decelerating" A deceleration operation is active.
Bit 15... Bit 24	-	-	-	Reserved
Bit 25	-	-	-	"AxisSimulation" The simulation is active.
Bit 26	-	-	-	"TorqueLimitingCommand" An "MC_TorqueLimiting" job is running.
Bit 27	-	-	-	"InLimitation" The drive operates at least at the threshold value (default 90%) of the torque limit.
Bit 28... Bit 31	-	-	-	Reserved

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using Mc_TorqueRange without SIEMENS telegram 10x, compare M_ACT with M_LIMIT_POS or M_LIMIT_NEG of telegram 750. InLimit = M_ACT * 0.9 > M_LIMIT_POS OR M_ACT * 0.9 < M_LIMIT_NEG. Evaluate the variable InLimit instead of StatusWord.%X27.

10.2.16 "StatusWord2" tag (speed axis)

The "<TO>.StatusWord2" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 0 "StopCommand") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description
StatusWord2	DWORD	-	RON	Status information of the technology object
Bit 0	BOOL	-	RON	"StopCommand" An "MC_Stop" job is running. The technology object is disabled.
Bit 1 to Bit 31	BOOL	-	RON	Reserved

10.2.17 "ErrorWord" tag (speed axis)

The "<TO>.ErrorWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the alarms requiring acknowledgment and serious errors alarm classes into consideration.

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

To read out the specific alarm number of the technology alarm with the highest priority associated with the technology object, evaluate the tag "<TO>.ErrorDetail.Number".

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" System error
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	"DriveFault" Error in drive
Bit 5	-	-	-	Reserved
Bit 6	-	-	-	"DynamicError" Specified dynamic values are limited to permissible values.
Bit 7	-	-	-	"CommunicationFault" Communication error Missing or faulty communication.
Bit 8... Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
Bit 14	-	-	-	Reserved
Bit 15	-	-	-	"AdaptionError" Error during data transfer
Bit 16 ... Bit 31	-	-	-	Reserved

10.2.18 "ErrorDetail" tag (speed axis)

The "<TO>.ErrorDetail" tag structure contains the alarm number and the effective local alarm response of the technology alarm pending on the technology object with the highest priority.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
ErrorDetail.	TO_Struct_ErrorDetail				
Number	UDINT	-	RON	Alarm number	
Reaction	DINT	0 to 5	RON	Effective alarm response	
				0	No reaction
				1	Stop with current dynamic values
				2	Stop with maximum dynamic values
				3	Stop with emergency stop ramp
				4	Remove enable
				5	Track setpoints

10.2.19 "WarningWord" tag (speed axis)

The "<TO>.WarningWord" tag indicates pending warnings at the technology object.

Information on the evaluation of the individual bits (e.g. bit 13 "PeripheralWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
WarningWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemWarning" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigWarning" Configuration error One or several configuration parameters are adjusted internally.
Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use

Tag	Data type	Values	W	Description
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	"DriveWarning" Warning of the drive When a warning message is pending at the drive that does not result in a TO alarm, this bit is not set. Evaluate the drive warnings directly using the status word of the drive.
Bit 5	-	-	-	Reserved
Bit 6	-	-	-	"DynamicWarning" Specified dynamic values are limited to permissible values.
Bit 7	-	-	-	"CommunicationWarning" Communication error Missing or faulty communication.
Bit 8... Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralWarning" Error accessing a logical address
Bit 14	-	-	-	Reserved
Bit 15	-	-	-	"AdaptionWarning" Error in automatic data transfer
Bit 16... Bit 31	-	-	-	Reserved

10.2.20 "ControlPanel" tag (speed axis)

The tag structure "<TO>.ControlPanel.<tag name>" contains no relevant data for you. This tag structure is internally used.

10.2.21 "InternalToTrace" tag (speed axis)

The tag structure "<TO>.InternalToTrace.<tag name>" contains no relevant data for you. This tag structure is internally used.

10.3 Tags of the positioning axis technology object

10.3.1 Actual values and setpoints (positioning axis)

The following tags indicate the setpoint and actual values of the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Position	LREAL	-	RON	Position setpoint	
Velocity	LREAL	-	RON	Velocity setpoint/speed setpoint	
ActualPosition	LREAL	-	RON	Actual position	
ActualVelocity	LREAL	-	RON	Actual velocity	
ActualSpeed	LREAL	-	RON	For PROFIdrive drives	Actual speed of the motor
				For drives with analog setpoint interface	0.0
				For drives with linear motor	0.0
Acceleration	LREAL	-	RON	Setpoint acceleration	
ActualAcceleration	LREAL	-	RON	Actual acceleration	
OperativeSensor	UDINT	1 to 4	RON	Operative encoder	
ModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles of the setpoint	
ActualModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles of the actual value	
VelocitySetpoint	LREAL	-1.0E12 to 1.0E12	RON	Output velocity setpoint/speed setpoint	

10.3.2 "Simulation" tag (positioning axis)

The tag structure "<TO>.Simulation.<tag name>" contains the configuration of the simulation mode. In simulation mode, you can simulate axes without a real drive in the CPU.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Simulation.	TO_Struct_AxisSimulation				
Mode	UDINT	0, 1	RES[1]	Simulation mode	
				0	No simulation, normal operation
				1	Simulation mode

[1] Technology version V2.0: RON

10.3.3 "VirtualAxis" tag (positioning axis)

The tag structure "<TO>.VirtualAxis.<tag name>" contains the configuration of the virtual operation of the axis. A virtual axis is often used as a virtual leading axis in order to generate the setpoints for several real following axes in synchronous operation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
VirtualAxis.	TO_Struct_VirtualAxis				
Mode	UDINT	0, 1	RON	Virtual axis	
				0	No virtual axis
				1	Technology version ≤ V7.0: The behavior of a virtual axis is identical to the behavior of an axis in simulation. The actual values are generated via the control loop and a simplified drive model. Technology version ≥ V8.0: In technology version V8.0, the behavior of the virtual axis has been changed. The behavior of a virtual axis is no longer identical to the behavior of an axis in simulation. The position and velocity setpoints are directly adopted as actual values with an application cycle delay. The feedback loop and the drive model are not simulated. The dynamic filter is effective. To maintain compatibility with virtual axes of technology versions ≤ V7.0 for an axis: 1. Switch on the axis in simulation (<TO>.Simulation.Mode = 1). 2. Deactivate the virtual axis (<TO>.VirtualAxisMode = 0).

10.3.4 "Actor" tag (positioning axis)

The tag structure "<TO>.Actor.<tag name>" contains the controller-side configuration of the drive.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Actor.	TO_Struct_Actor				
Type	DINT	0, 1	RON	Drive connection	
				0	Analog output
				1	PROFIdrive telegram
InverseDirection	BOOL	-	RES	Inversion of the setpoint	
				FALSE	No
				TRUE	Yes
DataAdaption	DINT	0, 1	RES	Automatic transfer of the drive values reference speed, maximum speed and reference torque	
				0	No automatic transfer, manual configuration of values
				1	Automatic transfer of values configured in the drive to the configuration of the technology object
Efficiency	LREAL	0.0 to 1.0	RES	Efficiency of mechanics (gear and leadscrew)	
MotorType	DINT	0.1	DL	Motor type	
				0	Round-frame motor (standard motor)
				1	Linear motor
LoadInertia	LREAL	0.0 to 1.0E12	DIR	Moment of inertia or weight of the load	
RemoveEnableReaction	WORD	16#0...16#7	RES[1]	Stop reaction on "Remove enable"	
				16#1	OFF1 – Ramp stop - Braking with ramp-function generator
				16#3	OFF2 – Coast stop - Coast down
				16#5	OFF3 – Quick stop - Quick stop
				16#7	OFF3 – Quick stop (compatible configuration for technology versions up to V7)
				16#0 16#2 16#4 16#6	Invalid
Interface.	TO_Struct_ActorInterface				
AddressIn	VREF	0 to 65535	RON	Input address for the PROFIdrive telegram	
AddressOut	VREF	0 to 65535	RON	Output address for the PROFIdrive telegram or the analog setpoint	

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

Tag	Data type	Values	W	Description
EnableDriveOutput	BOOL	-	RES	"Enable output" for analog drives FALSE: Disabled TRUE: Enabled
EnableDriveOutput-Address	VREF	0 to 65535	RON	Address for the "Enable output" for analog setpoint
DriveReadyInput	BOOL	-	RES	"Ready input" for analog drives The analog drive signals its readiness to receive speed setpoints. FALSE: Disabled TRUE: Enabled
DriveReadyInput-Address	VREF	0 to 65535	RON	Address for the "Enable input" for analog setpoint
EnableTorqueData	BOOL	-	RES	Torque data FALSE: Disabled TRUE: Enabled
TorqueDataAddressIn	VREF	0 to 65535	RON	Input address of the supplemental telegram
TorqueDataAddress-Out	VREF	0 to 65535	RON	Output address of additional telegram
DriveParameter.	TO_Struct_ActorDriveParameter			Valid when "<TO>.Actor.MotorType" = 0
ReferenceSpeed	LREAL	0.0 to 1.0E12	RES	Reference value (100%) for the speed setpoint (N-set) of the drive The speed setpoint is transferred in the PROFIdrive telegram as a normalized value from -200% to 200% of the "ReferenceSpeed". For setpoint specification via an analog output, the analog output can be operated in the range from -117% to 117%, provided the drive permits this.
MaxSpeed	LREAL	0.0 to 1.0E12	RES	Maximum value for the speed setpoint of the drive (N-set) (PROFIdrive: MaxSpeed ≤ 2 × ReferenceSpeed Analog setpoint: MaxSpeed ≤ 1.17 × ReferenceSpeed)
ReferenceTorque	LREAL	0.0 to 1.0E12	RES	Reference value (100%) for the drive torque
MotorInertia	LREAL	0.0 to 1.0E12	DIR	Moment of inertia of the motor
LinearMotorDrivePara-meter.	TO_Struct_LinearMotorActorDrive-Parameter			Valid when "<TO>.Actor.MotorType" = 1
ReferenceVelocity	LREAL	0.0 to 1.0E12	RES	Reference value (100%) for the velocity setpoint (N-set) of the drive The speed setpoint is transferred in the PROFIdrive telegram as a normalized value from -200% to 200% of the "ReferenceVelocity". For setpoint specification via an analog output, the analog output can be operated in the range from -117% to 117%, provided the drive permits this.

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

Tag	Data type	Values	W	Description
MaxVelocity	LREAL	0.0 to 1.0E12	RES	Maximum value for the velocity setpoint of the drive (N-set) (PROFIdrive: MaxVelocity ≤ 2 × ReferenceVelocity Analog setpoint: MaxVelocity ≤ 1.17 × ReferenceVelocity)
ReferenceForce	LREAL	0.0 to 1.0E12	RES	Reference value (100%) for the force of the drive
MotorMass	LREAL	0.0 to 1.0E12	DIR	Mass of linear motor

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "Actor.RemoveEnableReaction" parameter during runtime. The change takes effect directly.

10.3.5 "TorqueLimiting" tag (positioning axis)

The tag structure "<TO>.TorqueLimiting.<tag name>" contains the configuration of the force/torque limitation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
TorqueLimiting.	TO_Struct_TorqueLimiting				
LimitBase	DINT	0, 1	RES	Force/torque limiting	
				0	Motor side
				1	Load side
				Setting is not relevant for linear motors.	
PositionBasedMonitor-ings	DINT	0, 1	RES	Positioning and following error monitoring	
				0	Monitoring deactivated
				1	Monitoring activated
LimitDefaults.	TO_Struct_TorqueLimitingLimitDe-faults				
Torque	LREAL	0.0 ... 1.0E12	CAL	Limiting torque	
Force	LREAL	0.0 ... 1.0E12	CAL	Limiting force	

10.3.6 "Clamping" tag (positioning axis)

The tag structure "<TO>.Clamping.<tag name>" contains the configuration of the fixed stop detection.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Clamping.	TO_Struct_Clamping			
FollowingErrorDeviation	LREAL	0.001 to 1.0E12	DIR	Value of the following error starting from which the fixed stop is detected.
PositionTolerance	LREAL	0.001 to 1.0E12	DIR	Position tolerance for clamping monitoring

10.3.7 Sensor[1..4] tags (positioning axis)

The tag structure "<TO>.Sensor[1..4].<tag name>" contains the controller-end configuration of the encoder and the configuration of active and passive homing.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Sensor[1..4].	ARRAY [1..4] OF TO_Struct_Sensor

				0	"INCREMENTAL" Incremental
				1	"ABSOLUTE" Absolute
				2	"CYCLIC_ABSOLUTE" Cyclic absolute
InverseDirection	BOOL	-	RES	Inversion of the actual value	
				FALSE	No
				TRUE	Yes
System	DINT	0, 1	RES	Encoder system	
				0	"LINEAR" Linear encoder
				1	"ROTATORY" Rotary encoder
MountingMode	DINT	0 to 2	RES	Mounting type of encoder	
				0	On motor shaft
				1	On load side
				2	External measuring system

Tag	Data type	Values	W	Description	
DataAdaption	DINT	0, 1	RES	Automatic transfer of the drive values reference speed, maximum speed and reference torque in the device	
				0	No automatic transfer, manual configuration of values
				1	Automatic transfer of values configured in the drive to the configuration of the technology object
ActualVelocityMode	DINT	0, 1	RES	Type of calculation for actual speed value or actual velocity value	
				0	Actual value calculation from differentiation of the position change
				1	Actual value calculation with NACT value from the PROFIdrive telegram
Interface.	TO_Struct_SensorInterface				
AddressIn	VREF	0 to 65535	RON	Input address for the PROFIdrive telegram	
AddressOut	VREF	0 to 65535	RON	Output address for the PROFIdrive telegram	
Number	UDINT	1 to 2	RON	Number of the encoder in the telegram	
Parameter.	TO_Struct_SensorParameter				
Resolution	LREAL	1.0E-12 ... 1.0E12	RES	Resolution of a linear encoder (offset between two encoder pulses)	
StepsPerRevolution	UDINT	1 to 8388608	RES	Increments per rotary encoder revolution	
FineResolutionXist1	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST1" (cyclic actual encoder value)	
FineResolutionXist2	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST2" (absolute value of the encoder)	
DeterminableRevolutions	UDINT	0 to 8388608	RES	Number of differentiable encoder revolutions for a multi-turn absolute encoder (For a single-turn absolute encoder = 1; for an incremental encoder = 0)	
DistancePerRevolution	LREAL	0.0 to 1.0E12	RES	For technology objects < V8.0: Load distance per revolution of an externally mounted encoder For technology objects >= V8.0: Load travel per measuring wheel revolution of an externally mounted encoder	
BehaviorGx_XIST1	DINT	0, 1	RES	Evaluation of "Gx_XIST1" bits.	
				0	Based on the bits of the encoder resolution. The incremental actual value "Gx_XIST1" is transmitted with less than 32 bits in the PROFIdrive telegram. For example: At 16 bits, the value ranges from 0 to 65,535.
				1	32-bit value of the encoder value The "Gx_XIST1" incremental actual value is transferred with 32 bits of 0 to 4,294,967,295 in the PROFIdrive telegram.
ReferenceSpeed	LREAL	0.0 to 1.0E12	RES	Reference speed for NACT in PROFIdrive telegram with rotary encoder Only relevant for "ActualVelocityMode" = 1	

Tag	Data type	Values	W	Description	
ReferenceVelocity	LREAL	0.0 to 1.0E12	RES	Reference velocity for NACT in the PROFIdrive telegram with linear encoder Only relevant for "ActualVelocityMode" = 1	
Backlash.	TO_Struct_Backlash				
Enable	BOOL	-	DIR	Enable backlash compensation	
				FALSE	Disabled
				TRUE	Enabled
				If you enable or disable backlash compensation at runtime, you must home the axis again.	
Size	LREAL	0.0 to 1.0E12	DIR	Size of backlashes	
				If you change the size of backlashes during runtime, you have to home the axis again.	
Velocity	LREAL	0.0 to 1.0E12	DIR	Velocity for traversing of backlashes	
				0.0	Motor traverses backlashes within one servo cycle.
				> 0.0	Motor traverses backlash with the specified velocity.
DirectionAbsolute-Homing	DINT	0, 1	DIR	Direction of movement during or before absolute encoder adjustment	
				0	Positive

Units of measure (Page 34)

10.3.13 "Mechanics" tag (positioning axis)

The tag structure "<TO>.Mechanics.<tag name>" contains the configuration of the mechanics.

Tags

Legend (Page 393)

Tag		Data type	Value range	W	Description
Mechanics.		TO_Struct_Mechanics			
	LeadScrew	LREAL	1.0E-12 to 1.0E12	RES	Leadscrew pitch

10.3.14 "Modulo" tag (positioning axis)

The tag structure "<TO>.Modulo.<tag name>" contains the configuration of the modulo function.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Modulo.	TO_Struct_Modulo				
Enable	BOOL	-	RES	FALSE	Modulo conversion disabled
				TRUE	Modulo conversion enabled
Length	LREAL	0.001 to 1.0E12	RES	Modulo length When modulo conversion is enabled, a check is made for modulo length > 0.0	
StartValue	LREAL	-1.0E12 to 1.0E-12	RES	Modulo start value	

10.3.15 "DynamicLimits" tag (positioning axis)

The tag structure "<TO>.DynamicLimits.<tag name>" contains the configuration of the dynamic limits. During Motion Control, no dynamic values greater than the dynamic limits are permitted. If you specify greater values in a Motion Control instruction, then motion is performed using the dynamic limits, and a warning is indicated (alarm 501 to 503 - Dynamic values are limited).

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
DynamicLimits.	TO_Struct_DynamicLimits			
MaxVelocity	LREAL	0.0 to 1.0E12	RES	Maximum permissible velocity of the axis
Velocity	LREAL	0.0 to 1.0E12	DIR	Current maximum velocity of the axis The minimum from "MaxVelocity" and "Velocity" is effective for motion control.
MaxAcceleration	LREAL	0.0 to 1.0E12	DIR	Maximum permissible acceleration of the axis
MaxDeceleration	LREAL	0.0 to 1.0E12	DIR	Maximum permissible deceleration of the axis
MaxJerk	LREAL	0.0 to 1.0E12	DIR	Maximum permissible jerk on the axis

10.3.16 "DynamicDefaults" tag (positioning axis)

The tag structure "<TO>.DynamicDefaults.<tag name>" contains the configuration of the dynamic defaults. These settings will be used when you specify a dynamic value less than 0.0 in a Motion Control instruction (exceptions: "MC_MoveJog.Velocity", "MC_MoveVelocity.Velocity"). Changes to the default dynamic values will be applied at the next positive edge at the "Execute" parameter of a Motion Control instruction.

Tags

Legend (Page 393)

Tag		Data type	Values	W	Description
DynamicDefaults.		TO_Struct_DynamicDefaults			
	Velocity	LREAL	0.0 to 1.0E12	CAL	Default velocity
	Acceleration	LREAL	0.0 to 1.0E12	CAL	Default acceleration
	Deceleration	LREAL	0.0 to 1.0E12	CAL	Default deceleration
	Jerk	LREAL	0.0 to 1.0E12	CAL	Default jerk
	EmergencyDecelera-tion	LREAL	0.0 to 1.0E12	DIR	Emergency stop deceleration

10.3.17 "PositionLimits_SW" tag (positioning axis)

The tag structure "<TO>.PositionLimits_SW.<tag name>" contains the configuration of position monitoring with software limit switches. Software limit switches are used to limit the operating range of a positioning axis.

Tags

Legend (Page 393)

Tag		Data type	Values	W	Description	
PositionLimits_SW.		TO_Struct_PositionLimitsSW				
	Active	BOOL	-	DIR	FALSE	Monitoring deactivated
					TRUE	Monitoring enabled
	MinPosition	LREAL	-1.0E12 to 1.0E-12	DIR	Position of negative software limit switches	
	MaxPosition	LREAL	-1.0E12 to 1.0E-12	DIR	Position of positive software limit switches ("MaxPosition" > "MinPosition")	
	LimitReachedBehavior	DINT	0 ... 1	RES	Alarm response when a software limit switch is approached with a single axis job	
					0	Stop with maximum dynamic values
					1	Stop with current dynamic values
	LimitExceededBehavior	DINT	0 ... 1	RES	Alarm response when overrunning a software limit switch	
					0	Disable axis
					1	Keep emergency stop and axis enable

10.3.18 "PositionLimits_HW" tag (positioning axis)

The tag structure "<TO>.PositionLimits_HW.<tag name>" contains the configuration of position monitoring with hardware limit switches. Hardware limit switches are used to limit the traversing range of a positioning axis.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
PositionLimits_HW.	TO_Struct_PositionLimitsHW				
Active	BOOL	-	RES[1]	FALSE	Monitoring deactivated
				TRUE	Monitoring enabled
				With "Active", both (negative and positive) hardware limit switches are activated or deactivated.	
MinSwitchLevel	BOOL	-	RES	Level for activation of the negative hardware limit switch	
				FALSE	Low level (Low active)
				TRUE	High level (high-enabled)
MinSwitchAddress	VREF	0 to 65535	RES	Address for the negative hardware limit switch	
MaxSwitchLevel	BOOL	-	RES	Level for activation of the positive hardware limit switch	
				FALSE	Low level (Low active)
				TRUE	High level (high-enabled)
MaxSwitchAddress	VREF	0 to 65535	RES	Address for the positive hardware limit switch	
Mode	DINT	0, 1	RES	Type of HW limit switch	
				0	Switch non-traversable
				1	Switch traversable
AppoachBehavior	DINT	0, 1	RES	Alarm response when approaching a HW limit switch	
				0	Disable axis
				1	Keep emergency stop and axis enabled

[1] With the Motion Control instruction "MC_WriteParameter", you can change the "PositionLimits_HW.Active" parameter at runtime. The change takes effect directly.

See also

MC_WriteParameter: Write parameter V10 (Page 346)

10.3.19 "Homing" tag (positioning axis)

The tag structure "<TO>.Homing.<tag name>" contains the configuration for homing the TO.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Homing.	TO_Struct_Homing / TO_Struct_ExternalEncoder_Homing			
AutoReversal	BOOL	-	RES	Reversal at the hardware limit switches FALSE: No TRUE: Yes
ApproachDirection	BOOL	-	CAL	Direction of approach to the homing position switch FALSE: Positive direction TRUE: Negative direction
ApproachVelocity	LREAL	Linear: 0.0 to 10000.0 mm/s Rotary: 0.0 to 360000.0 °/s	CAL	Approach velocity Velocity during active homing at which the reference output cam and home position are approached.
ReferencingVelocity	LREAL	Linear: 0.0 to 1000.0 mm/s Rotary: 0.0 to 36000.0 °/s	CAL	Homing velocity Velocity during active homing at which the home position is approached.
HomePosition	LREAL	-1.0E12 to 1.0E12	CAL	Home position

10.3.20 "Override" tag (positioning axis)

The tag structure "<TO>.Override.<tag name>" contains the configuration of override parameters. The override parameters are used to apply a correction percentage to default values. An override change takes effect immediately, and is performed with the dynamic settings in effect in the Motion Control instruction.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Override.	TO_Struct_Override			
Velocity	LREAL	0.0 to 200.0%	DIR	Velocity or speed override Percentage correction of the velocity or speed

10.3.21 "PositionControl" tag (positioning axis)

The tag structure "<TO>.PositionControl.<tag name>" contains the settings of position control.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
PositionControl.	TO_Struct_PositionControl			
Kv	LREAL	0.0 to 2147480.0	DIR	Proportional gain of the closed loop position control ("Kv" > 0.0)
Kpc	LREAL	0.0 to 150.0%	DIR	Velocity precontrol of the position control Recommended setting: • Isochronous drive connection via PROFIdrive: 100.0% • Non-isochronous drive connection via PROFIdrive: 0.0 to 100.0% • Analog drive connection: 0.0 to 100.0%
EnableDSC	BOOL	-	RES	Dynamic Servo Control (DSC) FALSE: DSC disabled TRUE: DSC activated DSC is only possible with one of the following PROFIdrive telegrams: • Standard telegram 5 or 6 • SIEMENS telegram 105 or 106
SmoothingTimeByChangeDifference	LREAL	0.0 to 1.0E12 s	DIR	Smoothing time for the manipulated variable for switching operations, for example: • Encoder switchover • Change in P-gain ("Kv") • Switchover to emergency stop ramp
InitialOperativeSensor	UDINT	1 to 4	RES	Active sensor after initialization of the axis (sensor number 1 to 4) This encoder is used after startup of the CPU and after a restart of the technology object. At an operating mode transition from STOP → RUN of the CPU (without restart of the technology object), the encoder that was also active before the STOP is still being used.
ControlDifferenceQuantization.	TO_Struct_PositionDifferenceQuantification			
Mode	DINT	-	RES	Type of quantification Configuration of a quantization when a drive with stepper motor interface is connected 0: No quantification 1: Quantization corresponding to encoder resolution 2: Quantization to a direct value

Tag	Data type	Values	W	Description
Mode	DINT	-	RES	(configuration is performed using the parameter view (data structure))
Value	LREAL	0.001 to 1.0E12	RES	Value of quantification Configuration of a value for quantization to a direct value ("<TO>.PositionControl.ControlDifferenceQuantization.Mode" = 2) (configuration is performed using the parameter view (data structure))
VelocityModePowerOn	DINT	0 to 1	RES	Behavior of the velocity setpoint when the axis is enabled
				0 Velocity is set to "0" with maximum dynamic values of the axis (ramp).
				1 Velocity is immediately set to "0" without ramp.

10.3.22 "TorquePreControl" tag (positioning axis)

The tag structure "<TO>.TorquePreControl.<tag name>" contains the settings of the torque precontrol.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
TorquePreControl.	TO_Struct_TorquePreControl			
Mode	DINT	0, 1	RES	Mode of torque precontrol (effect only in position-controlled mode)
				0 Torque precontrol not in effect
				1 Torque precontrol based on the acceleration of the axis
Scale	LREAL	0.0 to 150.0	DIR	Weighting factor for the value of the torque precontrol [%]

10.3.23 "SetpointFilter" tag (positioning axis)

The tag structure "<TO>.SetpointFilter.<tag name>" contains the settings of the setpoint filter.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
SetpointFilter.	TO_Struct_SetpointFilter			
DynamicFilter.	TO_Struct_DynamicFilter			
Mode	DINT	0 to 2	RES	Dynamic filter mode

1) The dead time T_t is internally limited to sixteen times the value from the application cycle of the MC_Servo. No alarm is output at higher values.

Tag	Data type	Values	W	Description	
Mode	DINT	0 to 2	RES	0	Dynamic filter not active
				1	PT1/PT2 filter + dead time
				2	Sliding window demand + dead time
T1	LREAL	0.0 to 1.0E12	DIR	First time constant of the sliding window demand The value is internally limited to the 16-fold servo clock.	
T2	LREAL	0.0 to 1.0E12	DIR	Second time constant of the sliding window demand The value is internally limited to the 16-fold servo clock.	
Tt	LREAL	0.0 to 1.0E12[1)]	DIR	Additional dead time of the dynamic filter in time unit of the axis	

1) The dead time T_t is internally limited to sixteen times the value from the application cycle of the MC_Servo. No alarm is output at higher values.

10.3.24 "DynamicAxisModel" tag (positioning axis)

The tag structure "<TO>.DynamicAxisModel.<tag name>" contains the balancing filter settings.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
DynamicAxisModel.	TO_Struct_DynamicAxisModel			
VelocityTimeConstant	LREAL	0.0 to 1.0E12	DIR	Speed control loop substitute time [s]
AdditionalPositionTime-Constant	LREAL	0.0 to 1.0E12	DIR	Additive position control loop substitute time [s]
CurrentTimeConstant	LREAL	0.0 to 1.0E12	DIR	Current control loop substitute time in time unit of the axis

10.3.25 "FollowingError" tag (positioning axis)

The tag structure "<TO>.FollowingError.<tag name>" contains the configuration of the dynamic following error monitoring.

If the permissible following error is exceeded, then technology alarm 521 is output, and the technology object is disabled (alarm reaction: remove enable).

When the warning level is reached, a warning is output (technology alarm 522).

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
FollowingError.	TO_Struct_FollowingError				
EnableMonitoring	BOOL	-	RES	FALSE	Following error monitoring deactivated
				TRUE	Following error monitoring enabled

Tag	Data type	Values	W	Description
MinValue	LREAL	Linear: 0.0 to 1.0E12 Rotary: 0.001 to 1.0E12	DIR	Permissible following error at velocities below the value of "MinVelocity"
MaxValue	LREAL	Linear: 0.0 to 1.0E12 Rotary: 0.002 to 1.0E12	DIR	Maximum permissible following error, which may be reached at the maximum velocity.
MinVelocity	LREAL	0.0 to 1.0E12	DIR	"MinValue" is permissible below this velocity and is held constant.
WarningLevel	LREAL	0.0 to 100.0	DIR	Warning level Percentage value relative to the valid maximum following error
AdditionalSetpointDelay-Time	LREAL	0.0 to 1.0E12	DIR	Time constant for additional deceleration of position set-point to calculate the following error in the time unit of the axis

10.3.26 "PositioningMonitoring" tag (positioning axis)

The tag structure "<TO>.PositioningMonitoring.<tag name>" contains the configuration of position monitoring at the end of a positioning motion.

If the actual position value at the end of a positioning motion is reached within the tolerance time and remains in the positioning window for the minimum dwell time, then "<TO>.StatusWord.X6 (Done)" is set in the technology data block. This completes a Motion Control job.

If the tolerance time is exceeded, then technology alarm 541 "Positioning monitoring" with supplemental value 1: "Target range not reached" is displayed.

If the minimum dwell time is not met, then technology alarm 541 "Positioning monitoring" with supplemental value 2: "Exit target range again" is displayed.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
PositioningMonitoring.	TO_Struct_PositionMonitoring			
ToleranceTime	LREAL	0.0 to 1.0E12	DIR	Tolerance time Maximum permitted duration from reaching of velocity setpoint zero until entrance into the positioning window
MinDwellTime	LREAL	0.0 to 1.0E12	DIR	Minimum dwell time in positioning window
Window	LREAL	0.001 to 1.0E12	DIR	Positioning window

10.3.27 "StandstillSignal" tag (positioning axis)

The tag structure "<TO>.StandstillSignal.<tag name>" contains the configuration of the standstill signal.

If the actual velocity value is below the velocity threshold, and does not exceed it during the minimum dwell time, then the standstill signal "<TO>.StatusWord.X7 (Standstill)" is set.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StandstillSignal.	TO_Struct_StandstillSignal			Configuration for the standstill signal
VelocityThreshold	LREAL	0.0 to 1.0E12	DIR	Velocity threshold If velocity is below this threshold, the minimum dwell time begins.
MinDwellTime	LREAL	0.0 to 1.0E12	DIR	Minimum dwell time

10.3.28 "StatusPositioning" tag (positioning axis)

The tag structure "<TO>.StatusPositioning.<tag name>" indicates the status of a positioning motion.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusPositioning.	TO_Struct_StatusPositioning			
Distance	LREAL	-1.0E12 ... 1.0E12	RON	Distance to target position
TargetPosition	LREAL	-1.0E12 ... 1.0E12	RON	Target position
TargetPositionModulo-Cycle	DINT	-2147483648 ... 2147483647	RON	Number of modulo cycles to target position with positioning motions
FollowingError	LREAL	-1.0E12 ... 1.0E12	RON	Current following error
SetpointExecutionTime	LREAL	0 ... 1.0E12	RON	Setpoint execution time of the axis (Results from T_{lpo}, T_{vtc} or 1/kv, T_{Send} and T_O of the axis)
SuperimposedDistance	LREAL	0 ... 1.0E12	RON	Use the instructions "MC_MoveSuperimposed", "MC_MotionInSuperimposed", "MC_MotionInSuperimposedAxes" and "MC_HaltSuperimposed" to move the distance. The value is reset when the basic motion and the superimposed motion are completed or the basic motion is aborted.

10.3.29 "StatusDrive" tag (positioning axis)

The tag structure "<TO>.StatusDrive.<tag name>" indicates the status of the drive.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
StatusDrive.	TO_Struct_StatusDrive				
InOperation	BOOL	-	RON	Operation status of the drive	
				FALSE	Drive not ready Setpoints will not be executed.
				TRUE	Drive ready Setpoints can be executed.
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and drive	
				FALSE	Cyclic communication not established. Fault ZSW1.X3 (FaultPresent) is present. Possible causes: • The CPU is in STOP. • The drive has failed. • The "ControlRequested" bit in the status word of the drive has the value "FALSE". • The drive signals an error using the status word. • For isochronous configuration, the dynamic sign of life in the telegram has failed or is not supplied by the drive.
				TRUE	Cyclic communication OK and no fault effective
Error	BOOL	-	RON	FALSE	No drive error
				TRUE	Drive error
AdaptionState	DINT	0 to 4	RON	Status of automatic data transfer of drive parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer

10.3.30 "StatusServo" tag (positioning axis)

The tag structure "<TO>.StatusServo.<tag name>" indicates the status for the balancing filter.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusServo.	TO_Struct_StatusServo			
BalancedPosition	LREAL	-	RON	Position setpoint after the balancing filter
ControlDifference	LREAL	-	RON	Control deviation
PositionAfterDynamicFilter	LREAL	-	RON	Position setpoint after the dynamic filter

10.3.31 "StatusProvidedLeadingValue" tag (positioning axis)

The tag structure "<TO>.StatusProvidedLeadingValue.<tag name>" contains the provided leading value with leading value delay of the cross-PLC synchronous operation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusProvidedLeadingValue.	TO_Struct_StatusProvidedLeadingValue			Provided leading value
DelayedLeadingValue	TO_Struct_ProvidedLeadingValue			Leading value with leading value delay
Position	LREAL	-1.0E12 to 1.0E-12	RON	Position
Velocity	LREAL	-1.0E12 to 1.0E-12	RON	Velocity
Acceleration	LREAL	-1.0E12 to 1.0E-12	RON	Acceleration

10.3.32 StatusSensor[1..4] Tags (positioning axis)

The tag structure "<TO>.StatusSensor[1..4].<tag name>" indicates the status of the measuring system.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusSensor[1..4].	Array [1..4] OF TO_Struct_StatusSensor			
State	DINT	0 to 2	RON	Status of the actual encoder value

Tag	Data type	Values	W	Description	
State	DINT	0 to 2	RON	0	"NOT_VALID" Invalid
				1	"WAITING_FOR_VALID" Waiting for "Valid" status
				2	"VALID" Valid
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and encoder	
				FALSE	Not established
				TRUE	Established
Error	BOOL	-	RON	FALSE	No error in the measuring system
				TRUE	Error in the measuring system.
AbsEncoderOffset	LREAL	-	RON	Home position offset for value of an absolute value encoder. The value will be retentively stored in the CPU.	
Control	BOOL	-	RON	FALSE	Encoder is not active
				TRUE	Encoder is active
Position	LREAL	-	RON	Encoder position	
Velocity	LREAL	-	RON	Encoder velocity	
AdaptionState	DINT	0 to 4	RON	Status of automatic data transfer of encoder parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer
ModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles	
Adjusted	DINT	0, 1	RON	Homing status of the encoder	
				0	Encoder not homed
				1	Encoder homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment

10.3.33 "StatusExtrapolation" tag (positioning axis)

The tag structure "<TO>.StatusExtrapolation.<tag name>" indicates the status of the actual value extrapolation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusExtrapolation.	TO_Struct_StatusExtrapolation			
FilteredPosition	LREAL	-1.0E12 to 1.0E-12	RON	Position after position filter
FilteredVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Velocity after velocity filter and tolerance band
ExtrapolatedPosition	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated position
ExtrapolatedVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated velocity

10.3.34 "StatusKinematicsMotion" tag (positioning axis)

The "<TO>.StatusKinematicsMotion" tag contains status information of the technology object with regard to usage as kinematics axis.

Information on evaluating individual bits (e.g. bit 2 "MaxDecelerationExceeded") can be found in the "Evaluating StatusWord, ErrorWord, and WarningWord" section of the "S7-1500/S7-1500T Motion Control overview" documentation.

Tag

Legend (Page 393)

Tag	Data type	Values	W	Description	
StatusKinematicsMotion	DWORD	-	RON	Status information of the technology object	
Bit 0	-	-	-	"MaxVelocityExceeded"	
				0	The kinematics technology object calculated a lower velocity setpoint than the maximum velocity on the axis.
				1	The kinematics technology object calculated a higher velocity setpoint than the maximum velocity on the axis.
Bit 1	-	-	-	"MaxAccelerationExceeded"	
				0	The kinematics technology object calculated a lower setpoint acceleration calculated than the maximum acceleration of the axis.
				1	The kinematics technology object calculated a higher setpoint acceleration than the maximum acceleration of the axis.

Tag		Data type	Values	W	Description	
	Bit 2	-	-	-	"MaxDecelerationExceeded"	
					0	The kinematics technology object calculated a lower setpoint deceleration than the maximum deceleration of the axis.
					1	The kinematics technology object calculated a lower setpoint deceleration than the maximum deceleration of the axis.

10.3.35 "StatusTorqueData" tag (positioning axis)

The tag structure "<TO>.StatusTorqueData.<tag name>" shows the status of the force/torque data.

Tags

Legend (Page 393)

Tag		Data type	Value range	W	Description

					0	Inactive
					1	Active
	ActualTorque	LREAL	-1.0E12 ... 1.0E12	RON	Actual torque of the axis	
	ActualForce	LREAL	-1.0E12 ... 1.0E12	RON	Actual force of the axis	
	TotalTorqueAdditive	LREAL	-1.0E12 ... 1.0E12	RON	Effective additional torque of the axis	
	TotalForceAdditve	LREAL	-1.0E12 ... 1.0E12	RON	Effective additional force of the axis	

10.3.36 "StatusMotionIn" tag (positioning axis)

The tag structure "<TO>.StatusMotionIn.<tag name>" indicates the status of the "MotionIn" function.

Tags

Legend (Page 393)

Tag		Data type	Value range	W	Description	
StatusMotionIn.		TO_Struct_StatusMotionIn				
	FunctionState	DINT	0 to 2	RON	0	No "MotionIn" function active

Tag	Data type	Value range	W	Description	
FunctionState	DINT	0 to 2	RON	1	"MC_MotionInVelocity" active
				2	"MC_MotionInPosition" active
ActualSuperimposingAxis	DB_ANY	0 to 65535	RON	At the start of a "MC_MotionInSuperimposedAxes" job, the number of the technology data block of the currently used superimposing axis is displayed.	
				0	"MC_MotionInSuperimposedAxes" job inactive
StatusWord.	DWORD	-	RON	-	
Bit 0	Bool	-	RON	"MaxVelocityExceeded" The configured maximum velocity is exceeded during a MotionIn movement.	
Bit 1 ... Bit 31	Bool	-	RON	Reserved	

10.3.37 "StatusInterpreterMotion" tag (positioning axis)

The tag structure "<TO>.StatusInterpreterMotion.<tag name>" contains status information on motion jobs controlled by a technology object Interpreter.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusInterpreterMotion.	TO_Struct_StatusInterpreterMotion			
Interpreter	DB_ANY	0 to 65535		Controlling Interpreter technology object
StatusWord.	DWORD	-	RON	Status information
Bit 0	-	-	-	"ControlledByInterpreter" An MCL job is processed or active or the bit is set via the MCL instruction "setControlledByInterpreter()".
Bit 1	-	-	-	"MotionByInterpreter" An MCL motion job is in effect.
Bit 2 to Bit 31	-	-	-	Reserved

10.3.38 "StatusWord" tag (positioning axis)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 5 "HomingDone") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Enable" Enable status The technology object has been enabled.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object will be reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"ControlPanelActive" The axis control panel is active.
Bit 5	-	-	-	"HomingDone" Homing status The technology object is homed.
Bit 6	-	-	-	"Done" No motion job is in progress and the axis control panel is deactivated.
Bit 7	-	-	-	"Standstill" Standstill signal The axis is at a standstill.
Bit 8	-	-	-	"PositioningCommand" A positioning job is active ("MC_MoveRelative","MC_MoveAbsolute").
Bit 9	-	-	-	"JogCommand" An "MC_MoveJog" job is running.
Bit 10	-	-	-	"VelocityCommand" An "MC_MoveVelocity" job is running.
Bit 11	-	-	-	"HomingCommand" An "MC_Home" job is being processed.

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using MC_TorqueRange without SIEMENS telegram 10x, compare the values from telegram 750:
<InLimit> = ActualTorque (M_ACT) * 0.9 > UpperTorqueLimit (M_LIMIT_POS) OR ActualTorque (M_ACT) * 0.9 < LowerTorqueLimit (M_LIMIT_NEG)

Tag	Data type	Values	W	Description
Bit 12	-	-	-	"ConstantVelocity" The velocity setpoint is reached. A constant velocity set-point is output.
Bit 13	-	-	-	"Accelerating" An acceleration operation is active.
Bit 14	-	-	-	"Decelerating" A deceleration operation is active.
Bit 15	-	-	-	"SWLimitMinActive" A negative software limit switch has been approached or exceeded.
Bit 16	-	-	-	"SWLimitMaxActive" A positive software limit switch has been approached or exceeded.
Bit 17	-	-	-	"HWLimitMinActive" A negative hardware limit switch has been approached or exceeded.
Bit 18	-	-	-	"HWLimitMaxActive" A positive hardware limit switch has been approached or exceeded.
Bit 19 ... Bit 22	-	-	-	Reserved
Bit 23	-	-	-	"MoveSuperimposedCommand" An "MC_MoveSuperimposed" job is running.
Bit 24	-	-	-	Reserved
Bit 25	-	-	-	"AxisSimulation" The technology object is in simulation.
Bit 26	-	-	-	"TorqueLimitingCommand" An "MC_TorqueLimiting" job is running.
Bit 27	-	-	-	"InLimitation"[1] The drive operates at least at the threshold value (default 90%) of the torque limit/force limitation.
Bit 28	-	-	-	"NonPositionControlled" The axis is not in position-controlled mode.
Bit 29	-	-	-	"KinematicsMotionCommand" The axis is used for a kinematics job.
Bit 30	-	-	-	"InClamping" The axis is clamped at a fixed stop.
Bit 31	-	-	-	"MotionInCommand" An "MC_MotionInVelocity" job or an "MC_MotionInPosition" job is active.

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using MC_TorqueRange without SIEMENS telegram 10x, compare the values from telegram 750:
<InLimit> = ActualTorque (M_ACT) * 0.9 > UpperTorqueLimit (M_LIMIT_POS) OR ActualTorque (M_ACT) * 0.9 < LowerTorqueLimit (M_LIMIT_NEG)

10.3.39 "StatusWord2" tag (positioning axis)

The "<TO>.StatusWord2" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 0 "StopCommand") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description
StatusWord2	DWORD	-	RON	Status information of the technology object
Bit 0	BOOL	-	RON	"StopCommand" An "MC_Stop" job is running. The technology object is disabled.
Bit 1	BOOL	-	RON	Reserved
Bit 2	BOOL	-	RON	"PassingBacklash" The backlash is traversed. "<TO>.ActualPosition" does not hereby change.
Bit 3 ... Bit 5	BOOL	-	RON	Reserved
Bit 6	BOOL	-	RON	"MotionInSuperimposedCommand" An "MC_MotionInSuperimposed" job is running.
Bit 7	BOOL	-	RON	"HaltSuperimposedCommand" An "MC_HaltSuperimposed" job is running.
Bit 8	BOOL	-	RON	"MotionInSuperimposedAxesCommand" An "MC_MotionInSuperimposedAxes" job is running.
Bit 9	BOOL	-	RON	"PositionProfileCommand" An "MC_PositionProfile" job is running.
Bit 10	BOOL	-	RON	"OnProfile" An "MC_PositionProfile" job is running and the axis traverses the setpoint values of the time-based position profile.
Bit 11 to Bit 31	BOOL	-	RON	Reserved

10.3.40 "ErrorWord" tag (positioning axis)

The "<TO>.ErrorWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the alarms requiring acknowledgment and serious errors alarm classes into consideration.

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

To read out the specific alarm number of the technology alarm with the highest priority associated with the technology object, evaluate the tag "<TO>.ErrorDetail.Number".

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	"DriveFault" Error in drive
Bit 5	-	-	-	"SensorFault" Error in encoder system
Bit 6	-	-	-	"DynamicError" Specified dynamic values are limited to permissible values.
Bit 7	-	-	-	"CommunicationFault" Communication error Missing or faulty communication.
Bit 8	-	-	-	"SWLimit" Software limit switch reached or overtraveled.
Bit 9	-	-	-	"HWLimit" Hardware limit switch reached or overtraveled.
Bit 10	-	-	-	"HomingError" Error during homing operation The homing cannot be completed.
Bit 11	-	-	-	"FollowingErrorFault" Following error limits exceeded
Bit 12	-	-	-	"PositioningFault" Positioning error
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
Bit 14	-	-	-	Reserved

Tag		Data type	Values	W	Description
	Bit 15	-	-	-	"AdaptionError" Error in automatic data transfer
	Bit 16	-	-	-	"SuperimposingError" Error in the superimposition of the axis The superimposing axis specified in the Motion Control instruction was not configured as a possible superimposing axis.
	Bit 17 to Bit 31	-	-	-	Reserved

10.3.41 "ErrorDetail" tag (positioning axis)

The "<TO>.ErrorDetail" tag structure contains the alarm number and the effective local alarm response of the technology alarm pending on the technology object with the highest priority.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

Tags

Legend (Page 393)

Tag		Data type	Values	W	Description	
ErrorDetail.		TO_Struct_ErrorDetail				
	Number	UDINT	-	RON	Alarm number	
	Reaction	DINT	0 to 5	RON	Effective alarm response	
					0	No reaction
					1	Stop with current dynamic values
					2	Stop with maximum dynamic values
					3	Stop with emergency stop ramp
					4	Remove enable
					5	Track setpoints

10.3.42 "WarningWord" tag (positioning axis)

The "<TO>.WarningWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the acknowledgeable warnings alarm class into consideration.

Information on the evaluation of the individual bits (e.g. bit 13 "PeripheralWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all warnings pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
WarningWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemWarning" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigWarning" Configuration error One or several configuration parameters are adjusted internally.
Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	"DriveWarning" Warning of the drive When a warning message is pending at the drive that does not result in a TO alarm, this bit is not set. Evaluate the drive warnings directly using the status word of the drive.
Bit 5	-	-	-	"SensorWarning" Error in encoder system
Bit 6	-	-	-	"DynamicWarning" Specified dynamic values are limited to permissible values.
Bit 7	-	-	-	"CommunicationWarning" Communication error Missing or faulty communication.
Bit 8	-	-	-	"SWLimitMin" The negative software limit switch has been approached.
Bit 9	-	-	-	"SWLimitMax" The positive software limit switch has been approached.
Bit 10	-	-	-	"HomingWarning" Error during homing operation The homing cannot be completed.
Bit 11	-	-	-	"FollowingErrorWarning" Warning limit of following error monitoring reached/exceeded
Bit 12	-	-	-	"PositioningWarning" Positioning error
Bit 13	-	-	-	"PeripheralWarning" Error accessing a logical address
Bit 14	-	-	-	Reserved

Tag	Data type	Values	W	Description
Bit 15	-	-	-	"AdaptionWarning" Error in automatic data transfer
Bit 16	-	-	-	"SuperimposingWarning" Error in the superimposition of the axis The superimposing axis specified in the Motion Control instruction was not configured as a possible superimposing axis.
Bit 16... Bit 31	-	-	-	Reserved

10.3.43 "ControlPanel" tag (positioning axis)

The tag structure "<TO>.ControlPanel.<tag name>" contains no relevant data for you. This tag structure is internally used.

10.3.44 "InternalToTrace" tag (positioning axis)

The tag structure "<TO>.InternalToTrace.<tag name>" contains no relevant data for you. This tag structure is internally used.

10.4 Tags of the technology object external encoder

10.4.1 Actual values (external encoder)

The following tags indicate the actual values of the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
ActualPosition	LREAL	-	RON	Actual position
ActualVelocity	LREAL	-	RON	Actual velocity
ActualAcceleration	LREAL	-	RON	Actual acceleration
ActualModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles of the actual value

10.4.2 "Sensor" tag (external encoder)

The tag structure "<TO>.Sensor.<tag name>" contains the controller-side configuration for the encoder, and the configuration for passive homing.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Sensor.	TO_Struct_ExternalEncoder_Sensor				
Type	DINT	0 to 2	RON	Encoder type	
				0	"INCREMENTAL" Incremental
				1	"ABSOLUTE" Absolute
				2	"CYCLIC_ABSOLUTE" Cyclic absolute
InverseDirection	BOOL	-	RES	Inversion of the actual value	
				FALSE	No
				TRUE	Yes
System	DINT	0, 1	RES	Encoder system	
				0	"LINEAR" Linear encoder
				1	"ROTATORY" Rotary encoder
MountingMode	DINT	0 to 2	RES	Mounting type of encoder	
				0	On motor shaft
				1	On load side
				2	External measuring system
DataAdaption	DINT	0, 1	RES	Automatic transfer of the drive values reference speed, maximum speed and reference torque in the device	
				0	No automatic transfer, manual configuration of values
				1	Automatic transfer of values configured in the drive to the configuration of the technology object
ActualVelocityMode	DINT	0, 1	RES	Type of calculation for actual speed value or actual velocity value	
				0	Actual value calculation from differentiation of the position change
				1	Actual value calculation with NACT value from the telegram
Interface.					
AddressIn	VREF	0 to 65535	RON	Input address for the PROFIdrive telegram	
AddressOut	VREF	0 to 65535	RON	Output address for the PROFIdrive telegram	

Tag	Data type	Values	W	Description
Number	UDINT	1 to 2	RON	Number of the encoder in the telegram
Parameter.				
Resolution	LREAL	-1.0E12 ... 1.0E12	RES	Resolution of a linear encoder (offset between two encoder pulses)
StepsPerRevolution	UDINT	1 to 8388608	RES	Increments per rotary encoder revolution
FineResolutionXist1	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST1" (cyclic actual encoder value)
FineResolutionXist2	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST2" (absolute value of the encoder)
DeterminableRevolutions	UDINT	0 to 8388608	RES	Number of differentiable encoder revolutions for a multi-turn absolute encoder (For a single-turn absolute encoder = 1; for an incremental encoder = 0)
DistancePerRevolution	LREAL	0.0 to 1.0E12	RES	Load distance per revolution of an externally mounted encoder
BehaviorGx_XIST1	DINT	0, 1	RES	Evaluation of "Gx_XIST1" bits.
				0: Based on the bits of the encoder resolution. The incremental actual value "Gx_XIST1" is transmitted with less than 32 bits in the PROFIdrive telegram. For example: At 16 bits, the value ranges from 0 to 65,535.
				1: 32-bit value of the encoder value The "Gx_XIST1" incremental actual value is transferred with 32 bits of 0 to 4,294,967,295 in the PROFIdrive telegram.
ReferenceSpeed	LREAL	0.0 to 1.0E12	RES	Reference speed for NACT in PROFIdrive telegram with rotary encoder Only relevant for "ActualVelocityMode" = 1
ReferenceVelocity	LREAL	0.0 to 1.0E12	RES	Reference velocity for NACT in the PROFIdrive telegram with linear encoder Only relevant for "ActualVelocityMode" = 1
PassiveHoming.	TO_Struct_SensorPassiveHoming			
Mode	DINT	0 to 2	RES	Homing mode
				0: Use zero mark via PROFIdrive telegram
				1: Zero mark via PROFIdrive telegram and reference output cam
				2: Use homing mark via digital input
SideInput	BOOL	-	CAL	Side of the digital input for passive homing
				FALSE: Negative side
				TRUE: Positive side
Direction	DINT	0 to 2	CAL	Homing direction/approach direction to homing mark
				0: Positive homing direction
				1: Negative homing direction

Tag	Data type	Values	W	Description	
Direction	DINT	0 to 2	CAL	2	Current homing direction
DigitalInputAddress	VREF	0 to 65535	RON	Address of the digital input	
SwitchLevel	BOOL	-	RON	Signal level that is present at the digital input when homing mark is approached	
				FALSE	Low level
				TRUE	High level

10.4.3 "CrossPlcSynchronousOperation" tag (external encoder)

The tag structure "<TO>.CrossPlcSynchronousOperation.<tag name>" contains the configuration of the cross-PLC synchronous operation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
CrossPlcSynchronousOperation.	TO_Struct_CrossPlcSynchronousOperation				
Interface[1..32].	ARRAY [1..32] of TO_Struct_CrossPlcLeadingValueInterface				
EnableLeadingValueOutput	BOOL	-	RON	Provide cross-PLC leading value	
				FALSE	No
				TRUE	Yes
AddressOut	VREF	-	RON	Output address for the leading value telegram	
TelegramVersion	WORD	1, 2	RON	Leading value telegram version	
				1	Version 1 (technology version ≤ 8.0 and ≥ 10.0)
				2	Version 2 (technology version ≥ 9.0)
LocalLeadingValueDelayTime	LREAL	0.0 to 1.0E9	RES	Delay time of leading value output to the local following axes	

10.4.4 "Extrapolation" tag (external encoder)

The tag structure "<TO>.Extrapolation.<tag name>" contains the configuration of the actual value extrapolation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Extrapolation.	TO_Struct_Extrapolation			
LeadingAxisDependent-Time	LREAL	-	RON	Extrapolation time component (caused by leading axis) Results from the following times: • Time of actual value acquisition for the leading axis • Interpolator cycle clock • Time of position filter of actual value extrapolation (T1 + T2)
FollowingAxisDepend-entTime	LREAL	0.0 to 1.0E12	DIR	Extrapolation time component (caused by following axis) For a following axis with set velocity precontrol, the following times result in: • Communication cycle • Interpolator cycle clock • Speed control loop substitute time for the following axis • Output delay time of the setpoint at the following axis For a following axis without velocity precontrol, the following times result in: • Communication cycle • Interpolator cycle clock • Position control loop equivalent time (1/Kv from "<TO>.PositionControl.Kv") • Output delay time of the setpoint at the following axis
Settings.	TO_Struct_ExtrapolationSettings			
SystemDefinedExtra-polation	DINT	0, 1	RES	Leading axis dependent time 0 Not effective 1 Effective
ExtrapolatedVelocity-Mode	DINT	0, 1, 2	RES	Effective velocity value for the synchronization function 0 Filtered velocity Leading value velocity from filtered actual velocity 1 Extrapolated velocity Leading value velocity from extrapolation 2 Differentiated velocity Leading value velocity from differentiation of the extrapolated leading value position
PositionFilter.	TO_Struct_ExtrapolationPositionFil-ter			
T1	LREAL	0.0 to 1.0E12	DIR	Position filter time constant T1
T2	LREAL	0.0 to 1.0E12	DIR	Position filter time constant T2

Tag	Data type	Values	W	Description
VelocityFilter.	TO_Struct_ExtrapolationVelocityFilter			
T1	LREAL	0.0 to 1.0E12	DIR	Velocity filter time constant T1
T2	LREAL	0.0 to 1.0E12	DIR	Velocity filter time constant T2
VelocityTolerance.	TO_Struct_ExtrapolationVelocityTolerance			
Range	LREAL	0.0 to 1.0E12	DIR	Tolerance band width for velocity
Hysteresis.	TO_Struct_ExtrapolationHysteresis			
Value	LREAL	0.0 to 1.0E12	DIR	Hysteresis of the extrapolated actual position value

10.4.5 "LoadGear" tag (external encoder)

The tag structure "<TO>.LoadGear.<tag name>" contains the configuration of the load gear.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description
LoadGear.	TO_Struct_LoadGear			
Numerator	UDINT	1 to 4294967295	RES	Load gear numerator
Denominator	UDINT	1 to 4294967295	RES	Load gear denominator

10.4.6 "Properties" tag (external encoder)

The tag structure "<TO>.Properties.<tag name>" contains the configuration of the type of axis or motion.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
VelocityUnit	UDINT	-	RON	1070	ft/min
				1075	mi/h
TimeUnit	UDINT	-	RON	Unit for time	
				1054	s

1) Position values with higher resolution or six decimal places

10.4.8 "Mechanics" tag (external encoder)

The tag structure "<TO>.Mechanics.<tag name>" contains the configuration of the mechanics.

Tags

Legend (Page 393)

Tag	Data type	Value range	W	Description
Mechanics.	TO_Struct_Mechanics			
LeadScrew	LREAL	1.0E-12 to 1.0E12	RES	Leadscrew pitch

10.4.9 "Modulo" tag (external encoder)

The tag structure "<TO>.Modulo.<tag name>" contains the configuration of the modulo function.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description	
Modulo.	TO_Struct_Modulo				
Enable	BOOL	-	RES	FALSE	Modulo conversion disabled
				TRUE	Modulo conversion enabled
Length	LREAL	0.001 to 1.0E12	RES	Modulo length When modulo conversion is enabled, a check is made for modulo length > 0.0	
StartValue	LREAL	-1.0E12 to 1.0E-12	RES	Modulo start value	

10.4.10 "Homing" tag (external encoder)

The tag structure "<TO>.Homing.<tag name>" contains the configuration for homing the TO.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
Homing.	TO_Struct_Homing / TO_Struct_ExternalEncoder_Homing			
HomePosition	LREAL	-1.0E12 to 1.0E12	CAL	Home position

10.4.11 "StandstillSignal" tag (external encoder)

The tag structure "<TO>.StandstillSignal.<tag name>" contains the configuration of the standstill signal.

If the actual velocity value is below the velocity threshold, and does not exceed it during the minimum dwell time, then the standstill signal "<TO>.StatusWord.X7 (Standstill)" is set.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StandstillSignal.	TO_Struct_StandstillSignal			Configuration for the standstill signal
VelocityThreshold	LREAL	0.0 to 1.0E12	DIR	Velocity threshold If velocity is below this threshold, the minimum dwell time begins.
MinDwellTime	LREAL	0.0 to 1.0E12	DIR	Minimum dwell time

10.4.12 "StatusProvidedLeadingValue" tag (external encoder)

The tag structure "<TO>.StatusProvidedLeadingValue.<tag name>" contains the provided leading value with leading value delay of the cross-PLC synchronous operation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusProvidedLeadingValue.	TO_Struct_StatusProvidedLeadingValue			Provided leading value
DelayedLeadingValue	TO_Struct_ProvidedLeadingValue			Leading value with leading value delay

StatusSensor.	TO_Struct_StatusSensor				
State	DINT	0 to 2	RON	Status of the actual encoder value	
				0	"NOT_VALID" Invalid
				1	"WAITING_FOR_VALID" Waiting for "Valid" status
				2	"VALID" Valid
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and encoder	
				FALSE	Not established
				TRUE	Established
Error	BOOL	-	RON	FALSE	No error in the measuring system
				TRUE	Error in the measuring system.
AbsEncoderOffset	LREAL	-	RON	Home position offset for value of an absolute value encoder. The value will be retentively stored in the CPU.	
Control	BOOL	-	RON	FALSE	Encoder is not active

Tag	Data type	Values	W	Description	
Control	BOOL	-	RON	TRUE	Encoder is active
Position	LREAL	-	RON	Encoder position	
Velocity	LREAL	-	RON	Encoder velocity	
AdaptionState	DINT	-	RON	Status of automatic data transfer of encoder parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer
ModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles	
Adjusted	DINT	0 to 1	RON	Homing status of the encoder	
				0	Encoder not homed
				1	Encoder homed with one of the following homing types: • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment

10.4.14 "StatusExtrapolation" tag (external encoder)

The tag structure "<TO>.StatusExtrapolation.<tag name>" indicates the status of the actual value extrapolation.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusExtrapolation.	TO_Struct_StatusExtrapolation			
FilteredPosition	LREAL	-1.0E12 to 1.0E-12	RON	Position after position filter
FilteredVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Velocity after velocity filter and tolerance band
ExtrapolatedPosition	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated position
ExtrapolatedVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated velocity

10.4.15 "StatusWord" tag (external encoder)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 5 "HomingDone") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tag

Legend (Page 393)

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Enable" Enable status The technology object has been enabled.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	Reserved
Bit 5	-	-	-	"HomingDone" Homing status The technology object is homed.
Bit 6	-	-	-	"Done" No motion job is in progress and the axis control panel is deactivated.
Bit 7	-	-	-	"Standstill" standstill signal The external encoder is at a standstill.
Bit 8 ... Bit 10	-	-	-	Reserved
Bit 11	-	-	-	"HomingCommand" An "MC_Home" job is being processed.
Bit 12... Bit 31	-	-	-	Reserved

10.4.16 "ErrorWord" tag (external encoder)

The "<TO>.ErrorWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the alarms requiring acknowledgment and serious errors alarm classes into consideration.

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

To read out the specific alarm number of the technology alarm with the highest priority associated with the technology object, evaluate the tag "<TO>.ErrorDetail.Number".

You can use the "Get_Alarm" instruction, for example, to evaluate all warnings pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	Reserved
Bit 5	-	-	-	"SensorFault" Error in encoder system
Bit 6	-	-	-	Reserved
Bit 7	-	-	-	"CommunicationFault" Communication error Missing or faulty communication.
Bit 8	-	-	-	Reserved
Bit 9	-	-	-	Reserved
Bit 10	-	-	-	"HomingError" Error during homing operation The homing cannot be completed.
Bit 11	-	-	-	Reserved
Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address

Tag		Data type	Values	W	Description
	Bit 14	-	-	-	Reserved
	Bit 15	-	-	-	"AdaptionError" Error in automatic data transfer
	Bit 16 ... Bit 31	-	-	-	Reserved

10.4.17 "ErrorDetail" tag (external encoder)

The "<TO>.ErrorDetail.<tag name>" tag structure contains the alarm number and the effective local alarm response of the technology alarm with the highest priority pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

Tags

Legend (Page 393)

Tag		Data type	Values	W	Description	
ErrorDetail.		TO_Struct_ErrorDetail				
	Number	UDINT	-	RON	Alarm number	
	Reaction	DINT	0, 10	RON	Effective alarm response	
					0	No reaction
					10	Remove enable

10.4.18 "WarningWord" tag (external encoder)

The "<TO>.WarningWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the acknowledgeable warnings alarm class into consideration.

Information on the evaluation of the individual bits (e.g. bit 13 "PeripheralWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all warnings pending on the technology object.

Tags

Legend (Page 393)

Tag	Data type	Values	W	Description
WarningWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemWarning" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigWarning" Configuration error One or several configuration parameters are adjusted internally.
Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4	-	-	-	Reserved
Bit 5	-	-	-	"SensorWarning" Error in encoder system
Bit 6	-	-	-	Reserved
Bit 7	-	-	-	"CommunicationWarning" Communication error Missing or faulty communication.
Bit 8	-	-	-	Reserved
Bit 9	-	-	-	Reserved
Bit 10	-	-	-	"HomingWarning" Error during homing operation The homing cannot be completed.
Bit 11	-	-	-	Reserved
Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralWarning" Error accessing a logical address
Bit 14	-	-	-	Reserved
Bit 15	-	-	-	"AdaptionWarning" Error in automatic data transfer
Bit 16... Bit 31	-	-	-	Reserved

10.4.19 "InternalToTrace" tag (external encoder)

The tag structure "<TO>.InternalToTrace.<tag name>" contains no relevant data for you. This tag structure is internally used.

Introduction 1

Purpose of the documentation

This documentation provides important information that you need to configure and commission the integrated Motion Control functionality of the S7-1500 Automation systems.

Required basic knowledge

In order to understand this documentation, the following knowledge is required:

- General knowledge in the field of automation
- General knowledge in the field of drive engineering and motion control

Validity of the documentation

This documentation is valid for the S7-1500 product range.

Conventions

- The path specifications in the project tree assume that the "Technology objects" folder is open in the subtree of the CPU. The "Technology object" placeholder represents the name of the technology object.

  Example: "Technology object > Configuration > Basic parameters".
- The <TO> placeholder represents the name set in tags for the respective technology object.

  Example: <TO>.Actor.Type
- This documentation contains pictures of the devices described. The pictures may differ in minor details from the devices supplied.

You should also observe the notes that are marked as follows:

NOTE

A note contains important information about the product described in the documentation, about the handling of the product, and about sections in this documentation demanding your particular attention.

Industry Mall

The Industry Mall is the catalog and ordering system of Siemens Aktiengesellschaft for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

1.1 S7-1500 Motion Control Documentation Guide

Product information

Please also note the supplementary information on the Motion Control documentation:

- Product information on the S7-1500/1500T Motion Control documentation
  https://support.industry.siemens.com/cs/ww/en/view/109794046
  (https://support.industry.siemens.com/cs/ww/en/view/109794046)

Documentation

The documentation of the Motion Control functions is divided into the following documents:

- S7-1500/S7-1500T Motion Control Overview
  https://support.industry.siemens.com/cs/en/view/109990070
  (https://support.industry.siemens.com/cs/ww/en/view/109990070)

  This document describes the innovations in the technology versions, how to upgrade the technology version, functions that are used for all technology objects, and the operational sequence of Motion Control applications.
- S7-1500/S7-1500T Motion Control alarms and error IDs
  https://support.industry.siemens.com/cs/ww/en/view/109990076
  (https://support.industry.siemens.com/cs/ww/en/view/109990076)

  This document describes the technology alarms of the technology objects and the error identifications of the Motion Control instructions.
- S7-1500/S7-1500T Axis functions
  https://support.industry.siemens.com/cs/en/view/109990072
  (https://support.industry.siemens.com/cs/ww/en/view/109990072)

  This document describes the drive and encoder connection and functions for single-axis movements.
- S7-1500/S7-1500T Synchronous operation functions
  https://support.industry.siemens.com/cs/ww/en/view/109990074
  (https://support.industry.siemens.com/cs/ww/en/view/109990074)

  This document describes gearing, velocity synchronous operation and camming as well as cross-PLC synchronous operation.

- S7-1500/S7-1500T Measuring input and output cam functions
  https://support.industry.siemens.com/cs/ww/en/view/109990075
  (https://support.industry.siemens.com/cs/ww/en/view/109990075)
  This document describes the detection of the actual position via a measuring input and the output of switching signals via output cam or cam track.
- S7-1500T kinematics functions
  https://support.industry.siemens.com/cs/ww/en/view/109990073
  (https://support.industry.siemens.com/cs/ww/en/view/109990073)
  This document describes the control of kinematics with up to 6 interpolating axes.
- S7-1500T Interpreter functions
  https://support.industry.siemens.com/cs/ww/en/view/109990077
  (https://support.industry.siemens.com/cs/ww/en/view/109990077)
  This documentation describes the control of technology objects via an Interpreter program.

1.2 Function Manuals documentation guide

1.2.1 Information classes Function Manuals

The documentation for the SIMATIC S7-1500 automation system, for the 1513/1516pro-2 PN, SIMATIC Drive Controller CPUs based on SIMATIC S7-1500 and the SIMATIC ET 200MP, ET 200SP, ET 200AL and ET 200eco PN distributed I/O systems is arranged into three areas.

This arrangement enables you to access the specific content you require.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742705).

Basic information

The system manuals and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, SIMATIC Drive Controller, ET 200MP, ET 200SP, ET 200AL and ET 200eco PN systems. Use the corresponding operating instructions for 1513/1516pro-2 PN CPUs.

The STEP 7 online help supports you in the configuration and programming.

Examples:

- Getting Started S7-1500
- System manuals
- Operating instructions ET 200pro and 1516pro-2 PN CPU
- Online help TIA Portal

Device information

Equipment manuals contain a compact description of the module-specific information, such as properties, wiring diagrams, characteristics and technical specifications.

Examples:

- Equipment manuals for CPUs
- Equipment manuals for interface modules
- Equipment manuals for digital modules
- Equipment manuals for analog modules
- Equipment manuals for communication modules
- Equipment manuals for technology modules
- Equipment manuals for power supply modules
- Equipment manuals for BaseUnits

General information

The function manuals contain detailed descriptions on general topics relating to the SIMATIC Drive Controller and the S7-1500 automation system.

Examples:

- Function Manual Diagnostics
- Function Manual Communication
- Function Manuals Motion Control
- Function Manual Web Server
- Function Manual Cycle and Response Times
- PROFINET Function Manual
- PROFIBUS Function Manual

Product Information

Changes and supplements to the manuals are documented in a Product Information. The Product Information takes precedence over the device and system manuals.

You will find the latest Product Information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/de/en/view/68052815)
- SIMATIC Drive Controller (https://support.industry.siemens.com/cs/de/en/view/109772684/en)
- Motion Control (https://support.industry.siemens.com/cs/de/en/view/109794046/en)
- ET 200SP (https://support.industry.siemens.com/cs/de/en/view/73021864)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109765611)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP/SIMATIC Drive Controller (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109781058)

1.2.2 Basic tools

Tools

The tools described below support you in all steps: from planning, over commissioning, all the way to analysis of your system.

TIA Selection Tool

The TIA Selection Tool tool supports you in the selection, configuration, and ordering of devices for Totally Integrated Automation (TIA).

As successor of the SIMATIC Selection Tools , the TIA Selection Tool assembles the already known configurators for automation technology into a single tool.

With the TIA Selection Tool , you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/109767888)

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to perform commissioning and maintenance activities on various SIMATIC S7 stations as bulk operations independent of TIA Portal.

The SIMATIC Automation Tool offers a wide range of functions:

- Scanning of a PROFINET/Ethernet system network and identification of all connected CPUs
- Assignment of addresses (IP, subnet, Gateway) and device name (PROFINET device) to a CPU
- Transfer of the date and the programming device/PC time converted to UTC time to the module
- Program download to CPU
- RUN/STOP mode switchover
- CPU localization through LED flashing
- Reading out of CPU error information
- Reading the CPU diagnostic buffer
- Reset to factory settings
- Firmware update of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/98161300)

PRONETA

SIEMENS PRONETA (PROFINET network analysis) is a commissioning and diagnostic tool for PROFINET networks. PRONETA Basic has two core functions:

- In the network analysis, you get an overview of the PROFINET topology. Compare a real configuration with a reference installation or make simple parameter changes, e.g. to the names and IP addresses of the devices.
- The "IO test" is a simple and rapid test of the wiring and the module configuration of a plant, including documentation of the test results.

You can find SIEMENS PRONETA Basic on the Internet:
(https://support.industry.siemens.com/cs/ww/en/view/67460624)

SIEMENS PRONETA Professional is a licensed product that offers you additional functions. It offers you simple asset management in PROFINET networks and supports operators of automation systems in automatic data collection/acquisition of the components used through various functions:

- The user interface (API) offers an access point to the automation cell to automate the scan functions using MQTT or a command line.
- With PROFIenergy diagnostics, you can quickly detect the current pause mode or the readiness for operation of devices that support PROFIenergy and change these as needed.
- The data record wizard supports PROFINET developers in reading and writing acyclic PROFINET data records quickly and easily without PLC and engineering.

You can find SIEMENS PRONETA Professional on the Internet.
(https://www.siemens.com/proneta-professional)

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and the optimal use of resources

You can find SINETPLAN on the Internet (https://new.siemens.com/global/en/products/automation/industrial-communication/profinet/sinetplan.html).

1.2.3 SIMATIC Technical Documentation

Additional SIMATIC documents will complete your information. You can find these documents and their use at the following links and QR codes.

The Industry Online Support gives you the option to get information on all topics. Application examples support you in solving your automation tasks.

Overview of the SIMATIC Technical Documentation

Here you will find an overview of the SIMATIC documentation available in Siemens Industry Online Support:

Industry Online Support International (https://support.industry.siemens.com/cs/ww/en/view/109742705)

Watch this short video to find out where you can find the overview directly in Siemens Industry Online Support and how to use Siemens Industry Online Support on your mobile device:

Quick introduction to the technical documentation of automation products per video (https://support.industry.siemens.com/cs/us/en/view/109780491)

YouTube video: Siemens Automation Products - Technical Documentation at a Glance (https://youtu.be/TwLSxxRQQsA)

Retention of the documentation

Retain the documentation for later use.

For documentation provided in digital form:

1. Download the associated documentation after receiving your product and before initial installation/commissioning. Use the following download options:
   - Industry Online Support International: (https://support.industry.siemens.com)

     The article number is used to assign the documentation to the product. The article number is specified on the product and on the packaging label. Products with new, non-compatible functions are provided with a new article number and documentation.
   - ID link:

     Your product may have an ID link. The ID link is a QR code with a frame and a black frame corner at the bottom right. The ID link takes you to the digital nameplate of your product. Scan the QR code on the product or on the packaging label with a smartphone camera, barcode scanner, or reader app. Call up the ID link.
2. Retain this version of the documentation.

Updating the documentation

The documentation of the product is updated in digital form. In particular in the case of function extensions, the new performance features are provided in an updated version.

1. Download the current version as described above via the Industry Online Support or the ID link.
2. Also retain this version of the documentation.

mySupport

With "mySupport" you can get the most out of your Industry Online Support.

Registration	You must register once to use the full functionality of "mySupport". After registration, you can create filters, favorites and tabs in your personal workspace.
Support requests	Your data is already filled out in support requests, and you can get an overview of your current requests at any time.
Documentation	In the Documentation area you can build your personal library.
Favorites	You can use the "Add to mySupport favorites" to flag especially interesting or frequently needed content. Under "Favorites", you will find a list of your flagged entries.
Recently viewed articles	The most recently viewed pages in mySupport are available under "Recently viewed articles".
CAx data	The CAx data area gives you access to the latest product data for your CAx or CAe system. You configure your own download package with a few clicks: • Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files • Manuals, characteristics, operating manuals, certificates • Product master data

You can find "mySupport" on the Internet. (https://support.industry.siemens.com/My/ww/en)

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You can find the application examples on the Internet.
(https://support.industry.siemens.com/cs/ww/en/ps/ae)

Safety instructions 2

2.1 General safety instructions

The safety instructions can be found in section "Safety instructions" in the System Manual "SIMATIC S7-1500, ET 200MP Automation System" (https://support.industry.siemens.com/cs/ww/en/view/59191792) document.

Cybersecurity-relevant information can be found in the Industrial Cybersecurity section.

2.2 Warnings in this document

You can find explanations of the warnings used in this document in the "Legal information" section.

Industrial cybersecurity 3

Due to the digitalization and increasing networking of machines and industrial plants, the risk of cyber attacks is also growing. Appropriate protective measures are therefore mandatory, particularly in the case of critical infrastructure facilities.

3.1 Cybersecurity information

Siemens provides products and solutions with industrial cybersecurity functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial cybersecurity concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial cybersecurity measures that may be implemented, please visit
https://www.siemens.com/cybersecurity-industry.

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Cybersecurity RSS Feed under
https://new.siemens.com/cert.

Overview of functions

4

4.1 Measuring input technology object

The measuring input technology object acquires the actual position of an axis or external encoder at a signal change at the measurement input.

With the measuring input technology object, you can measure once (Page 35) or cyclically (Page 36).

For position detection via measuring input, you use various technology modules and onboard I/O of CPUs which you configure as measurement input. In addition, measuring via "Monitor measuring input" provides the possibility to record measurement events of a measurement input from multiple measuring inputs at the same time.

You can find an overview of the functions of the measuring input technology object in the "Motion Control instructions (Page 23)" section.

The following figure shows the basic principle of operation of the measuring input technology object:

Use with SIMATIC S7-PLCSIM

The measuring input technology object cannot be used with SIMATIC S7-PLCSIM. The measuring input technology object and the measuring input jobs used in the user program can be loaded into SIMATIC S7-PLCSIM, but have no function. Measured values are not shown.

Configuration

The following configurations are available in the measuring input technology object:

- Basic parameters
  - Units of measure (Page 25)
- Hardware interface > Measurement sensing input
  - Measuring using Timer DI (Page 27)
  - Measuring via SINAMICS (central measuring probe) (Page 28)
  - Measuring using PROFIdrive telegram (Page 29)
  - Monitoring measuring input (Page 31)
- Extended parameters
  - Adjustment for activation time of the measuring range (Page 33)

See also

Overview of measurement inputs and measuring types (Page 26)

4.2 Output cam technology object

The output cam technology object generates switching signals depending on the position of an axis or external encoder. The switching states can be evaluated in the user program and fed to digital outputs.

You can find an overview of the functions of the output cam technology object in the "Motion Control instructions (Page 23)" section.

The following figure shows the basic operating principle of the output cam technology object:

The output cam technology object supports distance output cams and time-based output cams and calculates the exact switching time. The switching signal can be output on a Timer DQ or at a digital output.

Output cam types

The following output cam types can be used:

- Distance output cam

  Distance output cams switch on between the start position and end position. Outside this range, the distance output cam is switched off.

- Time-based output cam

  Time-based output cams switch on for a defined time period when the start position is reached.

Configuration

The following configurations are available in the output cam technology object:

- Basic parameters
  - Output cam type > Distance output cam (Page 44)
  - Output cam type > Time-based output cam (Page 45)
  - Output cam reference > Position setpoint (Page 46)
  - Output cam reference > Current position (Page 46)
  - Units of measure (Page 25)
- Hardware interface
  - Output cam output > Output by Timer DQ (Page 47)
  - Output cam output > Output by digital output mode (Page 49)
- Extended parameters
  - Activation time (Page 50)
  - Hysteresis (Page 50)

4.3 Cam track technology object

The cam track technology object generates a switching signal sequence dependent on the position of an axis or external encoder. A cam track can consist of up to 32 individual output cams. The switching states can be evaluated in the user program or fed to digital outputs.

You can find an overview of the functions of the cam track technology object in the "Motion Control instructions (Page 23)" section.

The following figure shows the basic principle of operation of the cam track technology object:

Configuration

The following configurations are available in the cam track technology object:

- Basic parameters
  - Output cam type > Distance output cam (Page 44)
  - Output cam type > Time-based output cam (Page 45)
  - Output cam reference > Position setpoint (Page 63)
  - Output cam reference > Current position (Page 63)
  - Units of measure (Page 25)
- Hardware interface
  - Output cam track > Output by Timer DQ (Page 64)
  - Output cam track > Output by digital output module (Page 64)
- Extended parameters
  - Track data > Activation time (Page 68)
  - Track data > Hysteresis (Page 65)
  - Track data > Track dimensions (Page 65)
  - Output cam data (Page 68)

4.4 Motion Control instructions

You execute the functions of the measuring input, output cam and cam track technology objects using the Motion Control instruction in your user program or using the TIA Portal (under "Technology object > Commissioning").

The following table shows the Motion Control instructions that are supported by the technology objects:

Motion Control instruction	Validity		Technology object		
	S7-1500	S7-1500T	Measuring input (Page 17)	Output cam (Page 20)	Cam track (Page 22)
"MC_Reset" Acknowledge alarms, restart technology objects	✓	✓	✓	✓	✓
"MC_MeasuringInput" Start measuring once	✓	✓	✓	-	-
"MC_MeasuringInputCyclic" Start cyclic measuring	✓	✓	✓	-	-
"MC_AbortMeasuringInput" Cancel active measuring job	✓	✓	✓	-	-
"MC_OutputCam" Activate/deactivate output cam	✓	✓	-	✓	-
"MC_CamTrack" Activate/deactivate cam track	✓	✓	-	-	✓

4.5 Functions in STEP 7

The following table shows the functions supported by technology objects in STEP 7:

Functions in the TIA Portal	Technology object		
	Measuring input (Page 17)	**Output cam** (Page 20)	**Cam track** (Page 22)
"Diagnostics" Monitor and observe status and error messages of the technology object	✓	✓	✓

Configuring the technology object 5

5.1 Assignment

The measuring input, output cam and cam track technology objects are always assigned to a higher-level technology object whose position is evaluated.

These technology objects can be:

- Positioning axis
- Synchronous axis
- External encoder

Exactly one positioning axis, synchronous axis or external encoder technology object can be assigned to a measuring input, output cam and cam track technology object.

Multiple measuring input, output cam and cam track technology objects can be assigned to a positioning axis, synchronous axis or external encoder technology object.

To change an existing assignment, move the measuring input, output cam or cam track technology object to the desired higher-level technology object using drag-and-drop.

You can use the icon to directly access the configuration of the higher-level technology object.

5.2 Units of measure

The position is always shown in the unit of measure and with the resolution set on the higher-level technology object.

To use six decimal places in the selected unit, select the check box "Use position values with higher resolution" in the higher-level technology object.

With a time-based output cam as the output cam type, the unit of measure for the switch-on duration and other times is also indicated. This is always ms for output cams.

Measuring input functions 6

6.1 Defining the measurement input for measured value acquisition

6.1.1 Overview of measurement inputs and measuring types

You can only operate a measurement input with a technology object measuring input.

The following table shows an overview of the possible measurement inputs and the measuring types for the different measuring input types.

Measuring input type	Possible measurement inputs	Possible measuring types
Measuring using Timer DI (Page 27) ("STANDARD")	With Timer DI: • ET 200SP or ET 200MP TM Timer DIDQ • SIMATIC Drive Controller (X142)	• "MC_MeasuringInput" (Measuring once) • "MC_MeasuringInputCyclic" (Cyclic measuring)
Measuring via SINAMICS (central measuring probe) (Page 28) ("STANDARD")	Using telegram 39x of the drive control: • SINAMICS S120 CU320-2 (X122/X132) • SINAMICS S120 CU310-2 (X121/X131) • SIMATIC Drive Controller (X122/X132)	
Measuring using PROFIdrive telegram (Page 29) ("PROFIDRIVE")	Using PROFIdrive telegram of the drive axis: • SINAMICS S210 (X130) • SINAMICS S120 CU320-2 (X122/X132) • SINAMICS S120 CU310-2 (X121/X131) • SIMATIC Drive Controller (X122/X132) • CPU 1511C-1 PN / CPU 1512C-1 PN • ET 200SP or ET 200MP • TM Count 2x24V / TM Count 1x24V • TM PosInput 2 / TM PosInput 1 • TM PTO 4 / TM PTO 2x24V	"MC_MeasuringInput" (Measuring once)
Monitor measuring input (Page 31)("MONITORING")	Measurement input via the monitored measuring input with configured measurement input for "Measuring using Timer DI" or "Measuring via SINAMICS (central measuring probe)".	• "MC_MeasuringInput" (Measuring once) • "MC_MeasuringInputCyclic" (Cyclic measuring) The measuring jobs are initiated at the measuring input with measurement input. Measuring jobs to interconnected measuring inputs that monitor the measuring input with measurement input are rejected with an error. Interconnected measuring inputs support the measuring types of the measuring input with measurement input.

6.1.2 Measuring using Timer DI

With measured value acquisition via time stamp, the time points of the signal changes are recorded precisely. The time stamps are then transferred to the controller and the associated actual positions are determined in the technology object.

Measuring using Timer DI requires isochronous mode.

Configuring technology inputs on the Timer DI

You can operate the TM Timer DIDQ technology module centrally on an S7-1500 CPU or decentrally on a distributed I/O.

WARNING

Inaccurate time synchronization

When the technology module TM Timer DIDQ with the measuring input, output cam, or cam track technology object is used at the same time as the "TIO_Sync" function, the time synchronization of the technology module becomes inaccurate.

Do not use the "TIO_Sync" function if you are using the technology module TM Timer DIDQ with the measuring input, output cam, or cam track technology object.

To configure the inputs at the TM Timer DIDQ for use with a measuring input technology object, follow these steps:

1. Under "Basic parameters > Channel configuration", select the desired number of inputs.
2. Select the use with Motion Control technology object under "Basic parameters > Module use from the user program".
3. Under "Channel parameters", configure the following parameters of the input that you want to use as measurement input:
   – "Configuration of DI group": To be able to parameterize and use the inputs independently of each other, select "Use inputs individually".
   – "Operating mode": Select the "Timer DI" operating mode.
4. Then define an application-dependent input delay for the digital input that you want to use as measurement input.
5. Then select the "Isochronous mode" check box for the input and output under "Channel parameters > I/O addresses".
6. The organization block ("MC_Servo") and the process image ("PIP OB Servo") are updated automatically for the input and output addresses by selecting the channel in the input configuration at the technology object.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Interconnecting the Timer DI technology object

To configure a measuring input for measuring using Timer DI, follow these steps:

1. Select the "Measuring using Timer DI".
2. In the "Measuring input" selection box, select a configured measurement input.

   The selection box shows all channels that are configured correctly. For this purpose, you need to have configured the I/O channels as Timer DI beforehand.

6.1.3 Measuring via SINAMICS (central measuring probe)

With central measuring probes, the time points of the signal changes are recorded precisely. The time stamps are then transferred to the controller via telegram 39x and the associated actual positions are determined in the technology object.

Measurements via a central measuring probe are only possible for SINAMICS drives. The maximum usable cycle time on the bus is limited, see "Time-related boundary conditions (Page 39)".

Measurement using SINAMICS (central measuring probe) requires isochronous mode.

You can find more information on the telegrams in the "PROFIdrive telegrams configuration" section of the "S7-1500/S7-1500T Axis functions" documentation.

Configuring the central measuring probe in the drive

1. Configure the necessary central measuring probes on the drive side. For SINAMICS drives that are not configured via Startdrive, assign the inputs to the measuring inputs (p680) in the telegram without gaps and in ascending order.
2. With p728.8 to p728.15, you configure as input all DI/DQs used as measurement input on the Control Unit.
3. Use p680 of the Control Unit to specify the terminals for the central measuring probes.
4. Configure telegrams 391, 392 or 393 on the Control Unit or configure the telegrams 394 or 395 as free telegrams.

Configuring technology inputs on the SIMATIC Drive Controller

To configure the inputs of the X142 interface at SIMATIC Drive Controller for use with a measuring input technology object, follow these steps:

1. Under "DI/DQ 8x24VDC [X142] > Channel parameters", select the channel that you want to use as the measurement input.
2. Select the "Timer DI" operating mode.
3. Activate the "Isochronous mode" option under "DI/DQ 8x24VDC [X142] > I/O addresses".
4. The input and output addresses for the "MC_Servo" organization blocks and the "PIP OB Servo" process image are updated automatically when the channel is selected in the input configuration at the technology object.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Interconnecting the measuring input technology object

To interconnect the measuring input technology object with the inputs, follow these steps:

1. Select the "Measuring via SINAMICS (central measuring probe)".
2. In the "Measuring input" selection box, select a configured measurement input. The selection box shows all compatible telegram types. You are shown all terminals that can potentially be used as measuring inputs.

6.1.4 Measuring using PROFIdrive telegram

With measurement using PROFIdrive telegram, the measurement input is connected to the drive device and measurement takes place directly in the drive. The position value is determined on a signal change at the measurement input. The drive or encoder module communicates the determined position value to the technology object via the PROFIdrive telegram.

With measurement using PROFIdrive telegram, only one measuring input at a time can be active on an actual value or encoder in the PROFIdrive telegram. A maximum of two measuring inputs can be configured on an actual value or encoder in the PROFIdrive telegram via PROFIdrive; see section "Automatic transfer of drive and encoder parameters" of the "S7-1500/S7-1500T Axis functions" documentation.

The drive module and the TM Count, TM PosInput and Compact CPUs technology modules are available to you for measuring using the PROFIdrive telegram.

Interconnecting the measuring input technology object

To interconnect the measuring input technology object with the inputs, follow these steps:

1. Select "Measuring using PROFIdrive telegram (drive or external encoder)" under Hardware interface in the function view.
2. Select the number of the measuring input in the selection box. The input field is preset with the value "1".

Configuring an input to a drive module as measurement input

To configure the inputs with a drive for use with a measuring input technology object, follow these steps:

Select the parameter list in the drive configuration. Use the following PROFIdrive parameters to set the digital input on the drive that is to be used for the configured communication channel.

- Measurement input for the measuring input 1 ("<TO>.Parameter.PROFIdriveProbeNumber" = 1):

  The measurement inputs are set via the p488[0], p488[1] and p488[2] parameters.
- Measurement input for the measuring input 2 ("<TO>.Parameter.PROFIdriveProbeNumber" = 2):

  The measurement inputs are set via the p489[0], p489[1] and p489[2] parameters.

[0] corresponds to encoder 1, [1] to encoder 2 and [2] to encoder 3.

If you use two encoders, select the associated DI in the drive for each encoder. Various results are then transferred to the technology object depending on the selected encoder.

Configuring an input to a TM Count technology module as measurement input

For use with a measuring input, decentralized use with isochronous mode is required.

To configure the inputs at the TM Count for use with a measuring input technology object, follow these steps:

1. Select the "Position detection for "Motion Control" technology object" operating mode for the channel that you want to use as measurement input.
2. Under "Module parameters", configure the parameters for the encoder signals of the channel, depending on the selected encoder.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Configuring an input to a TM PosInput technology module as measurement input

For use with a measuring input, decentralized use with isochronous mode is required.

NOTE

Position detection with single-turn absolute encoder

When a single-turn absolute encoder is used and two edges are to be measured ("MC_MeasuringInput.Mode" = 2, 3 or 4), the distance between the measured edges of the measurement input must be < 1 encoder revolution. Otherwise, use a multi-turn absolute encoder.

To configure the inputs at the TM PosInput for use with a measuring input technology object, follow these steps:

1. Select the "Position detection for "Motion Control" technology object" operating mode for the channel that you want to use as measurement input.
2. Under "Module parameters", configure the parameters for the encoder signals of the channel, depending on the selected encoder.
3. The configuration of the encoder is required for use with an SSI absolute encoder. Information on the configuration is available in the documentation for the respective technology module.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Configuring an input on a CPU 1511C-1 PN/CPU 1512C-1 PN (onboard I/O devices) as measurement input

To configure the inputs at a compact CPU for use with a measuring input technology object, follow these steps:

1. Select the hardware input of the measurement input in the device configuration.
2. Select the desired input delay at the corresponding DI channel under "Input > Channel no. > Input parameters".

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

6.1.5 Measuring via "Monitor measuring input"

During measuring via "Monitor measuring input", the measuring event of a measurement input is captured by multiple measuring inputs at the same time. Other probes are interconnected with a probe with measuring input for this purpose.

The following figure shows the interconnection of multiple measuring inputs to a common measured signal:

The measuring event is recorded via a measuring input with measurement input ①. "Measuring using Timer DI" or "Measuring via SINAMICS (central measuring probe)" is configured as measurement input ② at this measuring input. The measuring input with measurement input is interconnected with further measuring inputs ③ that monitor the signal acquisition of the measuring input and record the signal at the same time.

The interconnected measuring inputs ③ are each assigned to different, higher-level technology objects ④.

NOTE

Position detection via interconnected measuring inputs is only possible when the measurement input for "Measuring using Timer DI" or "Measuring via SINAMICS (central measuring probe)" is configured at the monitored measuring input.

Configuring the measuring input technology object

To interconnect a measuring input with a measuring input with measurement input, follow these steps:

1. Select "Monitor measuring input".
2. In the selection box, select a measuring input with configured measurement input "Measuring using Timer DI" or "Measuring via SINAMICS (central measuring probe)". First the higher-level technology object and then the measuring input is shown in the selection box.

Programming

Start the jobs for one-time or cyclic measuring with the instructions "MC_MeasuringInput (Page 84)" and "MC_MeasuringInputCyclic (Page 87)" on the measuring input with measurement input. The configured measuring range only applies for the measuring input with measurement input.
When the measuring job is completed, all interconnected measuring inputs automatically output the captured measured values of the actual positions (<TO>.Status = TRIGGER_OCCURRED).
Measuring jobs at interconnected measuring inputs are rejected.

The measured values of the interconnected measuring inputs are output in the data block technology object (<TO>.MeasuredValues.MeasuredValue1 / <TO>.MeasuredValues.MeasuredValue2).

6.2 Defining the correction time for the measurement time

The time of the measurement can be corrected by setting a correction time (<TO>.Parameter.CorrectionTime) for the measuring input technology object.

Define a correction time for the measured signal in the "Hardware interface" configuration window if possible delay times in the measured signal are to be compensated.

Corrections may be required for the following examples:

- Times for mechanical displacement of the measuring input
- Times for the generation of the measured signal before the measurement input
- Filter times at measurement input

The correction time is included in the calculation for all measuring input types of the measuring input technology object.

Also note the time delay when measuring on a virtual axis, see section "Virtual axis" of the "S7-1500/S7-1500T Axis functions" documentation.

6.3 Type of measurement

Parameter settings

With the "Mode" parameter of the Motion Control instructions "MC_MeasuringInput (Page 84)" or "MC_MeasuringInputCyclic (Page 87)", you determine how many and which measuring events should be recorded.

"Mode" parameter in the Motion Control instruction	"MC_MeasuringInput"	"MC_MeasuringInputCyclic"
"Mode" = 0	Measure positive edge only	Measure positive edge only
"Mode" = 1	Measure negative edge only	Measure negative edge only
"Mode" = 2	Measure the next two edges	Measure the next two edges
"Mode" = 3	Measure the next two edges starting with the positive edge	-
"Mode" = 4	Measure the next two edges starting with the negative edge	-

6.4 Defining the measuring range

A measuring job can be activated directly or restricted to a defined measuring range.

The following graphic shows an example of measuring with measuring range in "Mode" = 0 (measurement of next positive edge):

Only measured values within the measuring range are displayed for the technology object.

- If no measuring edge within the measuring range is detected during a one-time measurement, the measuring job is canceled and an alarm is triggered.
- Cyclic measuring remains active even if no measuring edge within the measuring range was detected.

Parameter settings

You activate and define a measuring range in the Motion Control instruction "MC_MeasuringInput (Page 84)" or "MC_MeasuringInputCyclic (Page 87)".

Activating a measuring range

With the parameter "MeasuringRange" = TRUE, you limit acquisition of measured values to a defined measuring range.

Defining the start and end position of the measuring range

- With the "StartPosition" parameter, you define the start position of the measuring range.
- With the "Endposition" parameter, you define the end position of the measuring range.

For axes without modulo function, it is immaterial in which order the start and end positions are specified. If the start position is greater than the end position, the two values are interchanged in the application. If the start position for an axis with modulo function is greater than the end position, the measuring range is extended from the start position past the modulo transition of the axis to the end position.

Adjusting the activation time for measuring with measuring range

The measuring function must be active at the measurement input when the start of the measuring range is reached. To compensate for the communication time for activation in the Timer DI or drive, for example, the activation of the measurement in the technology object begins earlier then the measuring range start by the amount of the activation time.

The activation time for measuring with measuring range is divided up as follows:

- The activation time allocation defined and active on the system side is indicated in the "<TO>.Parameter.MeasuringRangeActivationTime" tag.
- In addition, you can define an additional activation time with the "<TO>.Parameter.MeasuringRangeAdditionalActivationTime" tag.

To adjust the activation time defined in the system, enter an additional activation time ("<TO>.Parameter.MeasuringRangeAdditionalActivationTime") in the "Extended parameters" configuration window.

6.5 Measuring once

With one-time measurement, up to two edges can be detected with one measuring job. The associated actual positions are signaled back in the function block and in the technology data block and can be further processed in the user program.

Measuring job for measuring once

Use the Motion Control instruction "MC_MeasuringInput (Page 84)" to start a measuring job for one-time measuring.

The "<TO>.Status" tag in the technology data block changes to "WAITING_FOR_TRIGGER".

The type of measurement ("Mode") set in the Motion Control instruction specifies the edges for which the measured values are to be acquired. The technology object activates the measurement when the selected edge is detected.

- The time of the respective edge is recorded at the measurement input. From the recorded time, the associated position is determined and output, taking into consideration a correction time, if present.
- With direct position detection, the detected position value is supplied directly from the drive or encoder module to the technology object via the PROFIdrive telegram.

The measurement is then finished. The finished measuring job is indicated in the function block in "MC_MeasuringInput.DONE" = TRUE or in the technology data block in "<TO>.Status" = "TRIGGER_OCCURRED".

Depending on the defined type of measurement, the acquired values are saved in the technology data block as follows:

Configured "Mode" parameter in Motion Control instruction "MC_MeasuringInput"	**Output of Motion Control instruction "MC_MeasuringInput"**	
	"MeasuredValue1"	**"MeasuredValue2"**
Measure positive edge only "Mode" = 0	Actual position at the time of the edge	–
Measure negative edge only "Mode" = 1		
Measure the next two edges "Mode" = 2	Actual position at the time of the first edge	Actual position at the time of the second edge
Measure the next two edges starting with the positive edge "Mode" = 3	Actual position at the time of the positive edge	Actual position at the time of the negative edge
Measure the next two edges starting with the negative edge "Mode" = 4	Actual position at the time of the negative edge	Actual position at the time of the positive edge

You start measuring once again with a new Motion Control instruction "MC_MeasuringInput".

If a new job is initiated with the function block, the outputs of the function block are initialized. The technology data block is not initialized. After detecting the first valid measuring cycle, the values in the technology data block and function block are consistent with one another.

Temporal requirements for measuring jobs via "MC_MeasuringInput"

You can find information on the temporal boundary conditions in the section "Time-related boundary conditions (Page 39)".

See also

Defining the measuring range (Page 33)

6.6 Cyclic measuring

With cyclic measuring, up to two measuring events can be acquired by the system in each position control cycle of the technology object and the associated measuring positions can be displayed. The measurements are continued cyclically until they are ended per command.

The determined measured values are displayed in the function block and the technology data block and can be read by the user program.

Cyclic measuring requires the measured value to be determined using hardware support of the type "Measuring using Timer DI (Page 27)" or "Measuring via SINAMICS (central measuring probe) (Page 28)".

Measuring edges at which a measured value could not be determined are indicated in a lost edge counter in the function block and in the technology data block.

Measuring job for cyclic measuring

You start cyclic measuring with the Motion Control instruction "MC_MeasuringInputCyclic (Page 87)". The measuring job is issued to the corresponding measuring hardware.

The type of measurement in the "Mode" parameter set in the Motion Control instruction specifies the edges for which the measured values are to be acquired.

The measuring time values are then forwarded to the technology object. The technology object determines the measuring positions for the measuring times taking into consideration any specified correction times.

Depending on the defined type of measurement, the acquired values are saved in the technology data block as follows:

Configured "Mode" parameter in Motion Control instruction "MC_MeasuringInputCyclic"	Display per position control cycle			
	"MeasuredValue1"	"MeasuredValue2"	"LostEdgeCounter1"[1]	"LostEdgeCounter2"[1]
Detect positive edges only "Mode" = 0	Actual position at the time of the first positive edge	Actual position at the time of the second positive edge	Number of positive or negative edges in excess of two in the position control cycle of acquisition of "MeasuredValue1" and "MeasuredValue2". The following applies here: • If a "MeasuredValue1" and a "MeasuredValue2" are acquired, the number of acquired and lost edges indicated in "LostEdgeCounter1" and "LostEdgeCounter2" are the same. • If only one "MeasuredValue1" is acquired, the "LostEdgeCounter1" is reset to "0". The value in "LostEdgeCounter2" remains changed.	
Detect negative edges only "Mode" = 1	Actual position at the time of the first negative edge	Actual position at the time of the second negative edge		
Detect positive and negative edges "Mode" = 2	Actual position at the time of the first positive edge in the position control cycle	Actual position at the time of the first negative edge in the position control cycle	Number of edges in excess of two in the position control cycle of acquisition of "MeasuredValue1" and "MeasuredValue2". The following applies here: • If a "MeasuredValue1" and a "MeasuredValue2" are acquired, the number of acquired and lost edges indicated in "LostEdgeCounter1" and "LostEdgeCounter2" are the same. • If only one "MeasuredValue1" is acquired, the "LostEdgeCounter1" is reset to "0". The value in "LostEdgeCounter2" remains changed. • If only one "MeasuredValue2" is acquired, the "LostEdgeCounter2" is reset to "0". The value in "LostEdgeCounter1" remains changed.	

1) Applies only to cyclic measuring via Timer DI.

The technology data block tag "<TO>.Status" changes from "INACTIVE" to "WAITING_FOR_TRIGGER" and remains in this status as long as additional events are awaited.

Measured values and counters

With a positive edge at the input "MC_MeasuringInputCyclic.Execute", outputs "MeasuredValue1Counter" and "MeasuredValue2Counter" are reset to "0". As a result, new events can be tracked immediately and new measured value entries can be detected.

All measuring event occurrences of the measuring job are incremented by "1" in the corresponding event counters "<TO>.MeasuredValues.MeasuredValue1Counter" and "<TO>.MeasuredValues.MeasuredValue2Counter" of the technology data block.

The acquired measured values are continuously captured in the technology data block irrespective of individual jobs. The values are only reset to "0" at power-up or restart of the technology object.

After a completed measurement, the measured values are output in the function block. The counters of the function block are set to "0" at a new measuring job. The measured value output in the technology data block always indicates the last acquired measured value.

Lost edge counter (LEC)

Measuring using Timer DI

If more than two edges to be detected occur within one position control cycle, a measured value cannot be evaluated for the other edges to be detected. The number of lost edges is recorded in the LEC.

The lost edges that are recorded in the LEC depend on the mode set in the Motion Control instruction. For example, if only positive edges are to be measured, the LEC records only the non-measured positive edges.

A maximum of seven lost edges can be counted and displayed in the LEC.

The number of lost edges is indicated in the function block and in the technology data block in:

- "LostEdgeCounter1"

  Lost cleared edges from the position control cycle in which "MeasuredValue1" was acquired.

  ⇒ The displayed value in "LostEdgeCounter1" is updated when counter "MeasuredValueCounter1" is incremented.

- "LostEdgeCounter2"

  Lost cleared edges from the position control cycle in which "MeasuredValue2" was acquired.

  ⇒ The displayed value in "LostEdgeCounter2" is updated when counter "MeasuredValueCounter2" is incremented.

Measuring via SINAMICS (central measuring probe)

During cyclic measuring using the central measuring probe, the LEC is always 0.

Examples of measured values and counters

The following figures show examples of divergence of "MeasuredValue1Counter" and "MeasuredValue2Counter" as a result of lost edges.

Example: Measurement at positive edges (Mode = 0)

Processing cycle TO Measuring input	N	N+1	N+2	N+3	N+4	N+5	N+6	N+7	N+8	N+9	N+10
Measuring input											
MeasuredValue1Counter	...	6	7	7	8	9	9	10	11	12	13
LostEdgeCounter1	...	0	0	0	0	0	0	1	0	1	0
MeasuredValue2Counter	...	6	7	7	7	7	7	8	8	9	9
LostEdgeCounter2	...	0	0	0	0	0	0	1	1	1	1

Example: Measurement at negative edges (Mode = 1)

Processing cycle TO Measuring input	N	N+1	N+2	N+3	N+4	N+5	N+6	N+7	N+8	N+9	N+10
Measuring input											
MeasuredValue1Counter	...	6	7	8	9	10	10	11	11	12	13
LostEdgeCounter1	...	0	0	0	1	0	0	1	1	1	0
MeasuredValue2Counter	...	6	7	7	8	8	8	9	9	10	10
LostEdgeCounter2	...	0	0	0	1	1	1	1	1	1	1

Example: Measurement at positive and negative edges (Mode = 2)

Processing cycle TO Measuring input	N	N+1	N+2	N+3	N+4	N+5	N+6	N+7	N+8	N+9	N+10
Measuring input											
MeasuredValue1Counter	...	6	7	7	8	9	9	10	11	12	13
LostEdgeCounter1	...	0	2	2	0	0	0	3	0	4	0
MeasuredValue2Counter	...	6	7	8	8	9	10	11	12	13	14
LostEdgeCounter2	...	0	2	0	0	0	0	3	0	4	0

Defining the measuring range (Page 33)

6.7 Cancel active measuring job

You can cancel an active measuring job with the Motion Control instruction "MC_AbortMeasuringInput (Page 91)".

If the measuring job was canceled successfully, "MC_AbortMeasuringInput.CommandAborted" = TRUE is shown at the function block.

You start another measurement with a new Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic".

6.8 Time-related boundary conditions

Depending on the hardware used and selection of edges to be detected, different system-inherent requirements apply to the time allowed after calling the Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic" until a measurement occurs and the results are displayed.

The following times must be distinguished here:

- Time until the measuring event can be captured
- Time until the measurement result is displayed or the measurement is finished.

The times calculated taking into account the current settings are indicated in configuration window "Extended parameters" of a measuring input.

Measuring using Timer DI

Description	Measuring once	Cyclic measuring
Time from output of a measuring job until measuring event detection becomes effective ("MeasuringRangeActivationTime")	$2 \times T_{servo}$	
Activation time for a measurement with measuring range	"MeasuringRangeActivationTime" + "MeasuringRange-AdditionalActivationTime"	
Minimum time after measuring event until measured value is available in the controller	$2 \times T_{servo} + T_{Send}$	$T_{servo} + T_{Send}$
Minimum time between two measuring events	$4 \times T_{servo} + T_{Send}$	T_{servo}

Measuring via SINAMICS (central measuring probe)

Description	Measuring once	Cyclic measuring
Time from output of a measuring job until measuring event detection becomes effective ("MeasuringRangeActivationTime")	$2 \times T_{servo}$	
Activation time for a measurement with measuring range	"MeasuringRangeActivationTime" + "MeasuringRange-AdditionalActivationTime"	
Minimum time after measuring event until measured value is available in the controller	$2 \times T_{servo}$	$T_{servo} + T_{Send}$
Minimum time between two measuring events	$4 \times T_{servo}$	$3 \times T_{servo}$

Measurement using PROFIdrive telegram (drive or external encoder)

Description	Times depending on the configuration at the Motion Control instruction "Mode" parameter in the "MC_MeasuringInput".	
Time from output of a measuring job until measuring event detection becomes effective ("MeasuringRangeActivationTime")	"Mode" 0.1, 2.3 and 4: • If T_{Send} and T_{servo} are the same: $3 \times T_{servo}$ • If T_{Send} and T_{servo} are different: $2 \times T_{servo}$	
Activation time for a measurement with measuring range	"Mode" 0, 1 or 2: "MeasuringRangeActivation-Time" + "MeasuringRangeAddition-alActivationTime" + $2 \times T_{servo}$	"Mode" 3 and 4: "MeasuringRangeActivation-Time" + "MeasuringRangeAddition-alActivationTime" + $3 \times T_{servo}$
Time from output of an "MC_MeasuringInput" job until measuring event detection becomes effective	"Mode" 0, 1, 2: "MeasuringRangeActivation-Time" + $2 \times T_{servo}$	"Mode" 3, 4: "MeasuringRangeActivation-Time" + $3 \times T_{servo}$
Time after measuring event until measured value is available in the controller	"Mode" 0, 1: $7 \times T_{servo}$	"Mode" 2, 3, 4: $13 \times T_{servo}$

Definition of tags

- T_{servo} = Call interval of the technology object in the servo cycle clock [ms]
- T_{Send} = Send clock [ms]
- "MeasuringRangeActivationTime" = See section "Measuring with measuring range (Page 33)"

NOTE

Maximum bus clock cycle

With the use of SINAMICS central measuring probes, the maximum bus clock cycle T_{Send} can be up to 8 ms.

To prevent asynchronous processing from overwriting a measured value that was just determined, a new one-time measuring job cannot be started until the active measurement has concluded. The sum of the activation time and the time until display or conclusion must be taken into account for this.

In the case of cyclic measuring, evaluation or temporary storage of the measurement results in the synchronous MC_PreInterpolator is recommended from the user perspective.

6.9 Tags: Measuring input technology object

The following technology object tags are relevant for measuring:

Status indicator		
Tag	**Description**	
<TO>.Status	Status of the measuring input function	
	0	Measurement is not active ("INACTIVE")
	1	The measuring input is waiting for a measuring event ("WAITING_FOR_TRIGGER")
	2	The measuring input has acquired one or more measured values ("TRIGGER_OCCURRED").
	3	Error during the measurement ("MEASURING_ERROR")
<TO>.InputState	Status of the measurement input	

Measurement input	
Tag	**Description**
<TO>.Parameter.MeasuringInputType	Measuring input type
<TO>.Parameter.PROFIdriveProbeNumber	Number of the measurement input to be used for a measurement via PROFIdrive telegram
<TO>.Parameter.MeasuringRangeActivationTime	System-defined activation time allocation [ms]
<TO>.Parameter.MeasuringRangeAdditionalActivationTime	Additional user-defined activation time allocation [ms]
<TO>.Parameter.CorrectionTime	User-defined correction time for the measurement result [ms]
<TO>.Interface.Address	I/O address for the digital measurement input

Measuring output	
Tag	**Description**
<TO>.MeasuredValues.MeasuredValue1	1st measured value
<TO>.MeasuredValues.MeasuredValue2	2nd measured value (when measuring two or more edges in one position control cycle)
<TO>.MeasuredValues.MeasuredValue1Counter	Count value for the first measured value
<TO>.MeasuredValues.MeasuredValue2Counter	Count value for the second measured value
<TO>.MeasuredValues.LostEdgeCounter1	Lost edges in the cycle clock of the first measured value acquisition Zero in the case of one-time measurement During cyclic measurement via SINAMICS equal to zero
<TO>.MeasuredValues.LostEdgeCounter2	Lost edges in the cycle clock of the second measured value acquisition Zero in the case of one-time measurement During cyclic measurement via SINAMICS equal to zero

StatusWord	
Tag	**Description**
<TO>.StatusWord.X0 (Control)	The technology object is in operation.
<TO>.StatusWord.X1 (Error)	An error occurred at the technology object.
<TO>.StatusWord.X2 (RestartActive)	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart.
<TO>.StatusWord.X3 (OnlineStartValuesChanged)	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object.
<TO>.StatusWord.X5 (CommunicationOk)	The measuring input is synchronized with the measurement input and can be used. With the monitoring measuring input, this bit always has the value "FALSE".

ErrorWord	
Tag	**Description**
<TO>.ErrorWord.X0 (SystemFault)	A system-internal error has occurred.
<TO>.ErrorWord.X1 (ConfigFault)	Configuration error One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program.
<TO>.ErrorWord.X2 (UserFault)	Error in user program at a Motion Control instruction or its use
<TO>.ErrorWord.X3 (CommandNotAccepted)	Command cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
<TO>.ErrorWord.X13 (PeripheralError)	Error accessing a logical address

ErrorDetail		
Tag	**Description**	
<TO>.ErrorDetail.Number	Alarm number You can find a list of the technology alarms and alarm responses in the "Technology alarms" section in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
<TO>.ErrorDetail.Reaction	Effective alarm response	
	0	No reaction
	6	End measuring input processing

Output cam functions

7

7.1 Defining the output cam type

Select an output cam type based on the desired switching behavior:

- Select the distance output cam (Page 44) for position-dependent switch-on/switch-off.
- Select the time-based output cam (Page 45) for position-dependent switch-on and time-dependent switch-off.

7.1.1 Configuring the distance output cam

A distance output cam switches between the start position and end position. Outside this range, the distance output cam is switched off.

Switch-on range

The switch-on range of distance output cams is defined by the start position and end position.

Start position smaller than end position

When the start position is less than the end position, the switch-on range begins with the start position and ends with the end position.

Start position greater than end position

When the start position is greater than the end position, there are two switch-on ranges as follows:

- Switch-on range beginning with the start position and ending with the positive range end (e.g. positive software limit switch, end of modulo range)
- Switch-on range beginning with the negative range end (e.g. negative software limit switch, start of modulo range) and ending with the end position

Mapping to an axis with modulo function

With active modulo function of the interconnected technology object, the start and end positions of the output cam are automatically mapped to values within the modulo range.

Example

- Modulo range = 0° to 50°
- Output cam start position = 80°
- Output cam end position = 220°

The specified start and end position of the distance output cam are outside the modulo range. The values are therefore mapped onto the modulo range. The start position is at 30° (80° mod 50° = 30°) and the end position is at 20° (220° mod 50° = 20°).

7.1.2 Configuring the time-based output cam

A time-based output cam switches on at the start position and remains set for the on-load factor.

Mapping to an axis with modulo function

In the case of active modulo function of the interconnected technology object, the start position of the output cam is automatically mapped to the value within the modulo range.

Example

- Modulo range = 0° to 50°
- Output cam start positions:
  - Output cam 1 = 20°
  - Output cam 2 = 30°
  - Output cam 3 = 80°

The time-based output cam 1 switches on at 20°, the time-based output cam 2 switches on at 30°. The specified start position of time-based output cam 3 is outside the modulo range. The

value for the start position is therefore mapped onto the modulo range so that the time-based output cam 3 switches on at 30°. All three output cams remain active the set on-load factor in each case.

7.2 Configuring the output cam reference

You define the position reference for the switching points of the output cams in the "Basic parameters > Output cam reference" configuration window.

The switching points of the output cams can be referenced to the following positions, depending on the interconnected technology object:

- Position setpoint

  Position setpoint of the interconnected synchronous/positioning axis
- Current position

  Actual position of the interconnected synchronous/positioning axis or the position of the interconnected external encoder

Homing the interconnected technology object

A change to the position of an axis or external encoder using Motion Control instruction "MC_Home" is regarded as a sudden position change.

The following behavior is possible for a position jump:

- Distance output cams are either skipped or correspondingly output.
- Time-based output cams are skipped. A time-based output cam is switched on only when the start position is overtraveled and remains switched on for the switch-on duration.
- Switched time-based output cams are not canceled by a homing operation.

Trace recording of output cams with reference to setpoint position

The CPU calculates the output time of the output cam in such a way that the output cam is switched when the position setpoint has been transferred from the PLC to the drive.

The communication time is not considered in the trace.

7.3 Configuring the output cam output

7.3.1 Activate/deactivate output cam output

In the "Hardware interface > Output cam output" configuration window, you activate and configure the output of the generated switching signals via a digital output.

When the output is activated, you can configure the following digital outputs:

- Output by Timer DQ (Page 47)

  Digital output with high degree of accuracy and reproducibility in the microsecond range on time-based IO modules basis

- Output by a digital module (Page 49)

  Digital output with switching accuracy depending on the output cycle of the I/O used

When output is deactivated, the output cam status is not output at the hardware output. The output cam status can be used internally in the user program by evaluating the relevant "<TO>.CamOutput" tag.

7.3.2 Configuring output by Timer DQ

In the case of signal output via time stamp, the times of the signal changes are determined by the technology object. The time stamps are then transferred to the hardware of the digital output and the edges are output with high precision.

Output by Timer DQ requires isochronous mode.

With output via a Timer DQ, you select a suitable channel in the "Output" field. The selection box shows all channels that are configured as Timer DQ. For this purpose, you need to have configured the I/O channels as Timer DQ beforehand.

Timer DQs are supported by:

- ET 200MP TM Timer DIDQ 16x24V
- ET 200MP TM Timer DIDQ 24x24V
- ET 200SP TM Timer DIDQ 10x24V
- SIMATIC Drive Controller (X142)

Configuring technology outputs on the Timer DQ

You can operate the TM Timer DIDQ technology module centrally on an S7-1500 CPU or decentrally on a distributed I/O.

WARNING

Inaccurate time synchronization

When the technology module TM Timer DIDQ with the measuring input, output cam, or cam track technology object is used at the same time as the "TIO_Sync" function, the time synchronization of the technology module becomes inaccurate.

Do not use the "TIO_Sync" function if you are using the technology module TM Timer DIDQ with the measuring input, output cam, or cam track technology object.

To configure the outputs at the TM Timer DIDQ for use with an output cam or cam track technology object, follow these steps:

1. Under "Basic parameters > Channel configuration", select the desired number of outputs (only ET 200MP TM Timer DIDQ 16x24V).
2. Select the use with Motion Control technology object under "Basic parameters > Module use from the user program".
3. Select the "Timer DQ" mode for the respective output under "Channel parameters".
4. Activate the "Isochronous mode" option for the input and output under "Channel parameters > I/O addresses".
5. The organization block ("MC_Servo") and the process image ("PIP OB Servo") are updated automatically for the input and output addresses by selecting the channel in the input configuration at the technology object.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Configuring technology outputs on the SIMATIC Drive Controller

To configure outputs of the X142 interface on the SIMATIC Drive Controller as an output for the output cam or cam track technology object, follow these steps:

1. Under "DI/DQ 8x24VDC [X142] > Channel parameters", select the channel that you want to use as the output.
2. Select the "Timer DQ" operating mode.
3. Activate the "Isochronous mode" option under "Channel parameters > I/O addresses".
4. The input and output addresses for the "MC_Servo" organization blocks and the "PIP OB Servo" process image are updated automatically when the channel is selected in the output configuration at the technology object.

You can find more information on configuring onboard I/O for Motion Control in the "Configuring technology modules and onboard I/O for Motion Control" section of the "Motion Control overview" function manual.

Timer DQ at the technology object

Follow these steps to configure output by Timer DQ:

1. Select the "Activate output" check box.
2. Select "Output by Timer DQ".
3. In the "Output" selection box, select a configured output cam output.

   The selection box shows all channels that are configured correctly. For this purpose, you need to have configured the I/O channels as Timer DQ beforehand.

7.3.3 Configuring output by digital module

Follow these steps to configure output by digital output module:

1. Select the "Activate output" check box.
2. Select "Output by digital output module".
3. In the "Output" selection box, select a digital output module.

   Only the digital outputs with previously defined PLC tags are displayed for selection.

7.3.4 Outputting multiple output cams to one output

You have the option to output multiple output cams to one digital output. The output of multiple output cams to one output is performed with either an AND or OR logic operation of the output cam signals to the output. The logic operation relates to the last signal to be output after the set inversion, if any.

To output multiple output cams to one output, configure the respective output cams as follows:

1. Select the "Activate output" check box
2. Select output by Timer DQ (Page 47) or a digital output module (Page 49).
3. In the "Output" selection box, select a configured output cam output.
4. Select the logical operation of the output cam signal at the output.

   All output cams that use the selected output are shown graphically.

Display of the switching state

The switching state of the output cam is displayed in the associated technology data block in "<TO>.CamOutput".

7.4 Defining the activation time and deactivation time

To compensate for communication times or switching times of the output and the connected actuator, enter an activation time or deactivation time at the output cam or cam track technology object.

The activation time is specified as the lead time for the switch-on edge, and the deactivation time as the lead time for the switch-off edge.

For the timers, the following must apply:

Switch on duration > deactivation time - activation time

You define the activation time (<TO>.Parameter.OnCompensation) and the deactivation time (<TO>.Parameter.OffCompensation) in the configuration window under "Configuration > Extended parameters > Activation time".

If the output cam has been switched with consideration of the derivative-action times and the current velocity changes afterwards, the output cam will not be switched again.

Influence of the digital outputs used

- When the output cam is output via timer DQ, the communication times are automatically taken into account.
- When the output cam is output via digital output, the communication times are not automatically taken into account.

You can find more information in the sections on switching behavior of distance output cams (Page 54) or time-based output cams (Page 58).

7.5 Configuring a hysteresis

Possible variations in the actual position/position setpoint can result in unwanted switch-on and switch-off of output cams.

Minimal changes of the actual value of an axis in standstill can result in the switching on or off of an actual value output cam with preset positive or negative effective direction. Even minimal changes of the setpoints of a switched-off axis in follow-up mode can result in switch-on or switch-off of an actual value output cam with specified positive or negative effective direction. Such unwanted switching states can be prevented by configuring a hysteresis (> 0.0). The configuration of a hysteresis value (> 0.0) is recommended in particular with reference to the actual position.

The hysteresis is a position tolerance within which the position values may vary without changing the switching state of the output cam. Changes of direction detected within the hysteresis are ignored.

You define the hysteresis value in the configuration of the output cam technology object under "Configuration > Extended parameters > Hysteresis" (<TO>.Parameter.Hysteresis).

Behavior

The hysteresis is activated on a direction reversal.

① Actual position
② Effective position
③ Hysteresis range

The hysteresis behavior depends on the output cam type:

- Distance output cam (Page 55)
- Time-based output cam (Page 59)

Hysteresis range

The maximum size of the hysteresis range in the system is:

- For an axis with modulo function, one quarter of the modulo range
- For an axis without modulo function, one quarter of the operating range

7.6 Inverted output

In the case of inverted output, the range in which the output cam output is switched on and the range in which it is switched off are swapped.

You define the operating mode with the "Mode" parameter of the Motion Control instruction "MC_OutputCam (Page 92)". With "Mode" = 2, you define the inverted output. The inverted output is active when the instruction is enabled via "Enable" = TRUE.

You can set the inverted output for both distance output cams and time-based output cams.

7.7 How distance output cams work

7.7.1 Defining the effective direction of distance output cams

You define the effective direction of the distance output cams with the "Direction" parameter of the Motion Control instruction "MC_OutputCam".

The following examples show the behavior of the distance output cams as a function of the set effective direction.

Example of "positive" effective direction ("Direction" = 1)

The distance output cam switches on when the switch-on range is reached in the **positive** direction. The distance output cam switches off in the event of a direction reversal 1.

If the position value is moved into the switch-on range of the distance output cam, the distance output cam switches on when there is positive motion direction of the interconnected technology object. The distance output cam remains switched off when the interconnected technology object is at a standstill.

Example of "negative" effective direction ("Direction" = 2)

The distance output cam switches on when the switch-on range is reached in the **negative** direction. The distance output cam switches off in the event of a direction reversal ①.

If the position value is moved into the switch-on range of the distance output cam, the distance output cam switches on when there is negative motion direction of the interconnected technology object. The distance output cam remains switched off when the interconnected technology object is at a standstill.

Example of "both directions" effective direction ("Direction" = 3)

The distance output cam switches on when the position of the interconnected technology object is within the switch-on range.

If the position value of the interconnected technology object is moved into the switch-on range of the distance output cam, the distance output cam switches on even when the interconnected technology object is at a standstill.

7.7.2 Activating/deactivating the distance output cam

You use Motion Control instruction "MC_OutputCam (Page 92)" to activate the specified distance output cam.

You determine the switch-on range of a distance output cam with the following parameters of the Motion Control instruction "MC_OutputCam":

- With the "OnPosition" parameter, you define the start position of an output cam. A setpoint output cam with the setting "MC_OutputCam.OnPosition" = 0 switches at position setpoint = 0.
- With the "OffPosition" parameter, you define the end position of an output cam.

You define the operating mode of an output cam with the "Mode" parameters of the Motion Control instruction "MC_OutputCam".

- When "Mode" = 1, the output cam is not output inverted.
- When "Mode" = 2, the output cam is output inverted (Page 51).
- When "Mode" = 3, the output cam is permanently switched on while "Enable" = TRUE .

When "MC_OutputCam.Enable" = TRUE, the input parameters are always read and take effect at the next position control cycle.

When a technological alarm occurs, the output cam is processed again after error acknowledgment.

NOTE

Enabling output cams

To guarantee precise switching, an output cam must be enabled for at least two application cycles before the output cam start is reached. Otherwise, distance output cams are imprecise.

Observe the switching behavior of the distance output cams (Page 54).

The "MC_OutputCam" job is deactivated by:

- Disabling the output cam with "MC_OutputCam.Enable" = FALSE.
- Only one instance of the "MC_OutputCam" function block can be active on an output cam in the user program. A second instance of the "MC_OutputCam" function block on a currently active output cam is rejected with an error.

7.7.3 Defining the switching behavior of distance output cams

The switch-on duration for distance output cams is determined by the switching positions and the current velocity.

After activation, a distance output cam switches on in the following cases:

- The position of the interconnected technology object reaches the start or end position with the configured effective direction ("Direction").
- The position of the interconnected technology object is moved into the switch-on range of the output cam (e.g. during homing) in the configured effective direction ("Direction"). When "Direction" = 3 (both effective directions), the output cam switches on even when the interconnected technology object is at a standstill.
- The output cam is switched on permanently with Motion Control instruction "MC_OutputCam" and "Mode" = 3.

An active distance output cam switches off in the following cases:

- The position is outside the switch-on range of the output cam.
- The position value is moved outside the switch-on range of the output cam.
- Motion Control instruction "MC_OutputCam" is set to "Enable" = FALSE.
- The motion direction of the interconnected technology object is reversed and no longer agrees with the enabled effective direction.

7.7.4 Hysteresis behavior of distance output cams

The following applies within the hysteresis:

- The switching state of distance output cams is not changed.
- The motion direction is not determined again.

After the hysteresis range is exited, distance output cams are set according to the output cam settings.

The following examples show the effects of the hysteresis on the switching behavior of output cams with positive effective direction.

① Direction reversal without hysteresis effect

② Hysteresis in effect

③ The switch-on position of the distance output cam is influenced according to the direction reversal and hysteresis.

7.8 How time-based output cams work

7.8.1 Defining the effective direction of time-based output cams

You define the effective direction of the time-based output cams with the "Direction" parameter of the Motion Control instruction "MC_OutputCam".

The following examples show the behavior of the time-based output cams as a function of the set effective direction.

Example of "positive" effective direction ("Direction" = 1)

The time-based output cam switches on when the start position is reached in the **positive** direction. At a direction reversal, the time-based output cam remains switched on for the specified switch-on duration ①.

If the position value of the interconnected technology object is directly on or behind the start position of the time-based output cam during the homing motion, the time-based output cam does not switch on.

Example of "negative" effective direction ("Direction" = 2)

The time-based output cam switches on when the start position is reached in the **negative** direction. At a direction reversal, the time-based output cam remains switched on for the specified switch-on duration ①.

If the position value of the interconnected technology object is directly on or behind the start position of the time-based output cam during the homing motion, the time-based output cam does not switch on.

Example of "both directions" effective direction ("Direction" = 3)

The time-based output cam switches on when the start position is reached. At a direction reversal, the time-based output cam remains switched on for the specified switch-on duration ①.

If the position value of the interconnected technology object is directly on or behind the start position of the time-based output cam during the homing motion, the time-based output cam does not switch on.

7.8.2 Activating/deactivating a time-based output cam

You use Motion Control instruction "MC_OutputCam (Page 92)" to activate the specified output cam.

You determine the switch-on range of a time-based output cam with the following parameters of the Motion Control instruction "MC_OutputCam":

- With the "OnPosition" parameter, you define the start position of an output cam. A setpoint output cam with the setting "MC_OutputCam.OnPosition" = 0 switches at position setpoint = 0.
- With the "Duration" parameter, you define the switch-on duration of an output cam.

You define the operating mode of an output cam with the "Mode" parameters of the Motion Control instruction "MC_OutputCam".

- When "Mode" = 1, the output cam is not output inverted.
- When "Mode" = 2, the output cam is output inverted (Page 51).
- When "Mode" = 3, the output cam is permanently switched on while "Enable" = TRUE.

When "MC_OutputCam.Enable" = TRUE, the input parameters are always read and take effect at the next position control cycle.

When a technological alarm occurs, the output cam is processed again after error acknowledgment.

NOTE

Enabling output cams

To guarantee precise switching, an output cam must be enabled for at least two application cycles before the output cam start is reached. Otherwise, time-based output cams are not switched on.

Observe the switching behavior of the time-based output cams (Page 58).

The "MC_OutputCam" job is deactivated by:

- Disabling the output cam with "MC_OutputCam.Enable" = FALSE.
- Only one instance of the "MC_OutputCam" function block can be active on an output cam in the user program. A second instance of the "MC_OutputCam" function block on a currently active output cam is rejected with an error.

7.8.3 Defining the switching behavior of time-based output cams

A time-based output cam switches on in the following cases:

- The start position has been reached and the motion direction of the interconnected technology object corresponds to the effective direction enabled by the instruction.

  NOTE

  – If the start position is reached again while an output cam is switched on, the switch-on duration is not re-triggered.

  – If due to the Motion Control instruction "MC_Home", the position value of the interconnected technology object is placed directly on or behind the start position of the output cam during the motion, the output cam does not switch on.

- The output cam is switched on permanently with Motion Control instruction "MC_OutputCam" and "Mode" = 3.

A time-based output cam switches off in the following cases:

- The configured switch-on duration has expired.
- Motion Control instruction "MC_OutputCam" is set to "Enable" = FALSE.

For time-based output cams, you indicate the switch-on duration at the "Duration" parameter of the "MC_OutputCam" instruction.

The derivative-action time dynamically shifts the switch-on and switch-off times of the time-based output cam depending on the velocity of the axis.

Example

An actuator (e.g. valve) is to open at position 200° and the derivative-action time is 0.5 s.

- With a velocity of 10°/s, the switch-on time is already at 195°.
- With a velocity of 20°/s, the switch-on time is already at 190°.

The switch-off time shifts accordingly.

7.8.4 Hysteresis behavior of time-based output cams

The following applies within the hysteresis:

- The motion direction is not determined again.
- If the start position of a time-based output cam is within the hysteresis, the time-based output cam is switched on when leaving the hysteresis with the corresponding effective direction.
- The switch-on duration of time-based output cams remains unchanged.

The following examples show the effects of the hysteresis on the switching behavior of output cams with positive effective direction.

① Direction reversal without hysteresis effect

② Hysteresis in effect

③ The start position of the time-based output cam is located within the hysteresis. The time-based output cam is switched on when leaving the hysteresis with the corresponding effective direction.

④ Switch-on duration

7.9 Tags: Output cam technology object

The following technology object tags are relevant:

Status indicator	
Tag	**Description**
<TO>.CamOutput	The output cam is switched.

Parameters		
Tag	**Description**	
<TO>.Parameter.OutputCamType	Output cam type	
	0	Distance output cam
	1	Time-based output cam
<TO>.Parameter.PositionType	Position reference	
	0	Position setpoint
	1	Actual position
<TO>.Parameter.OnCompensation	Activation time (lead time for the switch-on edge)	
<TO>.Parameter.OffCompensation	Deactivation time (lead time for the switch-off edge)	
<TO>.Parameter.Hysteresis	Hysteresis value	

Interface		
Tag	**Description**	
<TO>.Interface.EnableOutput	Activation of the output cam output	
	FALSE	No output
	TRUE	Output
<TO>.Interface.Address	I/O address of the output cam	
<TO>.Interface.LogicOperation	Logical operation of the output cam signals at the output	
	0	OR logic operation
	1	AND logic operation

Units	
Tag	**Description**
<TO>.Units.LengthUnit	Unit of the length data
<TO>.Units.TimeUnit	Unit of the time data

StatusWord	
Tag	**Description**
<TO>.StatusWord.X0 (Control)	The technology object is in operation.
<TO>.StatusWord.X1 (Error)	An error occurred at the technology object.
<TO>.StatusWord.X2 (RestartActive)	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart.
<TO>.StatusWord.X3 (OnlineStartValuesChanged)	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object.
<TO>.StatusWord.X4 (OutputInverted)	The output cam output is inverted.
<TO>.StatusWord.X5 (CommunicationOk)	The output cam is synchronized with the output module and available for use.

ErrorWord	
Tag	**Description**
<TO>.ErrorWord.X0 (SystemFault)	A system-internal error has occurred.
<TO>.ErrorWord.X1 (ConfigFault)	Configuration error One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program.
<TO>.ErrorWord.X2 (UserFault)	Error in user program at a Motion Control instruction or its use
<TO>.ErrorWord.X3 (CommandNotAccepted)	Command cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
<TO>.ErrorWord.X13 (PeripheralError)	Error accessing a logical address

ErrorDetail		
Tag	**Description**	
<TO>.ErrorDetail.Number	Alarm number You can find a list of the technology alarms and alarm responses in the "Technology alarms" section in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
<TO>.ErrorDetail.Reaction	Effective alarm response	
	0	No reaction
	6	Output cam processing is complete.

Cam track functions

8

8.1 Configuring the cam track

A cam track consists of up to 32 individual output cams that are specified within an adjustable track length.

① Start position

② End position

③ Cam track length

The output cams of the cam track can be set as distance output cams or time-based output cams. Only one of the two output cam types (Page 44) can be used in a cam track.

8.2 Defining the cam track reference

You define the position reference for the switching points of the output cams of a cam track in the "Basic parameters > Output cam reference" configuration window. The switching points of the output cams of a cam track can be referenced to the following positions, depending on the interconnected technology object:

- Actual position of a synchronous axis/positioning axis
- Position setpoint of a synchronous axis/positioning axis
- Position of an external encoder

8.3 Configuring the cam track output

8.3.1 Activate/deactivate cam track output

In the "Hardware interface > Output cam track output" configuration window, you activate and configure the output of the generated switching signals via a digital output.

When the output is activated, you can configure the following digital outputs:

- Output by Timer DQ (Page 64)

  Digital output with high degree of accuracy and reproducibility in the microsecond range on time-based IO modules basis

- Output by a digital module (Page 64)

  Digital output with switching accuracy depending on the output cycle of the I/O used

When output is deactivated, the output cam status is not output at the hardware output. The output cam status can be used internally in the user program by evaluating the relevant "<TO>.TrackOutput" tag.

8.3.2 Configuring output by Timer DQ

Configuring output by Timer DQ (Page 47) corresponds to that of the output cam technology object.

A maximum of two edges via Timer DQ (positive and negative) can be output per position control cycle. If multiple switch-on edges or switch-off edges are transmitted in one position control cycle clock, the last written values in each case are valid.

8.3.3 Configuring output by digital module

Configuring output by digital module (Page 49) corresponds to that of the output cam technology object.

A maximum of one edge via digital output module (positive or negative) can be output per position control cycle. If multiple switch-on edges or switch-off edges are transmitted in one position control cycle clock, the last written values in each case are valid.

8.3.4 Masking of individual output cams of a cam track

In order for output cams to be processed, they must be configured as valid in the technology data block with "<TO>.Parameter.Cam[1..32].Existent" = TRUE.

In addition, output cams of a cam track configured as valid can be defined as valid in the user program using bit masking ("<TO>.Parameter.CamMasking"). In the default setting, all valid output cams are enabled ("<TO>.Parameter.CamMasking" = 0xFFFFFFFF).

The cam track itself is activated/deactivated using the Motion Control instruction "MC_CamTrack".

8.4 Defining cam track data

8.4.1 Time offset of output cam switching points

Switching times of the output and the connected actuator (e.g. valve) can be compensated for using the activation time or deactivation time of the cam track technology object.

The time offset of output cam switching points corresponds to the activation time or deactivation time (Page 50) for the output cam technology object.

You define the activation time (<TO>.Parameter.OnCompensation) and the deactivation time (<TO>.Parameter.OffCompensation) in the configuration window under "Configuration > Extended parameters > Track data > Activation time".

8.4.2 Configuring a hysteresis

The behavior and effect of the hysteresis setting corresponds to the hysteresis (Page 50) for the output cam technology object.

You define the hysteresis value in the configuration of the cam track technology object under "Configuration > Extended parameters > Track data > Hysteresis" (<TO>.Parameter.Hysteresis).

8.4.3 Defining the track length

You define the length of the output cam track in the configuration of the cam track technology object under "Configuration > Extended parameters > Track data > Track dimensions"

Also take into account the output cam data of the individual output cams when defining the track length. Output cams whose start position lies outside the cam track length are not included. For the output cams to become active, increase the cam track length so that at least the respective start position of an output cam is within the new track length.

Track length for an axis with modulo function

For an axis with modulo function, the modulo length of the axis is displayed in the configuration window. The track length can be less than or greater than the modulo length of the axis. In order for the cam track to be mapped without offset in the modulo range and to prevent unwanted overrides, an integer ratio of modulo length to track length, and vice versa, is required.

Example Mapping without offset

① Axis with modulo length 360°

② Cam track with track length 120°

⇒ Ratio = 360° / 120° = **3**

The cam track is output 3 times on a modulo length.

Example Mapping with offset

① Axis with modulo length 360°

② Cam track with track length 160°

⇒ Ratio = 360° / 160° = **2.25**

The cam track is output 2.25 times on the first modulo length and continued correspondingly in the other modulo lengths.

8.4.4 Defining the axis reference position

You define the axis reference position of the output cam track in the configuration of the cam track technology object under "Configuration > Extended parameters > Track data > Track dimensions".

As reference position, enter the position of the higher-level axis or the external encoder starting from which the output of the cam track is to occur. The start of the cam track is placed at the entered position.

You can enter a negative or positive value for the reference position. The cam track is continued in both directions of the interconnected technology object.

Example

- Axis range = -1000 mm to +1000 mm
- Desired switching points of the output cam with reference to axis position:
  - Start position = -200 mm
  - End position = -100 mm
- Cam track length = 2000 mm
- Definition of output cam on the track:
  - Start position = 800 mm
  - End position = 900 mm

Axis reference position for an axis with modulo function

When a cam track is mapped onto an axis with modulo function, a reference position specified outside the modulo range is mapped within the modulo range.

During cyclic processing of the cam track, the continued reference position of the current cam track is displayed in the "<TO>.MatchPosition" tag. The continued reference position is independent of direction and always the position of the left boundary of the cam track. The unique detection and output of the position is only possible when the assigned technology object is in motion. The distance to the current reference position of the current cam track (<TO>.MatchPosition) is displayed in the "<TO>.TrackPosition" tag.

When the cam track is enabled by an "MC_CamTrack" job, the position of the cam track (<TO_CamTrack>.MatchPosition) is set as if the current position had been reached by a motion in the positive direction starting from the reference position (<TO_CamTrack>.ReferencePosition).

8.5 Configuring output cam data

The set output cam type is displayed.

Enter the properties for the output cams of the cam track that are to be output. You can set up to 32 individual output cams on a cam track.

The output cam positions are defined relative to the cam track. The start of the cam track is always 0.0. The output cam positions on the cam track are thus always positive.

In the configuration window under "Configuration > Basic parameters", define the individual output cams of the cam track. Depending on the set output cam type, you can define the following parameters in each case:

- **Valid**

  Only output cams set as "valid" are output and have a status display.
- **Start position**
  - The start position may not be greater than the end position for distance output cams.
  - If the start position is equal to the end position, the distance output cam does not switch.
  - The switching ranges of individual output cams are permitted to overlap.
  - Output cams whose start position lies outside the cam track length (Page 65) are not included. They become active only if the cam track length is increased so that at least the respective start position of an output cam is within the new track length.
- **End position**
  - The "End position" column is only displayed when distance output cam is set for the output cam type.
  - The end position must not be less than the start position.
- **Switch-on duration**

  The "Switch-on duration" column is only displayed when time-based output cam is set for the output cam type.

See also

Effective direction of distance output cams on a cam track (Page 71)

Effective direction of time-based output cams on a cam track (Page 72)

8.6 Activate/deactivate cam track

With the "MC_CamTrack (Page 96)" Motion Control instruction with "Enable" = TRUE, you can:

- Enable a cam track for the first time
- Change cam track data during cam track processing

The activation behavior differs when cam track data is applied. The configured cam track data (cam track data, data on the function block) is applied at different times depending on the set "Mode" parameter.

Activate a cam track for the first time

Calling the Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and "Mode" = 0 or 1 activates the cam track immediately ("<TO>.Status" changes to 1) and configured cam track data takes effect immediately.

Change cam track data of an already activated cam track ("<TO>.Status" = 1)

- With the call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and "Mode" = 0, the modified cam track data takes effect immediately.

  Previously activated distance output cams are aborted if their track signals are not still set due to the changed cam track data. Previously activated time-based output cams are always aborted.
- With the call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and "Mode" = 1, the cam track continues to be output with the prior configuration up to the cam track end. Modified cam track data takes effect at the end of the current track cycle.

  If you change a cam track with "Mode" = 1 during runtime of the user program, keep in mind the lead time of the cam track as reserve for the first output cam. Define the first output cam position in the cam track only after the following position:

  Position of first output cam > velocity of axis x lead time of the cam track (<TO>.Parameter.OnCompensation)

  Also keep in mind the internal system time for output cam calculation, even if you set the lead time 0.0.

Changing cam track data when modulo length is not a multiple of the track length

For the switching times to be set correctly, we recommend the following procedure for changes:

- Enter changes as soon as possible after start of a new cam track
- Enter a new reference position (<TO>.Parameter.ReferencePosition) for the changed cam track. The new reference position is composed as follows depending on the direction:
  - Positive effective direction: Current reference position (<TO>.MatchPosition) + cam track length (<TO>.Parameter.CamTrackLength)
  - Negative effective direction: Current reference position (<TO>.MatchPosition) - cam track length (<TO>.Parameter.CamTrackLength)
- Output the changes of the cam track when calling the Motion Control instruction "MC_CamTrack" and "Mode" = 1.

Example

The following figure shows an example of the differences in the activation behavior.

A1	A	The cam track is activated the first time with "MC_CamTrack.Enable" = TRUE and the output cams are output immediately with set "MC_CamTrack.Mode" = 0.
	B	After cam track data were changed (①), the cam track is activated by calling Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and the modified data takes effect immediately (①) with set "MC_CamTrack.Mode" = 0.
A2	A	The cam track is activated the first time with "MC_CamTrack.Enable" = TRUE and the output cams are output immediately with set "MC_CamTrack.Mode" = 1.
	B	After cam track data were changed (①), the cam track is activated by calling Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and the modified data takes effect at the end of the current track cycle (②) with set "MC_CamTrack.Mode" = 1.

8.7 Processing of a cam track

A cam track is processed cyclically.

The cam track is mapped onto the position of the interconnected technology object starting from the reference position and is continued cyclically in both directions.

When the cam track is processed, the output cams with start position within the track length are taken into consideration.

If the end of a cam track is overtraveled, connected output cams behave as follows within the cam track:

- Distance output cams whose end position lies outside the cam track are switched off when the cam track is left.
- Time-based output cams remain switched on for the set switch-on duration.

8.7.1 Effective direction of distance output cams on a cam track

The cam track is always active for both directions of the position of the interconnected technology object.

Distance output cams are switched when the switch-on range is overtraveled.

The following graphic shows the execution of a cam track with distance output cam depending on the motion direction of the axis.

With positive motion direction, the distance output cams of the cam track are output in the order Output cam N1, Output cam N2, Output cam N3. With negative motion direction, the distance output cams of the cam track are output in the order Output cam N3, Output cam N2, Output cam N1. The distance output cams switch on at ① and switch off at ②.

8.7.2 Effective direction of time-based output cams on a cam track

The cam track is always active for both directions of the position of the interconnected technology object.

The time-based output cams are switched when the start position is overtraveled.

The following graphic shows the execution of a cam track with time-based output cam depending on the motion direction of the axis.

With positive motion direction, the time-based output cams of the cam track are output in the order Output cam N1, Output cam N2, Output cam N3. With negative motion direction, the time-based output cams of the cam track are output in the order Output cam N3, Output cam N2, Output cam N1. The time-based output cams switch on at ① and remain switched on for the set switch-on duration ②.

8.7.3 Homing of an axis or an encoder during cam track processing

Homing of an axis or an encoder without modulo function

A change to the position of an axis or external encoder using Motion Control instruction "MC_Home" is regarded as a sudden position change. An enabled cam track is referenced to the changed position and processed further from there.

- Homing also has an effect on the current position of the cam track (<TO>.TrackPosition). The position is formed again as quickly as possible due to the offset.
- Distance output cams are either skipped or correspondingly output.
- Time-based output cams are skipped. A time-based output cam is switched on only when the start position is overtraveled and remains switched on for the switch-on duration.
- Switched time-based output cams are not canceled by a homing operation.

Recommendation:

Disable the cam track before or during homing.

Homing of an axis or an encoder with modulo function

- Homing also has an effect on the current position of the cam track (<TO>.TrackPosition).

  The homing of the assigned technology object influences the position of the subsequently active cam track on a direction-dependent basis. This is dependent on the position difference, the difference between the new position minus the original position. If the position difference is negative, you add the modulo length (<TO_Axis/TO_ExternalEncoder>.Modulo.Length).

  If this position difference is less than or equal to half the modulo length, the new position of the cam track (<TO_CamTrack>.MatchPosition) is set as if the new position had been reached by a motion in the positive direction starting from the original position.

  If this position difference is greater than half the modulo length, the new position of the cam track (<TO_CamTrack>.MatchPosition) is set as if the new position had been reached by a motion in the negative direction starting from the original position.
- Distance output cams are either skipped or correspondingly output.
- Time-based output cams are skipped. A time-based output cam is switched on only when the start position is overtraveled and remains switched on for the switch-on duration.
- Switched time-based output cams are not canceled by a homing operation.

Recommendation:

Disable the cam track before or during homing.

8.7.4 Changing the cam track data during operation

The data of a cam track and the parameters of the Motion Control instruction "MC_CamTrack" can be changed while track processing is enabled. The active Motion Control instruction "MC_CamTrack" is not aborted. The modified parameters take effect at the next call of the Motion Control instruction "MC_CamTrack".

The following parameters can be changed during operation and are in effect after another call of Motion Control instruction "MC_CamTrack".

- Cam track data in technology data block
  - Reference position (<TO>.Parameter.ReferencePosition)
  - Track length (<TO>.Parameter.CamTrackLength)
  - Bit masking of individual output cams (<TO>.Parameter.CamMasking)
  - Activation time (<TO>.Parameter.OnCompensation)
  - Deactivation time (<TO>.Parameter.OffCompensation)
  - Hysteresis value (<TO>.Parameter.Hysteresis)
  - Output cam data (<TO>.Parameter.Cam[1..32])
- Parameters in the function block
  - Enable (MC_CamTrack.Enable)
  - Mode (MC_CamTrack.Mode)
  - Inverted output (MC_CamTrack.InvertOutput)

Note the different activation behavior (Page 68) when changing the cam track data.

8.8 Tags: Cam track technology object

The following technology object tags are relevant:

Status indicator		
Tag	**Description**	
<TO>.Status	Status of the cam track function	
	0	Inactive
	1	Active
	2	Active and waiting for next track
<TO>.TrackOutput	An output cam of cam track is switched.	
<TO>.SingleCamState	Switched on output cam (bit-masked)	
<TO>.TrackPosition	Display of the current position within the cam track The distance to the current reference position of the current cam track (<TO>.MatchPosition) is displayed.	
<TO>.MatchPosition	Reference position of the current cam track During cyclic processing of the cam track, the continued reference position of the current cam track is displayed. The unique detection and output of the position is only possible when the assigned technology object is in motion.	

Parameters		
Tag	**Description**	
<TO>.Parameter.CamTrackType	Output cam type	
	0	Distance output cam
	1	Time-based output cam
<TO>.Parameter.PositionType	Position reference	
	0	Position setpoint
	1	Actual position
<TO>.Parameter.ReferencePosition	Reference position	
<TO>.Parameter.CamTrackLength	Track length	
<TO>.Parameter.CamMasking	Bit masking of individual output cams	
<TO>.Parameter.OnCompensation	Activation time (lead time for the switch-on edge)	
<TO>.Parameter.OffCompensation	Deactivation time (lead time for the switch-off edge)	
<TO>.Parameter.Hysteresis	Hysteresis value	
<TO>.Parameter.Cam[1..32].OnPosition	Start position (distance output cams and time-based output cams)	
<TO>.Parameter.Cam[1..32].OffPosition	End position (distance output cam)	
<TO>.Parameter.Cam[1..32].Duration	Switch-on duration (time-based output cam)	
<TO>.Parameter.Cam[1..32].Existent	Validity of an output cam	
	FALSE	Output cam is not used.
	TRUE	Output cam is used.

Interface		
Tag	**Description**	
<TO>.Interface.EnableOutput	Output cam output at the bit specified under "Address"	
	FALSE	No output
	TRUE	Output
<TO>.Interface.Address	I/O address for digital output cam output	

Units	
Tag	**Description**
<TO>.Units.LengthUnit	Unit of the length data
<TO>.Units.TimeUnit	Unit of the time data

StatusWord	
Tag	**Description**
<TO>.StatusWord.X0 (Control)	The technology object is in operation.
<TO>.StatusWord.X1 (Error)	An error occurred at the technology object.
<TO>.StatusWord.X2 (RestartActive)	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart.
<TO>.StatusWord.X3 (OnlineStartValuesChanged)	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object.
<TO>.StatusWord.X4 (OutputInverted)	The output cam output is inverted.
<TO>.StatusWord.X5 (CommunicationOk)	The cam track is synchronized with the output module and available for use.
<TO>.StatusWord.X6 (CamDataChanged)	The data of individual output cams has been changed but not yet taken effect with Motion Control instruction "MC_CamTrack".

ErrorWord	
Tag	**Description**
<TO>.ErrorWord.X0 (SystemFault)	A system-internal error has occurred.
<TO>.ErrorWord.X1 (ConfigFault)	Configuration error One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program.
<TO>.ErrorWord.X2 (UserFault)	Error in user program at a Motion Control instruction or its use.
<TO>.ErrorWord.X3 (CommandNotAccepted)	Command cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
<TO>.ErrorWord.X13 (PeripheralError)	Error accessing a logical address.

ErrorDetail		
Tag	**Description**	
<TO>.ErrorDetail.Number	Alarm number You can find a list of the technology alarms and alarm responses in the "Technology alarms" section in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
<TO>.ErrorDetail.Reaction	Effective alarm response	
	0	No reaction
	5	Cam track processing is complete.

Diagnostics 9

The description of Motion Control diagnostics is limited to the diagnostics view of the technology objects in TIA Portal, the technology alarms and the error IDs on Motion Control instructions.

"Debug" program mode is available for testing the execution of your Interpreter program.

The following descriptions can be found in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation:

- Diagnostics concept
- Technology alarms
- Error IDs in Motion Control instructions

A comprehensive description of the system diagnostics of the S7-1500 CPU can be found in the "Diagnostics" function manual (https://support.industry.siemens.com/cs/ww/en/view/59192926).

9.1 Measuring input technology object

9.1.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Measuring input status

The following table shows the possible states of the measuring input:

Status	Description
Active	The technology object is in operation. (<TO>.StatusWord.X0 (Control))
Waiting for measuring event	The measuring input is waiting for a measuring event. The technology data block tag "<TO>.Status" has the value "1" ("WAITING_FOR_TRIGGER").
Measured value present	The measuring input has acquired one or more measured values. The technology data block tag "<TO>.Status" has the value "2" ("TRIGGER_OCCURRED").
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))

Status	Description
Restart active	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart. (<TO>.StatusWord.X2 (RestartActive))
Measuring input ready	The measuring input is synchronized with the measurement input and can be used. With an interconnected measuring input that monitors another measuring input with measurement input, the bit always has the value "FALSE". (<TO>.StatusWord.X5 (CommunicationOK))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because the necessary conditions have not been met (e.g. axis assigned to the measuring input is not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

9.2 Output cam technology object

9.2.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Output cam status

The following table shows the possible states of the output cam:

Status	Description
Active	The technology object is in operation. (<TO>.StatusWord.X0 (Control))
Switched	The output cam is switched. (<TO>.CamOutput)
Inverted output for output cam	The output cam output is inverted. (<TO>.StatusWord.X4 (OutputInverted))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart. (<TO>.StatusWord.X2 (RestartActive))
Output cam output ready	The output cam is synchronized with the output module and available for use. (<TO>.StatusWord.X5 (CommunicationOk))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because the necessary conditions have not been met (e.g. axis assigned to the output cam is not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

9.3 Cam track technology object

9.3.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Cam track status

The following table shows the possible states of the cam track:

Status	Description
Active	The technology object is in operation. (<TO>.StatusWord.X0 (Control))
Switched	An output cam of cam track is switched. (<TO>.TrackOutput)
Inverted output for output cam	The output cam output is inverted. (<TO>.StatusWord.X4 (OutputInverted))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart. (<TO>.StatusWord.X2 (RestartActive))
Cam track output ready	The cam track is synchronized with the output module and available for use. (<TO>.StatusWord.X5 (CommunicationOk))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))

Error	Description
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because the necessary conditions have not been met (e.g. axis assigned to the cam track is not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

"StatusWord" tag (cam track) (Page 126)
"ErrorWord" tag (cam track) (Page 126)
"WarningWord" tag (cam track) (Page 128)

9.3.2 Cam track status

You use the "Technology object > Diagnostics > Cam track status" diagnostics function in the TIA Portal to monitor the status of the cam track. The Diagnostics function is available in online operation.

"Validity and masking of the output cams" area

The individual output cams of a cam track are shown in this area along with the status for the following properties:

Status	Description
Valid	Validity of the individual output cams of the cam track (<TO>.Parameter.Cam[1..32].Existent)
Masked	Bit masking of the individual cams of the cam track (<TO>.Parameter.CamMasking)
Effective	Switched on output cam (bit-masked) (<TO>.SingleCamState)

"Positions" area

The following status values are displayed in this area:

Status	Description
Current position in the cam track	Position during cam track processing within a cam track cycle The distance to the current reference position of the current cam track (<TO>.MatchPosition) is displayed. (<TO>.TrackPosition)
Current cam track start	Reference position of the current cam track During cyclic processing of the cam track, the continued reference position of the current cam track is displayed. The unique detection and output of the position is only possible when the assigned technology object is in motion. (<TO>.MatchPosition)

Instructions 10

10.1 MC_MeasuringInput V10

10.1.1 MC_MeasuringInput: Start measuring once V10

Description

Use the Motion Control instruction "MC_MeasuringInput" to start a measuring job for one-time measuring.

The Motion Control instruction offers you the following:

- Type of measurement (Page 33)
- Defining the measuring range (Page 33)
- Measuring once (Page 35)

Applies to

- Measuring input

Requirement

- The technology object has been configured correctly.
- The encoder of the axis must have "VALID" status ("<TO>.StatusSensor[1..4].State" = 2). Otherwise, the measuring job is rejected in the function block with an error indication.
- The communication between the measuring input and measurement input is established ("<TO>.StatusWord.CommunicationOK" = TRUE).
- Measurement using PROFIdrive is not possible during active or passive homing.
- The measuring input is not an interconnected measuring input that monitors a measuring input with measurement input. Measuring jobs can only be started at the measuring input with measurement input.

Override response

The override response for "MC_MeasuringInput" jobs is described in section "Override response V10: Measuring input jobs".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MeasuringInput":

Parameters	Declaration	Data type	Default value	Description	
MeasuringInput	INPUT	TO_MeasuringInput	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	0	Type of measurement (Page 35)	
				0	Measurement of next positive edge
				1	Measurement of next negative edge
				2	Measurement of next two edges
				3	Measurement of two edges, beginning with the positive edge • Rising edge = "MeasuredValue1" (measured value 1) • Falling edge = "MeasuredValue2" (measured value 2)
				4	Measurement of two edges, beginning with the negative edge • Falling edge = "MeasuredValue1" • Rising edge = "MeasuredValue2"
MeasuringRange	INPUT	BOOL	FALSE	Acquisition of measured values Observe the time-related boundary conditions (Page 39).	
				FALSE	Always acquire measured values
				TRUE	Acquire measured values only within the measuring range (Page 33)
StartPosition	INPUT	LREAL	0.0	Start position of the measuring range (Page 33) For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
EndPosition	INPUT	LREAL	0.0	End position of the measuring range (Page 33) For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
Done	OUTPUT	BOOL	FALSE	TRUE	The block has been completely processed. Measured values are valid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The measuring job has been aborted.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.

Parameters	Declaration	Data type	Default value	Description
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.
MeasuredValue1	OUTPUT	LREAL	0.0	First measured value
MeasuredValue2	OUTPUT	LREAL	0.0	Second measured value (for measurement of two edges)

10.1.2 MC_MeasuringInput: Function chart V10

Function chart: Start measuring once

An "Execute" job with "MC_MeasuringInput" = 0 initiated using "Mode" performs a measurement of the next positive edge of the signal at the measurement input. A successfully completed measurement is signaled with "Done" = TRUE. The determined measured value at the time ① (in the example: 50) is output using "MeasuredValue1".

10.2 MC_MeasuringInputCyclic V10

10.2.1 MC_MeasuringInputCyclic: Start cyclic measuring V10

Description

You start cyclic measuring with the Motion Control instruction "MC_MeasuringInputCyclic".

The Motion Control instruction offers you the following:

- Type of measurement (Page 33)
- Defining the measuring range (Page 33)
- Cyclic measuring (Page 36)

Applies to

- Measuring input

Requirement

- The technology object has been configured correctly.
- Cyclic measuring is possible when measuring using Timer DI and when measuring via SINAMICS.
- The communication between the measuring input and measurement input is established ("<TO>.StatusWord.CommunicationOK" = TRUE).
- The encoder of the axis operationally in effect must have "VALID" status ("<TO>.StatusSensor[1..4].State" = 2). Otherwise, the measuring job is rejected in the function block with an error indication.
- The measuring input is not an interconnected measuring input that monitors a measuring input with measurement input. Measuring jobs can only be started at the measuring input with measurement input.

Override response

The override response for "MC_MeasuringInputCyclic" jobs is described in section "Override response V10: Measuring input jobs".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MeasuringInputCyclic":

Parameters	Declaration	Data type	Default value	Description	
MeasuringInput	INPUT	TO_MeasuringInput	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	0	Type of measurement (Page 36)	
				0	Measurement of positive edges
				1	Measurement of negative edges
				2	Measurement of both edges
MeasuringRange	INPUT	BOOL	FALSE	Acquisition of measured values Observe the time-related boundary conditions (Page 39).	
				FALSE	Always acquire measured values
				TRUE	Acquire measured values only within the measuring range (Page 33)
StartPosition	INPUT	LREAL	0.0	Start position of the measuring range (Page 33) For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
EndPosition	INPUT	LREAL	0.0	End position of the measuring range (Page 33) For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The measuring job has been aborted.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
MeasuredValue1	OUTPUT	LREAL		First measured value	
MeasuredValue2	OUTPUT	LREAL		Second measured value (when measuring multiple edges in one position control cycle)	
MeasuredValue1Counter	OUTPUT	UDINT	0	Count value for the first measured value	

Parameters	Declaration	Data type	Default value	Description
MeasuredValue2Counter	OUTPUT	UDINT	0	Count value for the second measured value
LostEdgeCounter1	OUTPUT	UDINT	0	Count value for the lost edges in the cycle clock of the first measured value acquisition During cyclic measurement via SINAMICS equal to zero
LostEdgeCounter2	OUTPUT	UDINT	0	Count value for the lost edges in the cycle clock of the second measured value acquisition During cyclic measurement via SINAMICS equal to zero

10.2.2 MC_MeasuringInputCyclic: Function chart V10

Function chart: Start cyclic measuring

An "MC_MeasuringInputCyclic" job initiated using "Execute" (signal and start point not shown) (e.g. call in MC_PreServo) with "Mode" = 0 and without specified measuring range "MeasuringRange" = FALSE performs a measurement of the positive edges.

The actual position determined at the time of the first positive edge ① in the position control cycle is output using "MeasuredValue1", and count tag "MeasuredValue1Counter" is incremented by "1".

The actual position determined at the time of the second positive edge ② in the position control cycle is output using "MeasuredValue2", and count tag "MeasuredValue2Counter" is incremented by "1".

If additional positive edges occur in the same position control cycle ③, these are recorded in LostEdgeCounter1 and LostEdgeCounter2.

10.3 MC_AbortMeasuringInput V10

10.3.1 MC_AbortMeasuringInput: Cancel active measuring job V10

Description

With the Motion Control instruction "MC_AbortMeasuringInput", an active one-time or cyclic measuring job is aborted.

The Motion Control instruction offers you the following:

- Cancel active measuring job (Page 39)

Applies to

- Measuring input

Requirement

- The technology object has been configured correctly.

Override response

The override response for "MC_AbortMeasuringInput" jobs is described in section "Override response V10: Measuring input jobs".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_AbortMeasuringInput":

Parameters	Declaration	Data type	Default value	Description	
MeasuringInput	INPUT	TO_MeasuringInput	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Done	OUTPUT	BOOL	0	The function block has been processed. The measuring job has been deactivated.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameters	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job has been aborted.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

10.4 MC_OutputCam V10

10.4.1 MC_OutputCam: Activate/deactivate output cam V10

Description

You use Motion Control instruction "MC_OutputCam" to activate the specified output cam:

The Motion Control instruction offers you the following:

- Distance output cam:
  - Defining the effective direction of distance output cams (Page 52)
  - Activating/deactivating the distance output cam (Page 53)
  - Defining the switching behavior of distance output cams (Page 54)
- Time-based output cam:
  - Defining the effective direction of time-based output cams (Page 56)
  - Activating/deactivating a time-based output cam (Page 57)
  - Defining the switching behavior of time-based output cams (Page 58)

Applies to

- Output cam

Requirement

- The technology object has been configured correctly.
- The higher-level technology object must have a valid position.
- The communication between output cam and output module is established ("<TO>.StatusWord.CommunicationOK" = TRUE).
- Setpoint output cams are not output for an axis in non-position-controlled operation.

Override response

The "MC_OutputCam" job is aborted by:

- Disabling the output cam with "MC_OutputCam.Enable" = FALSE.
- Only one instance of the "MC_OutputCam" function block can be active on an output cam in the user program. A second instance of the "MC_OutputCam" function block on a currently active output cam is rejected with an error.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_OutputCam":

Parameters	Declaration	Data type	Default value	Description	
OutputCam	INPUT	TO_OutputCam	-	Technology object	
Enable	INPUT	BOOL	FALSE	FALSE	Output cam is disabled.
				TRUE	Output cam is being processed.
OnPosition	INPUT	LREAL	0.0	With distance output cams (Page 53): Start position of the output cam [unit of measurement of the interconnected technology object]	
				With time-based output cams (Page 57): Position of the output cam [unit of measurement of the interconnected technology object]	
				For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
OffPosition	INPUT	LREAL	0.0	End position of the distance output cam (Page 53) [unit of measurement of the interconnected technology object] For an axis or external encoder with active modulo function, position data outside the modulo range is mirrored in the modulo range.	
Duration	INPUT	LREAL	0.0	Switch-on duration of the time-based output cam (Page 58)[unit of measurement: ms] The value for the switch-on duration of a time-based output cam must be greater than 0.0.	
Mode	INPUT	DINT	1	Operating mode of the output cam (distance output cam (Page 53)/time-based output cam (Page 57))	
				1	Standard Output cam functionality (output not inverted)
				2	Output cam functionality with inverted output
				3	Output cam always ON (while "Enable" = TRUE)

Parameters	Declaration	Data type	Default value	Description	
Direction	INPUT	DINT	1	Effective direction of the output cam (distance output cam (Page 52)/time-based output cam (Page 56))	
				1	Positive direction
				2	Negative direction
				3	Both directions
CamOutput	OUTPUT	BOOL	-	Status display based on last call of Motion Control instruction "MC_OutputCam"	
Busy	OUTPUT	BOOL	FALSE	TRUE	The processing of the output cam is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

10.4.2 MC_OutputCam: Function chart V10

Function chart: Enable output cam

A1 Distance output cam

A2 Time-based output cam

An output cam is activated with "Enable" = TRUE. The output cam is output corresponding to the parameters.

The processing of the output cam is indicated with "Busy" = TRUE.

When activation direction "Direction" = 1 (positive) is set, the output cam behaves as follows, regardless of the output cam type setting:

- The distance output cam switches on at "OnPosition" ① and switches off again at "OffPosition" ②. At a direction reversal the output cam is switched off ④.
- The time-based output cam switches on at "OnPosition" ① and switches off again after expiration of the specified time "Duration" ③. A switched on time-based output cam remains active for the specified switch-on duration "Duration", even if overtravel of the start position occurs again in the reverse direction.

The switching state of the output cam is output using "CamOutput".

With "Enable" = FALSE, the specified output cam is disabled. "Busy" = FALSE shows that the output cam is not being processed.

10.5 MC_CamTrack V10

10.5.1 MC_CamTrack: Activate/deactivate cam track V10

Description

With the Motion Control instruction "MC_CamTrack", the processing of a cam track is enabled.

The Motion Control instruction offers you the following:

- Activation behavior (Page 68) of a cam track

Applies to

- Cam track

Requirement

- The technology object has been configured correctly.
- The higher-level technology object must have a valid position.
- The communication between output cam and output module is established ("<TO>.StatusWord.CommunicationOK" = TRUE).
- Setpoint output cams are not output for an axis in non-position-controlled operation.

Override response

- The "MC_CamTrack" job is canceled by disabling the cam track with "MC_CamTrack.Enable" = FALSE.
- Only one instance of the "MC_CamTrack" function block can be active on a cam track in the user program. A second instance of the "MC_CamTrack" function block on a currently active cam track is rejected with an error.
- The cam track is recalculated at a change of the parameters of the Motion Control instruction "MC_CamTrack" or in the technology data block. The cam track is processed in accordance with all parameter settings.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_CamTrack":

Parameters	Declaration	Data type	Default value	Description	
CamTrack	INPUT	TO_CamTrack	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The cam track is processed.
				FALSE	The cam track is disabled.
Mode	INPUT	DINT	0	0	When "Enable" = TRUE: The cam track processing is activated immediately. Cam track data takes effect immediately Previously activated distance output cams are canceled if their track signal is not still set due to the changed cam track data. Previously activated time-based output cams are always aborted.
					When "Enable" = FALSE: The cam track processing is ended immediately. Distance output cams/time-based output cams are canceled immediately.
				1	When "Enable" = TRUE: The cam track processing is activated immediately/with the next track cycle: • When a cam track is activated for the first time, the cam track processing begins immediately. • If the cam track processing is already active, the current cam track is output up to the end of the track cycle. The new cam track data then takes effect.
					When "Enable" = FALSE: The cam track processing is ended at the end of the cam track
				2	When "Enable" = TRUE: The cam track output is switched on immediately and remains switched on

Parameters	Declaration	Data type	Default value	Description	
Mode	INPUT	DINT	0	2	When "Enable" = FALSE: The cam track output is switched off immediately.
InvertOutput	INPUT	BOOL	FALSE	Inverted output	
				TRUE	The track output is output inverted.
				FALSE	The track output is output non-inverted.
TrackOutput	OUTPUT	BOOL	-	Indicates the switching state of the cam track.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The processing of the cam track is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

10.5.2 MC_CamTrack: Function chart V10

Function chart: Activate cam track

① Axis reference position

② Output cam configured as invalid

③ Start of cyclically continued cam track

A cam track is activated with "Enable" = TRUE. The cam track is output in accordance with the parameters set in the technology data block.

Tag		Value	Description
<TO>Parameter.			
	CamTrackType	0	Specified output cam type for the cam track is distance output cam

Tag		Value	Description
	ReferencePosition	20.0	Specified axis reference position for the cam track
	CamTrackLength	100.0	Specified length of the cam track
	CamTrack[1].Existent	TRUE	The first distance output cam of the cam track is specified as valid
	CamTrack[1].OnPosition	10.0	Start position for the first output cam of the cam track
	CamTrack[1].OffPosition	20.0	End position for the first output cam of the cam track
	CamTrack[2].Existent	FALSE	The second distance output cam of the cam track is specified as invalid
	CamTrack[2].OnPosition	30.0	Start position for the second output cam of the cam track
	CamTrack[2].OffPosition	50.0	End position for the second output cam of the cam track
	CamTrack[3].Existent	TRUE	The third distance output cam of the cam track is specified as valid
	CamTrack[3].OnPosition	60.0	Start position for the third output cam of the cam track
	CamTrack[3].OffPosition	90.0	End position for the third output cam of the cam track

10.6 Override response of Motion Control jobs V10

10.6.1 Override response V10: Homing and motion jobs

The following table shows how a new Motion Control job affects active homing and motion jobs:

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 0, 1 active MC_Move-Velocity MC_MoveJog	MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_Move-Super-imposed MC_Motion-InSuper-imposed MC_Motion-InSuper-imposed-Axes MC_Halt-Super-imposed	MC_Motion-InVelocity MC_Motion-InPosition
MC_Home[1)] "Mode" = 3, 5	A	A	A	A	A	N	A	A
MC_Home "Mode" = 9	A	-	-	-	-	N	-	-
MC_Halt "Mode" = 1	-	A	A	A	-	N	-	A
MC_Halt "Mode" = 0 **MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity MC_MoveJog**	-	A	A	A	A	N	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 0, 1 active MC_MoveVelocity MC_MoveJog	MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_MoveSuperimposed MC_MotionInSuperimposed MC_MotionInSuperimposedAxes MC_HaltSuperimposed	MC_MotionInVelocity MC_MotionInPosition

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 0, 1 active MC_Move-Velocity MC_MoveJog	MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_Move-Super-imposed MC_Motion-InSuper-imposed MC_Motion-InSuper-imposed-Axes MC_Halt-Super-imposed	MC_Motion-InVelocity MC_Motion-InPosition

MC_GearOut MC_CamOut waiting[4)]	N	N	N	N	N	N	-	N
MC_GearOut MC_CamOut active[5)]	N	N	N	N	N	N	A	N

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

NOTE

Override response with active fixed stop

With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

10.6.2 Override response V10: Synchronous operation jobs

The following table shows how a new Motion Control job affects the motion of the axis on active synchronous operation jobs:

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_Home[1] "Mode" = 3, 5	A	A	-	N	-	-	-	-	A
MC_Halt "Mode" = 0, 1 **MC_MoveAbsolute/ MC_MoveRelative** "BufferMode" = 0 Active **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog**	A	A	-	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

NOTE
Override response with active fixed stop
With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

10.6.3 Override response V10: Measuring input jobs

The following table shows which new Motion Control jobs will override active measuring input jobs:

⇒ **Active job** ⇓ **New job**	**MC_MeasuringInput**	**MC_MeasuringInputCyclic**
MC_Home "Mode" = 2, 3, 5, 8, 9, 10	B	B
MC_Home "Mode" = 0, 1, 6, 7, 11, 12	-	-
MC_MeasuringInput **MC_MeasuringInputCyclic** **MC_AbortMeasuringInput**	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B The running job is aborted with "ErrorID" = 16#80A3.

- No effect. Running job continues to be executed.

10.6.4 Override response V10: Kinematics motion commands

Single axis jobs are not overridden by kinematics jobs.

The following table shows how a new Motion Control job affects active kinematics motion jobs:

⇒ **Active job** ⇓ **New job**	**MC_MoveLinearAbsolute** **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt** **MC_DefineWorkspaceZone** **MC_DefineKinematicsZone** **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive** **MC_SetOcsFrame**	**MC_GroupInterrupt**	**MC_GroupStop**
MC_Home **MC_MoveSuperimposed** **MC_GearOut** **MC_CamOut**	N	N	N
MC_Halt **MC_MoveAbsolute/** **MC_MoveRelative/** **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog** **MC_Stop** **MC_GearIn** **MC_GearInPos** **MC_GearInVelocity** **MC_CamIn** **MC_MotionInVelocity** **MC_MotionInPosition**	A	A	A
MC_GroupStop	A	A	N
MC_GroupInterrupt **MC_GroupContinue**	B	A	N
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt**	-	-	N

⇒ Active job ⇓ New job	MC_MoveLinearAbsolute MC_MoveLinearRelative MC_MoveCircularAbsolute MC_MoveCircularRelative MC_MoveDirectAbsolute MC_MoveDirectRelative MC_TrackConveyorBelt MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive MC_SetOcsFrame	MC_GroupInterrupt	MC_GroupStop
MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive			
MC_SetOcsFrame	C, -	-	N

A The running job is aborted with "CommandAborted" = TRUE.

B Running job is interrupted or resumed.

C Synchronization of the OCS with the conveyor belt is aborted with "MC_SetOcsFrame" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed. A new kinematics job is added to the job sequence.

10.6.5 Override response V10: Interpreter jobs

The following table shows how a new Motion Control job affects running Interpreter jobs:

⇒ Active job ⇓ New job	MC_LoadProgram	MC_RunProgram	MC_StopProgram
MC_LoadProgram	N	N	N
MC_RunProgram	-[1]	N	N
MC_StopProgram	A	A	A[2]
MC_Reset	-/N[3]	-/N[3]	-/N[3]

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) The new job is also executed.

2) A new "MC_StopProgram" job with "Mode" = 0 cancels a running "MC_StopProgram" job with "Mode" = 1 or 2. A new "MC_StopProgram" job with "Mode" = 1 aborts a current "MC_StopProgram" job with "Mode" = 2.

3) An "MC_Reset" job with "Restart" = TRUE is rejected. Running job continues to be executed.

Override response for technology objects controlled by the Interpreter

The following table shows how a new Motion Control job acts in relation to a technology object controlled by the Interpreter during the execution of an Interpreter program ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)):

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_Power disable/enable with technology object	✓	✓
MC_Reset with "Restart" = TRUE	✓	✓
MC_Reset with "Restart" = FALSE	✓	-
MC_Home **MC_Halt** **MC_Stop**	✓	✓
MC_MoveAbsolute **MC_MoveRelative** **MC_MoveVelocity** **MC_MoveJog**	✓	✓
MC_SetAxisSTW **MC_WriteParameter**	✓	-
MC_MoveSuperimposed **MC_MotionInSuperimposed** **MC_MotionInSuperimposedAxes** **MC_HaltSuperimposed**	-	-
MC_MotionInVelocity **MC_MotionInPosition**	✓	✓
MC_GearIn **MC_GearInPos** **MC_GearInVelocity** **MC_GearOut** **MC_CamIn** **MC_CamOut**	✓	✓[1)]
MC_PhasingRelative **MC_PhasingAbsolute**	-	-
MC_LeadingValueAdditive	✓	-
MC_OffsetRelative **MC_OffsetAbsolute**	-	-
MC_TorqueAdditive **MC_TorqueRange**	✓	-
MC_TorqueLimiting	✓	-/✓[2)]
MC_SynchronizedMotionSimulation	✓	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative**	-	-
MC_GroupInterrupt **MC_GroupContinue**	-	-
MC_GroupStop	✓	✓
MC_KinematicsMotionSimulation	✓	-
MC_TrackConveyorBelt	-	-
MC_DefineTool **MC_SetTool** **MC_SetOcsFrame**	-	-
MC_KinematicsTransformation **MC_InverseKinematicsTransformation**	✓	-
MC_DefineWorkspaceZone **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_DefineKinematicsZone** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive**	-	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

NOTE

MC_Power

Note that a "MC_Power" request with "Enable" = FALSE always locks the specified technology object, even if the technology object was enabled via an Interpreter program with "powerOn()".

Mixed operation of MC_Power (SCL) and powerOn() (MCL) is not permitted.

NOTE

MC_Stop

Note that when starting a motion controlled by the Interpreter no "MC_Stop" job may be active, otherwise the motion job will be aborted.

NOTE

MC_GroupStop

Note that when starting a kinematics motion controlled by the Interpreter, no "MC_GroupStop" job may be active, otherwise the motion job will be aborted.

A "MC_GroupStop" job only affects active kinematics motions or if the kinematics technology object is controlled by the Interpreter ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)).

Tags of the technology object data blocks 11

11.1 Legend

Tag	Name of the tag	
Data type	Data type of the tag	
Values	Value range of the tag - minimum value to maximum value (L - linear specification R - rotary specification) If no specific value is shown, the value range limits of the relevant data type apply or the information under "Description".	
W	Effectiveness of changes in the technology data block	
	DIR	Direct: Values are changed via direct assignment and take effect at the start of the next MC_Servo.
	CAL	At call of Motion Control instruction: Values are changed directly and take effect at the start of the next MC_Servo after the call of the corresponding Motion Control instruction in the user program.
	RES	Restart: Changes to the start value in the load memory are made using the extended instruction "WRIT_DBL" (write to DB in load memory). Changes will not take effect until after restart of the technology object.
	RON	Read only: The tag cannot and must not be changed during runtime of the user program.
Description	Description of the tag	

Access to the tags is with "<TO>.<tag name>". The placeholder <TO> represents the name of the technology object.

11.2 Tags of the measuring input technology object

11.2.1 Display data (measuring input)

The "<TO>.Status" and "<TO>.InputState" tags show the status of the measuring input function and the measurement input.

Tags

Legend

Tag	Data type	Values	W	Description	
Status	DINT	-	RON	Status of the measuring input function	
				0	"INACTIVE" No measurement is active.

Tag	Data type	Values	W	Description	
Status	DINT	-	RON	1	"WAITING_FOR_TRIGGER" The measuring input is waiting for the measuring event.
				2	"TRIGGER_OCCURRED" One or more measured values have been captured.
				3	"MEASURING_ERROR" Error during the measurement
InputState	BOOL	-	RON	Status of the measurement input	
				FALSE	Measurement input inactive
				TRUE	Measurement input active

11.2.2 "Parameter" tag (measuring input)

The tag structure "<TO>.Parameter.<tag name>" contains the configuration of the basic parameters of the measuring input technology object.

Tags

Legend

Tag	Data type	Values	W	Description	
Parameter.	TO_MeasuringInput_Struct_Parameter				
MeasuringInputType	DINT	0...2	RON	Measuring input type	
				0	"STANDARD" Measurement using time stamp
				1	"PROFIDRIVE" Measuring event using PROFIdrive telegram
				2	"MONITORING" Measuring via "Monitor measuring input": Capture a measuring event of another measuring input technology object
PROFIdriveProbeNumber	UDINT	1, 2	RES	Number of the measurement input to be used for a measurement via PROFIdrive telegram	
MeasuringRangeActivationTime	LREAL	0.0 ... 1.0E12	RON	System share for activation time of measuring range	
MeasuringRangeAdditionalActivationTime	LREAL	0.0 ... 1.0E12	RES	Additional activation time when using measuring range limits [ms]	
CorrectionTime	LREAL	0.0 ... 1.0E12	RES	Correction time for the measurement result [ms]	

11.2.3 "Interface" tag (measuring input)

The tag structure "<TO>.Interface.<tag name>" contains the configuration of the input properties for the measuring input technology object.

Tags

Legend

Tag	Data type	Values	W	Description
Interface.	TO_MeasuringInput_Struct_Interface			
Address	VREF	-	RON	I/O address for the digital measurement input Not relevant for measuring via "Monitor measuring input" ("MeasuringInputType" = 2)

11.2.4 "Units" tag (measuring input)

The tag structure "<TO>.Units.<tag name>" shows the set technological units.

Tags

Legend

Tag	Data type	Values	W	Description	
Units.	TO_MeasuringInput_Struct_Units				
LengthUnit	UDINT	-	RON	Unit for position	
				1010	m
				1013	mm
				1536	mm[1)]
				1011	km
				1014	µm
				1015	nm
				1019	in
				1018	ft
				1021	mi
				1004	rad
				1005	°
				1537	°[1)]
TimeUnit	UDINT	-	RON	Unit for time	
				1056	ms

1) Position values with higher resolution or six decimal places.

11.2.5 "MeasuredValues" tag (measuring input)

The tag structure "<TO>.MeasuredValues.<tag name>" displays the measurement results.

Tags

Legend

Tag	Data type	Values	W	Description
MeasuredValues.	TO_MeasuringInput_Struct_MeasuringValues			
MeasuredValue1	LREAL	-1.0E12 ... 1.0E12	RON	First measured value
MeasuredValue2	LREAL	-1.0E12 ... 1.0E12	RON	Second measured value
MeasuredValue1Counter	UDINT	0 ... 2147483647	RON	Count value for the first measured value
MeasuredValue2Counter	UDINT	0 ... 2147483647	RON	Count value for the second measured value
LostEdgeCounter1	UDINT	0 ... 7	RON	LEC for measured value 1 (Zero in the case of one-time measurement)
LostEdgeCounter2	UDINT	0 ... 7	RON	LEC for measured value 2 (Zero in the case of one-time measurement)

11.2.6 "StatusWord" tag (measuring input)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 2 "RestartActive") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Control" The technology object is in operation.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.

Tag	Data type	Values	W	Description
Bit 4	-	-	-	Reserved
Bit 5	-	-	-	"CommunicationOK" The communication between the measuring input and measurement input is established. With an interconnected measuring input that monitors another measuring input with measurement input, this bit always has the value "FALSE".
Bit 6... Bit 31	-	-	-	Reserved

11.2.7 "ErrorWord" tag (measuring input)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4... Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
Bit 14... Bit 31	-	-	-	Reserved

11.2.8 "ErrorDetail" tag (measuring input)

The tag structure "<TO>.ErrorDetail.<tag name>" contains the alarm number and the effective local alarm response for the technology alarm that is currently pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Tags

Legend

Tag	Data type	Values	W	Description	
ErrorDetail.	TO_Struct_ErrorDetail				
Number	UDINT	-	RON	Alarm number	
Reaction	DINT	0, 6	RON	Effective alarm response	
				0	No reaction
				6	End measuring input processing

11.2.9 "WarningWord" tag (measuring input)

The "<TO>.WarningWord" tag indicates pending warnings at the technology object.

Information on the evaluation of the individual bits (e.g. bit 1 "ConfigWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
WarningWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemWarning" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigWarning" Configuration error One or several configuration parameters are adjusted internally.
Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.

Tag		Data type	Values	W	Description
	Bit 4... Bit 12	-	-	-	Reserved
	Bit 13				"PeripheralWarning" Error accessing a logical address
	Bit 14... Bit 31	-	-	-	Reserved

11.3 Tags of the output cam technology object

11.3.1 Display data (output cam)

The "<TO>.CamOutput" tag indicates the switching state of the output cam.

Tags

Legend

Tag	Data type	Values	W	Description	
CamOutput	BOOL	-	RON	Switching state of output cam	
				FALSE	Not switched
				TRUE	Switched

11.3.2 "Parameter" tag (output cam)

The tag structure "<TO>.Parameter.<tag name>" contains the configuration of the basic parameters of the output cam technology object.

Tags

Legend

Tag		Data type	Values	W	Description	
Parameter.		TO_OutputCam_Struct_Parameter				
	OutputCamType	DINT	0 ... 2	RES	Output cam type	
					0	Distance output cam
					1	Time-based output cam
					2	Switching output cam
	PositionType	DINT	0, 1	RES	Position reference	
					0	Position setpoint
					1	Actual position

Tag	Data type	Values	W	Description
OnCompensation	LREAL	0.0 ... 1.0E12	DIR	Activation time Lead time for the switch-on edge
OffCompensation	LREAL	0.0 ... 1.0E12	DIR	Deactivation time Lead time for the switch-off edge
Hysteresis	LREAL	0.0 ... 1.0E12	DIR	Hysteresis value For output cams with reference to actual position, always enter a hysteresis value (> 0.0).

11.3.3 "Interface" tag (output cam)

The tag structure "<TO>.Interface.<tag name>" contains the configuration of the output properties for the output cam technology object.

Tags

Legend

Tag	Data type	Values	W	Description	
Interface.	TO_OutputCam_Struct_Interface				
EnableOutput	BOOL	-	RES	Activation of the output cam output	
				FALSE	Output is deactivated
				TRUE	Output is activated
Address	VREF	-	RON	I/O address of the output cam	
LogicOperation	DINT	0, 1	RON	Logical operation of the output cam signals at the output	
				0	OR logic operation
				1	AND logic operation

11.3.4 "Units" tag (output cam)

The tag structure "<TO>.Units.<tag name>" shows the set technological units.

Tags

Legend

Tag	Data type	Values	W	Description	
Units.	TO_OutputCam_Struct_Units				
LengthUnit	UDINT	-	RON	Unit for position	
				1010	m
				1013	mm
				1536	mm[1)]
				1011	km
				1014	µm

1) Position values with higher resolution or six decimal places.

Tag	Data type	Values	W	Description	
LengthUnit	UDINT	-	RON	1015	nm
				1019	in
				1018	ft
				1021	mi
				1004	rad
				1005	°
				1537	°[1]
TimeUnit	UDINT	-	RON	Unit for time	
				1056	ms

[1] Position values with higher resolution or six decimal places.

11.3.5 "StatusWord" tag (output cam)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 2 "RestartActive") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Control" The technology object is in operation.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"OutputInverted" The output cam output is inverted.
Bit 5	-	-	-	"CommunicationOK" The communication between output cam and output module is established.
Bit 6... Bit 31	-	-	-	Reserved

11.3.6 "ErrorWord" tag (output cam)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4... Bit 12	-	-	-	Reserved
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
Bit 14... Bit 31	-	-	-	Reserved

11.3.7 "ErrorDetail" tag (output cam)

The tag structure "<TO>.ErrorDetail.<tag name>" contains the alarm number and the effective local alarm response for the technology alarm that is currently pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Tags

Tag	Data type	Values	W	Description	
ErrorDetail.	TO_Struct_ErrorDetail				
Number	UDINT	-	RON	Alarm number	
Reaction	DINT	0, 6	RON	Effective alarm response	
				0	No reaction
				6	Output cam processing is complete.

11.3.8 "WarningWord" tag (output cam)

The "<TO>.WarningWord" tag indicates pending warnings at the technology object.

Information on the evaluation of the individual bits (e.g. bit 1 "ConfigWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
WarningWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemWarning" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigWarning" Configuration error One or several configuration parameters are adjusted internally.
Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.

Tag	Data type	Values	W	Description
Bit 4... Bit 12	-	-	-	Reserved
Bit 13				"PeripheralWarning" Error accessing a logical address
Bit 14... Bit 31	-	-	-	Reserved

11.4 Tags of the cam track technology object

11.4.1 Display data (cam track)

The following tags indicate the status of the cam track:

Tags

Legend

Tag	Data type	Values	W	Description	
Status	DINT	0 ... 2	RON	0	"INACTIVE" Inactive
				1	"ACTIVE" Active
				2	"ACTIVE_WAITING_FOR_NEXT_CYCLE" Active and waiting for next track
TrackOutput	BOOL	-	RON	FALSE	Cam track is not output.
				TRUE	Cam track is output.
SingleCamState	DWORD	16#0 ... 16#FFFF_FFFF	RON	Switched on output cam (bit-masked)	
				0	Output cam is not switched on
				1	Output cam is switched on
TrackPosition	LREAL	-1.0E12 ... 1.0E12	RON	Display of the current position within the cam track	
MatchPosition	LREAL	-1.0E12 ... 1.0E12	RON	Reference position of the current cam track During cyclic processing of the cam track, the continued reference position of the current cam track is displayed. The unique detection and output of the position is only possible when the assigned technology object is in motion.	

11.4.2 "Parameter" tag (cam track)

The tag structure "<TO>.Parameter.<tag name>" contains the configuration of the basic parameters of the cam track technology object.

Tags

Legend

Tag	Data type	Values	W	Description	
Parameter.	TO_CamTrack_Struct_Parameter				
CamTrackType	DINT	0, 1	RES	Output cam type	
				0	Distance output cam
				1	Time-based output cam
PositionType	DINT	0, 1	RES	Position reference	
				0	Position setpoint
				1	Actual position
ReferencePosition	LREAL	-1.0E12 ... 1.0E12	DIR	Reference position	
CamTrackLength	LREAL	0.001 ... 1.0E12	DIR	Track length	
CamMasking	DWORD	16#0 ... 16#FFFF_FFFF	DIR	Bit masking of individual output cams	
OnCompensation	LREAL	0.0 ... 1.0E12	DIR	Activation time Lead time for the switch-on edge	
OffCompensation	LREAL	0.0 ... 1.0E12	DIR	Deactivation time Lead time for the switch-off edge	
Hysteresis	LREAL	0.0 ... 1.0E12	DIR	Hysteresis value For output cams with reference to actual position, always enter a hysteresis value (> 0.0).	
Cam[1..32].	ARRAY[1..32] OF TO_CamTrack_Struct_CamData				
OnPosition	LREAL	0.0 ... 1.0E12	CAL	With distance output cams and time-based output cams: Start position	
Offposition	LREAL	0.0 ... 1.0E12	CAL	With distance output cams: End position	
Duration	LREAL	0.001 ... 1.0E12	CAL	With time-based output cams: Switch-on duration	
Existent	BOOL	-	CAL	FALSE	Output cam is not used.
				TRUE	Output cam is used.

11.4.3 "Interface" tag (cam track)

The tag structure "<TO>.Interface.<tag name>" contains the configuration of the output properties for the cam track technology object.

Tags

Legend

Tag	Data type	Values	W	Description	
Interface.	TO_CamTrack_Struct_Interface				
EnableOutput	BOOL	-	RES	Output cam output at the bit specified under "<TO>.Interface.Address"	
				FALSE	No output
				TRUE	Output
Address	VREF	-	RON	I/O address for digital output cam output	

11.4.4 "Units" tag (cam track)

The tag structure "<TO>.Units.<tag name>" shows the set technological units.

Tags

Legend

Tag	Data type	Values	W	Description	
Units.	TO_CamTrack_Struct_Units				
LengthUnit	UDINT	-	RON	Unit for position	
				1010	m
				1013	mm
				1536	mm[1)]
				1011	km
				1014	µm
				1015	nm
				1019	in
				1018	ft
				1021	mi
				1004	rad
				1005	°
				1537	°[1)]
TimeUnit	UDINT	-	RON	Unit for time	
				1056	ms

1) Position values with higher resolution or six decimal places.

11.4.5 "StatusWord" tag (cam track)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 2 "RestartActive") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Control" The technology object is in operation.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"OutputInverted" The output cam output is inverted.
Bit 5	-	-	-	"CommunicationOK" The communication between cam track and output module is established.
Bit 6... Bit 31	-	-	-	Reserved

11.4.6 "ErrorWord" tag (cam track)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.

Tag		Data type	Values	W	Description
	Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
	Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
	Bit 3	-	-	-	"CommandNotAccepted" Command cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
	Bit 4... Bit 12	-	-	-	Reserved
	Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
	Bit 14... Bit 31	-	-	-	Reserved

11.4.7 "ErrorDetail" tag (cam track)

The tag structure "<TO>.ErrorDetail.<tag name>" contains the alarm number and the effective local alarm response for the technology alarm that is currently pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Tags

Legend

Tag		Data type	Values	W	Description	
ErrorDetail.		TO_Struct_ErrorDetail

14.3.9 "ErrorWord" tag (cam) 421
14.3.10 "ErrorDetail" tag (cam) 421
14.3.11 "WarningWord" tag (cam) 422

14.4 Tags of the leading axis proxy technology object 422
14.4.1 Leading value (leading axis proxy) 422
14.4.2 "Interface" tag (leading axis proxy) 423
14.4.3 "Parameter" tag (leading axis proxy) 423
14.4.4 "StatusExternalLeadingValue" tag (leading axis proxy) 423
14.4.5 "StatusWord" tag (leading axis proxy) 424
14.4.6 "'ErrorWord" tag (leading axis proxy) 425
14.4.7 "ErrorDetail" tag (leading axis proxy) 426
14.4.8 "WarningWord" tag (leading axis proxy) 426

Introduction 1

Purpose of the documentation

This documentation provides important information that you need to configure and commission the integrated Motion Control functionality of the S7-1500 Automation systems.

Required basic knowledge

In order to understand this documentation, the following knowledge is required:

- General knowledge in the field of automation
- General knowledge in the field of drive engineering and motion control

Validity of the documentation

This documentation is valid for the S7-1500 product range.

Conventions

- The path specifications in the project tree assume that the "Technology objects" folder is open in the subtree of the CPU. The "Technology object" placeholder represents the name of the technology object.

  Example: "Technology object > Configuration > Basic parameters".
- The <TO> placeholder represents the name set in tags for the respective technology object.

  Example: <TO>.Actor.Type
- This documentation contains pictures of the devices described. The pictures may differ in minor details from the devices supplied.

You should also observe the notes that are marked as follows:

NOTE

A note contains important information about the product described in the documentation, about the handling of the product, and about sections in this documentation demanding your particular attention.

Industry Mall

The Industry Mall is the catalog and ordering system of Siemens Aktiengesellschaft for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

1.1 S7-1500 Motion Control Documentation Guide

Product information

Please also note the supplementary information on the Motion Control documentation:

- Product information on the S7-1500/1500T Motion Control documentation
  https://support.industry.siemens.com/cs/ww/en/view/109794046
  (https://support.industry.siemens.com/cs/ww/en/view/109794046)

Documentation

The documentation of the Motion Control functions is divided into the following documents:

- S7-1500/S7-1500T Motion Control Overview
  https://support.industry.siemens.com/cs/en/view/109990070
  (https://support.industry.siemens.com/cs/ww/en/view/109990070)

  This document describes the innovations in the technology versions, how to upgrade the technology version, functions that are used for all technology objects, and the operational sequence of Motion Control applications.
- S7-1500/S7-1500T Motion Control alarms and error IDs
  https://support.industry.siemens.com/cs/ww/en/view/109990076
  (https://support.industry.siemens.com/cs/ww/en/view/109990076)

  This document describes the technology alarms of the technology objects and the error identifications of the Motion Control instructions.
- S7-1500/S7-1500T Axis functions
  https://support.industry.siemens.com/cs/en/view/109990072
  (https://support.industry.siemens.com/cs/ww/en/view/109990072)

  This document describes the drive and encoder connection and functions for single-axis movements.
- S7-1500/S7-1500T Synchronous operation functions
  https://support.industry.siemens.com/cs/ww/en/view/109990074
  (https://support.industry.siemens.com/cs/ww/en/view/109990074)

  This document describes gearing, velocity synchronous operation and camming as well as cross-PLC synchronous operation.

- S7-1500/S7-1500T Measuring input and output cam functions
  https://support.industry.siemens.com/cs/ww/en/view/109990075
  (https://support.industry.siemens.com/cs/ww/en/view/109990075)
  This document describes the detection of the actual position via a measuring input and the output of switching signals via output cam or cam track.
- S7-1500T kinematics functions
  https://support.industry.siemens.com/cs/ww/en/view/109990073
  (https://support.industry.siemens.com/cs/ww/en/view/109990073)
  This document describes the control of kinematics with up to 6 interpolating axes.
- S7-1500T Interpreter functions
  https://support.industry.siemens.com/cs/ww/en/view/109990077
  (https://support.industry.siemens.com/cs/ww/en/view/109990077)
  This documentation describes the control of technology objects via an Interpreter program.

1.2 Function Manuals documentation guide

1.2.1 Information classes Function Manuals

The documentation for the SIMATIC S7-1500 automation system, for the 1513/1516pro-2 PN, SIMATIC Drive Controller CPUs based on SIMATIC S7-1500 and the SIMATIC ET 200MP, ET 200SP, ET 200AL and ET 200eco PN distributed I/O systems is arranged into three areas.

This arrangement enables you to access the specific content you require.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742705).

Basic information

The system manuals and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, SIMATIC Drive Controller, ET 200MP, ET 200SP, ET 200AL and ET 200eco PN systems. Use the corresponding operating instructions for 1513/1516pro-2 PN CPUs.

The STEP 7 online help supports you in the configuration and programming.

Examples:

- Getting Started S7-1500
- System manuals
- Operating instructions ET 200pro and 1516pro-2 PN CPU
- Online help TIA Portal

Device information

Equipment manuals contain a compact description of the module-specific information, such as properties, wiring diagrams, characteristics and technical specifications.

Examples:

- Equipment manuals for CPUs
- Equipment manuals for interface modules
- Equipment manuals for digital modules
- Equipment manuals for analog modules
- Equipment manuals for communication modules
- Equipment manuals for technology modules
- Equipment manuals for power supply modules
- Equipment manuals for BaseUnits

General information

The function manuals contain detailed descriptions on general topics relating to the SIMATIC Drive Controller and the S7-1500 automation system.

Examples:

- Function Manual Diagnostics
- Function Manual Communication
- Function Manuals Motion Control
- Function Manual Web Server
- Function Manual Cycle and Response Times
- PROFINET Function Manual
- PROFIBUS Function Manual

Product Information

Changes and supplements to the manuals are documented in a Product Information. The Product Information takes precedence over the device and system manuals.

You will find the latest Product Information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/de/en/view/68052815)
- SIMATIC Drive Controller (https://support.industry.siemens.com/cs/de/en/view/109772684/en)
- Motion Control (https://support.industry.siemens.com/cs/de/en/view/109794046/en)
- ET 200SP (https://support.industry.siemens.com/cs/de/en/view/73021864)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109765611)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP/SIMATIC Drive Controller (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109781058)

1.2.2 Basic tools

Tools

The tools described below support you in all steps: from planning, over commissioning, all the way to analysis of your system.

TIA Selection Tool

The TIA Selection Tool tool supports you in the selection, configuration, and ordering of devices for Totally Integrated Automation (TIA).

As successor of the SIMATIC Selection Tools , the TIA Selection Tool assembles the already known configurators for automation technology into a single tool.

With the TIA Selection Tool , you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/109767888)

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to perform commissioning and maintenance activities on various SIMATIC S7 stations as bulk operations independent of TIA Portal.

The SIMATIC Automation Tool offers a wide range of functions:

- Scanning of a PROFINET/Ethernet system network and identification of all connected CPUs
- Assignment of addresses (IP, subnet, Gateway) and device name (PROFINET device) to a CPU
- Transfer of the date and the programming device/PC time converted to UTC time to the module
- Program download to CPU
- RUN/STOP mode switchover
- CPU localization through LED flashing
- Reading out of CPU error information
- Reading the CPU diagnostic buffer
- Reset to factory settings
- Firmware update of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/98161300)

PRONETA

SIEMENS PRONETA (PROFINET network analysis) is a commissioning and diagnostic tool for PROFINET networks. PRONETA Basic has two core functions:

- In the network analysis, you get an overview of the PROFINET topology. Compare a real configuration with a reference installation or make simple parameter changes, e.g. to the names and IP addresses of the devices.
- The "IO test" is a simple and rapid test of the wiring and the module configuration of a plant, including documentation of the test results.

You can find SIEMENS PRONETA Basic on the Internet:
(https://support.industry.siemens.com/cs/ww/en/view/67460624)

SIEMENS PRONETA Professional is a licensed product that offers you additional functions. It offers you simple asset management in PROFINET networks and supports operators of automation systems in automatic data collection/acquisition of the components used through various functions:

- The user interface (API) offers an access point to the automation cell to automate the scan functions using MQTT or a command line.
- With PROFIenergy diagnostics, you can quickly detect the current pause mode or the readiness for operation of devices that support PROFIenergy and change these as needed.
- The data record wizard supports PROFINET developers in reading and writing acyclic PROFINET data records quickly and easily without PLC and engineering.

You can find SIEMENS PRONETA Professional on the Internet.
(https://www.siemens.com/proneta-professional)

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and the optimal use of resources

You can find SINETPLAN on the Internet (https://new.siemens.com/global/en/products/automation/industrial-communication/profinet/sinetplan.html).

1.2.3 SIMATIC Technical Documentation

Additional SIMATIC documents will complete your information. You can find these documents and their use at the following links and QR codes.

The Industry Online Support gives you the option to get information on all topics. Application examples support you in solving your automation tasks.

Overview of the SIMATIC Technical Documentation

Here you will find an overview of the SIMATIC documentation available in Siemens Industry Online Support:

Industry Online Support International (https://support.industry.siemens.com/cs/ww/en/view/109742705)

Watch this short video to find out where you can find the overview directly in Siemens Industry Online Support and how to use Siemens Industry Online Support on your mobile device:

Quick introduction to the technical documentation of automation products per video (https://support.industry.siemens.com/cs/us/en/view/109780491)

YouTube video: Siemens Automation Products - Technical Documentation at a Glance (https://youtu.be/TwLSxxRQQsA)

Retention of the documentation

Retain the documentation for later use.

For documentation provided in digital form:

1. Download the associated documentation after receiving your product and before initial installation/commissioning. Use the following download options:
   - Industry Online Support International: (https://support.industry.siemens.com)

     The article number is used to assign the documentation to the product. The article number is specified on the product and on the packaging label. Products with new, non-compatible functions are provided with a new article number and documentation.
   - ID link:

     Your product may have an ID link. The ID link is a QR code with a frame and a black frame corner at the bottom right. The ID link takes you to the digital nameplate of your product. Scan the QR code on the product or on the packaging label with a smartphone camera, barcode scanner, or reader app. Call up the ID link.
2. Retain this version of the documentation.

Updating the documentation

The documentation of the product is updated in digital form. In particular in the case of function extensions, the new performance features are provided in an updated version.

1. Download the current version as described above via the Industry Online Support or the ID link.
2. Also retain this version of the documentation.

mySupport

With "mySupport" you can get the most out of your Industry Online Support.

Registration	You must register once to use the full functionality of "mySupport". After registration, you can create filters, favorites and tabs in your personal workspace.
Support requests	Your data is already filled out in support requests, and you can get an overview of your current requests at any time.
Documentation	In the Documentation area you can build your personal library.
Favorites	You can use the "Add to mySupport favorites" to flag especially interesting or frequently needed content. Under "Favorites", you will find a list of your flagged entries.
Recently viewed articles	The most recently viewed pages in mySupport are available under "Recently viewed articles".
CAx data	The CAx data area gives you access to the latest product data for your CAx or CAe system. You configure your own download package with a few clicks: • Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files • Manuals, characteristics, operating manuals, certificates • Product master data

You can find "mySupport" on the Internet. (https://support.industry.siemens.com/My/ww/en)

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You can find the application examples on the Internet.
(https://support.industry.siemens.com/cs/ww/en/ps/ae)

Safety instructions 2

2.1 General safety instructions

The safety instructions can be found in section "Safety instructions" in the System Manual "SIMATIC S7-1500, ET 200MP Automation System" (https://support.industry.siemens.com/cs/ww/en/view/59191792) document.

Cybersecurity-relevant information can be found in the Industrial Cybersecurity section.

2.2 Warnings in this document

You can find explanations of the warnings used in this document in the "Legal information" section.

Industrial cybersecurity 3

Due to the digitalization and increasing networking of machines and industrial plants, the risk of cyber attacks is also growing. Appropriate protective measures are therefore mandatory, particularly in the case of critical infrastructure facilities.

3.1 Cybersecurity information

Siemens provides products and solutions with industrial cybersecurity functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial cybersecurity concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial cybersecurity measures that may be implemented, please visit
https://www.siemens.com/cybersecurity-industry.

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Cybersecurity RSS Feed under
https://new.siemens.com/cert.

New features V10.0

4

4.1 New synchronous operation functions V10.0

Technology version V10.0 contains the following new features:

Actual value extrapolation (S7-1500T)

- The leading value velocity can be differentiated from the extrapolated leading value position ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 2).
- When the effective extrapolation time amounts to zero and the extrapolation is omitted, the position and velocity filters remain active.

Camming (S7-1500T)

- Use the Motion Control instruction "MC_SetCamRangeScaling (Page 360)" to scale a cam range. Up to two scaling ranges are possible. Range scaling can also be used during synchronous camming. An active range scaling is displayed in the online view of the cam diagnostics. In addition, range scaling can be simulated offline in the configuration of the cam.

Cross-PLC synchronous operation (S7-1500T)

- The leading axis proxy supports different leading value telegram versions. Observe the compatibility of the technology versions. (Page 211)
- If multiple PROFINET interfaces of a CPU support the "PROFINET with IRT" functionality, you can operate the CPU as an isochronous I-device. The PROFINET interface configured as an I-device is used for isochronous data exchange with the higher-level IO Controller, through which you can realize cross-PLC synchronous operation. The other PROFINET interface can synchronize with the I-device interface and operate connected IO devices isochronously.

4.2 Upgrade to technology version V10.0

Permissible following error - changes to the default values

As of technology version V10.0, the following default values for the permissible following error for the rotary axis have been updated:

- <TO>.FollowingError.MinValue: 30°
- <TO>.FollowingError.MaxValue: 360°

You handle compatibility between versions as follows:

- After upgrading to technology version V10.0, the existing default values or the configured values remain unchanged.
- When changing to an older technology version, the values set in V10.0 are retained.

Configuration of the "6-axis articulated arm with central wrist" kinematics type

As of technology version V10.0, the configuration of the kinematics type "6-axis articulated arm with central wrist" has been extended by the parameter Length L6 (<TO>.Kinematics.Parameter[7]).

After upgrading to technology version V10.0, the length L6 has the default value (0.0).

When upgrading to a technology version <V10.0, the configured Length L6 value is not considered.

Actual value extrapolation in synchronous operation

If the effective extrapolation time is zero, the actual value extrapolation is omitted.

Up to technology version V9.0, the positioning filter and the velocity filter are inactive in this case.

As of technology version V10.0, the filtered actual values are evaluated with the hysteresis and used as the leading value.

Cross-PLC synchronous operation

Note the compatible leading value telegram versions for cross-PLC synchronous operation (Page 211).

Leading value telegram version 2

If you upgrade the technology version V8.0 to the technology version V10.0, the leading value telegram version 2 is used automatically.

To make the leading value of the leading value telegram version 1 available, proceed as follows:

1. Open the "Technology object > Configuration > Leading value settings" configuration window of the leading axis.
2. To show rows 2 to 32 in the table in the "Provision of leading value" area, select the "Show all transfer areas" check box.
3. To use the leading value telegram version 1, clear the check box of the corresponding transfer area in the "Leading value telegram V2" table column.

   The leading value telegram version depends on the technology version of the receiver.

Overview of functions

5

Synchronous operation enables a following axis to be linked to a leading axis and move synchronously with it. The synchronous operation relationship between the leading and following axes is specified by a synchronous operation function.

Gearing

During gearing (Page 49), the position of the following axis results from the position of the leading axis multiplied by the gear ratio. You specify the gear ratio as a ratio of two integers. The result is a linear synchronous operation function.

Gearing (S7-1500T)

The following axis can be synchronized in advance or synchronized subsequently via the leading value path or dynamic parameters. For this purpose, you can specify corresponding reference positions of leading and following axis that define the relation of the axes to each other.

As an alternative to the setpoint, the extrapolated actual value can be interconnected as a leading value for synchronous operation. As a result, you can use an external encoder technology object as the leading value.

In addition, the following axis can be desynchronized to a presettable stop position via the leading value path or dynamic parameters.

Velocity synchronous operation (S7-1500T)

During velocity synchronous operation (Page 94), the velocity of the following axis results from the velocity of the leading axis multiplied by the gear ratio, regardless of the position. You specify the gear ratio as a ratio of two integers either once or variably during synchronization.

Camming (S7-1500T)

During camming (Page 102), the leading axis and following axis are coupled by a synchronous operation function, which you specify using a cam technology object. The cam technology object (TO_Cam, TO_Cam_10k, TO_Cam_600Seg, TO_Cam_6kSeg) defines a function f(x) by means of interpolation points and/or segments. Gaps between the defined interpolation points and segments of the cam are closed by interpolation during runtime of the user program. The transmission behavior during camming is expressed by the cam curve.

Synchronous operation phases

A synchronous operation runs in the following phases:

- Pending synchronous operation (S7-1500T)

  The following axis waits for the starting conditions of the synchronizing motion to be fulfilled.

- Synchronization

  The following axis is synchronized to the leading value.

- Synchronous travel

  The following axis follows the position of the leading axis according to the synchronous operation function.

- End or override synchronous operation

  An active synchronous operation is overridden by motion jobs, e.g. "MC_Halt" on the following axis.

- Waiting synchronization job (S7-1500T)

  The following axis waits for the starting conditions of the desynchronization motion to be fulfilled.

- Desynchronize synchronous operation (S7-1500T)

  The following axis is desynchronized from the leading value. The following axis stops at a defined position and synchronous operation is ended.

Cross-PLC synchronous operation (S7-1500T)

Cross-PLC synchronous operation (Page 207) enables synchronous operation via multiple CPUs. You can configure leading and following axes on different CPUs. The CPUs can be configured in the same project or in various projects.

The synchronous operation function, e.g. a gearing, is executed on the CPU of the following axis. The leading axis proxy technology object (TO_LeadingAxisProxy) represents the leading axis for the local synchronous operation within a CPU. The leading axis proxy evaluates the leading value telegram and provides the leading value for the local following axes.

5.1 Synchronous axis technology object

The synchronous axis technology object includes all functions of the positioning axis technology object.

A synchronous axis can also follow the motions of a leading axis. The synchronous operation relationship between the leading and following axes is specified by a synchronous operation function.

You can find an overview of the supported instructions of the synchronous axis technology object in the section "Motion Control instructions for synchronous operation (Page 32)".

The figure below shows the basic principle of operation of the synchronous axis technology object:

Configuration

The following non-isochronous specific configurations correspond to the positioning axis technology object:

- Basic parameters
  - Axis or encoder type
  - Units of measure
  - Modulo setting
  - Virtual axis
  - Axis in simulation
- Hardware interface
  - Connecting PROFIdrive drives
  - Connecting encoders via PROFIdrive
  - Transferring drive and encoder parameters automatically
  - Connecting stepper motors
  - Connecting drives with analog setpoint interface
  - Connecting force/torque data via SIEMENS additional telegram 750
- Mechanics
  - Configuring drive and encoder direction for positioning axis/synchronous axis
  - Configuring the load gear
  - Configuring the encoder gear
  - Configuring the leadscrew pitch
  - Configuring inertia values
  - Configuring backlash compensation
- Dynamic default
- Emergency stop
- Configuring the alarm responses
- Limits
  - Position limits
  - Dynamic limits
  - Torque limits
  - Fixed stop detection
- Homing
  - Active homing
  - Passive homing

- Position monitoring functions
  - Positioning monitoring
  - Following error
  - Standstill signal
- Control loop
  - Configuring position controller in the PLC
  - Configuring position controller for drives with DSC
  - Configuring a dynamic filter
  - Switching the position control off and on
- Superimposing axes

You can find a description of the configuration parameters in the "S7-1500/S7-1500T Axis functions" documentation.

The following configurations of the synchronous axis technology object are specific to synchronous operation:

- Leading value interconnections (Page 37)
- Leading value settings
  - Configuring provision of the leading value (Page 238)
  - Configuring the delay time (Page 245)
- Actual value extrapolation (Page 38)
- Configuring the reverse tolerance of the leading value (Page 44)

You can find a description of the configuration parameters in the "S7-1500/S7-1500T synchronous operation functions" documentation.

5.2 Cam technology object

Term definition

The following section discusses the "Cam technology object" in general. This refers to the cam technology object of the type "TO_Cam" and of the types "TO_Cam_10k", "TO_Cam_600Seg" and "TO_Cam_6kSeg". If a specific cam technology object is meant, the type is explicitly mentioned.

Cam technology object

The cam technology object defines a transfer function y = f(x). The dependency of an output value on an input value is described in this transfer function in a unit-neutral manner. A cam technology object can be used multiple times.

You define the transfer function y = f(x) in the configuration of the technology object (Page 103) using interpolation points and/or segments. Depending on the cam type, the cam technology object can contain up to the following number of interpolation points and segments:

Icon	Cam type	Interpolation points	Segments
	TO_Cam	1 000	50
10k	TO_Cam_10k	10 000	50
600	TO_Cam_600Seg	50	600
6k	TO_Cam_6kSeg	50	6 000

Ranges between interpolation points and segments are interpolated using the Motion Control instruction "MC_InterpolateCam (Page 350)". During runtime of the user program, the settings can be changed or redefined via the technology data block as described in the section "Changing the synchronous operation function of the cam online (Page 137)".

An interpolated cam can be applied as a synchronous operation function for camming (Page 102). You can find an overview of the supported instructions of the cam technology object in the section "Motion Control instructions for synchronous operation (Page 32)".

The figure below shows the basic operating principle of the cam technology object:

In addition, you can position a positioning axis or a synchronous axis with time-related position profile relatively or absolutely. Specify the time-based position profile via the cam technology object.

You can find more information on the topic "Time-based position profile" in the "Moving an axis relatively or absolutely with a time-based position profile" section in the "S7-1500/S7-1500T Axis functions" document.

Configuration

The following configurations are available in the cam technology object:

- Configuring the synchronous operation function of the cam (Page 103)

5.3 Leading axis proxy technology object

With cross-PLC synchronous operation, the leading axis proxy technology object represents the leading axis for local synchronous operation within a CPU. The leading axis proxy adjust the time of the leading value so that the following axes on the different CPUs are synchronous, and it provides the leading value for the local following axes.

You can find an overview of the supported instructions of the leading axis proxy technology object in the section "Motion Control instructions for synchronous operation (Page 32)".

The figure below shows the basic principle of operation of the leading axis proxy technology object:

Configuration

The following configurations are available in the leading axis proxy technology object:

- Basic parameters
- Leading value settings
  - Configuring provision of the leading value (Page 238)
  - Configuring the tolerance time (Page 241)
  - Configuring the delay time (Page 245)

5.4 Motion Control instructions for synchronous operation

You execute the functions of the synchronous axis, cam and leading axis proxy technology objects using Motion Control instructions in your user program or using the TIA Portal (under "Technology object > Commissioning").

The following table shows the additional Motion Control instructions for synchronous operation that are supported by the technology objects in addition to the axis functions:

Motion Control instruction	Validity		Technology object		
	S7-1500	S7-1500T	Synchronous axis (Page 25)	Cam (Page 27)[1]	Leading axis proxy (Page 31)
"MC_Reset" Acknowledge alarms, restart technology objects	✓	✓	✓	✓	✓
"MC_GearIn" Start gearing	✓	✓	✓	-	✓
"MC_GearInPos" Start gearing with specified synchronous positions	-	✓	✓	-	✓
"MC_GearInVelocity" Start velocity synchronous operation	-	✓	✓	-	✓
"MC_PhasingRelative" Relative shift of leading value on the following axis	-	✓	✓	-	✓
"MC_PhasingAbsolute" Absolute shift of leading value on the following axis	-	✓	✓	-	✓
"MC_OffsetRelative" Relative shift of following value on the following axis.	-	✓	✓	-	-
"MC_OffsetAbsolute" Absolute shift of following value on the following axis.	-	✓	✓	-	-
"MC_CamIn" Start camming	-	✓	✓	✓	✓
"MC_SynchronizedMotionSimulation" Simulate synchronous operation	-	✓	✓	-	-

[1] Applies to the cam technology object of the type "TO_Cam", "TO_Cam_10k", "TO_Cam_600Seg" and "TO_Cam_6kSeg".

Motion Control instruction	Validity		Technology object		
	S7-1500	S7-1500T	Synchronous axis (Page 25)	Cam (Page 27)[1]	Leading axis proxy (Page 31)
"MC_LeadingValueAdditive" Specify additive leading value	-	✓	✓	-	-
"MC_GearOut" Desynchronize gearing	-	✓	✓	-	-
"MC_CamOut" Desynchronize camming	-	✓	✓	-	-
"MC_InterpolateCam" Interpolate cam	-	✓	-	✓	-
"MC_GetCamLeadingValue" Read out leading value of a cam	-	✓	-	✓	-
"MC_GetCamFollowingValue" Read out following value of a cam	-	✓	-	✓	-
"MC_GetCamFollowingValueCyclic" Cyclically read out following value of a cam	-	✓	-	✓	-
"MC_CopyCamData" Copy calculated cam elements	-	✓	-	✓	-
"MC_SetCamRangeScaling" Scaling a cam range	-	✓	-	✓	-

[1] Applies to the cam technology object of the type "TO_Cam", "TO_Cam_10k", "TO_Cam_600Seg" and "TO_Cam_6kSeg".

5.5 Mode of operation of the instructions in synchronous operation

The following graphic shows the general influence of the Motion Control instructions on the following axis in synchronous operation:

① Effective leading value
(<TO>.StatusSynchronizedMotion.EffectiveLeadingValue)

② Leading value of the synchronous operation function
(<TO>.StatusSynchronizedMotion.FunctionLeadingValue)

③ Following value of the synchronous operation function
(<TO>.StatusSynchronizedMotion.FunctionFollowingValue)

④ Following value after following value offset
(<TO>.StatusSynchronizedMotion.FunctionFollowingValue.Position + <TO>.StatusSynchronizedMotion.Offset)

Additive leading value

With an "MC_LeadingValueAdditive (Page 347)" job, you specify an additive leading value (Page 205) cyclically in addition to the active leading value of a following axis.

Leading value offset

With a "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)" job you shift the effective leading value on a following axis in gearing (Page 72) or in camming (Page 183).

A simultaneous following value offset is not permitted. You can only start a new job for leading value offset once a previous job for following value offset has been completed.

Synchronous operation function

With an "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)" job, you start gearing (Page 49) between a leading axis and a following axis.

With an "MC_CamIn (Page 323)" job, you start a camming (Page 102) between a leading axis and a following axis.

With an "MC_GearInVelocity (Page 293)" job, you start velocity synchronous operation (Page 94) between a leading axis and a following axis.

Following value offset

With an "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)" job, you move the following value on a following axis in gearing (Page 79) or in camming (Page 188).

A simultaneous leading value offset is not permitted. You can only start a new job for following value offset once a previous job for leading value offset has been completed.

Superimposed motion

With a "MC_MoveSuperimposed" job, you superimpose the following value with a relative positioning motion independent of the motion of the leading axis.

With a "MC_MotionInSuperimposed" job, you superimpose the subsequent value by specifying values for position, velocity and acceleration for each application cycle. The superimposed motion is independent of the motion of the leading axis.

With a "MC_MotionInSuperimposedAxes" job, you superimpose the following value with a movement of another axis. The superimposed motion is independent of the motion of the leading axis.

In velocity synchronous operation with "MC_GearInVelocity", a superimposed motion is only possible if the following axis is in position-controlled mode.

With a "MC_HaltSuperimposed" job, you stop a superimposed motion independently of the base motion.

Preparing synchronous operation 6

6.1 Creating technology objects

For synchronous operation, you need technology objects for the leading and following axes. You can also create multiple following axes for one leading axis. For a camming, you also need a cam technology object (S7-1500T).

Requirement

- You have created an S7-1500 CPU for gearing with "MC_GearIn (Page 279)".

  Note that an actual value coupling is only possible with an S7-1500T CPU.
- You have created an S7-1500T CPU for one of the following synchronous operation types:
  - Gearing with specified synchronous position with "MC_GearInPos (Page 283)"
  - Velocity synchronous operation with "MC_GearInVelocity (Page 293)"
  - Camming with "MC_CamIn (Page 323)"

Procedure

To create technology objects for synchronous operation, follow these steps:

1. As leading axis, create one of the technology objects:
   - Positioning axis
   - Synchronous axis
   - External encoder (S7-1500T)
2. As following axis, create a synchronous axis technology object.
3. Configure the configuration parameters of the leading and following axes that are not specific for synchronous operation. You can find a description of the configuration parameters in the "S7-1500/S7-1500T Axis functions" documentation.
4. For a camming, create a cam technology object (S7-1500T).

6.2 Defining leading value interconnection

6.2.1 Interconnecting the leading value

A leading value for a synchronous operation is provided by a leading axis or an external encoder (S7-1500T). The leading value is specified and coupled in the user program with the call of the corresponding Motion Control instruction for synchronous operation. The leading value is switched when you call the Motion Control instruction again, specifying a different leading axis.

The following rules apply to the master value coupling:

- A leading axis or an external encoder (S7-1500T) can output the leading value for multiple following axes.
- You can interconnect a following axis with multiple leading value-capable technology objects. The following technology objects are leading value-capable:
  - Positioning axis
  - Synchronous axis (Page 25)
  - External encoder (S7-1500T)

  The Leading axis proxy technology object is only relevant for a cross-PLC synchronous operation (Page 207) (S7-1500T).

  All interconnections required during operation must be set up during the configuration of the synchronous axis technology object.
- You can select only one leading value at a time to be coupled and evaluated during the runtime of your user program.
- The leading values and following values are coupled without conversion in the respective configured unit of measure. If, for example, a linear leading axis moves by 10 mm, a rotary following axis moves by 10° with a gear ratio of 1:1.

Procedure

To interconnect the required leading values of a following axis, follow these steps:

1. Open the "Technology object > Configuration > Leading value interconnections" configuration window of the synchronous axis.
2. In the "Possible leading values" table column, add all leading value-capable technology objects that you need during operation as leading values for the following axis.

   You can use the technology objects added to the table with the corresponding Motion Control instruction as leading values for the following axis. All configured leading value interconnections for the technology object are displayed in the cross-reference list of the technology object.
3. Select the coupling type of the leading value in the "Type of coupling" table column:
   - Setpoint coupling (Page 38)
   - Actual value coupling (Page 38) (S7-1500T)

   The "Delayed" selection is only relevant for a cross-PLC synchronous operation (Page 207) (S7-1500T).

6.2.2 Setpoint coupling

With a setpoint coupling, the setpoints of the leading axis are used as the leading value for the synchronous operation.

The setpoints of the following technology objects can be connected as leading value for the synchronous operation:

- Positioning axis
- Synchronous axis
- Leading axis proxy (S7-1500T)

6.2.3 Actual value coupling and actual value extrapolation

For applications in which setpoint coupling is not possible, e.g. when using an external encoder, or does not make sense from a technical perspective, the S7-1500T CPU also offers actual value coupling for synchronous operation. In actual value coupling, the extrapolated actual values of a technology object are used as the leading value.

The actual values of the following technology objects can be used as a leading value for the synchronous operation:

- Positioning axis
- Synchronous axis
- External encoder

Actual value extrapolation of the leading value

With an actual value coupling, delay times result from the processing of the actual values. To compensate for these delay times, the actual value is extrapolated on the leading value side. This means that the leading value is extrapolated based on previously known values.

Delay times at constant velocity or at constant acceleration or deceleration can be compensated for with the extrapolation. For technical reasons, changes of acceleration or deceleration (jerk) during extrapolation always cause a displacement of the following axis relative to the leading value.

The effective extrapolation time consists of a leading axis-dependent part, a configured following axis-dependent part and, optionally, the time from the cross-PLC synchronous operation:

- **Leading axis-dependent part**

  The leading axis-dependent part is calculated automatically and displayed at the leading axis in the "<TO>.Extrapolation.LeadingAxisDependentTime" tag of the technology object. You can disable the leading axis-dependent part using the tag "<TO>.Extrapolation.Settings.SystemDefinedExtrapolation" = 0.

- **Following axis-dependent part**

  The following axis-dependent part is calculated automatically and displayed at the following axis in the "<TO>.StatusPositioning.SetpointExecutionTime" tag of the technology object. You configure the value under "Technology object > Configuration > Extended parameters > Actual value extrapolation" (<TO>.Extrapolation.FollowingAxisDependentTime).

- **Time from the cross-PLC synchronous operation**

  For cross-PLC synchronous operation, the output delay of the leading value at the locally coupled following axes is automatically taken into account. The displayed value is equal to the leading value delay and corresponds to the delay time entered at the leading axis or at the external encoder. You configure the delay time under "Technology object > Configuration > Leading value settings" (<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime).

The extrapolated actual value is evaluated with a configurable hysteresis before it is output as the leading value. The hysteresis evaluation prevents an inversion of the leading value, which may result from extrapolation of a noisy value.

If the effective extrapolation time is zero, extrapolation is omitted and the filtered actual value is evaluated directly with the hysteresis.

NOTICE
Machine damage If you change the extrapolation time during user program runtime in increments that are too large, damage to the machine may occur. Change the extrapolation time only by a small amount.

The following diagram shows the sequence of the actual value extrapolation.

① Actual position value

② Actual velocity value

③ Position filter T1 (<TO>.Extrapolation.PositionFilter.T1) and T2 (<TO>.Extrapolation.PositionFilter.T2)

④ Velocity filters T1 (<TO>.Extrapolation.VelocityFilter.T1) and T2 (<TO>.Extrapolation.VelocityFilter.T2)

⑤ Tolerance band width for velocity (<TO>.Extrapolation.VelocityTolerance.Range)

⑥ Hysteresis value in the configured unit of length (<TO>.Extrapolation.Hysteresis.Value)

⑦ Extrapolation time component caused by the leading axis (<TO>.Extrapolation.LeadingAxisDependentTime)

⑧ Extrapolation time component caused by the following axis (<TO>.Extrapolation.FollowingAxisDependentTime)

⑨ Portion of the extrapolation time from the cross-PLC synchronous operation (<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime)

⑩ Differentiation of the extrapolated leading value position

⑪ Extrapolated leading value position

⑫ Leading value velocity, depending on the switch position:
- Leading value velocity from the differentiation of the extrapolated leading value position ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 2)
- Leading value velocity from the extrapolation with hysteresis ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 1)
- Leading value velocity from the filtered actual velocity value ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 0)

Filtering the actual values

Noisy encoder signals lead to high velocity step changes, which also affect the extrapolation. These step changes can be reduced or compensated for by using suitable filter settings. The position filter is a PT2 filter. The velocity filter is a PT2 filter with configurable tolerance bandwidth.

The actual position value is blended by the actual position filter. The actual velocity value is blended by the velocity filter and further "stabilized" by the tolerance band. The filtered position value is then extrapolated taking into account the filtered velocity value.

The leading value velocity is calculated as follows, depending on the configured mode:

- The leading value velocity results from the differentiation of the extrapolated leading value position ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 2).
- The leading value velocity results from the extrapolation ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 1).
- The leading value velocity results from the filtered velocity value without extrapolation ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 0).

Recommended settings.

Set the total of the time constants T1 and T2 of the position filter significantly smaller than the time constants T1 and T2 of the velocity filter.

Tolerance band

The tolerance band acts on the filtered velocity value in the interpolation cycle. The position of the tolerance band is automatically shifted in the direction of the velocity value as soon as it changes in one direction by more than half of the tolerance band from the last output value.

A new output value is simultaneously formed with the shift of the tolerance band. This corresponds to the filtered velocity value minus half the tolerance band. As long as the velocity value remains within the tolerance band, no new output value is formed.

① Tolerance band

Filtered velocity before tolerance band

Filtered velocity according to tolerance band

Hysteresis

The hysteresis acts on the filtered extrapolated position value in the interpolation cycle. A change of direction only takes effect when the position value changes in the direction opposite at least by the hysteresis value. The hysteresis or reverse tolerance prevents undesired reversing of the leading value on a position reversal within the tolerance band.

① Hysteresis or reverse tolerance

Extrapolated position before hysteresis or reverse tolerance

Extrapolated position after hysteresis or reverse tolerance

Configuring actual value extrapolation

To configure the actual value extrapolation of the leading value, follow these steps:

1. Open the "Technology object > Configuration > Extended parameters > Actual value extrapolation" configuration window of the leading axis.
2. In the "Position filter T1" and "Position filter T2" input fields, enter the time constants of the PT2 filter for smoothing the position. To activate the position filter, select the "Consider leading axis" check box.
3. In the "Hysteresis value" input field, enter a value for applying the hysteresis function to the extrapolated actual value of the position. The specification is made in the configured length unit.
4. In the "Velocity filter T1" and "Velocity filter T2" input fields, enter the time constants of the PT2 filter for smoothing the actual velocity.
5. In the "Tolerance band width" input field, enter the tolerance band width of the smoothed actual velocity. For optimized application of the tolerance band, enter the same bandwidth for the tolerance band as the width of the noise signal.
6. In the "Following axis" input field, specify the following axis proportion for the extrapolation of the leading value. The value (unchanged or offset against user-specific runtimes) from the "<TO>.StatusPositioning.SetpointExecutionTime" tag of the following axis is used as the basis.

   The leading axis-dependent extrapolation is displayed in the "Leading axis" field. The leading axis-dependent extrapolation time is calculated from the sum of the actual value

acquisition time at the leading axis, (T_i), the interpolator time (T_{Ipo}) and the sum of position filters T1 and T2:

Leading axis-dependent extrapolation time = $T_i + T_{Ipo} + T1 + T2$

The time from a cross-PLC synchronous operation is displayed in the "cross-PLC" field. The time from the cross-PLC synchronous operation corresponds to the set delay time in the configuration window "Technology object > Configuration > Leading value settings".

7. Define the speed value to be used in the "Leading value velocity" selection list:
   - To take over the leading value velocity from the filtered actual velocity value, select the "Filtered speed" entry ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 0).
   - To take over the leading value velocity from the extrapolation with hysteresis, select the "Extrapolated velocity" entry ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 1).
   - To take over the leading value velocity from the differentiation of the extrapolated leading value position, select the "Differentiated velocity" entry ("<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode" = 2).
8. To take the leading axis-dependent extrapolation into account when calculating the effective extrapolation time, select the "Consider leading axis" check box. Otherwise, the leading axis-dependent extrapolation is not taken into account when calculating the effective extrapolation time and the filtered actual values are used.

   In the "Effective extrapolation time" field, the sum of the leading-axis time, the following axis- dependent time and the delay time of the cross-PLC synchronization is displayed.

A guideline to configuring the actual value extrapolation can be found in Siemens Industry Online Support in FAQ entry 109763337 (https://support.industry.siemens.com/cs/ww/en/view/109763337).

6.2.4 Tags: Actual value extrapolation

The following technology object tags are relevant for the actual value extrapolation:

Configuration		
Tag	**Description**	
<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime	For cross-PLC synchronous operation: The delay time of leading value output to the local following axes	
<TO>.Extrapolation.LeadingAxisDependentTime	On the leading axis: Leading axis-dependent portion of the extrapolation time, which results from T_i, T_{Ipo}, and T_{Filter}.	
<TO>.Extrapolation.FollowingAxisDependentTime	On the leading axis: Following-axis dependent portion of the extrapolation time Enter the value from the "<TO>.StatusPositioning.SetpointExecutionTime" tag of the following axis (unchanged or compensated with user-specific times).	
<TO>.Extrapolation.Settings.SystemDefinedExtrapolation	Effectiveness of the leading axis-dependent portion of the extrapolation time (<TO>.Extrapolation.LeadingAxisDependentTime)	
	0	Not effective
	1	Effective
<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode	0	"FilteredVelocity" Leading value velocity from filtered actual velocity

Configuration		
Tag	**Description**	
<TO>.Extrapolation.Settings.ExtrapolatedVelocityMode	1	"VelocityFromExtrapolation" Leading value velocity from extrapolation
	2	"VelocityByDifferentiation" Leading value velocity from differentiation of the extrapolated leading value position
<TO>.Extrapolation.PositionFilter.T1	Position filter time constant T1	
<TO>.Extrapolation.PositionFilter.T2	Position filter time constant T2	
<TO>.Extrapolation.VelocityFilter.T1	Velocity filter time constant T1	
<TO>.Extrapolation.VelocityFilter.T2	Velocity filter time constant T2	
<TO>.Extrapolation.VelocityTolerance.Range	Tolerance band width for velocity	
<TO>.Extrapolation.Hysteresis.Value	Hysteresis value (in the configured unit of length)	

Status displays	
Tag	**Description**
<TO>.StatusPositioning.SetpointExecutionTime	Setpoint execution time of the axis Results from T_{lpo}, T_{vtc} or 1/kv, T_{Send} and T_O of the axis.

6.3 Configuring the reverse tolerance of the leading value

The leading value must not reverse during the synchronization and desynchronization of the following axis. In order not to interrupt the synchronization or desynchronization when there are slight fluctuations in the leading value during an actual value coupling, for example, with an external encoder, you can define a reverse tolerance of the leading value.

The reverse tolerance is constantly based on the leading value of this following axis. Within the reverse tolerance, the leading value is unchanged from the perspective of the following axis. A reversal of the leading value within the reverse tolerance is not recognized by the following axis. If the leading value reverses before synchronization, the leading value for the following axis remains unchanged until the leading value leaves the tolerance range in the synchronization direction. Only then does the synchronization start.

Set the reverse tolerance as small as possible. Use the measured fluctuations in the actual value or the extrapolation error as a direct guide.

The reverse tolerance of the leading value is effective during synchronization and desynchronization with the following synchronization profiles:

- Synchronizing gearing with"MC_GearInPos (Page 283)"

SyncProfileReference	Synchronization profile
0	Synchronization in advance using dynamic parameters (Page 61)
1	Synchronization in advance using leading value distance (Page 63)

NOTE

Display of reverse-adjusted position value

The reverse-adjusted position value is not displayed in the technology object data block.

Leading value direction

Set the reverse tolerance for the positive, negative, or both directions of the leading value. The leading value direction defines the tolerated direction of the leading value to leave the tolerance range:

- Positive direction

  The reverse tolerance is effective if there is a positive leading value motion during synchronization or desynchronization.

Position of the leading axis

Leading value for following axis

- Negative direction

  The reverse tolerance is effective in the event of a negative leading value motion during synchronization or desynchronization.

Position of the leading axis

Leading value for following axis

- Positive and negative direction

  The reverse tolerance is effective for both positive and negative leading value motion during synchronization or desynchronization.

Procedure

To configure the reverse tolerance of the leading value, follow these steps:

1. Open the configuration window "Technology object > Configuration > Reverse tolerance of the leading value" of the synchronous axis technology object.
2. In the "Leading value direction" selection list, select the tolerated direction of the leading value to leave the tolerance range (<TO>.SynchronizedMotion.LeadingValueToleranceDirection).

   If synchronization and desynchronization is only allowed in one direction, configure the reverse tolerance only in that direction.
3. In the "Reverse tolerance" input box, enter the reverse tolerance of the leading value in the length unit of the axis (<TO>.SynchronizedMotion.LeadingValueReversalTolerance).

6.4 Position control in synchronous operation

Gearing or camming with setpoint coupling

A following axis is set into position-controlled operation with the start of a synchronous operation job. If the leading axis is in non-position-controlled operation at the start of the synchronous operation job, the technology alarm 603 is output and the technology object is disabled (alarm response: remove enable). Synchronization is started only after the position control has been activated and the start position of the synchronization has been reached.

NOTE

Switching the operating mode of the leading axis

If the leading axis is set to non-position-controlled operation during active synchronous operation, the setpoint of the leading axis is set to zero.

The coupling gives the setpoint of the following axis a setpoint step-change. The setpoint step-change is compensated according to the constant function. The only limiting factor is the maximum speed of the drive. A following error may occur on the following axis.

Gearing or camming with actual value coupling (S7-1500T)

A following axis is set into position-controlled operation with the start of a synchronous operation job. If the leading axis is in non-position-controlled operation at the start of the synchronous operation and the actual values are valid, the following axis is synchronized.

If the leading axis is set to the non-position-controlled mode during active synchronization, the synchronization remains active.

Velocity synchronous operation (S7-1500T)

A following axis can be operated in position-controlled or non-position-controlled mode during active synchronous operation (Page 97). You specify the operating mode of the following axis at the "MC_GearInVelocity" job.

The operating mode of the leading axis is irrelevant during an active synchronous operation.

Gearing

7

7.1 Gearing with "MC_GearIn"

With the Motion Control instruction "MC_GearIn (Page 279)", you start gearing between a leading axis and a following axis. During gearing, the position of the following axis results from the position of the leading axis multiplied by the gear ratio. You specify the gear ratio as a ratio of two integers. The result is a linear synchronous operation function.

You can start synchronous operation when the leading axis is at a standstill or when it is in motion. Synchronous travel begins after synchronization when the following axis has reached the velocity and acceleration of the leading axis, taking into account the gear ratio.

Slope of line; transmission ratio
Gear ratio = "MC_GearIn.RatioNumerator"/"MC_GearIn.RatioDenominator"

- - - Synchronization

① Synchronous position of following axis starting at which the leading and following axes move synchronously

② Synchronous position of leading axis starting at which the leading and following axes move synchronously

You have the following options for gearing with "MC_GearIn":

- Defining gear ratio (Page 50)
- Synchronizing following axis using dynamic parameters (Page 52)
- Synchronous travel in gearing (Page 53)
- Specify additive leading value with "MC_LeadingValueAdditive" (Page 205) (S7-1500T)
- Set gearing to simulation mode with "MC_SynchronizedMotionSimulation" (Page 203) (S7-1500T)
- Desynchronize following axis with "MC_GearOut" (Page 84) (S7-1500T)

Also note the dynamic limits of the following axis in gearing with "MC_GearIn" (Page 51).

7.1.1 Defining gear ratio

During gearing, the position of the following axis results from the position of the leading axis multiplied by the gear ratio. You specify the gear ratio at the Motion Control instruction "MC_GearIn (Page 279)" as the relationship between two integers (numerator/denominator). The result is a linear synchronous operation function.

Numerator of the gear ratio

With the "RatioNumerator" parameter, you define the numerator of the gear ratio. You can define the numerator of the gear ratio as positive or negative. This yields the following behavior:

- Positive gear ratio:

  The leading and following axes move in the same direction.
- Negative gear ratio:

  The following axis moves in the opposite direction of the leading axis.

The value "0" is not permitted for the numerator of the gear ratio.

Denominator of the gear ratio

With the "RatioDenominator" parameter, you define the denominator of the gear ratio. Only positive values are permitted for the denominator of the gear ratio.

Display of the gear ratio

The current gear ratio of an active "MC_GearIn" job is shown on the synchronous axis in the "<TO>.StatusSynchronizedMotion.ActualRatioNumerator" and "TO>.StatusSynchronizedMotion.ActualRatioDenominator" tags.

Example 1: Positive gear ratio

Leading axis and following axis are rotary axes and each has a traversing range from 0 ° to 360 ° with enabled "Modulo" setting.

Parameter inputs:

- "RatioNumerator" = 5
- "RatioDenominator" = 1

When the leading axis moves by 10 °, the following axis moves by 50 ° in the "Synchronous" status of the gearing.

Example 2: Negative gear ratio

Leading axis and following axis are rotary axes and each has a traversing range from 0 ° to 360 ° with enabled "Modulo" setting.

Parameter inputs:

- "RatioNumerator" = -3
- "RatioDenominator" = 1

When the leading axis moves by 10 °, the following axis moves by -30 ° in the "Synchronous" status of the gearing.

7.1.2 Dynamic limits of the following axis in gearing with "MC_GearIn"

If a synchronous axis is operated as a following axis in the gearing with the Motion Control instruction "MC_GearIn (Page 279)", the following dynamic limits apply, depending on the phase of the synchronous operation:

Synchronization

During the synchronizing phase, dynamic limits configured for the technology object apply to the following axis.

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

If the programmed dynamics of the synchronization function are greater than the maximum dynamics of the following axis, the synchronization process is only completed when the resulting final velocity is lower than the maximum velocity of the following axis.

Synchronous travel

During synchronous travel, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

End or override synchronous operation

As soon as synchronous operation has been overridden, the dynamic limits configured for the technology object apply to the following axis again. With the start of the overriding job, the active dynamics are transitioned (smoothed) to the configured dynamic limits and the specifications for the Motion Control instruction.

Desynchronization (S7-1500T)

You can find more information on dynamic limits during desynchronization in the section "Dynamic limits of the following axis during desynchronization with "MC_GearOut" (Page 90).

7.1.3 Synchronizing following axis using dynamic parameters with "MC_GearIn"

During gearing (Page 49), synchronization establishes the relationship between the leading axis and following axis. Synchronization begins immediately after the "MC_GearIn" job starts.

Parameter inputs

You define the dynamic behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearIn (Page 279)":

- With the "Acceleration" parameter, you specify the acceleration of the following axis.
- With the "Deceleration" parameter, you specify the deceleration of the following axis.
- With the "Jerk" parameter, you specify the jerk of the following axis.

Observe the dynamic limits (Page 51) of the following axis during synchronization.

During synchronization

Synchronization begins after the "MC_GearIn" job starts. Active motion jobs are overridden.

The synchronization duration and distance are dependent on the following parameters:

- Dynamics of the following axis at the start time of the "MC_GearIn" job
- Dynamic settings for synchronization
- Dynamics of the leading axis

The synchronization is indicated in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis. The leading value must not reverse during synchronization.

① Time when synchronization starts

If the programmed dynamic response of the synchronous operation function is greater than the maximum dynamic response of the following axis, the corresponding technology alarms 502 or 503 are output at the following axis. The speed of the following axis is also limited; however, no Technology Alarm 501 is generated. The synchronization process is only completed when the resulting final velocity is lower than the maximum velocity of the following axis (<TO>.DynamicLimits.MaxVelocity).

After synchronization

If the following axis has reached the velocity and the acceleration of the leading axis, taking into account the gear ratio, the following axis is synchronized. The following axis travels synchronously with the leading axis.

7.1.4 Synchronous travel in gearing with "MC_GearIn"

As soon as the following axis is synchronized to a leading value, the following axis follows the dynamics of the leading axis according to the gear ratio. The transmission behavior during gearing is expressed by a linear relationship between the leading value and the following value.

The following value is calculated as follows:

Position of following axis (following value) = Synchronous position of following axis + gear ratio × (Position of leading axis - Synchronous position of leading axis)

The "Synchronous" status is indicated in the Motion Control instruction "MC_GearIn (Page 279)" with the parameter "InGear" = TRUE and in the "<TO>.StatusWord.X22 (Synchronous)" tag of the technology object.

NOTE

Avoid homing the leading axis in synchronous operation

Avoid homing the leading axis during an active synchronous operation. Homing the leading axis during synchronous operation corresponds to a setpoint step-change on the following axis. The following axis compensates for the jump according to the synchronous operation function and limited only to the maximum speed of the drive.

7.2 Gearing with "MC_GearInPos"

With the Motion Control instruction "MC_GearInPos (Page 283)", you start gearing between a leading axis and a following axis. During gearing, the position of the following axis results from the position of the leading axis multiplied by the gear ratio depending on the synchronous positions. You specify the gear ratio as a ratio of two integers. The result is a linear synchronous operation function.

In contrast to the gearing with "MC_GearIn" (Page 49), for gearing with "MC_GearInPos" you also specify the synchronous positions of the leading and following axes, which define the reference of the axes to one another.

You can start synchronous operation when the leading axis is at a standstill or when it is in motion. Synchronous travel begins after synchronization when the following axis has reached the velocity and acceleration of the leading axis, taking into account the gear ratio.

Slope of line; transmission ratio
Gear ratio = "MC_GearInPos.RatioNumerator"/"MC_GearInPos.RatioDenominator"

Synchronization in advance

Subsequent synchronization

① Leading value distance with synchronization in advance

② Leading value distance with subsequent synchronization

You have the following options for gearing with "MC_GearInPos":

- Defining gear ratio (Page 55)
- Defining direction of synchronization (Page 59)
- Defining synchronous positions and type of synchronization:
  - Synchronizing following axis in advance using dynamic parameters (Page 61)
  - Synchronizing following axis in advance using leading value distance (Page 63)
  - Subsequent synchronizing of following axis using leading value distance (Page 65)
  - Subsequent synchronization of following axis using leading axis distance starting at current leading value position with calculated synchronous position of the following axis (Page 67)
  - Subsequent synchronization of following axis using leading value distance with calculated synchronous position of the following axis (Page 69)
- Synchronous travel in gearing (Page 72)
- Specify additive leading value with "MC_LeadingValueAdditive" (Page 205)
- Offset leading value absolute or relative with "MC_PhasingAbsolute" or "MC_PhasingRelative" (Page 72)
- Absolute or relative following value offset with "MC_OffsetAbsolute" or "MC_OffsetRelative" (Page 79)
- Set gearing to simulation mode with "MC_SynchronizedMotionSimulation" (Page 203)
- Desynchronize following axis with "MC_GearOut" (Page 84)
- Cancel a pending gearing with "MC_GearOut" (Page 91)

Also note the dynamic limits of the following axis in gearing with "MC_GearInPos" (Page 56).

7.2.1 Defining gear ratio

During gearing, the position of the following axis results from the position of the leading axis multiplied by the gear ratio depending on the synchronous positions. You specify the gear ratio at the Motion Control instruction "MC_GearInPos (Page 283)" as the relationship between two integers (numerator/denominator). The result is a linear synchronous operation function.

Numerator of the gear ratio

With the "RatioNumerator" parameter, you define the numerator of the gear ratio. You can define the numerator of the gear ratio as positive or negative. This yields the following behavior:

- Positive gear ratio:

  The leading and following axes move in the same direction.
- Negative gear ratio:

  The following axis moves in the opposite direction of the leading axis.

The value "0" is not permitted for the numerator of the gear ratio.

Denominator of the gear ratio

With the "RatioDenominator" parameter, you define the denominator of the gear ratio. Only positive values are permitted for the denominator of the gear ratio.

Display of the gear ratio

The current gear ratio of an active "MC_GearInPos" job is shown on the synchronous axis in the "<TO>.StatusSynchronizedMotion.ActualRatioNumerator" and "TO>.StatusSynchronizedMotion.ActualRatioDenominator" tags.

Example 1: Positive gear ratio

Leading axis and following axis are rotary axes and each has a traversing range from 0 ° to 360 ° with enabled "Modulo" setting.

Parameter inputs:

- "RatioNumerator" = 5
- "RatioDenominator" = 1

When the leading axis moves by 10 °, the following axis moves by 50 ° in the "Synchronous" status of the gearing.

Example 2: Negative gear ratio

Leading axis and following axis are rotary axes and each has a traversing range from 0 ° to 360 ° with enabled "Modulo" setting.

Parameter inputs:

- "RatioNumerator" = -3
- "RatioDenominator" = 1

When the leading axis moves by 10 °, the following axis moves by -30 ° in the "Synchronous" status of the gearing.

7.2.2 Dynamic limits of the following axis in gearing with "MC_GearInPos"

If a synchronous axis is operated as a following axis in the gearing with the Motion Control instruction "MC_GearInPos (Page 283)", the following dynamic limits apply, depending on the phase of the synchronous operation:

Pending synchronous operation

If synchronous operation is not active, the configured dynamic limits of the following axis apply. If there is already a synchronous operation active, the descriptions in the following sections apply.

Synchronization using dynamic parameters

During synchronization using dynamic parameters, the dynamic limits configured at the technology object apply to the following axis:

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

Synchronization via leading value distance and synchronous operation

When synchronizing via the leading value distance and during synchronous travel, the dynamics of the following axis are only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

End or override synchronous operation

As soon as synchronous operation has been overridden, the dynamic limits configured for the technology object apply to the following axis again. With the start of the overriding job, the active dynamics are transitioned (smoothed) to the configured dynamic limits and the specifications for the Motion Control instruction.

Desynchronization

You can find more information on dynamic limits during desynchronization in the section "Dynamic limits of the following axis during desynchronization with "MC_GearOut" (Page 90).

7.2.3 Synchronizing gearing

7.2.3.1 Parameter overview for synchronizing with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. With the parameter "SyncProfileReference" you define the type of synchronization:

SyncProfileReference	Synchronization profile
0	Synchronization in advance using dynamic parameters (Page 61)
1	Synchronization in advance using leading value distance (Page 63)
3	Subsequent synchronization using leading value distance (Page 65)
4	Subsequent synchronization using leading value distance starting from current leading value position with calculated synchronous position of the following axis (Page 67)
5	Subsequent synchronization using leading value distance with calculated synchronous position of the following axis (Page 69)

Depending on the synchronization profile, different parameters of the Motion Control instruction "MC_GearInPos (Page 283)" are relevant:

Parameters	SyncProfileReference				
	0	1	3	4	5
RatioNumerator	✓	✓	✓	✓	✓
RatioDenominator	✓	✓	✓	✓	✓
MasterSyncPosition	✓	✓	✓	-	✓
SlaveSyncPosition	✓	✓	✓	-	-
MasterStartDistance	-	✓	✓	✓	✓
Velocity	✓	-	-	-	-
Acceleration	✓	-	-	-	-
Deceleration	✓	-	-	-	-
Jerk	✓	-	-	-	-
SyncDirection	✓	✓	✓	✓	✓

7.2.3.2 Defining direction of synchronization with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. If you have activated the "Modulo" setting for the following axis, you can define the direction of the synchronization with the "SyncDirection" parameter of the Motion Control instruction "MC_GearInPos (Page 283)".

In the examples below, the transformation ratio is 1:1.

Positive direction

With "SyncDirection" = 1, the following axis may only travel in positive direction during synchronization. In this example, the synchronous position is 360.0.

Negative direction

With "SyncDirection" = 2, the following axis may only travel in negative direction during synchronization. In this example, the synchronous position is 0.0.

Shortest distance

With "SyncDirection" = 3, changes in direction of the following axis are permitted during synchronization. In this example, the synchronous position is 0.0.

7.2.3.3 Synchronizing following axis in advance using dynamic parameters with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. During synchronization in advance using dynamic parameters, synchronization begins in such a way that the leading and following axis are synchronous when the synchronous positions are reached.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInPos (Page 283)":

- With the parameter "SyncProfileReference" = 0, you define the type of synchronization as synchronization in advance using dynamic parameters.
- With the parameters "MasterSyncPosition" and "SlaveSyncPosition", you define the synchronous positions of the leading and following axis which determine the relationship of the axes to each other. For synchronization in advance, the synchronous position is the position starting from which the leading axis and following axis travel synchronously.
- With the parameters "Velocity", "Acceleration", "Deceleration" and "Jerk" you define the dynamics for the synchronization of the following axis.

Until synchronization

After the start of the "MC_GearInPos" job, a motion profile for the following axis is calculated continuously. The motion profile is calculated based on the following parameters:

- Specified synchronous positions of the leading and following axis at the Motion Control instruction
- Specified dynamics of the Motion Control instruction
- Current position and dynamics of the leading and following axes
- Synchronous operation function

The calculation determines the synchronization length and thus the start position of the leading axis for the synchronization.

The start position of the leading axis is derived in the following way:

Start position = Synchronous position of leading axis - Synchronization length

The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 2).

If the leading and following axes are already at their synchronous positions when the "MC_GearInPos" job is started, synchronous operation immediately has "Synchronous" status. In terms of application, you can only achieve this with a setpoint coupling by positioning the leading and following axes absolutely in the synchronous positions.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the start position. The synchronization is indicated in the Motion Control instruction "MC_GearInPos" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value connection, e.g. with an external encoder, you can define a reverse tolerance of the guide value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is limited to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

If the programmed dynamic response of the synchronous operation function is greater than the maximum dynamic response of the following axis when the "Execute" parameter is set, the corresponding technology alarms 501, 502, or 503 are output at the following axis.

After synchronization

The following axis is synchronized as soon as the leading axis has reached the synchronous position. The following axis travels synchronously with the leading axis (Page 72).

7.2.3.4 Synchronizing following axis in advance using leading value distance with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. During synchronization in advance using the leading value distance, synchronization begins in such a way that the leading and following axis are synchronous when the synchronous positions are reached.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInPos (Page 283)":

- With the parameter "SyncProfileReference" = 1, you define the type of synchronization as synchronization in advance using the leading value distance.
- With the parameters "MasterSyncPosition" and "SlaveSyncPosition", you define the synchronous positions of the leading and following axis which determine the relationship of the axes to each other. For synchronization in advance, the synchronous position is the position starting from which the leading axis and following axis travel synchronously.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Until synchronization

After the start of the "MC_GearInPos" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation determines the required dynamic response and thus the start position of the leading axis for the synchronization.

The start position of the leading axis is derived in the following way:

Start position = Synchronous position of leading axis - Synchronization length

The leading axis must be at least the leading value distance away from the synchronous position. The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 2).

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_GearInPos" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_GearInPos" job is started, synchronous operation immediately has "Synchronous" status. In terms of application, you can only achieve this with a setpoint coupling by positioning the leading and following axes absolutely in the synchronous positions.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the start position. The synchronization is indicated in the Motion Control instruction "MC_GearInPos" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The following axis is synchronized as soon as the leading axis has reached the synchronous position. The following axis travels synchronously with the leading axis (Page 72).

7.2.3.5 Subsequent synchronizing of following axis using leading value distance with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. With subsequent synchronization using the leading value distance, synchronization begins as soon as the leading value has reached the synchronous position of the leading axis.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInPos (Page 283)":

- With the parameter "SyncProfileReference" = 3, you define the type of synchronization as subsequent synchronization using the leading value distance.
- With the parameters "MasterSyncPosition" and "SlaveSyncPosition", you define the synchronous positions of the leading and following axis which determine the relationship of the axes to each other. For subsequent synchronization, the synchronous position of the leading axis is the start position for synchronization. The synchronous position of the following axis is a theoretical position which is assigned to the synchronous position of the leading axis.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Until synchronization

After starting the "MC_GearInPos" job, a motion profile for the slave axis is calculated depending on the start position and the synchronous position of the following axis as well as on the specified leading value distance. The calculation determines the required dynamic response and the position of the leading axis as of which the leading axis and the following axis travel synchronously.

The status "Waiting" is displayed at the following axis until the leading value has reached the synchronous position of the leading axis
(<TO>.StatusSynchronizedMotion.WaitingFunctionState = 2).

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_GearInPos" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_GearInPos" job is started, synchronous operation immediately has "Synchronous" status. In terms of application, you can only achieve this with a setpoint coupling by positioning the leading and following axes absolutely in the synchronous positions.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the synchronous position. The synchronization is indicated in the Motion Control instruction "MC_GearInPos" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The position of the leading axis from which the leading axis and following axis travel synchronously is derived in the following way:

Position axes synchronous = Synchronous position of leading axis + Synchronization length

As soon as the leading axis has reached this position, the following axis is synchronized. The following axis travels synchronously with the leading axis (Page 72).

7.2.3.6 Subsequent synchronization of following axis using leading axis distance starting at current leading value position with calculated synchronous position of the following axis with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. With subsequent synchronization using the leading value distance from the current leading value position with calculated synchronous position of the following axis, synchronization begins as soon as the "MC_GearInPos" job takes effect. The leading and following axis are synchronous as soon as the leading value has passed the leading value distance. The "MC_GearInPos" Motion Control instruction calculates the synchronous position of the following axis.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInPos (Page 283)":

- With the parameter "SyncProfileReference" = 4, you define the type of synchronization as subsequent synchronization using the leading value distance from the current leading value position with calculated synchronous position of the following axis.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Starting the "MC_GearInPos" job

After the start of the "MC_GearInPos" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation determines the required dynamic response of the following axis so that the leading axis and the following axis travel synchronously at the end of the leading value distance.

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_GearInPos" job is started, dynamic jumps can occur at the following axis.

The "Gearing with specified synchronous position" status is shown immediately at the following axis (<TO>.StatusSynchronizedMotion.FunctionState = 2).

If the leading and following axes are at standstill when the "MC_GearInPos" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the "MC_GearInPos" job takes effect and the leading axis is moving. The synchronization is indicated in the Motion Control instruction "MC_GearInPos" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

If the "Modulo" setting is enabled for leading axis and following axis, the leading value distance can be several Modulo cycles long.

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. If the leading axis moves with constant velocity, the acceleration of the following axis remains constant until the "Synchronous" status. This leads to a velocity profile without jerk limitation of the following axis (trapezoidal velocity profile). If the following axis is already in motion when synchronization starts, the following axis performs a motion transition. This can lead to a non-trapezoidal speed profile.

Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The position of the leading axis from which the leading axis and following axis travel synchronously is derived in the following way:

Position axes synchronous = Current leading value position at job start + synchronization length

The calculated synchronous position of the following axis results from the synchronization length and the dynamic response of the leading axis.

The following axis is synchronized when the following axis has reached the velocity of the leading axis, taking into account the gear ratio. The following axis travels synchronously with the leading axis (Page 72).

7.2.3.7 Subsequent synchronization of following axis using leading value distance with calculated synchronous position of the following axis with "MC_GearInPos"

During gearing (Page 54), synchronization establishes the relationship between the leading axis and following axis. With subsequent synchronization using the leading value distance with calculated synchronous position of the following axis, synchronization begins as soon as the leading value has reached the synchronous position of the leading axis. The leading and following axis are synchronous as soon as the leading value has passed the leading value distance. The "MC_GearInPos" Motion Control instruction calculates the synchronous position of the following axis.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInPos (Page 283)":

- With the parameter "SyncProfileReference" = 5, you define the type of synchronization as subsequent synchronization using the leading value distance with calculated synchronous position of the following axis.
- With the "MasterSyncPosition" parameter, you define the synchronous position of the leading axis. For subsequent synchronization, the synchronous position of the leading axis is the start position for synchronization.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Until synchronization

After the start of the "MC_GearInPos" job, a motion profile for the following axis is calculated depending on the start position and the specified leading value distance. The calculation determines the required dynamic response of the following axis so that the leading axis and the following axis travel synchronously at the end of the leading value distance.

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_GearInPos" job is started, dynamic jumps can occur at the following axis.

The status "Waiting" is displayed at the following axis until the leading value has reached the synchronous position of the leading axis (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 2).

When the leading value has reached the synchronous position of the leading axis, the "Gearing with specified synchronous position" status is shown immediately at the following axis (<TO>.StatusSynchronizedMotion.FunctionState = 2).

If the leading axis is already at its synchronous position when the "MC_GearInPos" job is started and the following axis is at standstill, synchronous operation immediately has "Synchronous" status. In terms of application, you can only achieve this with a setpoint coupling by the absolute positioning of the leading axis at the synchronous position.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the synchronous position. The synchronization is indicated in the Motion Control instruction "MC_GearInPos" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time at which the "MC_GearInPos" job is started

② Time when synchronization starts

③ Time when synchronization is complete

④ Duration from start of the "MC_GearInPos" job until the start of synchronization

⑤ Duration from the start of synchronization until the end of synchronization

If the "Modulo" setting is enabled for leading axis and following axis, the leading value distance can be several Modulo cycles long. The leading distance value has about three Modulo cycles in the following example:

① Time at which the "MC_GearInPos" job is started

② Time when synchronization starts

③ Leading value distance

④ Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. If the leading axis moves with constant velocity, the acceleration of the following axis remains constant until the "Synchronous" status. This leads to a velocity profile without jerk limitation of the following axis (trapezoidal velocity profile). If the following axis is already in motion when synchronization starts, the following axis performs a motion transition. This can lead to a non-trapezoidal speed profile.

Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The position of the leading axis from which the leading axis and following axis travel synchronously is derived in the following way:

Position axes synchronous = Synchronous position of leading axis + Synchronization length

The calculated synchronous position of the following axis results from the synchronization length and the dynamic response of the leading axis.

The following axis is synchronized when the following axis has reached the velocity of the leading axis, taking into account the gear ratio. The following axis travels synchronously with the leading axis (Page 72).

7.2.4 Synchronous travel in gearing with "MC_GearInPos"

As soon as the following axis is synchronized to a leading value, the following axis follows the position of the leading axis according to the synchronous positions and the gear ratio. The transmission behavior during gearing is expressed by a linear relationship between the leading value and the following value.

The following value is calculated as follows:

Position of following axis (following value) = Synchronous position of following axis + gear ratio × (Position of leading axis - Synchronous position of leading axis)

The "Synchronous" status is indicated in the Motion Control instruction "MC_GearInPos (Page 283)" with the parameter "InSync" = TRUE and in the "<TO>.StatusWord.X22 (Synchronous)" tag of the technology object.

NOTE

Avoid homing the leading axis in synchronous operation

Avoid homing the leading axis during an active synchronous operation. Homing the leading axis during synchronous operation corresponds to a setpoint step-change on the following axis. The following axis compensates for the jump according to the synchronous operation function and limited only to the maximum speed of the drive.

7.2.5 Leading value offset during gearing

7.2.5.1 Leading value offset on the following axis during gearing using dynamic parameters

With a leading value offset, you offset the effective leading value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". You can move the effective leading value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the leading value offset.

The leading value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during leading value offset with the following parameters of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)":

- With the parameter "ProfileReference" = 0, you specify the type of leading value offset as offset using dynamic parameters.
- With the "PhaseShift" parameter, you specify the leading value offset on the following axis.
- With the "Velocity" parameter, you specify the additive velocity of the following axis during the leading value offset.
- With the "Acceleration" parameter, you specify the additive acceleration of the following axis during the leading value offset.
- With the "Deceleration" parameter, you specify the additive deceleration of the following axis during the leading value offset.
- With the "Jerk" parameter, you specify the additive jerk of the following axis during the leading value offset.

During the leading value offset

The leading value offset via dynamic parameters is effective immediately, regardless of the leading value position. The leading value is offset on the following axis. The dynamic values are added to the values of the synchronous operation motion. The required travel distance of the following axis to offset the leading value is calculated by the system.

During leading value offset, the speed of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The configured velocity limit may be exceeded (<TO>.DynamicLimits.MaxVelocity).

Acceleration, deceleration, and jerk of the following axis are limited to the dynamic limits configured on the technology object:

- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The leading value offset is indicated in the Motion Control instruction with the parameter "StartPhasing" = TRUE and in the "<TO>.StatusWort.X24 (PhasingCommand)" tag of the technology object. The "AbsolutePhaseShift" or "CoveredPhaseShift" parameter shows the absolute leading value portion already shifted.

After the leading value offset

As soon as the following axis has offset the leading value, the leading value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

The leading value offset only has an effect in the "Synchronous" status of the gearing. When the gearing is overridden, the leading value offset is reset to zero.

7.2.5.2 Leading value offset on the following axis during gearing using leading value distance as of current leading value position

With a leading value offset, you offset the effective leading value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". You can move the effective leading value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the leading value offset.

The leading value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during leading value offset with the following parameters of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)":

- With the parameter "ProfileReference" = 1, you specify the type of leading value offset as offset using leading value distance as of the current leading value position.
- With the "PhaseShift" parameter, you specify the leading value offset on the following axis.
- With the "PhasingDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the leading value offset.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 77).

During the leading value offset

After starting the jobs, the following axis begins with the leading value offset starting from the current position. Within the traversing distance of the leading axis, the following axis offsets the leading value at continuous velocity and acceleration. The required dynamics of the following axis to offset the leading value is calculated by the system. During leading value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The leading value offset is indicated in the Motion Control instruction with the parameter "StartPhasing" = TRUE and in the "<TO>.StatusWort.X24 (PhasingCommand)" tag of the technology object. The "AbsolutePhaseShift" or "CoveredPhaseShift" parameter shows the absolute leading value portion already shifted.

The leading value must not reverse during the leading value offset on the following axis. When the leading value reverses, the "MC_PhasingAbsolute" job or "MC_PhasingRelative" job is canceled with "ErrorID" = 16#808C.

After the leading value offset

As soon as the following axis has offset the leading value, the leading value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

The leading value offset only has an effect in the "Synchronous" status of the gearing. When the gearing is overridden, the leading value offset is reset to zero.

7.2.5.3 Leading value offset on the following axis during gearing using leading value distance as of specific leading value position

With a leading value offset, you offset the effective leading value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". You can move the effective leading value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the leading value offset.

The leading value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during leading value offset with the following parameters of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)":

- With the parameter "ProfileReference" = 2, you specify the type of leading value offset as offset using leading value distance as of a specific leading value position.
- With the "PhaseShift" parameter, you specify the leading value offset on the following axis.
- With the "PhasingDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the leading value offset.
- With the "StartPosition" parameter, you specify the leading value position from which the leading value offset starts.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 77).

Until the leading value offset

After starting the job, the status "Waiting" is displayed at the following axis when the leading value is at standstill and until the leading value has reached the leading value position (<TO>.StatusWord2.X3 = TRUE (PhasingCommandWaiting)).

During the leading value offset

As soon as the leading value has reached the leading value position, the following axis begins to offset the leading value. Within the traversing distance of the leading axis, the following axis offsets the leading value at continuous velocity and acceleration. The required dynamics of the following axis to offset the leading value is calculated by the system. During leading value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The leading value offset is indicated in the Motion Control instruction with the parameter "StartPhasing" = TRUE and in the "<TO>.StatusWort.X24 (PhasingCommand)" tag of the technology object. The "AbsolutePhaseShift" or "CoveredPhaseShift" parameter shows the absolute leading value portion already shifted.

The leading value must not reverse during the leading value offset on the following axis. When the leading value reverses, the "MC_PhasingAbsolute" job or "MC_PhasingRelative" job is canceled with "ErrorID" = 16#808C. The waiting job is not canceled.

After the leading value offset

As soon as the following axis has offset the leading value, the leading value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

The leading value offset only has an effect in the "Synchronous" status of the gearing. When the gearing is overridden, the leading value offset is reset to zero.

7.2.5.4 Defining the direction of the leading value distance of a leading value offset on the following axis during gearing

With a leading value offset, you offset the effective leading value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". With the "Direction" parameter of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)", you specify the direction of the leading value distance in relation to the direction of motion of the effective leading value.

Defining leading value distance in the positive direction of motion of the effective leading value

With "Direction" = 1, the following axis only offsets the leading value when the leading axis travels in the positive direction.

Defining leading value distance in the negative direction of motion of the effective leading value

With "Direction" = 2, the following axis only offsets the leading value when the leading axis travels in the negative direction.

Defining leading value distance in the current direction of motion of the effective leading value

With "Direction" = 3, the following axis offsets the leading value regardless of the direction in which the leading axis is currently traveling.

7.2.5.5 Canceling a pending leading value offset in the gearing

With an "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)" job with "ProfileReference" = 5, you cancel a pending "MC_PhasingAbsolute" or "MC_PhasingRelative" job. Canceling a waiting job has no effect on an active leading value offset.

7.2.6 Following value offset during gearing

7.2.6.1 Following value offset on the following axis during gearing using leading value distance as of current leading value position

With a following value offset, you offset the following value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". You can move the following value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the following value offset.

The following value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during following value offset with the following parameters of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)":

- With the parameter "ProfileReference" = 1, you specify the type of following value offset as offset using leading value distance as of the current leading value position.
- With the "Offset" parameter, you specify the following value offset on the following axis.
- With the "OffsetDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the following value offset.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 82).

During the following value offset

After starting the job, the following axis begins with the following value offset starting from the current position. Within the traversing distance of the leading axis, the following axis offsets the following value at continuous velocity and acceleration. The required dynamics of the following axis for the following value offset is calculated by the system. During following value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The following value offset is indicated in the Motion Control instruction with the parameter "StartOffset" = TRUE and in the "<TO>.StatusWort2.X4 (OffsetCommand)" tag of the technology object. The "AbsoluteOffset" or "CoveredOffset" parameter shows the absolute following value portion already shifted.

The leading value must not reverse during the following value offset on the following axis. When the leading value reverses, the "MC_OffsetAbsolute" job or "MC_OffsetRelative" job is canceled with "ErrorID" = 16#808C.

After the following value offset

As soon as the following axis has offset the following value, the following value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

The following value offset only has an effect in the "Synchronous" status of the gearing. When the gearing is overridden, the following value offset is reset to zero.

7.2.6.2 Following value offset on the following axis during gearing using leading value distance as of specific leading value position

With a following value offset, you offset the following value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". You can move the following value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the following value offset.

The following value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during following value offset with the following parameters of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)":

- With the parameter "ProfileReference" = 2, you specify the type of following value offset as offset using leading value distance as of a specific leading value position.
- With the "Offset" parameter, you specify the following value offset on the following axis.
- With the "OffsetDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the following value offset.
- With the "StartPosition" parameter, you specify the leading value position from which the following value offset starts.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 82).

Until the following value offset

After starting the job, the status "Waiting" is displayed at the following axis when the leading value is at standstill and until the leading value has reached the leading value position (<TO>.StatusWord2.X5 = TRUE (OffsetCommandWaiting)).

During the following value offset

As soon as the leading value has reached the leading value position, the following axis begins to offset the following value. Within the traversing distance of the leading axis, the following axis offsets the following value at continuous velocity and acceleration. The required dynamics of the following axis for the following value offset is calculated by the system. During following value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The following value offset is indicated in the Motion Control instruction with the parameter "StartOffset" = TRUE and in the "<TO>.StatusWort2.X4 (OffsetCommand)" tag of the technology object. The "AbsoluteOffset" or "CoveredOffset" parameter shows the absolute following value portion already shifted.

The leading value must not reverse during the following value offset on the following axis. When the leading value reverses, the "MC_OffsetAbsolute" job or "MC_OffsetRelative" job is canceled with "ErrorID" = 16#808C. The waiting job is not canceled.

After the following value offset

As soon as the following axis has offset the following value, the following value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

The following value offset only has an effect in the "Synchronous" status of the gearing. When the gearing is overridden, the following value offset is reset to zero.

7.2.6.3 Defining the direction of the leading value distance of a following value offset on the following axis during gearing

With a following value offset, you offset the following value on the following axis during gearing with "MC_GearIn (Page 279)" or "MC_GearInPos (Page 283)". With the "Direction" parameter of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)", you specify the direction of the leading value distance in relation to the direction of motion of the effective leading value.

Defining leading value distance in the positive direction of motion of the effective leading value

With "Direction" = 1, the following axis only offsets the following value when the leading axis travels in the positive direction.

Defining leading value distance in the negative direction of motion of the effective leading value

With "Direction" = 2, the following axis only offsets the following value when the leading axis travels in the negative direction.

Defining leading value distance in the current direction of motion of the effective leading value

With "Direction" = 3, the following axis offsets the following value regardless of the direction in which the leading axis is currently traveling.

7.2.6.4 Canceling a pending following value offset in the gearing

With an "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)" job with "ProfileReference" = 5, you cancel a pending "MC_OffsetAbsolute" or "MC_OffsetRelative" job. Canceling a pending job has no effect on an active following value offset.

7.3 Desynchronizing gearing

7.3.1 Desynchronizing following axis using dynamic parameters with "MC_GearOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and gearing is ended. For desynchronization using dynamic parameters, desynchronization begins in such a way that the following axis comes to a standstill when the stop position is reached.

With the Motion Control instruction "MC_GearOut" you can desynchronize a gearing which you have started either with a "MC_GearIn (Page 279)" job or with a "MC_GearInPos (Page 283)" job.

Parameter inputs

You define the behavior of the following axis for desynchronization with the following parameters of the Motion Control instruction "MC_GearOut (Page 338)":

- With the parameter "SyncProfileReference" = 0, you specify the type of desynchronization as desynchronization using dynamic parameters.
- With the "SlavePosition" parameter, you specify the stop positions of the following axis. The stop position of the following axis is the position at which the following axis comes to a standstill and the desynchronization is completed.
- With the "Deceleration" parameter, you specify the deceleration of the following axis.
- With the "Jerk" parameter, you specify the jerk of the following axis.
- With the "SyncOutDirection" parameter, you specify the direction of the desynchronization (Page 88).

Until desynchronization

After the start of the "MC_GearOut" job, a motion profile for the following axis is calculated continuously. The motion profile is calculated based on the following parameters:

- Specified stop position of the following axis in the Motion Control instruction
- Specified dynamics of the Motion Control instruction
- Current position and dynamics of the leading and following axes
- Synchronous operation function
- Superimposed motion of the following axis
- Additive leading value of the following axis

The distance of the following axis and thus the starting position of the following axis for desynchronization results from the calculation.

The start position of the following axis is derived in the following way:

Start position = stop position of the following axis - travel distance of the following axis

The status "Waiting" is displayed at the following axis until the following value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 4).

During desynchronization

The following axis begins to desynchronize as soon as the following value has reached the start position. Desynchronization is indicated in the Motion Control instruction "MC_GearOut" with the parameter "StartSyncOut" = TRUE and in the "<TO>.StatusWord2.X1 (DesynchronizingCommand)" tag of the technology object. The synchronous operation is no longer in the "Synchronous" status. Superimposed jobs of the following axis are canceled.

The following axis moves to the stop position with the specified dynamics, independent of the leading value. The dynamic response of the following axis is limited to the dynamic limits configured on the technology object.

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

During desynchronization, several modulo revolutions of both axes are generally possible.

After desynchronization

As soon as the following axis reaches the stop position, the following axis is desynchronized. The following axis is at a standstill. The status is indicated in the Motion Control instruction "MC_GearOut" with the parameter "Done" = TRUE and in the "<TO>.StatusWord.X7 (Standstill)" tag of the technology object.

See also

Configuring the reverse tolerance of the leading value (Page 44)

7.3.2 Desynchronizing following axis using leading value distance with "MC_GearOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and gearing is ended. For desynchronization using the leading value distance, desynchronization begins in such a way that the following axis comes to a standstill when the stop position is reached.

With the Motion Control instruction "MC_GearOut" you can desynchronize a gearing which you have started either with a "MC_GearIn (Page 279)" job or with a "MC_GearInPos (Page 283)" job.

Parameter inputs

You define the behavior of the following axis for desynchronization with the following parameters of the Motion Control instruction "MC_GearOut (Page 338)":

- With the parameter "SyncProfileReference" = 1, you specify the type of desynchronization as desynchronization using the leading value distance.
- With the "SlavePosition" parameter, you specify the stop positions of the following axis. The stop position of the following axis is the position at which the following axis comes to a standstill and the desynchronization is completed.

- With the "MasterStopDistance" parameter, you define the leading value distance (desynchronization length).
- With the "SyncOutDirection" parameter, you specify the direction of the desynchronization (Page 88).

Until desynchronization

After the start of the "MC_GearOut" job, a motion profile is calculated depending on the specified leading value distance. The calculation determines the required dynamics and thus the start position of the leading axis for the desynchronization.

The start position of the leading axis is derived in the following way:

Start position = leading value position when the stop position of the following axis is reached - leading value distance

The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 4).

During desynchronization

The following axis begins to desynchronize as soon as the leading value has reached the start position. Desynchronization is indicated in the Motion Control instruction "MC_GearOut" with the parameter "StartSyncOut" = TRUE and in the "<TO>.StatusWord2.X1 (DesynchronizingCommand)" tag of the technology object. The synchronous operation is no longer in the "Synchronous" status. Superimposed jobs of the following axis are canceled.

The following axis travels to the stop position depending on the leading value distance The dynamics of the following axis during desynchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. The dynamic response of the following axis is thereby only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

Changes in the dynamics of the leading axis during desynchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object.

During desynchronization, several modulo revolutions of both axes are generally possible.

The leading value must not reverse during desynchronization. In order to avoid interrupting the desynchronization when there are slight fluctuations in the leading value during an actual value coupling, for example, with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when desynchronization starts

② Time when desynchronization is complete

If the leading axis stops during desynchronization, high dynamic values can occur at the following axis as soon as the leading axis starts moving again and the following axis continues moving to the specified stop position. To avoid these high dynamic values at the following axis, use desynchronization via dynamic parameters ("SyncProfileReference" = 0).

After desynchronization

As soon as the following axis reaches the stop position, the following axis is desynchronized. The following axis is at a standstill. The status is indicated in the Motion Control instruction "MC_GearOut" with the parameter "Done" = TRUE and in the "<TO>.StatusWord.X7 (Standstill)" tag of the technology object.

7.3.3 Defining direction of desynchronization with "MC_GearOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and gearing is ended. You can specify the desynchronization direction with the "SyncOutDirection" parameter of the Motion Control instruction "MC_GearOut (Page 338)".

Desynchronizing the following axis in positive traversing direction

With "SyncOutDirection" = 1, the following axis is only desynchronized when the following axis moves in the positive direction.

Desynchronizing the following axis in negative traversing direction

With "SyncOutDirection" = 2, the following axis is only desynchronized when the following axis moves in the negative direction.

Desynchronizing the following axis in the current traversing direction

With "SyncOutDirection" = 3, the following axis is desynchronized in the direction in which the following axis is currently moving.

7.3.4 Dynamic limits of the following axis during desynchronization with "MC_GearOut"

If a synchronous axis is desynchronized as a following axis in the gearing with the Motion Control instruction "MC_GearOut (Page 338)", the following dynamic limits apply, depending on the type of the synchronous operation:

Desynchronization via dynamic parameters

During synchronization using dynamic parameters, the dynamic limits configured at the technology object apply to the following axis.

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

Desynchronization using leading value distance

When desynchronizing via the leading value distance, the dynamic response of the following axis is thereby only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

7.3.5 Canceling pending gearing with "MC_GearOut"

With a "MC_GearOut (Page 338)" job with "SyncProfileReference" = 5, you cancel a pending gearing. Canceling a pending gearing has no influence on an active gearing.

7.4 Tags: Gearing

The following technology object tags are relevant for gearing:

Configuration		
Tag	**Description**	
<TO>.SynchronizedMotion.LeadingValueReversalTolerance	Reverse tolerance of the leading value during synchronization with "MC_GearInPos" and desynchronization with "MC_GearOut" in length unit of the axis	
<TO>.SynchronizedMotion.LeadingValueTolerenceDirection	Tolerated leading value direction to leave the tolerance range	
	1	Positive
	2	Negative
	3	Positive and negative

Status indicators		
Tag	**Description**	
<TO>.StatusSynchronizedMotion.FunctionState	Indication of which synchronous operation function is active	
	0	No synchronous operation active
	1	Gearing ("MC_GearIn")
	2	Gearing with specified synchronous positions ("MC_GearInPos")
	3	Camming ("MC_CamIn")
	4	Desynchronization of gearing ("MC_GearOut")
	5	Desynchronization of camming ("MC_CamOut")
	6	Velocity synchronous operation ("MC_GearInVelocity")
<TO>.StatusSynchronizedMotion.WaitingFunctionState	Indication of which synchronous operation function is waiting	
	0	No synchronous operation waiting
	1	Reserved
	2	Gearing with specified synchronous positions waiting ("MC_GearInPos")
	3	Camming waiting ("MC_CamIn")
	4	Desynchronization of gearing waiting ("MC_GearOut")
	5	Desynchronization of camming waiting ("MC_CamOut")
<TO>.StatusSynchronizedMotion.ActualMaster	When a synchronous operation job is started, the number of the technology data block of the currently used leading axis is displayed.	
	0	Synchronous operation inactive

Status indicators	
Tag	**Description**
<TO>.StatusSynchronizedMotion.ActualRatio-Denominator	Current denominator of the gear ratio of an active "MC_GearIn", "MC_GearInPos" or "MC_GearInVelocity" job
<TO>.Position	Setpoints of the axis
<TO>.Velocity	
<TO>.Acceleration	
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Position	Effective leading value including an additive leading value with an "MC_LeadingValueAdditive" job
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Velocity	
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Acceleration	
<TO>.StatusSynchronizedMotion.PhaseShift	Current absolute leading value offset with an "MC_PhasingAbsolute" or "MC_PhasingRelative" job
<TO>.StatusSynchronizedMotion.Function-LeadingValue.Position	Leading value of the synchronous operation function after a leading value offset with an "MC_PhasingAbsolute" job or "MC_PhasingRelative" job including an additive leading value with a "MC_LeadingValueAdditive" job
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Position	Following value of the synchronous operation function before a following value offset with an "MC_OffsetAbsolute" job or "MC_OffsetRelative" job
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Velocity	
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Acceleration	
<TO>.StatusSynchronizedMotion.Offset	Current absolute following value offset with an "MC_OffsetAbsolute" or "MC_OffsetRelative" job
<TO>.StatusSynchronizedMotion.StatusWord.X0 (MaxVelocityExceeded)	Set to the value "TRUE" when the maximum velocity configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X1 (MaxAccelerationExceeded)	Set to the value "TRUE" when the maximum acceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X2 (MaxDecelerationExceeded)	Set to the value "TRUE" when the maximum deceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusWord.X21 (Synchronizing)	Set to the value "TRUE" when the synchronous axis synchronizes to a leading value.
<TO>.StatusWord.X22 (Synchronous)	Set to the value "TRUE" when the synchronous axis is synchronized and moves synchronously to the leading axis.
<TO>.StatusWord2.X1 (DesynchronizingCommand)	Set to the value "TRUE" when the synchronous axis desynchronizes.
<TO>.StatusWord.X24 (PhasingCommand)	Is set to the value "TRUE" if a job for leading value offset is active ("MC_PhasingAbsolute", "MC_PhasingRelative").
<TO>.StatusWord2.X3 (PhasingCommandWaiting)	Is set to the value "TRUE" if a job for leading value offset is pending ("MC_PhasingAbsolute", "MC_PhasingRelative").

Status indicators	
Tag	**Description**
<TO>.StatusWord2.X4 (OffsetCommand)	Is set to the value "TRUE" if a job for following value offset is active ("MC_OffsetAbsolute", "MC_OffsetRelative").
<TO>.StatusWord2.X5 (OffsetCommandWaiting)	Is set to the value "TRUE" if a job for following value offset is waiting ("MC_OffsetAbsolute", "MC_OffsetRelative").
<TO>.ErrorWord.X14 (SynchronousError)	Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.

Velocity synchronous operation

8

With the Motion Control instruction "MC_GearInVelocity (Page 293)" you start a velocity synchronous operation between a leading axis and a following axis. During velocity synchronous operation, the velocity of the following axis results from the velocity of the leading axis multiplied by the gear ratio, regardless of the position. You specify the gear ratio as a ratio of two integers either once or variably during synchronization. This results in a linear transformation ratio.

You can start synchronous operation when the leading axis is at a standstill or when it is in motion. Synchronous travel begins after synchronization when the following axis has reached the velocity and acceleration of the leading axis, taking into account the gear ratio.

Slope of line or transmission ratio
Gear ratio = "MC_GearInVelocity.RatioNumerator"/"MC_GearInVelocity.RatioDenominator"

For velocity synchronous operation with "MC_GearInVelocity", you have the following options:

- Defining gear ratio (Page 95)
- Specify gear ratio once or dynamically (Page 96)
- Defining position control of the following axis (Page 97)
- Synchronize following axis using dynamic parameters (Page 99)
- Synchronous travel in velocity synchronous operation (Page 100)
- Specify additive leading value with "MC_LeadingValueAdditive" (Page 205)
- Set velocity synchronous operation with "MC_SynchronizedMotionSimulation" in simulation (Page 203)

Also note the Dynamic limits of the following axis in velocity synchronous operation (Page 98).

8.1 Defining gear ratio

During velocity synchronous operation, the velocity of the following axis results from the velocity of the leading axis multiplied by the gear ratio, regardless of the position. You specify the gear ratio at the Motion Control instruction "MC_GearInVelocity (Page 293)" as the relationship between two integers (numerator/denominator).

Numerator of the gear ratio

With the "RatioNumerator" parameter, you define the numerator of the gear ratio. You can define the numerator of the gear ratio as positive or negative. This yields the following behavior:

- Positive gear ratio:

  The leading and following axes move in the same direction.
- Negative gear ratio:

  The following axis moves in the opposite direction of the leading axis.

The value "0" is not permitted for the numerator of the gear ratio.

Denominator of the gear ratio

With the "RatioDenominator" parameter, you define the denominator of the gear ratio. Only positive values are permitted for the denominator of the gear ratio.

Display of the gear ratio

The current gear ratio of an active "MC_GearInVelocity" job is shown on the synchronous axis in the "<TO>.StatusSynchronizedMotion.ActualRatioNumerator" and "TO>.StatusSynchronizedMotion.ActualRatioDenominator" tags.

Example 1: Positive gear ratio

Leading axis and following axis are rotary axes.

Parameter inputs:

- "RatioNumerator" = 5
- "RatioDenominator" = 1

If the leading axis moves at 100 °/s, the following axis moves at 500 °/s in the "Synchronous" status of the velocity synchronous operation .

Example 2: Negative gear ratio

The leading axis is a linear axis. The following axis is a rotary axis.

Parameter inputs:

- "RatioNumerator" = -3
- "RatioDenominator" = 1

If the leading axis moves at 100 mm/s, the following axis moves at -300 °/s in the "Synchronous" status of the velocity synchronous operation .

8.2 Specify gear ratio once or dynamically

For a velocity synchronous operation , you can either preset the gear ratio once at the start of the job or change it continuously during an active synchronous operation.

Make sure that the dynamic limits of the following axis (Page 98) are not exceeded by the changed gear ratios.

Parameter inputs

You define the behavior with the following parameters of the Motion Control instruction "MC_GearInVelocity (Page 293)":

- You define the mode for presetting the gear ratio (Page 95) with the parameter "ContinuousUpdate" .

Specify gear ratio once

With "ContinuousUpdate" = FALSE, the gear ratio specified at the start time of the "MC_GearInVelocity" job is used as long as the job is active.

To change the gear ratio if necessary, you must start the job again with a rising edge of the parameter "Execute" = TRUE. The following axis then synchronizes again.

Specify gear ratio dynamically

With "ContinuousUpdate" = TRUE you can change the gear ratio dynamically while the "MC_GearInVelocity" job is active. Changes of the parameter values "RatioNumerator" and "RatioDenominator" are effective immediately.

That the mode for dynamic presetting of the gear ratio is active is indicated at the motion control instruction "MC_GearInVelocity" with the parameter "ContinuousUpdateActive" = TRUE.

Recommendation

You can specify only integer values as numerator ("RatioNumerator") and denominator ("RatioDenominator") of the gear ratio.

To achieve as continuous a change as possible in the gear ratio, multiply the numerator and denominator by a high factor. This increases the resolution of the gear ratio and reduces the quantization error.

Example

The gear ratio should change gradually from 1.0 to 1.1.

Parameter assignment 1:

"RatioNumerator" = 100 ... 110

"RatioDenominator" = 100 ... 100

Increasing the counter in steps of 1 increases the gear ratio by 0.01 each time.

Parameter assignment 2:

"RatioNumerator" = 1 000 000 ... 1 100 000

"RatioDenominator" = 1 000 000 ... 1 000 000

Increasing the counter in steps of 1 increases the gear ratio by 0.000001 each time.

With parameter assignment 2 you get a higher resolution and can change the gear ratio in smaller steps than with parameter assignment 1.

8.3 Defining position control of the following axis

During a velocity synchronous operation, the following axis can be operated in position-controlled or non-position-controlled mode. You specify the operating mode of the following axis independently of the operating mode of the leading axis at the motion control instruction "MC_GearInVelocity".

Parameter inputs

You define the behavior of the following axis with the following parameters of the Motion Control instruction "MC_GearInVelocity (Page 293)":

- You define the operating mode of the following axis with the parameter "PositionControlled".

Position-controlled mode

As soon as the "MC_GearInVelocity" job with "PositionControlled" = TRUE becomes effective, the following axis is switched to position-controlled operation. The configured position monitorings of the following axis are active.

Superimposed motion, e.g. with a "MC_MoveSuperimposed" job, and travel to a fixed stop is only possible in position-controlled operation.

Non-position-controlled mode

As soon as the "MC_GearInVelocity" job with "PositionControlled" = FALSE becomes effective, the following axis is switched to non-position-controlled operation. The configured position monitorings of the following axis are deactivated.

The position setpoint of the following axis is irrelevant in non-position-controlled operation. The zero position setpoint is displayed in "<TO>.Position" tag of the technology object.

8.4 Dynamic limits of the following axis in velocity synchronous operation

If a synchronous axis is operated as a following axis in velocity synchronous operation with the Motion Control instruction "MC_GearInVelocity (Page 293)", the following dynamic limits apply depending on the phase of the synchronous operation:

Synchronization

During synchronization, the velocity of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The configured velocity limit may be exceeded (<TO>.DynamicLimits.MaxVelocity).

For acceleration, deceleration, and jerk of the following axis, the dynamic limits configured on the technology object apply:

- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

Synchronous travel

During synchronous travel, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

End or override synchronous operation

As soon as synchronous operation has been overridden, the dynamic limits configured for the technology object apply to the following axis again. With the start of the overriding job, the active dynamics are transitioned (smoothed) to the configured dynamic limits and the specifications for the Motion Control instruction.

8.5 Synchronizing following axis using dynamic parameters with "MC_GearInVelocity"

During velocity synchronous operation, the synchronization establishes the relationship between the leading and following axes. Synchronization begins immediately after the "MC_GearInVelocity" job starts.

Parameter inputs

You define the dynamic behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_GearInVelocity (Page 293)":

- With the "Acceleration" parameter, you specify the acceleration of the following axis.
- With the "Deceleration" parameter, you specify the deceleration of the following axis.
- With the "Jerk" parameter, you specify the jerk of the following axis.

Observe the dynamic limits (Page 98) of the following axis during synchronization.

During synchronization

Synchronization begins after the "MC_GearInVelocity" job starts. Active motion jobs are overridden.

The synchronization duration and distance are dependent on the following parameters:

- Dynamics of the following axis at the start time of the "MC_GearInVelocity" job
- Dynamic settings for synchronization
- Preset gear ratio at the start time of the "MC_GearInVelocity" job
- Dynamics of the leading axis

The synchronization is indicated in the Motion Control instruction "MC_GearInVelocity" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

① Time when synchronization starts

② Time when synchronization is complete

The specified gear ratio at the start time of the "MC_GearInVelocity" job is used for the synchronization. If you use a variable gear ratio with "ContinuousUpdate" = TRUE, changes to the gear ratio are only taken into account after synchronization.

After synchronization

The following axis is synchronized when the following axis has reached the velocity of the leading axis, taking into account the gear ratio. The following axis travels synchronously with the leading axis.

8.6 Synchronous travel in velocity synchronous operation with "MC_GearInVelocity"

As soon as the following axis is synchronized, it follows the velocity of the leading axis depending on the specified gear ratio.

The following value velocity is obtained as follows:

Following value velocity = leading value velocity × gear ratio

The "Synchronous" status is indicated in the Motion Control instruction "MC_GearInVelocity (Page 293)" with the parameter "InSync" = TRUE and in the "<TO>.StatusWord.X22 (Synchronous)" tag of the technology object.

If the gear ratio changes when "ContinuousUpdateActive" = TRUE, the "Synchronous" status is retained.

8.7 Tags: Velocity synchronous operation

The following tags of the technology object are relevant for the velocity synchronous operation :

Status indicators		
Tag	**Description**	
<TO>.StatusSynchronizedMotion.FunctionState	Indication of which synchronous operation function is active	
	0	No synchronous operation active
	1	Gearing ("MC_GearIn")
	2	Gearing with specified synchronous positions ("MC_GearInPos")
	3	Camming ("MC_CamIn")
	4	Desynchronization of gearing ("MC_GearOut")
	5	Desynchronization of camming ("MC_CamOut")
	6	Velocity synchronous operation ("MC_GearInVelocity")
<TO>.StatusSynchronizedMotion.ActualMaster	When a synchronous operation job is started, the number of the technology data block of the currently used leading axis is displayed.	
	0	Synchronous operation inactive
<TO>.StatusSynchronizedMotion.ActualRatio-Numerator	Current counter of the gear ratio of an active "MC_GearIn", "MC_GearInPos" or "MC_GearInVelocity" job	

Status indicators	
Tag	**Description**
<TO>.StatusSynchronizedMotion.ActualRatio-Denominator	Current denominator of the gear ratio of an active "MC_GearIn", "MC_GearInPos" or "MC_GearInVelocity" job
<TO>.Position	Setpoints of the axis
<TO>.Velocity	
<TO>.Acceleration	
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Position	Effective leading value including an additive leading value with an "MC_LeadingValueAdditive" job
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Velocity	
<TO>.StatusSynchronizedMotion.Effective-LeadingValue.Acceleration	
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Position	Following value of the synchronous operation function
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Velocity	
<TO>.StatusSynchronizedMotion.Function-FollowingValue.Acceleration	
<TO>.StatusSynchronizedMotion.StatusWord.X0 (MaxVelocityExceeded)	Set to the value "TRUE" when the maximum velocity configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X1 (MaxAccelerationExceeded)	Set to the value "TRUE" when the maximum acceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X2 (MaxDecelerationExceeded)	Set to the value "TRUE" when the maximum deceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusWord.X21 (Synchronizing)	Set to the value "TRUE" when the synchronous axis synchronizes to a leading value.
<TO>.StatusWord.X22 (Synchronous)	Set to the value "TRUE" when the synchronous axis is synchronized and moves synchronously to the leading axis.
<TO>.ErrorWord.X14 (SynchronousError)	Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.

Camming

9

With the Motion Control instruction "MC_CamIn (Page 323)", you start a camming operation between a leading axis and a following axis. You specify the synchronous operation function with a cam (Page 27). To use a cam for camming, the cam must be interpolated. The utilized cam can be scaled on a job-related basis and applied shifted.

You can start synchronous operation when the leading axis is at a standstill or when it is in motion. Synchronous travel begins after synchronization of the following axis.

Transfer function:
Following value = f(leading value)

Synchronization in advance

Subsequent synchronization

① Leading value distance with synchronization in advance

② Leading value distance with subsequent synchronization

You have the following options for camming with "MC_CamIn":

- Defining the synchronous operation function (Page 103)
- Interpolate cam with "MC_InterpolateCam" (Page 142)
- Scaling and shifting cam (Page 150)
- Scaling a cam range with "MC_SetCamRangeScaling" (Page 153)
- Defining application mode of the cam (Page 157)
- Defining direction of synchronization (Page 161)
- Define synchronous position and type of synchronization:
  - Synchronizing following axis in advance using dynamic parameters (Page 163)
  - Synchronizing following axis in advance using leading value distance (Page 164)
  - Synchronizing the following axis in advance via the leading value path from the current leading value position (Page 167)
  - Subsequent synchronizing of following axis using leading value distance (Page 171)
  - Subsequent synchronizing of following axis using leading axis value starting at current leading value position (Page 173)

  - Directly set the following axis synchronously (Page 175)
  - Directly set the following axis synchronously at end of the cam (Page 176)
- Synchronous travel in camming (Page 179)
- Reading a leading value with "MC_GetCamLeadingValue" (Page 179)
- Reading a following value with "MC_GetCamFollowingValue" (Page 181)
- Reading a following value cyclically with "MC_GetCamFollowingValueCyclic" (Page 182)
- Specify additive leading value with "MC_LeadingValueAdditive" (Page 205)
- Offset leading value absolute or relative with "MC_PhasingAbsolute" or "MC_PhasingRelative" (Page 183)
- Absolute or relative following value offset with "MC_OffsetAbsolute" or "MC_OffsetRelative" (Page 188)
- Changing synchronous operation function during Runtime (Page 137)
- Set camming to simulation mode with "MC_SynchronizedMotionSimulation" (Page 203)
- Desynchronize following axis with "MC_CamOut" (Page 193)
- Cancel a pending camming with "MC_CamOut" (Page 200)

Also note the dynamic limits of the following axis in camming with "MC_CamIn" (Page 159).

NOTE

Using "DB_ANY" data type with the cam technology object

In Motion Control instructions with technology version ≥ V6.0, direct assignment of the "DB_ANY" data type at the "Cam" parameter leads to an access error. Due to this access error, the CPU changes to the "STOP" state.

Use a data type conversion function for the cam technology object. A description of the procedure can be found in the section "Parameter transfer for function blocks" of the "S7-1500/S7-1500T Motion Control Overview documentation".

9.1 Configuring the synchronous operation function of the cam

9.1.1 Structure and operation of the cam editor

You configure a cam technology object (Page 27) using the cam editor.

You create the cam function using a chart a table containing the elements of the curve and the properties of the elements. Transitions are calculated between the individual elements of the curve (e.g. points, lines, polynomials). The curve reflects the path-related dependency between the leading axis (leading values, abscissa in the chart) and following axis (following values, ordinate in the chart).

The cam editor offers you the following support when creating a cam:

- Optimization of the curve form
- Generation of continuous and jerk-free transitions between curve elements
- Velocity-optimized design of the cam

The figure below shows the layout of the editor:

① Toolbar

② Curve diagram
The leading value range (definition range) is displayed on the abscissa (x axis).
The following value range (value range) is displayed on the ordinate (y axis).

①+② Graphical editor

③ Tabular editor

④ Inspector window (properties and display)

Toolbar

Use the toolbar to operate the graphical editor and import or export cams.

Graphical editor

In the graphical editor, you edit the elements of the curve graphically. The elements can be added, edited and deleted. Up to four charts can be created one above the other with synchronized abscissa. The setpoint curve as well as the curves for the effective position, velocity, acceleration and the jerk can be displayed in the charts.

The definition of the cam starts with the first defined interpolation point or the first segment and ends with the last interpolation point or the last segment. In contrast, the configurable display range of the leading value and the configurable value display range of the following value is used in the properties of the cam editor (Inspector window) only for display in the graphical editor.

Tabular editor

All elements of the curve are listed in the tabular editor. Existing elements can be edited or deleted. New elements can be added.

Inspector window

In the Inspector window, you configure the properties of the curve and of the selected element in the "Properties" tab. You configure the graphic view in the "Display" tab:

- Profile (e.g. leading and following value range, optimization and interpolation of the profile, number of elements used)
- Element (e.g. derivatives, polynomial coefficients, optimization of the element)
- Graphical view (e.g. line type, line color, scaling of the view)

Elements of the curve

The following table shows the elements that can be used to define the curve:

Element	Description
Point	A point assigns a following value to a leading value. Depending on the interpolation type, the curve runs through the point with these coordinates or only uses the point for orientation. The velocity, acceleration and jerk can be defined in this point using the first, second and third derivative.
Point group	A point group combines two or more points into an commonly interpolated element and allows precise interpolation between these points.
Line	A line describes a motion with constant velocity from the start point of the line to the end point. The incline of the line specifies the constant velocity.
Sine	A sine element describes a motion according to the sine function. The sine function can be adjusted with the phase angle in the start point and end point, the period length, the amplitude as well as the oscillation zero point (offset).
Polynomial	A polynomial describes a motion according to a polynomial function of the 7th degree maximum. Polynomials can be defined by entering the boundary conditions or the polynomial coefficients. Optionally, you can configure a trigonometric polynomial component.
Inverse sine (approximated)	An inverse sine describes a motion according to the arcsine function. An inverse sine is approximated using interpolation points of the arcsine function.
Transition	Transitions interpolate the range between two elements. The ranges are automatically interpolated by the controller or using a configurable optimization according to VDI Guideline 2143. Transitions are added automatically.

9.1.1.1 Structure of the graphical editor

The graphical editor is divided into the following areas:

- Toolbar
- Curve diagram

Toolbar

The toolbar at the top of the graphical editor provides you with icons for the following functions:

Symbol	Function	Description
	Importing cam from file	See section "Importing a cam (Page 136)"
	Exporting cam to file	See section "Exporting a cam (Page 135)"
	Edit elements/Move view	• Selecting and moving of individual elements • Moving the view using the drag-and-drop feature To switch from any tool to the "Edit elements/Move view" tool, press the <Esc> key.
	Activate zoom selection	Zoom into selected area
	Activate vertical zoom	Vertical zoom into selected area without horizontal scaling Alternative: <Ctrl> +drag to ordinate keeping mouse button pressed
	Activate horizontal zoom	Horizontal zoom into selected area without vertical scaling Alternative: <Ctrl> +drag to abscissa keeping mouse button pressed
	Zoom in	Enlargement of the display Alternative: <Ctrl> + mouse wheel up in curve diagram
	Zoom out	Reduction of the display Alternative: <Ctrl> + mouse wheel down in curve diagram
	Show all	Display of entire definition and value range
	Zoom into curve	Zoom to the following value range of the curve that you selected in the legend of the chart
	Activate snap grid	Alignment of inputs and element end points to the configurable snap grid and to other element end points
	Inserting a point	Adding a point to the chart
	Inserting a line	Adding a line to the chart
	Inserting a sine	Adding a sine element to the chart
	Inserting a polynomial	Adding a polynomial to the chart
	Inserting an inverse sine	Adding an inverse sine to the chart
	Insert point group	Add a point group to the chart
	View: A chart with positions	Display of one chart with the following curves of the cam opened in the editor: • Preset curve • Effective position

Symbol	Function	Description
	View: A chart with all curves	Display of one chart with the following curves of the cam opened in the editor: • Preset curve • Effective position • Effective velocity • Effective acceleration • Effective jerk
	View: Four charts with all curves	Display of four charts with the following curves of the cam opened in the editor: • Chart with setpoint curve and effective position • Chart with effective velocity • Chart with effective acceleration • Chart with effective jerk
	Vertical measuring lines	Displaying and moving of vertical measuring lines Hold down the left mouse button and drag to draw a measuring range. The vertical position of the measuring lines can be moved. The function values for the measuring line positions are displayed in the chart. The difference of the measuring lines is displayed between the measuring lines.
	Horizontal measuring lines	Displaying and moving of horizontal measuring lines Hold down the left mouse button and drag to draw a measuring range. The horizontal position of the measuring lines can be moved. The function values for the measuring line positions are displayed in the chart. The difference of the measuring lines is displayed between the measuring lines.
	Show legend	Showing or hiding of the legend in the curve diagram. To display values for a specific curve on the ordinate, click on the name of the corresponding curve in the legend.
	Read out and display online curve one time	Display of the position values of the cam read back from the CPU (orange) The cam editor reads out the cam that was already loaded into the CPU. The read out "Online curve" is displayed in the graphical editor.

Curve diagram

In the curve diagram, you enter the elements of the curve and adjust the curve by selecting and moving elements.

Chart areas outside the leading value or following value range configured in "Profile > General (Page 112)" are grayed out. Elements outside the leading or following value range are displayed with a warning ("Element is outside the definition range").

You can display various curves (position, velocity, acceleration and jerk) one above the other in up to four charts by configuring the graphical view accordingly. When multiple charts are displayed, you can adapt the graphs to match the separator lines.

You can zoom the view in manual mode using "<Ctrl> + mouse wheel" and "<Ctrl> + drag with mouse button pressed" on the abscissa or ordinate.

The editor shows messages for checking the entered curve via warning triangles . The tooltip of the waring triangle shows the message text. Configure the checking of the curve in the "Check (Page 115)" configuration window.

Display of the online curve

When you click the icon , the cam editor reads the data from the technology object data block and displays the curve in the graphical editor:

Cam status	Interpolation status	Description
Data not modified (CamDataChanged = 0)	Not interpolated (Interpolated = 0)	Only the points and segments of the cam are displayed.
	Interpolated (Interpolated = 1)	The interpolated cam is displayed.
Data modified (CamDataChanged = 1)	Not interpolated (Interpolated = 0)	Only the points and segments of the cam are displayed.
	Interpolated (Interpolated = 1)	The interpolated cam as well as changed points and segments are displayed.

9.1.1.2 Shortcut menu in the graphical editor

Use the shortcut menu in the graphical editor to call up the following functions:

Function	Description
Show all	Displaying the entire definition range and value range
Zoom into curve	Displaying the curve selected in the legend of the chart
Zoom in	Enlargement of the display
Zoom out	Reduction of the display
Open charts and curves	Opening of the "Charts and curves (Page 116)" dialog
Cut	Removing the selected elements and copying them to the clipboard
Copy	Copying of the selected elements to the clipboard
Insert	Pasting of the elements from the clipboard to the last element
Delete	Deletion of the selected elements Transitions to existing elements are also deleted.
Insert special	Open the "Insert elements (Page 129)" dialog
Group points	Combine the selected points into a group of points The entry is displayed under the following conditions: • Only points are selected in the graphic or tabular editor. • There are no other elements between the selected points.
Dissolve point group	Ungrouping the selected point group into individual points
Show/hide measuring point labels	Showing or hiding the measuring points The entry is displayed under the following conditions: • Measuring lines are displayed. • Measuring points are hidden or displayed.
Move	Open the "Move elements (Page 130)" dialog
Scale	Open the "Scale elements (Page 131)" dialog

9.1.1.3 Structure of the tabular editor

The tabular editor shows all elements of the curve, sorted by their leading values. The elements can be adjusted. New elements can be added.

The following properties are displayed in the corresponding column for each element of the curve:

Column/Property	Description
First column	Sequential number of the element
Second column	Display of calculation problems that might occur with warning triangle ⚠ The alarm text is displayed in the tooltip of the warning triangle.
Element type	• Display or change the element type • Adding elements Possible element types: • Point • Point group • Line • Sine • Polynomial • Inverse sine • Transition
Start	Parameter values at start point of the element
Leading value	Leading values at start point of the element
Following value	Following values at start point of the element
Position[1)]	Calculated effective position at start point of the element
Velocity[1)]	Calculated effective velocity at start point of the element
Acceleration[1)]	Calculated effective acceleration at start point of the element
Jerk[1)]	Calculated effective jerk at start point of the element
End	Parameter values at end point of the element
Leading value	Leading values at end point of the element
Following value	Following values at end point of the element
Position[1)]	Calculated effective position at end point of the element
Velocity[1)]	Calculated effective velocity at end point of the element
Acceleration[1)]	Calculated effective acceleration at end point of the element
Jerk[1)]	Calculated effective jerk at end point of the element
Comment	Optional comment for element.

1) Displayed according to the configuration in "Properties (Inspector window) > Graphical view > Charts and curves".

9.1.1.4 Shortcut menu in the tabular editor

Use the shortcut menu in the tabular editor to call up the following functions:

Function	Description
Insert row above	Insert a table row or element before the selected row or element If no transition exists before the element, the selected element and the adjoining elements are changed.
Insert row below	Insert a table row or element after the selected row or element If no transition exists after the element, the selected element and the adjoining elements are changed.
Cut	Removing the selected elements and copying them to the clipboard
Copy	Copying of the selected elements to the clipboard
Insert	Pasting of the elements from the clipboard to the last element
Delete	Deletion of the selected elements Transitions to existing elements are also deleted.
Insert special	Open the "Insert elements (Page 129)" dialog
Group points	Combine the selected points into a group of points The entry is displayed under the following conditions: • Only points are selected in the graphic or tabular editor. • There are no other elements between the selected points.
Dissolve point group	Ungroups the selected point group into individual points
Move	Open the "Move elements (Page 130)" dialog
Scale	Open the "Scale elements (Page 131)" dialog

9.1.1.5 Operating the cam editor

The procedure described here shows the basic operation of the cam editor. This procedure serves as a recommendation.

The basic operation can include the follow tasks:

- Adapting defaults
- Creating and adapting the curve
- Set interpolation and optimization of transitions (Page 147)

Adapting defaults

To adjust the leading and following value range of the cam profile as well as the graphical view, follow these steps:

1. In the properties (Inspector window), open the "Profile > General (Page 112)" configuration window.
2. Configure the leading value range and the following value range of the curve definition.

   The graphical view is automatically adapted to the inputs.

3. In the area navigation of the Inspector window, open the "Display (Page 112)" tab.
4. Configure the following configuration windows:
   - The display of the charts and curves
   - The grid spacing for aligning inputs in the graphical editor
   - The decimal places displayed in the cam editor.

Creating and adapting the curve

To create and adapt the curve, follow these steps:

1. Use the graphical editor and/or the tabular editor to add the elements of the cam:
   - On the toolbar, click the icon for inserting the corresponding element. Place the element at the required position in the graphical editor.
   - Use <Add> to insert the corresponding elements in the "Element type" column of the tabular editor. Adjust the position of the elements using the start and end values.

   Transitions between the elements are added automatically.
2. To edit an element, select it in the graphical or tabular editor.

   The element is highlighted in the graphical and in the tabular editor. The "Element > Parameter" configuration window is displayed in the properties (Inspector window), or in case of a transition, "Element > Characteristic".
3. The elements can be adjusted as follows:
   - Move the element or the drag handles of the element in the graphical editor.
   - Adjust the start and end values in the tabular editor.
   - Configure additional element-specific parameters in the properties (Inspector window) in the "Element > Parameter" configuration window.
   - Set the interpolation of the transitions with the properties (Inspector window).

The number of elements used is displayed in the properties (Inspector window) in the "Profile > Statistics (Page 131)" properties window.

See also

System interpolation (Page 144)
Configuring transitions (Page 142)
Configuration charts - Charts and curves (Page 116)
Interpolate cam with "MC_InterpolateCam" (Page 150)

9.1.2 Configure the profile and display of the cam

9.1.2.1 Properties and display in the inspector window

You configure further element-specific parameters in the inspector window in the following tabs:

- The parameters for the profile of the cam as well as for the elements are displayed in the "properties" tab. The corresponding parameters are displayed depending on the selected element:
  - If no element of the curve is selected, only the settings for the profile of the cam are displayed.
  - If an element of the curve is selected, the parameters of the element are additionally displayed.
- In the "Display" tab you can configure the graphic view of the charts and curves.

9.1.2.2 Configuration of profile - General

Configure the display range of the graphical editor in the "General" configuration window.

The entries for the leading and following value range only affect the display in the graphical editor. The cam is interpolated in the definition range between the following values:

- First defined interpolation point or start of the first segment of the cam (<TO>.StatusCam.StartLeadingValue)
- Last defined interpolation point or end of the last segment of the cam (<TO>.StatusCam.EndLeadingValue)

Scope of validity of the leading value

In this area, configure the scope of validity of the leading value in the graphical editor:

Parameters	Description
Start	In this field, configure the lowest permissible value for the scope of validity of the leading value.
End	In this field, configure the highest permissible value for the scope of validity of the leading value.

Following value display range

In this area, you can configure the limitation of the following value range in the graphical editor:

Parameters	Description
Minimum	In this field you configure the lowest permissible value for the following value display range.
Maximum	In this field you configure the greatest permissible value for the following value display range.

9.1.2.3 Configuration of profile - Effective runtime curves

In the configuration window "Effective Runtime curves > General settings", configure the values for the leading and following axes that are applied for the effective curve. The Runtime emulation calculates the effective curve with these applied values and displays this in the graphical editor with the applied limits.

The inputs are not downloaded into the CPU. This means the cam is interpolated without these inputs. You can use these applied values to test and visualize how the cam behaves during operation, for example, when entering a scaling at an "MC_CamIn" job.

If you use the cam for the positioning job with time-based position profile with an "MC_PositionProfile" job, you can optionally select the "Use cam as time-based position profile" check box. The configured cam is not changed by this. The specifications for position range and time value range in the configuration of the technology object only affect the display in the graphical editor. You can find a description of this function in the "Moving an axis relatively or absolutely with a time-based position profile" section in the "S7-1500/S7-1500T Axis functions" documentation.

Settings of the leading axis

Configure the calculation and display of the curve on the leading value end in this area:

Parameters	Description
Use cam as time-based position profile	Select the check box if you use the cam for the positioning job with time-based position profile. The unit of measure is automatically set to seconds. The other configuration parameters of the leading axis are grayed out. The inputs are not downloaded into the CPU. Activation is optional and is not necessary to perform the "MC_PositionProfile" job.
Copy from axis	Using the button and the "Copy leading value settings of axis" dialog, select an axis whose maximum velocity is applied as the velocity for the leading axis.
Scaling factor	Configure a leading value-side scaling factor in this field. This visualizes a scaled curve. You enter a scaling during runtime with an "MC_CamIn" job.
Unit of measure	In the selection list, select the unit of measure for the leading value. If the "Use cam as time-based position profile" check box is selected, the unit of measure is automatically set to seconds.
Unit of measure for the first derivative	In the selection list, select the unit of measure for the first derivative of the leading value.
Velocity	Configure the velocity of the leading axis applied for the Runtime emulation of the curve in this field.

Settings of the following axis

Configure the calculation and display of the curve on the following value side in this area:

Parameters	Description
Copy from axis	Using the button and the "Copy following value settings of axis" dialog, select an axis whose maximum dynamic values are applied as the limits to be checked during calculation and display of the curve.
Scaling factor	Configure a following value-side scaling factor in this field. This visualizes a scaled curve. You enter a scaling during runtime with an "MC_CamIn" job.
Unit of measure	In the selection list, select the unit of measure for the following value.
Unit of measure for the first derivative	In the selection list, select the unit of measure for the first derivative of the following value.
Maximum velocity	Configure the maximum velocity for the following axis in this field.
Maximum acceleration	Configure the maximum acceleration for the following axis in this field.
Maximum jerk	Configure the maximum jerk for the following axis in this field.

9.1.2.4 Profile configuration - Range scaling

In the "Effective Runtime curves > Range scaling" configuration window, configure the values for up to two scaling ranges that are applied for the effective curve. The Runtime emulation calculates the effective curve with these applied values and displays this in the graphical editor with the applied limits.

The inputs are not downloaded into the CPU. This means the cam is interpolated without these inputs. The applied values can be used to test and visualize how the cam behaves during operation when you scale a range with a "MC_SetCamRangeScaling (Page 360)" job. To make it easier to call up the Motion Control instruction, you can use the "Copy SCL code" button to copy the tested values as program code snippets to the clipboard.

Scaling range 1 and 2

Configure the calculation and display of the curve with the scaling ranges 1 and 2 in these areas:

Parameters	Description
Scaling mode	In the selection list, select whether the scaling range refers to the leading value range or the following value range. If you select the value "No scaling", the corresponding scaling range is not simulated.
Start point	Configure the start value of the scaling range in this field. Start point ≤ End point
End point	Configure the end value of the scaling range in this field. Start point ≤ End point
Scaling factor	Configure the scaling factor of the scaling range in this field.
Copy SCL code	Use this button to copy the configuration values as program code snippets in SCL to the clipboard.

The configured scaling ranges are indicated by markers at the edge of the graphical editor. The scaling factor is displayed in the tooltip of the area selection. If the scaling ranges overlap, the effective scaling factor is displayed.

See also

Scaling a cam range (Page 153)

9.1.2.5 Configuration of profile - Check

In the "Check" configuration window, you configure which criteria the cam editor checks when entering the curve. When you activate a check, the graphical and the tabular editor display corresponding messages via a warning triangle on the element. Use the tooltip at the warning triangle to display the message text.

NOTE

Use the checking options for the final check of the cam and enable all checks before completing the cam. If necessary, make adjustments to the cam profile.

Checking of limit violations

Configure the checks for compliance with the configured limits in this area:

Check/Element	Description
Check curve definition of the leading and following value ranges	Select this check box to have the cam editor check the curve accordingly.
Check adherence to the maximum values of the derivatives of the effective runtime curve	Select this check box to have the cam editor check the curve accordingly.

Verification of VDI suitability

Select the "Check the suitability of transitions in accordance with VDI" check box to have the cam editor check the VDI suitability of the curve.

The cam editor checks the following with this:

- Support of the transition classification of the currently selected VDI transition
- Boundary value adjustment according to VDI

Verification of continuity

In the "Required continuity" list, select which parameter the cam editor checks for continuity:

- Position
- Velocity
- Acceleration
- Jerk

If a function or a derivative is discontinuous, all higher derivatives are also discontinuous.

9.1.2.6 Configuration charts - Charts and curves

In the "Charts and curves" configuration window, configure the display of the graphical editor.

"Reset to defaults" button

Use this button to reset all settings of the view of charts and curves to the default settings.

Configuration table

Configure the display of the graphical editor in the table:

Column	Description
Show	Show or hide charts 1 to 4
Visible	Show or hide curves in the chart You can show or hide online curves already offline. The curve becomes visible when you have shown the curve, established an online connection and read out the online curve.
Name	Name of chart or curve New curves can be added. Existing curves can be removed. Curves of other cams can also be displayed. The name of the other cam is also displayed in the table and in the legend of the chart. A curve can be inserted multiple times in a chart, e.g. in order to display it with different scalings.
Color	Line color of the curve
Line type	Line type of the curve
Offset of the leading values[1)]	Movement of the curve on the abscissa
Multiplier for leading values[1)]	Scaling of abscissa
Offset of the following values[1)]	Movement of the curve on the ordinate
Multiplier for following values[1)]	Scaling of ordinate

1) Only affects the display of the curve in the chart. You specify the scaling and shifting of the cam during camming in the Motion Control instruction "MC_CamIn".

9.1.2.7 Configuration charts - Snap grid

In the "Snap grid" configuration window, you configure the grid spacing for aligning inputs to the grid in the graphical editor. When "Snap" is activated, inputs and element end points are aligned to this grid and to other element end points.

Snap grid spacing

In this area, configure the grid spacing of the snap grid:

Parameter	Description
Grid spacing leading value	Configure the grid spacing on the abscissa (leading values) in this field.
Grid spacing following value	Configure the grid spacing on the ordinate (following values) in this field.

9.1.2.8 Configuration - Decimal places

In the "Decimal places" configuration window, you configure how many decimal places are used to represent the values in the graphical and tabular editor as well as in the configuration windows. The values are rounded in the displays. The settings do not affect the calculation of the curves. The curves are calculated with higher accuracy regardless of the settings.

Displayed decimal places

In this area, configure the displayed decimal places:

Parameter	Description
Tabular editor and configuration window	In this field, configure the number of decimal places for displaying values in the tabular editor and in the configuration windows.
Graphical editor	In this field, configure the number of decimal places for displaying values in the graphical editor.

9.1.3 Inserting and configuring cam elements

9.1.3.1 Inserting and configuring a point

A point assigns a following value to a leading value. The curve runs through the point with these coordinates.

By means of the first, second and third derivatives, the velocity, acceleration and jerk can be defined in this point. The derivative are only taken into consideration during VDI-based optimization of transitions of the point to other elements.

Inserting a point

To add a point to the curve, follow these steps:

1. On the toolbar, click the icon "Insert point".
2. In Chart 1, click on the desired position.
   The point is inserted. The coordinates are displayed for the point. The tabular editor and the view of the properties (Inspector window) are updated. A transition to any element is inserted automatically.

Moving a point

To move a point in the graphical editor, follow these steps:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the point in chart 1.
3. Use the drag-and-drop feature to move the point to the desired position.

Adapting parameters

The parameters of the point can be adjusted in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected point in this area:

Parameter/Option	Description
Leading value of the point	
Leading value	In this field, configure the leading value of the point (value in the definition area).
Following values of the point	
Following value	Configure the following value of the point (value in the range of the function) in this field.
Use first derivative	By selecting the check box, you can specify the first derivative at the selected point and include it in the interpolation of the cam.
First derivative	Configure the value of the first derivative in the selected point in this field.

Parameter/Option	Description
Use second derivative	By selecting the check box, you can specify the second derivative at the selected point and include it in the interpolation of the cam.
Second derivative	Configure the value of the second derivative in the selected point in this field.
Use third derivative	By selecting the check box, you can specify the third derivative at the selected point and include it in the interpolation of the cam.
Third derivative	Configure the value of the third derivative in the selected point in this field.

The derivative are only taken into consideration during VDI-based optimization of transitions of the point to other elements.

9.1.3.2 Inserting and configuring a point group

A point group combines two or more points into a commonly interpolated element and allows precise interpolation between the points.

Insert point group

To add a point group to the curve, proceed as follows:

1. On the toolbar, click the icon "Insert point group".
2. In Chart 1, click on the desired position at which you want to insert the point group. The point group is inserted. The coordinates of the start point and the end point are displayed at the point group. The tabular editor and the view of the properties (Inspector window) are updated. If a different element already exists, a transition to the existing element is automatically inserted.

Adapt point group

To adapt a point group in the graphical editor, proceed as follows:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the point group in chart 1.

   The point group is highlighted graphically with drag handles. The following drag handles are displayed:

   – Start point of the point group
   – End point of the point group

3. Use the drag-and-drop feature to move the handles or the whole point group to the desired position.

   If further interpolation points are configured between the start point and the end point in the point group, the cam editor handles the interpolation points as follows:

   – Definition type of the leading value "Relative to segment"

     The interpolation points are shifted relative to the start and end points.

   – Definition type of the leading value "Absolute in the profile"

     The interpolation points are not moved.

Adapting parameters

You can adjust the parameters of the point group in the graphical editor, in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected point group in this area:

Parameter/Option	Description
Leading values of the point group	
Start	In this field, configure the start point of the point group in the leading value range (definition area).
End	In this field, configure the end point of the point group in the leading value area (definition area).
Interpolation points	
Definition type of the leading values	In the drop-down list, select how the leading values of the interpolation points are specified: • Relative to segment You specify the leading values of the interpolation points relative to the group of points from 0.0 to 1.0. The value 0.0 corresponds to the beginning of the point group. The value 1.0 corresponds to the end of the point group. • Absolute in the profile You specify the leading values of the interpolation points as absolute values.
Definition type of the following values	In the drop-down list, select how the following values of the interpolation points are specified: • Relative to segment You specify the following values of the interpolation points relative to the following value range of the point group from 0.0 to 1.0. The value 0.0 corresponds to the configured minimum following value of the point group. The value 1.0 corresponds to the configured maximum following value of the point group. • Absolute in the profile You specify the following values of the interpolation points as absolute values.
Minimum following value	In this field, configure the minimum following value for the point group in the following value range.
Maximum following value	In this field, configure the maximum following value of the point group in the following value range (value range).

Parameter/Option	Description
	Use this "Insert interpolation point" icon to add an interpolation point to the point group.
Interpolation points	This table shows the configured interpolation points sorted by increasing leading value. Add interpolation points using the icon. Delete interpolation points by marking a row and pressing the <Delete> key. If you delete all points except one, the element type is changed from "Point group" to "Point".
Leading value	In this field, configure the leading value of the interpolation point (value in the definition area).
Following value	In this field, configure the following value of the interpolation point (value in the value range).
Interpolation	
Interpolation type	In the drop-down list, select the interpolation type to be used for interpolating the point group: • Interpolation with cubic splines • Interpolation with Bézier splines
Approximation	
Mapping method	Select the mapping method in the drop-down list: • Point approximation • Segment approximation
Number of interpolation points	Configure the number of interpolation points for the point approximation in this field.
Maximum following value tolerance	In this field, enter the maximum permissible deviation (absolute) of the approximation from the interpolation points. If the configured value is exceeded, a warning is displayed in the graphical editor at the point group.

9.1.3.3 Inserting and configuring the line

A line describes a motion with constant velocity from the start point to the end point of the line. The incline of the line specifies the constant velocity.

Inserting a line

To add a line to the curve, follow these steps:

1. On the toolbar, click the icon "Insert line".
2. Use the drag-and-drop feature in chart 1 to draw the line from the start position to the end position.
   The straight line is inserted. The coordinates of the start point and end point are displayed for the line. The tabular editor and the view of the properties (Inspector window) are updated. A transition to any element is inserted automatically.

Moving a line

To move a line in the graphical editor, follow these steps:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the line in chart 1.

   The line is graphically highlighted with drag handles. The following drag handles are displayed:

   – Start point of the line
   – End point of the line
3. Use the drag-and-drop feature to move the handles or the entire line to the desired position.

Adapting parameters

The parameters of the line can be adjusted in the graphical editor, in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected line in this area:

Parameters	Description
Leading values of the line	
Start	Configure the start point of the line in the leading value range (definition range) in this field.
End	Configure the end point of the line in the leading value range (definition range) in this field.
Following values of the line	
Definition by	In the selection list, select the parameters to be used to define the line: • Following values at start and end • Following value at the start and incline • Incline and following value at end The corresponding parameters are displayed based on the selection.
Start	Configure the start point of the line in the following value range (value range) in this field.
End	Configure the end point of the line in the following value range (value range) in this field.
Incline	Configure the incline of the line in this field.

9.1.3.4 Inserting and configuring a sine

A sine element describes a motion according to the sine function. The sine function can be adjusted with the phase angle in the start point and end point, the period length, the amplitude as well as the oscillation zero point (offset).

Inserting a sine

To add a sine to the curve, follow these steps:

1. On the toolbar, click the icon "Insert sine".
2. In Chart 1, click on the position desired position. The mouse pointer points to the start position of the sine here.

   The sine is inserted. The coordinates of the start point and end point are displayed for the sine. The tabular editor and the view of the properties (Inspector window) are updated. A transition to any element is inserted automatically.

Adjusting a sine

To adjust a sine in the graphical editor, follow these steps:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the sine in chart 1.

   The sine is graphically highlighted with drag handles and guide lines for the zero line and the amplitude. The following drag handles are displayed:

   – Leading value or offset at the left or right edge

     These drag handles can also be used to adjust the inclination of an inclined sine.

   – Leading value at the left or right edge
   – Phase on the left or right edge
   – Amplitude
3. Use the drag-and-drop feature to move the handles or the entire sine to the desired position.

Adapting parameters

The parameters of the sine can be adjusted in the graphical editor, in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected sine element in this area:

Parameters	Description
Leading values of the sine	
Start	Configure the start point of the sine element in the leading value range (definition range) in this field.
End	Configure the end point of the sine element in the leading value range (definition range) in this field.

Parameters	Description
Trigonometric parameters	
Amplitude	Configure the amplitude of the sine element in this field.
Definition by	In the drop-down list, select how the sine element is defined: • Phase at start and at end • Phase at start and period length • Phase at start and frequency • Period length and phase at end • Frequency and phase at end The corresponding parameters are displayed based on the selection.
Phase angle at start	Configure the phase angle at the start of the sine element in this field.
Phase angle at end	Configure the phase angle at the end of the sine element in this field.
Period length	Configure the period length of the sine element in this field.
Frequency	Configure the frequency of the sine element in this field.
Extended parameters	
Segment type	Select the variant of the sine element in the drop-down list. • Sine • Inclined sine If you have configured an inclined sine, additional orientation lines are displayed in the graphical editor for the amplitude and center position. The corresponding parameters are displayed based on the selection.
Offset	Configure the oscillation midpoint of the sine element in this field.
Definition of inclination as a function of:	In the drop-down list, select how the inclined sine element is defined: • Offset at start and end • Offset at start and inclination • Inclination and offset at end The corresponding parameters are displayed based on the selection.
Offset at start	Configure the center of oscillation at the start of the sine element in this field.
Offset at end	Configure the center of oscillation at the end of the sine element in this field.
Inclination	Configure the inclination of the sine element in this field.

9.1.3.5 Inserting and configuring a polynomial

A polynomial describes a motion according to a polynomial function of the 7th degree maximum. Polynomials can be defined by entering the boundary conditions or the polynomial coefficients. Optionally, you can configure a trigonometric polynomial component.

Inserting a polynomial

To add a polynomial to the curve, follow these steps:

1. On the toolbar, click the icon "Insert polynomial".
2. In Chart 1, click on the position desired position. In so doing, the mouse pointer points to the start position of the polynomial.

   The polynomial is inserted. The coordinates of the start point and end point are displayed for the polynomial. The tabular editor and the view of the properties (Inspector window) are updated. If a different element already exists, a transition to the existing element is automatically inserted.

Adjusting a polynomial

To adjust a polynomial in the graphical editor, follow these steps:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the polynomial in chart 1.

   The polynomial is graphically highlighted with drag handles. The following drag handles are displayed:

   – Leading value and following value on the left or right edge
   – Position of point of inflection (lambda: relative to the element or absolute in the profile)
3. Use the drag-and-drop feature to moves sizing handles or the entire polynomial to the required position.

Adapting parameters

You can adjust the parameters of the polynomial in the graphical editor, in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected polynomial in this area:

Parameters	Description
Leading values of the polynomial	
Start	Configure the start point of the polynomial in the leading value range (definition range) in this field.
End	Configure the end point of the polynomial in the leading value range (definition range) in this field.

Parameters	Description
Polynomial parameters	
Definition by	In the selection list, select how the polynomial is defined: • Coefficients • Boundary values The corresponding parameters are displayed based on the selection.
Coefficients	Configure the coefficients of the 6th degree polynomial function in these fields: $P(x) = a_6x^6 + a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0$ The coefficients are shown in scientific notation, e.g. "9.6450617283e-11".
Following value - Left boundary value	Configure the following value at the start of the polynomial in this field.
Following value - Right boundary value	Configure the following value at the end of the polynomial in this field.
Use first derivative	Select the check boxes to specify the first derivative (speed) in the left or right boundary value of the polynomial and include it in the interpolation of the cam.
First derivative - left boundary value	Configure the first derivative (velocity) for the following value at the start of the polynomial in this field.
First derivative - right boundary value	Configure the first derivative (velocity) for the following value at the end of the polynomial in this field.
Use second derivative	Select the check boxes to specify the second derivative (acceleration) in the left or right boundary value of the polynomial and include it in the interpolation of the cam.
Second derivative - left boundary value	Configure the second derivative (acceleration) for the following value at the start of the polynomial in this field.
Second derivative - right boundary value	Configure the second derivative (acceleration) for the following value at the end of the polynomial in this field.
Use third derivative	Select the check boxes to specify the third derivative (jerk) in the left or right boundary value of the polynomial and include it in the interpolation of the cam.
Third derivative - left boundary value	Configure the third derivative (jerk) for the following value at the start of the polynomial in this field.
Third derivative - right boundary value	Configure the third derivative (jerk) for the following value at the end of the polynomial in this field.
Lambda	In the selection list, select how the turning point of the polynomial is specified in the "Lambda position" field: • No lambda Do not enter any value. The position of the point of inflection is calculated automatically. • Relative to the element You specify the leading value of the turning point relative to the polynomial from 0.0 to 1.0. The value 0.0 corresponds to the beginning of the polynomial. The value 1.0 corresponds to the end of the polynomial. • Absolute in the profile You specify the leading value of the point of inflection as an absolute value.
	In this field, configure the leading value of the point of inflection for the polynomial according to the selection in the selection list.

Parameters	Description
Extended parameters	
Segment type	In the selection list, select whether or not the polynomial is to have a trigonometric component. When "Polynomial with trigonometric portion" is selected, the corresponding trigonometric parameters are displayed, as they are with sine. When a sine element is converted to a polynomial, the sine element is configured as a polynomial with trigonometric portion. The shape of the element is retained. You have the option to define the trigonometric portion of the polynomial using the following formula: $Y(x) = a_6x^6 + a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 + b_0\sin((b_1x) + b_2)$ $a_{0...6}$: Coefficient of order 0 to 6 of the polynomial b_0: Amplitude of the trigonometric portion b_1: Period of the trigonometric portion b_2: Phase offset of the trigonometric portion
Amplitude	Configure the amplitude of the trigonometric component in this field.
Definition by	In the selection list, select how the trigonometric component is defined: • Phase at start and at end • Phase at start and period length • Phase at start and frequency • Period length and phase at end • Frequency and phase at end The corresponding parameters are displayed based on the selection.
Phase angle at start	Configure the phase angle at the start of the trigonometric component in this field.
Phase angle at end	Configure the phase angle at the end of the trigonometric component in this field.
Period length	Configure the period length of the trigonometric component in this field.
Frequency	Configure the frequency of the trigonometric component in this field.

9.1.3.6 Inserting and configuring an inverse sine

An inverse sine describes a motion according to the arcsine function. The arcsine function is the inverse function of the sine function. An inverse sine is approximated using interpolation points of the arcsine function.

The inverse sine is defined within the definition range [-1, 1]. The inverse sine can be calculated for the entire definition range or a restricted definition range of the arcsine function.

Inserting an inverse sine

To add an inverse sine to the curve, follow these steps:

1. On the toolbar, click the icon "Insert inverse sine".
2. In Chart 1, click on the position desired position. In so doing, the mouse pointer points to the start position of the inverse sine.

   The sine is inserted. The coordinates are displayed for the point. The tabular editor and the view of the properties (Inspector window) are updated. A transition to any element is inserted automatically.

Adjusting an inverse sine

To adjust an inverse sine in the graphical editor, follow these steps:

1. On the toolbar, click the icon "Edit elements/Move view".
2. Select the inverse sine in chart 1.

   The inverse sine is graphically highlighted with drag handles. The following drag handles are displayed:

   – Start point of the inverse sine
   – End point of the inverse sine
3. Use the drag-and-drop feature to move the handles or the entire inverse sine to the desired position.

Adapting parameters

The parameters of the inverse sine can be adjusted in the graphical editor, in the tabular editor as well as in the inspector window under "Properties > Element > Parameter".

Configure the parameters of the selected inverse sine in this area:

Parameters	Description
Leading values of the inverse sine	
Start	Configure the start point of the inverse sine in the leading value range (definition range) in this field.
End	Configure the end point of the inverse sine in the leading value range (definition range) in this field.

Parameters		Description
Following values of the inverse sine		
	Minimum	Configure the minimum value of the inverse sine in the following value range (value range) in this field.
	Maximum	Configure the maximum value of the inverse sine in the following value range (value range) in this field.
Definition range		
	Not mirrored/mirrored	Select whether or not the inverse sine is to be mirrored about the abscissa.
	Start	Configure the start point in the definition range of the arcsine function that is to be used in this field.
	End	Configure the end point in the definition range of the arcsine function that is to be used in this field.
Approximation		
	Number of interpolation points	Configure the number of interpolation points for the approximation in this field.
	Maximum following value tolerance	In this field, specify the maximum permitted deviation (absolute) of the approximation from the arcsine function. If the configured value is exceeded, a warning is displayed in the graphical editor for the arcsine element.

9.1.3.7 Inserting elements from the clipboard

You can paste copied elements in both the graphical and the tabular editor. Independent of the cam type, you can also paste copied elements from other cams. Observe the maximum number of interpolation points and segments depending on the cam type (Page 27).

Insert element after the last element

To insert an element from the clipboard after the last element, follow these steps:

1. Open the shortcut menu in graphic or tabular editor.
2. Select "Insert" from the shortcut menu entry.
   The element from the clipboard is inserted after the last element.

Insert element using insert mode

To insert an element from the clipboard using a selected insert mode, follow these steps:

1. If necessary, select the elements to be overwritten.
2. Open the shortcut menu in graphic or tabular editor.
3. Select the "Insert special" entry from the shortcut menu.
   The "Insert elements" dialog opens.

4. In the "Insert mode" selection list, select the desired insert mode:

Insert mode	Description
Overwrite from the end to the left	You overwrite the selected elements with the elements from the clipboard starting from the end in the direction of smaller leading values. The end of the inserted elements then lies at the end of the selected elements. Elements that are located in the leading value range of the elements in the clipboard are overwritten or truncated.
Overwrite from the start to the right	You overwrite the selected elements with the elements from the clipboard starting from the start in the direction of bigger leading values. The start of the inserted elements then lies at the start of the selected elements. Elements that are located in the leading value range of the elements in the clipboard are overwritten or truncated.
Overwrite from the middle	Starting from the center, you overwrite the selected elements with the elements from the clipboard. The center of the inserted elements then lies at the center of the selected elements. Elements that are located in the leading value range of the elements in the clipboard are overwritten or truncated.
Scale selection to the leading value range	The elements in the clipboard are scaled to the leading value range of selected elements. The start and end of the inserted elements then lie at the start and end of the selected elements.
Apply leading values from the clipboard	The elements in the clipboard are inserted with the leading values at the start and end. Elements that are located in the leading value range of the elements in the clipboard are overwritten or truncated.

5. Click "OK".

   The element from the clipboard is inserted using the selected insert mode.

9.1.3.8 Move elements

To move an element, follow these steps:

1. In the graphical or tabular editor, open the shortcut menu of the element that is to be moved.
2. Select the "Move" shortcut menu entry.

   The "Move elements" dialog opens.
3. In the "Horizontal distance" field, enter the shift of the selection on the abscissa (x-axis).
4. In the "Vertical distance" field, enter the shift of the selection on the ordinate (y-axis).
5. Click "OK".

   The element is moved the entered distance.

9.1.3.9 Scale elements

To scale an element, follow these steps:

1. In the graphical or tabular editor, open the shortcut menu of the element that is to be scaled.
2. Select the "Scale" shortcut menu entry.

   The "Scale elements" dialog opens.
3. In the "Leading value range" field, enter the scaling length (leading value side) to which you want to scale the selection.
4. Select the direction of scaling in the "Anchor point" selection list:

Direction	Description
Links	The selection is adjusted by the left boundary point to the scaling length.
Center	The selection is adjusted by the center point to the scaling length.
Right	The selection is adjusted by the right boundary point to the scaling length.

5. Click "OK".

   The element is scaled using the selected parameter values.

9.1.3.10 Deleting elements

To delete an element in the graphical editor, follow these steps:

1. Select the element that is to be deleted.
2. Press the <Del> key.

   The element is deleted. The graphical editor and the view of the properties (Inspector window) are updated. A transition to any element present is also deleted.

9.1.3.11 Show elements used

The "Statistics" properties window shows an overview of the number of elements of the cam, as well as the minimum and maximum values of the effective curves for the slave value and the derivatives.

Used elements

In the statistics, a distinction is made between points and segments:

- Point

  A leading value / following value coordinate on the cam through which the curve runs
- Segments

  All elements and transitions calculated by a 6th degree polynomial with trigonometric part

The "Elements used" area shows the number of curve elements used:

Parameters	Description
Points	This field shows the number of used points of the cam. A cam of the type "TO_Cam" consists of a maximum of 1000 points. A cam of the type "TO_Cam_10k" consists of a maximum of 10 000 points. A cam of the type "TO_Cam_600Seg" or "TO_Cam_6kSeg" consists of a maximum of 50 points.
Segments	This field shows the number of used segments of the cam. A cam of the type "TO_Cam" or "TO_Cam_10k" consists of a maximum of 50 segments. A cam of the type "TO_Cam_600Seg" consists of a maximum of 600 segments. A cam of the type "TO_Cam_6kSeg" consists of a maximum of 6 000 segments.

The use of points and segments depends on the compilation and configuration of the elements.

If an element or a transition is defined via a point or several interpolation points, the number of specified interpolation points determines the number of points used. The following elements or transitions are calculated using interpolation points:

- "Point" element
- "Inverse sine" element
- "Point group" element with "Point approximation" mapping option
- "Double-harmonic transition" motion rule according to VDI Guideline

All other elements and transitions according to the VDI guideline are defined using 6th degree polynomials with a trigonometric component and thus count as segments in the statistics.

The following table shows the use of points and segments per element:

Element	Number of used points	Number of used segments
Point	1	0
Point at a transition with VDI-based optimization	0	0
Point group with point approximation mapping method	Number of interpolation points configured. ("Properties (Inspector window) > Element > Parameter > Approximation > Number of interpolation points") Default setting: 32	0
Point group with segment approximation mapping method	0	Number of interpolation points configured - 1
Line	0	1
Sine	0	1
Polynomial		
< of the 7th degree	0	1
of the 7th degree	0	2

Lambda = turning point of the curve

Element	Number of used points	Number of used segments
Inverse sine	Number of interpolation points configured. ("Properties (Inspector window) > Element > Parameter > Approximation > Number of interpolation points") Default setting: 32	0
Inverse sine to the right of a transition with VDI-based optimization	Number of interpolation points configured - 1	0
Transition with system interpolation	0	0
Transition with VDI-based optimization		
Motion rule		
Sine	0	1
Sine with relative Lambda ≠ 0.5	0	2
Inclined sine	0	1
Inclined sine with relative Lambda ≠ 0.5	0	2
Polynomial	0	1
Sinus with relative Lambda ≠ 0.5	0	2
Modified acceleration trapezoid		
Motion task		
Dwell-in-reverse	0	5
Reverse-in-dwell	0	5
Dwell-in-dwell	0	6
Modified sine		
Motion task		
Dwell-in-dwell	0	3
Constant velocity-in-constant velocity	0	4
Constant-velocity-in-dwell	0	4
Dwell-in-constant velocity	0	4
Sine line combination	0	3
Harmonic combination	0	3
Double-harmonic transition	Number of interpolation points configured. ("Properties (Inspector window) > Element > Parameter > Approximation > Number of interpolation points") Default setting: 32	0
Quadratic parabola	0	2

Lambda = turning point of the curve

Value ranges

This area shows the minimum and maximum values of the effective curves for the following value and the derivatives.

Boundary conditions

The following boundary conditions apply to the input and use of points and segments:

- **Points**

  With points with the same leading values, the point that you have entered last or which is listed in the tabular editor is active.

- **Segments**
  - Gaps between segments are filled with a transition segment.
  - For gaps in the leading value range of less than 1.0E-4, segment end points and segment start points are pulled together.
  - For gaps in the leading value range greater than 1.0E-4, a new transition segment is inserted.
  - For overlaps, the new segment is inserted from the start point and used completely. When the previous segment is defined in excess of the new segment, the previous segment continues to be used after the end point of the new segment.

- **Interpolation points and segments** (mixed cams)

  The segment is used when points are defined in the same range.

9.1.4 Transferring the synchronous operation function of the cam to the technology object data block

After you have configured the synchronous operation function of the cam in the cam editor, compile the cam technology object. By compiling, the configuration is transferred from the cam editor to the technology object data block of the cam. All existing values are overwritten.

Requirement

- You have defined the synchronous operation function of the cam in the cam editor or imported it.

Procedure

To transfer the synchronous operation function of the cam to the technology object data block, follow the steps below:

1. Select the can technology object in the project tree.
2. Select the "Compile > Software (only changes)" entry in the shortcut menu.

Result

The configuration of the synchronous operation function is transferred from the cam editor to the technology object data block of the cam. All existing values are overwritten.

9.1.5 Exporting cam

You can export cams using the toolbar of the cam editor.

In the cam diagnostics, you export snapshots of cams offline and online.

You can perform the following tasks via the export:

- Archive cams
- Generate cam in the cam editor from an exported snapshot of a cam generated during runtime
- Exchange cams between TIA Portal and external software tools

Export formats

The table below shows the supported export formats, their use and special features:

Format	Comment
MCD exchange format	Exchange of cams between the TIA Portal and the NX Mechatronics Concept Designer The following elements are exported in a different form, while maintaining the profile of the cam: • Polynomial of the 7th degree The format does not support 7th degree polynomials. You can define polynomials of the 7th degree using boundary values in the cam editor. If you configure all three derivatives at the right and left boundary values, which corresponds to a 7th degree polynomial. A 7th degree polynomial is mapped into two 6th degree polynomials during export. • Point group With the "Point group" element, the export depends on the mapping method. With the "Point approximation" mapping method, the interpolation points are exported and the transitions between the points are interpolated with the system interpolation. With the "Segment approximation" mapping method, the point group is exported in segments. • Inverted sine The "Inverted sine" element is exported using interpolation points.
SIMOTION SCOUT CamTool format	Exchange of cams between the TIA Portal and the SIMOTION SCOUT CamTool The same special features apply to this format as to the MCD Exchange format.
Point list	Export cams as x and y values for processing in, for example, spreadsheet or word processing programs With the point list, you export points at isochronous distances from the leading value. In addition to the following values, you also have the option to export velocity, acceleration and jerk. Select as many points as possible in order to export the cam with a high degree of accuracy.
Binary format	Exchange of cams between multiple TIA Portal projects. With the binary format you export all configuration data of the cam without restrictions. In addition, your settings for the displaying the charts, such as colors of the curves, are exported.

Procedure

To export a cam, follow these steps:

1. On the toolbar, click the icon "Export cam to file".

   The "Export cam" dialog opens.
2. Select the desired export format from the "Export as" drop-down list.
3. Select the desired delimiter:
   - When you select the "Comma" delimiter, a CSV file is created.
   - When you select the "Tabulator" delimiter, a TXT file is created.
   - This selection is not possible for the binary format.
4. If you export the cam as a point list, enter the number of points and optionally activate the curves to be exported for velocity, acceleration and jerk.

   The more points you export, the more accurately the point list maps the configured cam.
5. Enter a file name in the "File name" box.
6. Select the directory to which the file is written.
7. Click the "Export" button.

   The cam is exported to the selected directory in the specified format.

9.1.6 Importing a cam

You can import cams using the toolbar of the cam editor.

In the cam diagnostics, you import snapshots of cams.

You can perform the following tasks via the import:

- Archive cams
- Generate cam in the cam editor from an exported snapshot of a cam generated during runtime
- Exchange cams between TIA Portal and external software tools

You can import cams of different cam types as long as the respective maximum number of possible points and segments is not exceeded.

NOTICE
Machine damage Importing corrupt files (*.txt, *.csv) can result in unwanted behavior of the axes. Each time you import a cam from a file, check the integrity of the imported data.

Import formats

The following table shows the supported file formats for importing a cam:

File format	Comment
SIMOTION SCOUT CamTool format[1)]/MCD *.txt	MCD exchange format is automatically detected, imported data: • Interpolated points • Lines • Sine elements • Inverse sine elements • Polynomials • Transitions If the maximum number of possible points is reached in a pure point list, you can select whether all points are imported or whether the points are interpolated and then reduced.
SIMOTION SCOUT CamTool format[1)]/MCD *.csv	
Binary format *.bin	The binary format is used for exchanging cams between multiple TIA Portal installations.

1) Export the geometry "as polynomials" in SIMOTION SCOUT.

Procedure

To import a cam, follow these steps:

1. On the toolbar, click the icon "Import cam from file".

   The "Cam import" dialog opens.
2. Select the file type of the file to be imported.
3. From the file directory, select the file to be imported.
4. Click the "Open" button.

   The cam is imported into the cam editor and opened. All previous entries in the editor are discarded.
5. Compile the cam technology object (Page 134).

   The configuration from the cam editor is transferred to the technology object data block. All existing values are overwritten.

9.2 Changing the synchronous operation function of the cam online

You can configure the y = f(x) function of the cam using the cam editor in the configuration of the technology object (Page 103). Alternatively, for dynamic cam plate calculations, you can define or change the synchronous operation function of the cam during the runtime of the user program. The cam technology object must already be created for this.

To change the synchronous operation function of a cam online, you have the following options:

- Changing the synchronous operation function of the cam manually (Page 138)
- Copy calculated cam elements (Page 139)
- Creating the synchronous operation function of the cam with the "LCamHdl" library (Page 140)

Then, you can transfer the synchronous operation function of the cam defined online to the offline project (Page 141).

9.2.1 Changing the synchronous operation function of the cam manually

The following tags of the technology object data block (Page 415) of the cam are relevant for defining the synchronous operation function of a cam manually in runtime:

- <TO>.Point[i]
- <TO>.ValidPoint[i]
- <TO>.Segment[i]
- <TO>.ValidSegment[i]
- <TO>.InterpolationSettings

You can adapt the tags in runtime via the user program. You can use the "<TO>.ValidPoint[i]" and "<TO>.ValidSegment[i]" tags to determine which cam elements included for the interpolation. If the value is "TRUE", the element "<TO>.Point[i]" or "<TO>.Segment[i]" with the corresponding index "i" is included in the interpolation. You can determine the interpolation type (Page 150) using the "<TO>.InterpolationSettings" tag.

Requirement

- The cam technology object has been created. Configuration via the cam editor is not required.
- The project is downloaded to the CPU.
- The cam elements to be adapted should not be edited by an active copy operation of an "MC_CopyCamData (Page 358)" job.

Procedure

To manually change the synchronous operation function of a cam in runtime, follow these steps:

1. Calculate the points and segments of the cam depending on your application.
2. Define the calculated points in the technology object data block of the cam.
   ```
   <TO>.Point[i] := Point; // data type TO_Cam_Struct_PointData
   ```
3. Set the defined points to valid.
   ```
   <TO>.ValidPoint[i] := TRUE;
   ```
4. Set all undefined points to invalid.
   ```
   <TO>.ValidPoint[i] := FALSE;
   ```
5. Define the calculated segments in the technology object data block of the cam.
   ```
   <TO>.Segment[i] := Segment; // data type TO_Cam_Struct_SegmentData
   ```
6. Set the defined segments to valid.
   ```
   <TO>.ValidSegment[i] := TRUE;
   ```

7. Set all undefined segments to invalid.
```
<TO>.ValidSegment[i] := FALSE;
```
8. Make the interpolation settings of the cam.
```
<TO>.InterpolationSettings.InterpolationMode := 1;
<TO>.InterpolationSettings.BoundaryConditions := 0;
```
The values "1" and "0" are only used as examples. Adapt them as needed.
9. Interpolate the cam with a "MC_InterpolateCam (Page 350)" job.

Check the synchronous operation function of the cam

Use the cam diagnostics (Page 261) to analyze and check the generated cam. This provides you with a graphical view of the cam, a list of all valid cam elements and the interpolation type.

9.2.2 Copy calculated cam elements

You use an "MC_CopyCamData (Page 358)" job to copy calculated cam elements to a cam. You can use the same job to copy points and segments to the technology object data block of the cam.

Cam elements to be copied

Save or calculate the cam elements in a data block. Create an array for points of the "TO_Cam_Struct_PointData" type and an array for segments of the "TO_Cam_Struct_Segment-Data" type. The size of the arrays depends on the use case and is variable.

The consistency of the cam elements in the data block is your responsibility. The cam elements must not change during an active copy operation of an "MC_CopyCamData" job.

Specify the arrays for points and segments at the "ArrayOfPoints" and "ArrayOfSegments" parameters of the "MC_CopyCamData" job. Define the number of elements to be copied at the "NumberOfPoints" and "NumberOfSegments" parameters.

Use the "StartPointArray" and "StartSegmentArray" parameters to define the index of the first element to be copied in the array, respectively. Use the "StartPointCam" and "StartSegmentCam" parameters to define the respective index in the cam starting at which the elements to be copied are to be inserted.

Copy mode

Following the copy operation, the inserted cam elements are set as valid ("ValidPoint" = TRUE, "ValidSegment" = TRUE).

With copy mode "Mode" = 0, you specify that all defined elements already present in the cam are set as invalid before the copy operation ("ValidPoint" = FALSE, "ValidSegment" = FALSE). This results in only the inserted elements being valid after the copy operation. Use this copy mode to completely regenerate the cam and overwrite its previous synchronous operation function.

Use copy mode "Mode" = 1 to specify that all defined elements already present in the cam remain valid ("ValidPoint" = TRUE, "ValidSegment" = TRUE). This results in both the inserted

elements and the still existing elements not overwritten being valid after the copy operation. Use this copy mode to append cam elements to the previous synchronous operation function of the cam, or to partially overwrite the synchronous operation function of cam.

Copy operation

Copying of cam elements is possible during active cam synchronization.

An active copy operation is indicated by the "MC_CopyCamData.Busy" = TRUE parameter, in the "<TO>.StatusWord.X7 (CopyCamDataActive)" tag as well as in the status and error bits of the diagnostics of the technology object. Only one active "MC_CopyCamData" job is possible at a given time on a cam.

As soon as the cam elements have been copied and set to valid, the copy operation is complete. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE. The "<TO>.StatusWord.X4 (CamDataChanged)" tag of the technology object is set to "TRUE".

Before you can use the cam with the inserted elements, the cam must be interpolated. To do this, start an "MC_InterpolateCam" job.

9.2.3 Creating the synchronous operation function of the cam with the "LCamHdl" library

The "LCamHdl" library provides function blocks that support you in creating jerkless cams in accordance with VDI guideline 2143. The function blocks perform the required calculations of the segments for different profile types, e.g. the polynomial coefficients.

In addition, you can use the optimized "Basic" function block with a simplified user interface to define the synchronous operation function of the cam in terms of points and associated dynamic values. From this, the function block calculates the corresponding segments according to a 5th degree polynomial function.

More information

You can find additional information about the "LCamHdl" library in the Siemens Industry Online Support under entry ID 105644659 (https://support.industry.siemens.com/cs/ww/en/view/105644659).

An application example shows the creation of cams with the "LCamHdl" library and switching of two cams using the example of a press. The application example can be found in the Siemens Industry Online Support under entry ID 109749460 (https://support.industry.siemens.com/cs/ww/en/view/109749460).

9.2.4 Transferring the synchronous operation function of the cam defined online to the offline project

After you have defined or changed the synchronous operation function of the cam at runtime of the user program, you can transfer the synchronous operation function to the offline project. To do this, use the cam diagnostics.

Requirement

- You have adapted the synchronous operation function of a cam online.
- The current cam data is contained in the technology object data block.

Procedure

To transfer the adapted synchronous operation function of the cam to the offline project, follow the steps below:

1. Open the cam diagnostics.
2. Save a snapshot of the online configuration of the cam (Page 273).
3. Export the saved snapshot in binary format (Page 274).
4. Open the cam configuration.
5. Import the exported snapshot of the cam (Page 274).
6. Compile the cam technology object (Page 134).

   The configuration from the cam editor is transferred to the technology object data block of the cam. All existing values are overwritten.

   An online/offline inconsistency is displayed for the Cam technology object because the start values differ.
7. Load the Cam technology object to the CPU again.

Result

You have transferred the synchronous operation function of the cam defined online to the offline project.

9.3 Interpolating a cam

9.3.1 Configuring transitions

To use a cam in the user program, you must interpolate the cam after downloading to the CPU or after adapting the technology object data block. The interpolation closes the gaps between the defined interpolation points and segments of the cam. These missing ranges are called transitions. The interpolation type defines how the transitions are interpolated.

Configuring interpolation

You specify the interpolation type in the configuration of the technology object. You can set the interpolation separately for each transition in the cam. The following methods are possible:

- System interpolation (Page 144):

  The system interpolation is the default for interpolation of the transitions. You configure the system interpolation for all transitions in the properties (Inspector window) in the "Profile > System interpolation" configuration window.

- Interpolation according to VDI Guideline 2143 (Page 147):

  You can adapt each transition separately according to the VDI Guideline 2143. The settings in the properties (Inspector window) in the "Profile > Default optimization settings" configuration window are hereby taken into consideration.

"Characteristic" configuration window

In the "Characteristic" configuration window, you configure the parameters for optimizing the selected transition in the properties (Inspector window):

Parameters	Description
Interpolation settings of the transition	
Optimization method	Select the optimization method in the drop-down list: • System interpolation (Page 144) The CPU defines the optimization parameters automatically according to the settings of the system interpolation. • VDI-based optimization (Page 147) Adjust the optimization manually. The inputs are applied automatically according to the VDI Guideline 2143.
Motion task	The transition type is determined from the properties of the adjacent elements of the transition and displayed in this field.
Continuity at start/end	In the drop-down lists, select which parameter is continuous in the boundary points and is to be included for optimization: • Default optimization setting (setting under "Profile > Default optimization settings") • Position • Velocity (bumpless) • Acceleration (jerkless) • Jerk (jerk continuity permitted on one side only)

Parameters	Description
Optimization target	In the drop-down list, select the optimization target: • Default optimization setting (setting under "Profile > Default optimization settings") • Not specified • Velocity (Cv) • Acceleration (Ca) • Jerk (Cj) • Dynamic torque (Cmdyn)
Selection of motion rule	
Motion rule	In the drop-down list, select the motion rule according to which optimization is to occur: • Line • Quadratic parabola • Sine • Polynomial • Inclined sine • Modified acceleration trapezoid • Modified sine • Harmonic combination • Double-harmonic transition • Sine line combination The selection is automatically limited to the motion rules that can be applied according to the motion task and the selected boundary conditions. Additional parameters are displayed depending on the selected motion rule. If you have changed the motion task in such a way that the motion rule can no longer be applied, a notice is displayed. In this case, you need to select a motion rule that can be applied.
Parameter used	In the drop-down list, select the parameters to be included in the optimization: • Lambda • Maximum acceleration (Ca) • Maximum deceleration (Ca*) The selection is automatically limited to the parameters that can be applied according to the motion rule.
Lambda	In the drop-down list, select the transition point in the "Lambda position" field: • No lambda Do not enter any value. The position of the point of inflection is calculated automatically. • Relative to segment Specify the leading value of the point of inflection relative to the transition from 0.0 to 1.0. The value 0.0 corresponds to the beginning of the transition. The value 1.0 corresponds to the end of the transition. • Absolute in the profile You specify the leading value of the point of inflection as an absolute value.
Lambda position	In this field, configure the leading value of the point of inflection for the transition according to the selection in the "Lambda" drop-down list.
Maximum acceleration (Ca)	Configure the maximum acceleration (Ca) for the transition in this field.

Parameters	Description
Maximum deceleration (Ca*)	Configure the maximum deceleration (Ca*) for the transition in this field.
Approximation	
Number of interpolation points	In this field, configure the number of interpolation points for the transition.
Maximum following value tolerance	In this field, enter the maximum permitted deviation (absolute) of the approximation from the motion rule. If the configured value is exceeded, a warning is displayed in the graphical editor at the transition.
Characteristic values of the transition	The characteristic values of the transition that are relevant according to VDI 2143 are displayed in this area. The maximum value and the standardized value are displayed for the following characteristic values: • Velocity (Cv) • Acceleration (Ca) • Deceleration (Ca*) • Jerk (Cj) • Dynamic torque (Cmdyn)

9.3.2 System interpolation

With system interpolation, the transitions are interpolated according to the interpolation type and the response in the boundary points of the transition segment. The following interpolation methods are possible:

- **Linear interpolation**

  Gaps in the curve are closed with a straight line.

Specified position (point)
Interpolated position
Resulting velocity (scaled)
Resulting acceleration
Resulting jerk

- **Interpolation with cubic splines**

  The interpolated curve runs through the interpolation points and the segments of the curve.

  After interpolation has been completed, the value range of the following value of the cam can be greater than before interpolation.

Specified position (point)
Interpolated position
Resulting velocity (scaled)
Resulting acceleration (scaled)
Resulting jerk (scaled)

- **Interpolation with Bézier splines**

  The interpolated curve runs along the interpolation points and through the segments of the curve.

  The range of the cam is not changed by interpolation.

Specified position (point)
Interpolated position
Resulting velocity (scaled)
Resulting acceleration (scaled)
Resulting jerk (scaled)

NOTE

Differences in the interpolation types

Depending on the definition of the cam, high dynamic responses can result when interpolating with cubic splines, as the interpolated curve always runs through the specified points. The course of the curve for interpolation via cubic splines runs through all specified points, while the course of the curve for interpolation via Bézier splines is only based on the points and thus results in lower dynamic values.

If required, select an interpolation using Bézier splines in order to obtain a smooth, slower interpolated curve.

"System interpolation" configuration window

In the "System interpolation" configuration window, configure the interpolation of transitions according to the system specifications in the properties (Inspector window). These settings are used when the "System interpolation" optimization method is used for a transition (Page 142) (default setting).

Configure the interpolation type and the behavior of the boundary points in this area:

Parameter	Description
Interpolation type	In the drop-down list, select the interpolation type by which the transitions in the curve are interpolated: • Linear interpolation In linear interpolation, the transitions (magenta) between the cam elements (blue) are defined by a straight line. • Interpolation with cubic splines In the interpolation with cubic splines, the transitions (magenta) between the cam elements (blue) are defined so that the interpolated curve runs through all the cam elements. The acceleration (green) in the transition is linear. • Interpolation with Bézier splines In the interpolation with Bézier splines, the transitions (magenta) between the cam elements (blue) are defined so that the interpolated curve is based on specified points and the curve runs through other cam element types.
Behavior at boundary	In the drop-down list, select which behavior of the interpolation applies to a cyclic use of the cam in the boundary points: • No restrictions The areas between the elements are closed. • First derivative continuous (velocity continuous) The cam is interpolated in such a way that the first derivative (velocity) is equal at the start and end of the cam.

MC_InterpolateCam: Interpolate cam V10 (Page 350)

9.3.3 Interpolation according to VDI Guideline 2143

The VDI Guideline 2143 deals with motion rules for cam gears. The aim of these motion rules is to achieve high running quality and to avoid jolts and jerks.

The VDI Guideline 2143 distinguishes between areas of usage and motion transitions:

- Areas of usage correspond to the sequences in a process, which means the inserted elements of the cam.
- Motion transitions are transitions between areas of usage that are not directly relevant to the process but must meet specific boundary conditions, for example, velocity consistency.

The following motion tasks are defined based on VDI Guideline 2143:

Motion task	Designation	Properties
Dwell	R	Velocity = 0 Acceleration = 0
Constant velocity	G	Velocity ≠ 0 Acceleration = 0
Reverse	U	Velocity = 0 Acceleration ≠ 0
Motion	B	Velocity ≠ 0 Acceleration ≠ 0

The graphic below shows an example of the motion jobs:

The following graphic shows the possible combinations of motion jobs:

Adjust the optimization of a transition

To adapt the optimization of a transition according to the VDI Guideline 2143, follow these steps:

1. Select the transition in the graphical or tabular editor.
2. In the properties (Inspector window), open the "Element > Characteristic (Page 142)" configuration window.
3. Select the optimization method "VDI-based optimization" in the "Optimization method" drop-down list.
4. If necessary, change the default settings.

   The selection of the parameters is automatically limited to the settings that can be applied according to VDI Guideline 2143.

You interpolate the cam with the Motion Control instruction "MC_InterpolateCam (Page 350)" according to the settings for the VDI optimization. Note that, in contrast to system interpolation, the optimization of transitions according to VDI Guideline 2143 directly occupies segments in the technology object data block. This optimization type is thus not possible via "MC_InterpolateCam" during runtime.

"Default optimization settings" configuration window

You configure the default values for optimization of transitions according to VDI Guideline 2143 in the "Profile > Default optimization settings" configuration window in the properties (Inspector window). The default values are used when the "VDI-based optimization" optimization method is selected for a transition (Page 142) and when the setting "Default optimization setting" is selected for the continuity or the optimization target.

Configure the default settings for continuity requirement and optimization target in this area:

Parameter	Description
Continuity	In the drop-down list, select which parameter is continuous in the boundary points and is to be taken into consideration for optimization: • Position • Velocity • Acceleration • Jerk
Optimization target	In the drop-down list, select the optimization target according to the VDI Guideline: • Not specified • Velocity (Cv) • Acceleration (Ca) • Jerk (Cj) • Dynamic torque (Cmdyn)

9.3.4 Interpolate cam with "MC_InterpolateCam"

To use a cam in the user program, you must interpolate the cam after downloading to the CPU or after adapting the technology object data block. The interpolation closes the gaps between the defined interpolation points and segments of the cam. The interpolation type defines how missing ranges are interpolated.

NOTE

Improving system performance

To improve the system performance for interpolating the cam technology object, select the "Improve system performance" check box in the properties of MC_Interpolator under "General > Multi-core processor".

After you have configured the interpolation type (Page 142), you interpolate a cam in the user program with the Motion Control instruction "MC_InterpolateCam (Page 350)". After starting the "MC_InterpolateCam" job, the cam is interpolated in the definition range from the minimum to the maximum value in the leading value range:

- The minimum value in the leading value range is the first defined interpolation point or start of the first segment of the cam (<TO>.StatusCam.StartLeadingValue) with the associated following value (<TO>.StatusCam.StartFollowingValue).
- The maximum value in the leading value range is the last defined interpolation point or end of the last segment of the cam (<TO>.StatusCam.EndLeadingValue) with the associated following value (<TO>.StatusCam.EndFollowingValue).

As soon as the cam has been interpolated, this is indicated on the "MC_InterpolateCam" Motion Control instruction with parameter "Done" = TRUE and in the tag "<TO>.StatusWord.X5 (Interpolated)" = TRUE of the technology object. After interpolation, an explicit value in the value range is assigned to each value in the definition range.

9.4 Scaling and shifting cam

You can scale and shift the utilized cam for camming (Page 102) at the Motion Control instruction "MC_CamIn" in the leading and following value range. The configured cam is not changed by this. In contrast, the specification for leading and following value range in the configuration of the technology object only effect the display in the graphical editor.

The following diagram shows the general sequence of scaling and shifting the cam:

Position following axis = f[(Position leading axis - Leading value shift) / Leading value scaling] × Following value scaling + Following value shift

Parameter inputs

You define the use of the cam with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the "MasterScaling" parameter, you specify the scaling of the cam in the leading value range. The value "0.0" is invalid.
- With the "SlaveScaling" parameter, you specify the scaling of the cam in the following value range.
- You define the offset of the cam in the leading value range with the parameter "MasterOffset".
- You define the offset of the cam in the following value range with the parameter "SlaveOffset".

Scaling of the cam

The figure below shows the basic effect of scaling the cam with the parameters "MasterScaling" and "SlaveScaling":

Shifting of the cam

The following figure shows the basic effect of the leading value and following value offset as well as the position of the cam with the following parameter values:

- "MasterOffset" > 0
- "SlaveOffset" > 0
- Start position of the cam > 0
- "MasterSyncPosition" > 0

① Start position of the cam
First defined interpolation point or start of the first segment of the cam (<TO>.StatusCam.StartLeadingValue)

② Leading value distance with synchronization in advance ("MasterStartDistance")

③ Synchronous position of the leading axis relative to the starting position of the cam ("MasterSyncPosition")

④ Leading value distance with subsequent synchronization ("MasterStartDistance")

⑤ End position of the cam
Last defined interpolation point or end of the last segment of the cam (<TO>.StatusCam.EndLeadingValue)

9.5 Scaling a cam range

Use the Motion Control instruction "MC_SetCamRangeScaling" to scale a cam range. The configuration of the cam technology object is not changed.

You can use range scaling during camming. The range scaling is also in effect for the scaling of the cam by the "MC_CamIn" job.

Parameter inputs

You define the use of the cam with the following parameters of the Motion Control instruction "MC_SetCamRangeScaling (Page 360)":

- Use the "Mode" parameter to define the scaling mode.
- With the "RangeNumber" parameter, you define the number of the scaling range.
- Use the "RangeStartPoint" parameter to define the start point. The start point must be less than or equal to the end point.
- Use the "RangeEndPoint" parameter to define the end point. The end point must be greater than or equal to the start point.
- Use the "RangeScaling" parameter to define the scaling factor. Only values > 0.0 are permitted.

Scaling mode

The scaling mode defines whether the scaling range refers to the leading value range or the following value range:

- Use the "Mode" = 1 parameter to define a range scaling in the leading value range.
- Use the "Mode" = 2 parameter to define a range scaling in the following value range.

Scaling range

Use the "RangeStartPoint" and "RangeEndPoint" parameters to define the start and end of the scaling range. The scaling range always refers to the unscaled interpolated cam.

With the "RangeNumber" parameter, you define the number of the scaling range. Up to two scaling ranges are possible for one cam. The scaling ranges may overlap.

① Unscaled interpolated cam

② Scaled cam with the first range scaling in the leading value range

③ Scaled cam with the first and second range scaling in the leading value range

In the chart ②, the cam ① is scaled with a "MC_SetCamRangeScaling" job in the leading value range:

- "Mode" = 1
- "RangeNumber" = 1
- "RangeStartPoint" = 180.0
- "RangeEndPoint" = 360.0
- "RangeScaling" = 0.5

In the chart ③, the scaled cam ② is scaled again with a "MC_SetCamRangeScaling" job in the leading value range. The parameter specifications refer to the unscaled cam ①:

- "Mode" = 1
- "RangeNumber" = 2
- "RangeStartPoint" = 90.0
- "RangeEndPoint" = 360.0
- "RangeScaling" = 0.5

The two scaling ranges overlap.

NOTE

Discontinuity of the first derivative

The range scaling of an interpolated cam leads to discontinuities in the first derivative of the cam. This also applies to interpolation with cubic splines or Bézier splines.

Recommendation: Apply a range scaling within a dwell range of the cam.

Scaling range outside the definition or value range

You can also define the scaling range outside the definition or value range of the cam. If the scaling range is in a range in which the values are lower than the lowest value of the definition or value range of the cam, the range scaling also influences the definition or value range of the cam. If the scaling range is in a range in which the values are greater than the highest value of the definition or value range of the cam, the definition or value range of the cam remains unaffected.

① Unscaled interpolated cam

② Scaled cam with range scaling in the leading value range

③ Scaled cam with range scaling in the leading value range and range scaling in the following value range

In the chart ②, the cam ① is scaled with a "MC_SetCamRangeScaling" job in the leading value range:

- "Mode" = 1
- "RangeNumber" = 1
- "RangeStartPoint" = -360.0
- "RangeEndPoint" = -180.0
- "RangeScaling" = 2

In the chart ③, the scaled cam ② is scaled with a "MC_SetCamRangeScaling" job in the following value range. The parameter specifications refer to the unscaled cam ①:

- "Mode" = 2
- "RangeNumber" = 2
- "RangeStartPoint" = -360.0
- "RangeEndPoint" = -180.0
- "RangeScaling" = 2

Difference to scaling with "MC_CamIn"

When scaling the entire cam with "MC_CamIn" via the parameters "MasterScaling" and "SlaveScaling", position 0.0 is the reference point for the scaling calculation.

When scaling the entire cam with "MC_SetCamRangeScaling", the reference point for the scaling calculation is the lowest value in the leading value range and in the following value range.

① Unscaled interpolated cam

② With "MC_SetCamRangeScaling" scaled cam

③ With "MC_CamIn" scaled cam

In the chart ②, the cam ① is scaled with two "MC_SetCamRangeScaling" jobs. In the chart ③, the cam ① is scaled with a "MC_CamIn" job. In both cases, the cam is scaled by a factor of 0.5 from -360.0 to 360.0 in the leading value range and in the following value range.

After the "MC_SetCamRangeScaling" job has started

The scaling of the cam is calculated after starting the "MC_SetCamRangeScaling" job. The scaling takes effect immediately as soon as the job is completed with "Done" = TRUE. The status is indicated with the tag "<TO>.StatusWord.X9 (CamRangeScaled)" = TRUE of the cam technology object.

NOTE

Dynamic jumps

The range scaling takes effect immediately. If camming with "MC_CamIn" is active, dynamic jumps may occur on the following axis.

Check the dynamic behavior with range scaling.

Recommendation:

- Perform range scaling in the leading value range only in a dwell range of the following axis while the following axis moves the range to be scaled so that the following axis is stationary before and after the applied range scaling.
- Do not perform range scaling in the leading value range if the range to be scaled has already been moved by the following axis in the current cam cycle.
- Do not perform range scaling in the following value range if the range to be scaled is moved from the following axis.

If the cam is interpolated again, all range scaling is reset.

9.6 Defining application mode of the cam

For camming (Page 102), you can define the application mode of the cam. The following modes are available:

- Not cyclic
- Cyclic
- Cyclic appending

A cam is defined between the start position (<TO>.StatusCam.StartLeadingValue) and end position (<TO>.StatusCam.EndLeadingValue) after the interpolation.

Parameter inputs

You define the use of the cam with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the "ApplicationMode" parameter, you define the application mode of the cam.

Not cyclic

With the "ApplicationMode" = 0 parameter, you define the application mode of the cam as "Not cyclic".

The cam is run exactly once. When the cam is run through in the positive direction, synchronous operation is ended when the end position of the cam is reached. When the cam is run through in the negative direction, synchronous operation is ended when the start position of the cam is reached.

To prevent step changes in the dynamic values, the velocity of the following axis must be zero at the start and end position of the cam.

The end of the synchronous operation is reached on the setpoint side with the parameter "EndOfProfile" = TRUE of the "MC_CamIn" job. To wait with the further program processing until the following axis has reached the setpoint on the actual value side, evaluate the "<TO>.StatusWord.X6 (Done)" tag of the following axis.

If the "<TO>.StatusWord.X6 (Done)" tag is set to TRUE, the "<TO>.StatusWord.X22 (Synchronous)" tag of the technology object and the "InSync" parameter of the "MC_CamIn" job are reset to FALSE. With this, synchronous operation is ended.

You can find more information on reaching the positioning window in the section ""PositioningMonitoring" tag (synchronous axis) (Page 398)".

Cyclic

With the "ApplicationMode" = 1 parameter, you define the application mode of the cam as "Cyclical".

The cam is run cyclically. When the cam is run through in the positive direction, the cam is repeated from the start position when the end position of the cam is reached. When the cam is run through in the negative direction, the cam is repeated from the end position when the start position of the cam is reached.

To prevent step changes in the dynamic values, the start and end positions of the cam must be match, and the velocity at the start and end position must be identical. For a velocity continuous transition, use the setting "First derivative continuous (velocity continuous)" under "Properties (Inspector window) > System interpolation > Behavior at boundary" (<TO>.InterpolationSettings.BoundaryConditions = 1) for interpolation of the cam.

Cyclic appending

With the "ApplicationMode" = 2 parameter, you define the application mode of the cam as "Cyclic appending".

The cam is run cyclically. When the cam is run through in the positive direction, the end position of the cam is used as the start position for the next run. When the cam is run through in the negative direction, the start position of the cam is used as the start position for the next run. The position difference between the start and end position on the following value side is added up.

To prevent step changes in the dynamic values, the velocity at the start and end position must be identical. For a velocity continuous transition, use the setting "First derivative continuous (velocity continuous)" under "Properties (Inspector window) > System interpolation > Behavior at boundary" (<TO>.InterpolationSettings.BoundaryConditions = 1) for interpolation of the cam.

9.7 Dynamic limits of the following axis in camming

If a synchronous axis is operated as a following axis in cam synchronization with the Motion Control instruction "MC_CamIn (Page 323)" or desynchronized with the Motion Control instruction "MC_CamOut (Page 343)", the following dynamic limits apply depending on the phase of the synchronization:

Pending synchronous operation

If synchronous operation is not active, the configured dynamic limits of the following axis apply. If there is already a synchronous operation active, the descriptions in the following sections apply.

Synchronization and desynchronization via dynamic parameters

When synchronizing with "MC_CamIn" and desynchronization with "MC_CamOut" via dynamic parameters, the dynamic limits configured on the technology object apply to the following axis:

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

Synchronization and desynchronization via leading value distance and synchronous operation

When synchronizing and desynchronizing via the leading value distance with "MC_CamOut" and during synchronous travel, the dynamics of the following axis are only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

End or override synchronous operation

As soon as synchronous operation has been overridden, the dynamic limits configured for the technology object apply to the following axis again. With the start of the overriding job, the active dynamics are transitioned (smoothed) to the configured dynamic limits and the specifications for the Motion Control instruction.

9.8 Synchronizing camming

9.8.1 Parameter overview for synchronizing with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With the parameter "SyncProfileReference" you define the type of synchronization:

SyncProfileReference	Synchronization profile
0	Synchronization in advance using dynamic parameters (Page 163)
1	Synchronization in advance using leading value distance (Page 164)
2	Direct synchronous setting (Page 175)
3	Subsequent synchronization using leading value distance (Page 171)
4	Subsequent synchronization using leading value distance starting from current leading value position (Page 173)
5	Direct synchronous setting at the end of the cam (Page 176)
6	Synchronization in advance using leading value distance starting from current leading value position (Page 167)
7	Direct synchronous setting to specific leading value position (Page 177)

Depending on the synchronization profile, different parameters of the Motion Control instruction "MC_CamIn (Page 323)" are relevant:

Parameters	SyncProfileReference							
	0	1	2	3	4	5	6	7
MasterOffset	✓	✓	-	✓	✓	-	-	✓
SlaveOffset	✓	✓	-	✓	✓	-	✓	-
MasterScaling	✓	✓	✓	✓	✓	✓	✓	✓
SlaveScaling	✓	✓	✓	✓	✓	✓	✓	✓
MasterSyncPosition	✓	✓	✓	✓	-	✓	✓	✓
MasterStartDistance	-	✓	-	✓	✓	-	✓	-
Velocity	✓	-	-	-	-	-	-	-
Acceleration	✓	-	-	-	-	-	-	-
Deceleration	✓	-	-	-	-	-	-	-
Jerk	✓	-	-	-	-	-	-	-
ApplicationMode	✓	✓	✓	✓	✓	✓	✓	✓
SyncDirection	✓	✓	-	✓	✓	-	✓	-

9.8.2 Defining direction of synchronization with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. If you have activated the "Modulo" setting for the following axis, you can define the direction of the synchronization with the "SyncDirection" parameter of the Motion Control instruction "MC_CamIn (Page 323)".

Positive direction

With "SyncDirection" = 1, the following axis may only travel in positive direction during synchronization. In this example, the synchronous position is 0.0.

Negative direction

With "SyncDirection" = 2, the following axis may only travel in negative direction during synchronization. In this example, the synchronous position is 0.0.

Shortest distance

With "SyncDirection" = 3, changes in direction of the following axis are permitted during synchronization. In this example, the synchronous position is 90.0.

9.8.3 Synchronizing following axis in advance using dynamic parameters with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. During synchronization in advance using dynamic parameters, synchronization begins in such a way that the leading and following axis are synchronous when the synchronous position is reached.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 0, you define the type of synchronization as synchronization in advance using dynamic parameters.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position establishes the relationship between leading value and following value. The synchronous position must be within the definition of the cam. With "MasterSyncPosition" ≠ 0.0, you move the synchronous position within the cam without changing the position of the cam. For synchronization in advance, the synchronous position is the position starting from which the leading and following axes are synchronous.
- With the parameters "Velocity", "Acceleration", "Deceleration" and "Jerk" you define the dynamics for the synchronization of the following axis.

Until synchronization

After the start of the "MC_CamIn" job, a motion profile for the following axis is calculated continuously. The motion profile is calculated based on the following parameters:

- Specified synchronous position of the Motion Control instruction
- Specified dynamics of the Motion Control instruction
- Current position and dynamics of the leading and following axes
- Synchronous operation specified via cam

The calculation determines the synchronization length and thus the start position of the leading axis for the synchronization.

The start position of the leading axis is derived in the following way:

Start position = Synchronous position of leading axis - Synchronization length

The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3).

If the leading axis is already in its synchronous position when the "MC_CamIn" job is started, the leading axis must first cross the start position to start synchronization. If the leading and following axes are already at their synchronous positions when the "MC_CamIn" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the start position. The synchronization is indicated in the Motion Control instruction "MC_CamIn" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is limited to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

If the programmed dynamic response of the synchronous operation function is greater than the maximum dynamic response of the following axis when the "Execute" parameter is set, the corresponding technology alarms 501, 502, or 503 are output at the following axis.

After synchronization

The following axis is synchronized as soon as the leading axis has reached the synchronous position. The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.8.4 Synchronizing following axis in advance using leading value distance with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. During synchronization in advance using the leading value distance, synchronization begins in such a way that the leading and following axis are synchronous when the synchronous position is reached.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 1, you define the type of synchronization as synchronization in advance using the leading value distance.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position establishes the relationship between leading value and following value. The synchronous position must be within the definition of the cam. With "MasterSyncPosition" ≠ 0.0, you move the synchronous position within the cam without changing the position of the cam. For

synchronization in advance, the synchronous position is the position starting from which the leading and following axes are synchronous.

- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Until synchronization

After the start of the "MC_CamIn" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation determines the required dynamic response and thus the start position of the leading axis for the synchronization.

The start position of the leading axis is derived in the following way:

Start position = Synchronous position of leading axis - Synchronization length

The leading axis must be at least the leading value distance away from the synchronous position. The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3).

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_CamIn" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_CamIn" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the start position. The synchronization is indicated in the Motion Control instruction "MC_CamIn" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the

dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The following axis is synchronized as soon as the leading axis has reached the synchronous position. The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.8.5 Synchronizing following axis in advance via the leading value path from the current leading value position with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. For synchronization in advance, the leading value path from the current leading value position begins as soon as the "MC_CamIn" job becomes effective and the leading axis is in motion.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 6, you define the type of synchronization as synchronization in advance via the leading value path from the current leading value position.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position establishes the relationship between leading value and following value. The synchronous position must be within the definition of the cam. With "MasterSyncPosition" ≠ 0.0, you move the synchronous position within the cam without changing the position of the cam. For synchronization in advance, the synchronous position is the position starting from which the leading and following axes are synchronous.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).
- With the "SlaveOffset" parameter, you define the offset of the cam in the following value range (Page 150). The offset of the cam in the leading value range is calculated automatically.

After the "MC_CamIn" job has started

After the start of the "MC_CamIn" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation results in the required dynamics and the offset of the cam in the leading value range.

If the leading axis is at a standstill when the job starts, the status "Waiting" is displayed on the following axis (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3) until the leading axis is set in motion.

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_CamIn" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_CamIn" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the "MC_CamIn" job takes effect and the leading axis is moving. The synchronization is indicated in the Motion Control instruction "MC_CamIn" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time at which the job becomes effective and the synchronization begins.

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the

dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The cam is offset accordingly in the master value range. The offset results from the current leading value position and the default values of the parameters "MasterSyncPosition", "MasterStartDistance" and "SlaveOffset". The offset in the leading value range is displayed in the "<TO>.StatusSynchronizedMotion.MasterOffset" tag of the technology object.

① Current leading value position

② Current following value position

The following axis is synchronized as soon as the leading axis has reached the synchronous position. The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.8.6 Subsequent synchronizing of following axis using leading value distance with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With subsequent synchronization using the leading value distance, synchronization begins as soon as the leading value has reached the synchronous position of the leading axis.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 3, you define the type of synchronization as subsequent synchronization using the leading value distance.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position establishes the relationship between leading value and following value. The synchronous position must be within the definition of the cam. With "MasterSyncPosition" ≠ 0.0, you move the synchronous position within the cam without changing the position of the cam. For subsequent synchronization, the synchronous position of the leading axis is the start position from which synchronization starts.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Until synchronization

After the start of the "MC_CamIn" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation determines the required dynamic response and the position of the leading axis as of which the leading axis and the following axis travel synchronously.

The status "Waiting" is displayed at the following axis until the leading value has reached the synchronous position of the leading axis (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3).

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_CamIn" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_CamIn" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the leading value has reached the synchronous position. The synchronization is indicated in the Motion Control instruction "MC_CamIn" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when synchronization starts

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the

dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The position of the leading axis from which the leading axis and following axis travel synchronously is derived in the following way:

Position axes synchronous = Synchronous position of leading axis + Synchronization length

As soon as the leading axis has reached this position, the following axis is synchronized. The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.8.7 Subsequent synchronizing of following axis using leading axis value starting from the current leading value position with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With subsequent synchronization using the leading value distance from the current leading value position, synchronization begins as soon as the "MC_CamIn" job takes effect and the leading axis is set in motion.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 4, you define the type of synchronization as subsequent synchronization using the leading value distance from the current leading value position. The position of the leading axis must be within the definition of the cam, which may be scaled or shifted.
- With the "MasterStartDistance" parameter, you specify the leading value distance (synchronization length).

Starting the "MC_CamIn" job

After the start of the "MC_CamIn" job, a motion profile is calculated for the following axis depending on the specified leading value distance. The calculation determines the required dynamic response and the position of the leading axis as of which the leading axis and the following axis travel synchronously.

If the leading axis is at a standstill when the job starts, the status "Waiting" is displayed on the following axis (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3) until the leading axis is set in motion.

NOTE

Dynamic jumps

If the following axis is in motion and the leading value is at standstill when the "MC_CamIn" job is started, dynamic jumps can occur at the following axis as soon as the leading axis is set in motion and the following axis starts synchronizing.

If the leading and following axes are already at their synchronous positions when the "MC_CamIn" job is started, synchronous operation immediately has "Synchronous" status.

During synchronization

The following axis begins to synchronize as soon as the "MC_CamIn" job takes effect and the leading axis is moving. The synchronization is indicated in the Motion Control instruction "MC_CamIn" with the parameter "StartSync" = TRUE and in the "<TO>.StatusWord.X21 (Synchronizing)" tag of the following axis.

The leading value must not reverse during synchronization. To avoid interrupting synchronization in the event of slight fluctuations in the leading value during an actual value coupling, e.g. with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time at which the job becomes effective and the synchronization begins.

② Time when synchronization is complete

The dynamics of the following axis during synchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. Changes in the dynamics of the leading axis during synchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the

configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The dynamic response of the following axis is only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

After synchronization

The position of the leading axis from which the leading axis and following axis travel synchronously is derived in the following way:

Position axes synchronous = Current leading value position at job start + synchronization length

As soon as the leading axis has reached this position, the following axis is synchronized. The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.8.8 Directly set following axis synchronously with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With directly set synchronously, the leading and following axes move synchronously immediately without synchronization motion.

This type of synchronization is mainly suitable for synchronizing at a standstill.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 2, you specify the type of synchronization as directly set synchronously.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position must be within the definition of the cam. With directly set synchronously, the synchronous position is the position in the cam via which the relation between leading axis and following axis is established.

After the "MC_CamIn" job has started

After the "MC_CamIn" job has started, the status "Synchronous" is set directly at the current leading value position and at the current following value position.

The synchronous position specified in the cam is assigned to the position setpoint of the leading axis in the leading value range and to the position setpoint of the following axis in the following value range. The cam is offset accordingly. The current offset results from the cam and is displayed at the "<TO>.StatusSynchronizedMotion.MasterOffset" and "<TO>.StatusSynchronizedMotion.SlaveOffset" tags of the technology object.

The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

Additional information

For more information on direct synchronous setting, refer to the FAQ entry 109758886 (https://support.industry.siemens.com/cs/ww/en/view/109758886) in the Siemens Industry Online Support.

9.8.9 Directly set following axis synchronously at end of the cam with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With directly set synchronously at the end of the cam, you change another cam or the current cam with a new scaling at the end of the active cam. Camming must already be active for this ("MC_CamIn.InSync" = TRUE). The synchronous operation remains in "synchronous" status without a synchronous operation of the following axis.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 5, you specify the type of synchronization as directly set synchronously.
- With the "MasterSyncPosition" parameter, you define the synchronous position relative to the start position of the cam. The synchronous position must be within the definition of the cam. With directly set synchronously at the end of the cam, the specified synchronous position of the cam to be changed is automatically moved to the end position of the active cam. To do this, the cam to be inserted is moved in the leading value range and in the following value range. This means that there is no setpoint jump in the following value.

NOTE

Dynamic jumps

Note that dynamic jumps on the following axis can occur in the transition between the two cams if the velocity and acceleration are discontinuous.

Dynamic jumps on the following axis

To determine dynamic jumps on the following axis, use the "MC_GetCamFollowingValue (Page 354)" instruction, for example, to check the following values for velocity and acceleration in the following positions:

- End position of the active cam (<TO>.StatusCam.EndLeadingValue)
- Synchronous position of the ("MasterSyncPosition") cam to be changed

If the parameter values "MC_GetCamFollowingValue.FirstDerivative" of both jobs match, the transition between the cams is constant in velocity. If the parameter values "MC_GetCamFollowingValue.SecondDerivative" of both jobs match, the transition between the cams is constant in acceleration.

To avoid dynamic jumps on the following axis when changing the active cam with new scaling with the start position as synchronous position, use the setting

"<TO>.InterpolationSettings.BoundaryConditions" = 1 for theinterpolation of the cam (Page 142). This gives you a steady velocity transition.

After the "MC_CamIn" job has started

The status "Waiting" is displayed at the following axis until the leading value has reached the end of the active cam or the active cam cycle ("<TO>.StatusSynchronizedMotion.WaitingFunctionState" = 3).

When reaching the end of the cam

When the end of the cam is reached ("EndOfProfile" = TRUE), the replaced cam becomes active directly at the current leading value position and at the current following value position starting from the specified synchronous position. The cam is offset accordingly. The offset is displayed in the "<TO>.StatusSynchronizedMotion.MasterOffset" and "<TO>.StatusSynchronizedMotion.SlaveOffset" tags of the technology object.

The synchronous operation remains in "synchronous" status. The following axis travels synchronously with the leading axis in accordance with the cam profile.

9.8.10 Directly set the following axis synchronously at specific leading value position with "MC_CamIn"

During camming (Page 102), synchronization establishes the relationship between the leading axis and following axis. With direct synchronous setting at specific leading value position, the leading and following axes move synchronously immediately without synchronization motion.

This type of synchronization is particularly suitable if one of the following points applies:

- The offset of the cam in the following value range should be calculated automatically. The following axis is at a standstill.
- When changing cams, the cams should be replaced in rest areas. The following axis is at a standstill.
- During cam change, the cams are defined as overlapping. The cams should be changed at the same position in the center of the overlapping areas.

Parameter inputs

You define the behavior of the following axis for synchronization with the following parameters of the Motion Control instruction "MC_CamIn (Page 323)":

- With the parameter "SyncProfileReference" = 7, you define the type of synchronization as direct synchronous setting at specific leading value position.
- With the parameter "MasterSyncPosition", you define the synchronous position of the leading axis relative to the start position of the cam. The synchronous position must be within the definition of the cam. With direct synchronous setting at specific leading value position, the synchronous position is the position in the cam via which the relation between the leading and following axis is established.
- You define the offset of the cam in the leading value range (Page 150) with the "MasterOffset" parameter. The offset of the cam in the following value range is calculated automatically.

Until the specified leading value position is reached

Until the leading value has reached the specified leading value position, the status "Waiting" is displayed on the following axis after the start of the "MC_CamIn" job ("<TO>.StatusSynchronizedMotion.WaitingFunctionState" = 3).

If the leading axis is already at its synchronous position when the "MC_CamIn" job is started, the synchronous operation immediately has "Synchronous" status.

When the specified leading value position is reached

As soon as the leading value reaches the specified leading value position, the status "synchronous" is set immediately at the current following value position. If the "MC_CamIn" job replaces already active camming without following error, the following axis remains in "synchronous" status.

NOTE

Dynamic jumps

Note that dynamic jumps on the following axis can occur in the event of discontinuity of the velocity and acceleration in the transition to the new the cam.

The synchronous position specified in the cam is assigned to the position setpoint of the leading axis in the leading value range and to the position setpoint of the following axis in the following value range. The cam is offset accordingly. The current offset results from the cam and the default value of the "MasterOffset" parameter. The offset in the following value range is displayed in the "<TO>.StatusSynchronizedMotion.SlaveOffset" tag of the technology object.

The following axis travels synchronously with the leading axis in accordance with the cam profile (Page 179).

9.9 Synchronous travel in camming with "MC_CamIn"

As soon as the following axis is synchronized to a leading value, the following axis follows the position of the leading axis according to the cam profile. The transmission behavior during camming is expressed by the cam curve.

The "Synchronous" status is indicated in the Motion Control instruction "MC_CamIn (Page 323)" with the parameter "InSync" = TRUE and in the "<TO>.StatusWord.X22 (Synchronous)" tag of the technology object.

NOTE

Avoid homing the leading axis in synchronous operation

Avoid homing the leading axis during an active synchronous operation. Homing the leading axis during synchronous operation corresponds to a setpoint step-change on the following axis. The following axis compensates for the jump according to the synchronous operation function and limited only to the maximum speed of the drive.

9.10 Reading out leading and following values during camming

9.10.1 Reading the leading value in camming

With the Motion Control instruction "MC_GetCamLeadingValue", you read the leading value that is defined for a following value from a cam.

If an area of the cam is scaled with an "MC_SetCamRangeScaling" job ("<TO>.StatusWord.X9 (CamRangeScaled)" = TRUE), the "MC_GetCamLeadingValue" job affects the scaled and interpolated cam.

Parameter inputs

You use the following parameters of the Motion Control instruction "MC_GetCamLeadingValue (Page 352)" to define the settings:

- With the parameter "FollowingValue", you define the following value for which the leading value is to be read.
- You define an approach value for the sought leading value with the parameter "ApproachLeadingValue".
- You define the approach direction for the sought leading value with the parameter "ApproachDirection".
- You define the offset of the cam in the leading value range with the MasterOffset" parameter.
- You define the offset of the cam in the following value range with the "SlaveOffset" parameter.
- You define the scaling of the cam in the leading value range with the "MasterScaling" parameter.
- You define the scaling of the cam in the following value range with the "SlaveScaling" parameter.

The cam technology object is not changed with the specification of offset and scaling of the cam. You can find more information on offset and scaling of the cam in the section "Scaling and shifting cam (Page 150)".

Approach value and approach direction

Since the same following values can be defined for different leading values, specify an approach value for the sought leading value in the "ApproachLeadingValue" parameter. If the following value is used multiple times in the cam, it can be used to limit the searched leading value. The approach value refers to the – if applicable, offset and scaled – leading values of the cam. The approach value can lie inside or outside the definition range of the cam.

In addition, you can define a search direction with the "ApproachDirection" parameter. With "ApproachDirection" = 1, the search is carried out in the positive direction from the specified approach value. With "ApproachDirection" = 2, the search is carried out in the negative direction. With "ApproachDirection" = 3, the nearest value is searched for independent of direction.

If the specified approach value "ApproachLeadingValue" already corresponds to the sought leading value, this leading value is only found with "ApproachDirection" = 3. With "ApproachDirection" = 1 or 2, the closest value in the specified search direction is found in each case.

Example

In the following example, the following value for which the leading value is to be read is defined as "FollowingValue" = 0.5. For the approach value for the sought leading value ①, "ApproachLeadingValue" = 225.0 is specified.

① Approach value for the sought leading value ("ApproachLeadingValue")

With "ApproachDirection" = 1, the search is carried out in the positive direction from the approach value. The read leading value is "Value" = 270.0.

With "ApproachDirection" = 2, the search is carried out in the negative direction from the approach value. The read leading value is "Value" = 90.0.

With "ApproachDirection" = 3, the nearest value is searched for from the approach value independent of direction. The read leading value is "Value" = 270.0.

After the "MC_GetCamLeadingValue" job has started

The leading value is read after the "MC_GetCamLeadingValue" job has started. As soon as the job is completed with "Done" = TRUE, the parameter "Value" contains the read leading value.

9.10.2 Reading the following value in camming

With the Motion Control instruction "MC_GetCamFollowingValue", you read the following value that is defined for a leading value from a cam.

If an area of the cam is scaled with an "MC_SetCamRangeScaling" job ("<TO>.StatusWord.X9 (CamRangeScaled)" = TRUE), the "MC_GetCamFollowingValue" job affects the scaled and interpolated cam.

Parameter inputs

You use the following parameters of the Motion Control instruction "MC_GetCamFollowingValue (Page 354)" to define the settings:

- With the "LeadingValue" parameter, you define the leading value for which the following value is to be read.
- You define the offset of the cam in the leading value range with the "MasterOffset" parameter.
- You define the offset of the cam in the following value range with the "SlaveOffset" parameter.
- You define the scaling of the cam in the leading value range with the "MasterScaling" parameter.
- You define the scaling of the cam in the following value range with the "SlaveScaling" parameter.
- With the "ApplicationMode" parameter, you define the read mode. The read mode defines which values are read out.

The cam technology object is not changed with the specification of offset and scaling of the cam. You can find more information on offset and scaling of the cam in the section "Scaling and shifting cam (Page 150)".

After the "MC_GetCamFollowingValue" job has started

The following value is read after the "MC_GetCamFollowingValue" job has started. As soon as the job is completed with "Done" = TRUE, the following parameters contain the read following value depending on the specified read mode "ApplicationMode":

- When "ApplicationMode" = 0, 1, 2, 3:

  The "Value" parameter contains the position.
- When "ApplicationMode" = 1, 2, 3:

  The "FirstDerivative" parameter contains the velocity.
- When "ApplicationMode" = 2, 3:

  The "SecondDerivative" parameter contains the acceleration.
- When "ApplicationMode" = 3:

  The "ThirdDerivative" parameter contains the jerk.

9.10.3 Reading out the following value cyclically during camming

You read the following value that has been defined for a leading value from a cam cyclically with the Motion Control instruction "MC_GetCamFollowingValueCyclic". Several "MC_GetCamFollowingValueCyclic" jobs related to the same cam are possible simultaneously.

If an area of the cam is scaled with an "MC_SetCamRangeScaling" job ("<TO>.StatusWord.X9 (CamRangeScaled)" = TRUE), the "MC_GetCamFollowingValueCyclic" job affects the scaled and interpolated cam.

Parameter inputs

You use the following parameters of the Motion Control instruction "MC_GetCamFollowingValueCyclic (Page 356)" to define the settings:

- With the "LeadingValue" parameter, you define the leading value for which the following value is to be read.
- You define the offset of the cam in the leading value range with the "MasterOffset" parameter.
- You define the offset of the cam in the following value range with the "SlaveOffset" parameter.
- You define the scaling of the cam in the leading value range with the "MasterScaling" parameter.
- You define the scaling of the cam in the following value range with the "SlaveScaling" parameter.
- With the "ApplicationMode" parameter, you define the read mode. The read mode defines which values are read out.

The cam technology object is not changed with the specification of offset and scaling of the cam. You can find more information on offset and scaling of the cam in the section "Scaling and shifting cam (Page 150)".

During the active "MC_GetCamFollowingValueCyclic" job

The following value is read cyclically as long as the parameter "Enable" = TRUE. Job processing is done synchronously so that the result is output directly. If the parameter "Valid" = TRUE, the following parameters contain the valid following value read for the leading value of the same application cycle depending on the specified read mode "ApplicationMode":

- When "ApplicationMode" = 0, 1, 2, 3:

  The "Value" parameter contains the position.
- When "ApplicationMode" = 1, 2, 3:

  The "FirstDerivative" parameter contains the velocity.
- When "ApplicationMode" = 2, 3:

  The "SecondDerivative" parameter contains the acceleration.
- When "ApplicationMode" = 3:

  The "ThirdDerivative" parameter contains the jerk.

If the leading value is outside the definition range of the cam, the parameter values for the following value are invalid ("Valid" = FALSE).

9.11 Leading value offset during camming

9.11.1 Leading value offset on the following axis during camming using leading value distance as of current leading value position

With a leading value offset, you offset the effective leading value on the following axis during camming with "MC_CamIn (Page 323)". You can move the effective leading value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the leading value offset.

The leading value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during leading value offset with the following parameters of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)":

- With the parameter "ProfileReference" = 1, you specify the type of leading value offset as offset using leading value distance as of the current leading value position.
- With the "PhaseShift" parameter, you specify the leading value offset on the following axis.
- With the "PhasingDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the leading value offset.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 185).

During the leading value offset

After starting the jobs, the following axis begins with the leading value offset starting from the current position. Within the traversing distance of the leading axis, the following axis offsets the leading value at continuous velocity and acceleration. The required dynamics of the following axis to offset the leading value is calculated by the system. During leading value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The leading value offset is indicated in the Motion Control instruction with the parameter "StartPhasing" = TRUE and in the "<TO>.StatusWort.X24 (PhasingCommand)" tag of the technology object. The "AbsolutePhaseShift" or "CoveredPhaseShift" parameter shows the absolute leading value portion already shifted.

The leading value must not reverse during the leading value offset on the following axis. When the leading value reverses, the "MC_PhasingAbsolute" job or "MC_PhasingRelative" job is canceled with "ErrorID" = 16#808C.

After the leading value offset

As soon as the following axis has offset the leading value, the leading value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

The leading value offset only has an effect in the "Synchronous" status of the camming. When the camming is overridden, the leading value offset is reset to zero.

9.11.2 Leading value offset on the following axis during camming using leading value distance as of specific leading value position

With a leading value offset, you offset the effective leading value on the following axis during camming with "MC_CamIn (Page 323)". You can move the effective leading value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the leading value offset.

The leading value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

Parameter inputs

You define the behavior of the following axis during leading value offset with the following parameters of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)":

- With the parameter "ProfileReference" = 2, you specify the type of leading value offset as offset using leading value distance as of a specific leading value position.
- With the "PhaseShift" parameter, you specify the leading value offset on the following axis.
- With the "PhasingDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the leading value offset.
- With the "StartPosition" parameter, you specify the leading value position from which the leading value offset starts.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 185).

Until the leading value offset

After starting the job, the status "Waiting" is displayed at the following axis when the leading value is at standstill and until the leading value has reached the leading value position (<TO>.StatusWord2.X3 = TRUE (PhasingCommandWaiting)).

During the leading value offset

As soon as the leading value has reached the leading value position, the following axis begins to offset the leading value. Within the traversing distance of the leading axis, the following axis offsets the leading value at continuous velocity and acceleration. The required dynamics of the following axis to offset the leading value is calculated by the system. During leading value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The leading value offset is indicated in the Motion Control instruction with the parameter "StartPhasing" = TRUE and in the "<TO>.StatusWort.X24 (PhasingCommand)" tag of the technology object. The "AbsolutePhaseShift" or "CoveredPhaseShift" parameter shows the absolute leading value portion already shifted.

The leading value must not reverse during the leading value offset on the following axis. When the leading value reverses, the "MC_PhasingAbsolute" job or "MC_PhasingRelative" job is canceled with "ErrorID" = 16#808C. The waiting job is not canceled.

After the leading value offset

As soon as the following axis has offset the leading value, the leading value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

The leading value offset only has an effect in the "Synchronous" status of the camming. When the camming is overridden, the leading value offset is reset to zero.

9.11.3 Defining the direction of the leading value distance of a leading value offset on the following axis during camming

With a leading value offset, you offset the effective leading value on the following axis during camming with "MC_CamIn (Page 323)". With the "Direction" parameter of the Motion Control instruction "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)", you specify the direction of the leading value distance in relation to the direction of motion of the effective leading value.

Defining leading value distance in the positive direction of motion of the effective leading value

With "Direction" = 1, the following axis only offsets the leading value when the leading axis travels in the positive direction.

Defining leading value distance in the negative direction of motion of the effective leading value

With "Direction" = 2, the following axis only offsets the leading value when the leading axis travels in the negative direction.

Defining leading value distance in the current direction of motion of the effective leading value

With "Direction" = 3, the following axis offsets the leading value regardless of the direction in which the leading axis is currently traveling.

9.11.4 Canceling a pending leading value offset in the camming

With an "MC_PhasingAbsolute (Page 304)" or "MC_PhasingRelative (Page 297)" job with "ProfileReference" = 5, you cancel a pending "MC_PhasingAbsolute" or "MC_PhasingRelative" job. Canceling a waiting job has no effect on an active leading value offset.

9.12 Following value offset during camming

9.12.1 Following value offset on the following axis during camming using leading value distance as of current leading value position

With a following value offset, you offset the following value on the following axis during camming with "MC_CamIn (Page 323)". You can move the following value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the following value offset.

The following value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

For camming, the offset of the following value with an "MC_OffsetAbsolute" or "MC_OffsetRelative" job (<TO>.StatusSynchronizedMotion.Offset) starts at the start value "<TO>.StatusSynchronizedMotion.SlaveOffset".

Parameter inputs

You define the behavior of the following axis during following value offset with the following parameters of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)":

- With the parameter "ProfileReference" = 1, you specify the type of following value offset as offset using leading value distance as of the current leading value position.
- With the "Offset" parameter, you specify the following value offset on the following axis.
- With the "OffsetDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the following value offset.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 191).

During the following value offset

After starting the job, the following axis begins with the following value offset starting from the current position. Within the traversing distance of the leading axis, the following axis offsets the following value at continuous velocity and acceleration. The required dynamics of the following axis for the following value offset is calculated by the system. During following value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The following value offset is indicated in the Motion Control instruction with the parameter "StartOffset" = TRUE and in the "<TO>.StatusWort2.X4 (OffsetCommand)" tag of the technology object. The "AbsoluteOffset" or "CoveredOffset" parameter shows the absolute following value portion already shifted.

The leading value must not reverse during the following value offset on the following axis. When the leading value reverses, the "MC_OffsetAbsolute" job or "MC_OffsetRelative" job is canceled with "ErrorID" = 16#808C.

After the following value offset

As soon as the following axis has offset the following value, the following value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

The following value offset only has an effect in the "Synchronous" status of the camming. When the camming is overridden, the following value offset is reset to zero.

9.12.2 Following value offset on the following axis during camming using leading value distance as of specific leading value position

With a following value offset, you offset the following value on the following axis during camming with "MC_CamIn (Page 323)". You can move the following value absolutely or relatively. The leading value of the leading value source and the position of the leading axis are not influenced by the following value offset.

The following value offset always refers to the effective leading value. The effective leading value is made up of the leading value of the leading value source and the additive leading value. If you do not use an additive leading value via "MC_LeadingValueAdditive (Page 347)", the effective leading value corresponds to the leading value of the leading value source. You can find an overview in the "Mode of operation of the instructions in synchronous operation (Page 34)" section. In the following, "leading value" refers to the effective leading value.

For camming, the offset of the following value with an "MC_OffsetAbsolute" or "MC_OffsetRelative" job (<TO>.StatusSynchronizedMotion.Offset) starts at the start value "<TO>.StatusSynchronizedMotion.SlaveOffset".

Parameter inputs

You define the behavior of the following axis during following value offset with the following parameters of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)":

- With the parameter "ProfileReference" = 2, you specify the type of following value offset as offset using leading value distance as of a specific leading value position.
- With the "Offset" parameter, you specify the following value offset on the following axis.
- With the "OffsetDistance" parameter, you specify the leading value distance (traversing distance of the leading axis) during the following value offset.
- With the "StartPosition" parameter, you specify the leading value position from which the following value offset starts.
- With the "Direction" parameter, you specify the direction of the leading value distance in relation to the direction of motion of the leading value (Page 191).

Until the following value offset

After starting the job, the status "Waiting" is displayed at the following axis when the leading value is at standstill and until the leading value has reached the leading value position (<TO>.StatusWord2.X5 = TRUE (OffsetCommandWaiting)).

During the following value offset

As soon as the leading value has reached the leading value position, the following axis begins to offset the following value. Within the traversing distance of the leading axis, the following axis offsets the following value at continuous velocity and acceleration. The required dynamics of the following axis for the following value offset is calculated by the system. During following value offset, the dynamics of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

The following value offset is indicated in the Motion Control instruction with the parameter "StartOffset" = TRUE and in the "<TO>.StatusWort2.X4 (OffsetCommand)" tag of the technology object. The "AbsoluteOffset" or "CoveredOffset" parameter shows the absolute following value portion already shifted.

The leading value must not reverse during the following value offset on the following axis. When the leading value reverses, the "MC_OffsetAbsolute" job or "MC_OffsetRelative" job is canceled with "ErrorID" = 16#808C. The waiting job is not canceled.

After the following value offset

As soon as the following axis has offset the following value, the following value offset is active on the following axis. The status is indicated in the Motion Control instruction with the parameter "Done" = TRUE and in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

The following value offset only has an effect in the "Synchronous" status of the camming. When the camming is overridden, the following value offset is reset to zero.

9.12.3 Defining the direction of the leading value distance of a following value offset on the following axis during camming

With a following value offset, you offset the following value on the following axis during camming with "MC_CamIn (Page 323)". With the "Direction" parameter of the Motion Control instruction "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)", you specify the direction of the leading value distance in relation to the direction of motion of the effective leading value.

Defining leading value distance in the positive direction of motion of the effective leading value

With "Direction" = 1, the following axis only offsets the following value when the leading axis travels in the positive direction.

Defining leading value distance in the negative direction of motion of the effective leading value

With "Direction" = 2, the following axis only offsets the following value when the leading axis travels in the negative direction.

Defining leading value distance in the current direction of motion of the effective leading value

With "Direction" = 3, the following axis offsets the following value regardless of the direction in which the leading axis is currently traveling.

9.12.4 Canceling a pending following value offset in the camming

With an "MC_OffsetAbsolute (Page 317)" or "MC_OffsetRelative (Page 311)" job with "ProfileReference" = 5, you cancel a pending "MC_OffsetAbsolute" or "MC_OffsetRelative" job. Canceling a pending job has no effect on an active following value offset.

9.13 Desynchronize camming

9.13.1 Desynchronizing following axis using dynamic parameters with "MC_CamOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and camming is ended. For desynchronization using dynamic parameters, desynchronization begins in such a way that the following axis comes to a standstill when the stop position is reached.

With the Motion Control instruction "MC_CamOut" you can desynchronize a camming which you have started either with a "MC_CamIn (Page 323)" job.

Parameter inputs

You define the behavior of the following axis for desynchronization with the following parameters of the Motion Control instruction "MC_CamOut (Page 343)":

- With the parameter "SyncProfileReference" = 0, you specify the type of desynchronization as desynchronization using dynamic parameters.
- With the "SlavePosition" parameter, you specify the stop positions of the following axis. The stop position of the following axis is the position at which the following axis comes to a standstill and the desynchronization is completed.
- With the "Deceleration" parameter, you specify the deceleration of the following axis.
- With the "Jerk" parameter, you specify the jerk of the following axis.
- With the "SyncOutDirection" parameter, you specify the direction of the desynchronization (Page 197).

Until desynchronization

After the start of the "MC_CamOut" job, a motion profile for the following axis is calculated continuously. The motion profile is calculated based on the following parameters:

- Specified stop position of the following axis in the Motion Control instruction
- Specified dynamics of the Motion Control instruction
- Current position and dynamics of the leading and following axes
- Synchronous operation function
- Superimposed motion of the following axis
- Additive leading value of the following axis

The distance of the following axis and thus the starting position of the following axis for desynchronization results from the calculation.

The start position of the following axis is derived in the following way:

Start position = stop position of the following axis - travel distance of the following axis

The status "Waiting" is displayed at the following axis until the following value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 5).

During desynchronization

The following axis begins to desynchronize as soon as the following value has reached the start position. Desynchronization is indicated in the Motion Control instruction "MC_CamOut" with the parameter "StartSyncOut" = TRUE and in the "<TO>.StatusWord2.X1 (DesynchronizingCommand)" tag of the technology object. The synchronous operation is no longer in the "Synchronous" status. Superimposed jobs of the following axis are canceled.

The following axis moves to the stop position with the specified dynamics, independent of the leading value. The dynamic response of the following axis is limited to the dynamic limits configured on the technology object.

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

During desynchronization, several modulo revolutions of both axes are generally possible.

After desynchronization

As soon as the following axis reaches the stop position, the following axis is desynchronized. The following axis is at a standstill. The status is indicated in the Motion Control instruction "MC_CamOut" with the parameter "Done" = TRUE and in the "<TO>.StatusWord.X7 (Standstill)" tag of the technology object.

See also

Configuring the reverse tolerance of the leading value (Page 44)

9.13.2 Desynchronizing following axis using leading value distance with "MC_CamOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and camming is ended. For desynchronization using the leading value distance, desynchronization begins in such a way that the following axis comes to a standstill when the stop position is reached.

With the Motion Control instruction "MC_CamOut" you can desynchronize a camming which you have started either with a "MC_CamIn (Page 323)" job.

Parameter inputs

You define the behavior of the following axis for desynchronization with the following parameters of the Motion Control instruction "MC_CamOut (Page 343)":

- With the parameter "SyncProfileReference" = 1, you specify the type of desynchronization as desynchronization using the leading value distance.
- With the "SlavePosition" parameter, you specify the stop positions of the following axis. The stop position of the following axis is the position at which the following axis comes to a standstill and the desynchronization is completed.

- With the "MasterStopDistance" parameter, you define the leading value distance (desynchronization length).
- With the "SyncOutDirection" parameter, you specify the direction of the desynchronization (Page 197).

Until desynchronization

After the start of the "MC_CamOut" job, a motion profile is calculated depending on the specified leading value distance. The calculation determines the required dynamics and thus the start position of the leading axis for the desynchronization.

The start position of the leading axis is derived in the following way:

Start position = leading value position when the stop position of the following axis is reached - leading value distance

The status "Waiting" is displayed at the following axis until the leading value has reached the start position (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 5).

During desynchronization

The following axis begins to desynchronize as soon as the leading value has reached the start position. Desynchronization is indicated in the Motion Control instruction "MC_CamOut" with the parameter "StartSyncOut" = TRUE and in the "<TO>.StatusWord2.X1 (DesynchronizingCommand)" tag of the technology object. The synchronous operation is no longer in the "Synchronous" status. Superimposed jobs of the following axis are canceled.

The following axis travels to the stop position depending on the leading value distance. The dynamics of the following axis during desynchronization is obtained from the calculated motion profile and the current dynamics of the leading axis. The dynamic response of the following axis is thereby only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity).

Changes in the dynamics of the leading axis during desynchronization are superimposed with the calculated motion profile in accordance with the synchronous operation function. This can have the result that the configured dynamic limits at the following axis are violated. This is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object.

During desynchronization, several modulo revolutions of both axes are generally possible.

The leading value must not reverse during desynchronization. In order not to interrupt desynchronization when there are slight fluctuations in the leading value during an actual value coupling, for example, with an external encoder, you can define a reverse tolerance of the leading value (Page 44).

① Time when desynchronization starts

② Time when desynchronization is complete

If the leading axis stops during desynchronization, high dynamic values can occur at the following axis as soon as the leading axis starts moving again and the following axis continues moving to the specified stop position. To avoid these high dynamic values at the following axis, use desynchronization via dynamic parameters ("SyncProfileReference" = 0).

After desynchronization

As soon as the following axis reaches the stop position, the following axis is desynchronized. The following axis is at a standstill. The status is indicated in the Motion Control instruction "MC_CamOut" with the parameter "Done" = TRUE and in the "<TO>.StatusWord.X7 (Standstill)" tag of the technology object.

9.13.3 Defining direction of desynchronization with "MC_CamOut"

Desynchronization ends the synchronous operation relationship between the leading and following axis and camming is ended. You can specify the desynchronization direction with the "SyncOutDirection" parameter of the Motion Control instruction "MC_CamOut (Page 343)".

Desynchronizing the following axis in positive traversing direction

With "SyncOutDirection" = 1, the following axis is only desynchronized when the following axis moves in the positive direction.

Desynchronizing the following axis in negative traversing direction

With "SyncOutDirection" = 2, the following axis is only desynchronized when the following axis moves in the negative direction.

Desynchronizing the following axis in the current traversing direction

With "SyncOutDirection" = 3, the following axis is desynchronized in the direction in which the following axis is currently moving.

9.13.4 Dynamic limits of the following axis during desynchronization with "MC_CamOut"

If a synchronous axis is desynchronized as a following axis in the camming with the Motion Control instruction "MC_CamOut (Page 343)", the following dynamic limits apply, depending on the type of desynchronization:

Desynchronization via dynamic parameters

During synchronization using dynamic parameters, the dynamic limits configured at the technology object apply to the following axis.

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

The SW limit switches also continue to be monitored with the configured dynamic limits of the following axis.

Desynchronization using leading value distance

When desynchronizing via the leading value distance and during synchronous travel, the dynamics of the following axis are only limited to the maximum value for the speed setpoint of the drive (<TO>.Actor.DriveParameter.MaxSpeed). With a linear motor, the dynamic response of the following axis is limited to the maximum value for the velocity setpoint of the drive (<TO>.Actor.LinearMotorDriveParameter.MaxVelocity). The dynamics of the following axis results from the synchronous operation function.

If the dynamic limits configured for the following axis are exceeded, this is indicated in the "<TO>.StatusSynchronizedMotion.StatusWord.X0 ... X2" tags of the technology object. The SW limit switches continue to be monitored with the configured dynamic limits of the following axis.

If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

9.13.5 Canceling pending camming with "MC_CamOut"

With a "MC_CamOut (Page 343)" job with "SyncProfileReference" = 5 you cancel a pending camming. Canceling a pending camming has no effect on an active cam camming.

9.14 Tags: Camming

The following technology object tags are relevant for camming:

Synchronous axis

Configuration		
Tag	**Description**	
<TO>.SynchronizedMotion.LeadingValueReversalTolerance	Reverse tolerance of the leading value during synchronization with "MC_CamIn" and desynchronization with "MC_CamOut" in length unit of the axis	
<TO>.SynchronizedMotion.LeadingValueTolerenceDirection	Tolerated leading value direction to leave the tolerance range	
	1	Positive
	2	Negative
	3	Positive and negative

Status displays		
Tag	**Description**	
<TO>.StatusSynchronizedMotion.FunctionState	Indication of which synchronous operation function is active	
	0	No synchronous operation active
	1	Gearing ("MC_GearIn")
	2	Gearing with specified synchronous positions ("MC_GearInPos")
	3	Camming ("MC_CamIn")
	4	Desynchronization of gearing ("MC_GearOut")
	5	Desynchronization of camming ("MC_CamOut")
	6	Velocity synchronous operation ("MC_GearInVelocity")
<TO>.StatusSynchronizedMotion.WaitingFunctionState	Indication of which synchronous operation function is waiting	
	0	No synchronous operation waiting
	1	Reserved
	2	Gearing with specified synchronous positions waiting ("MC_GearInPos")
	3	Camming waiting ("MC_CamIn")
	4	Desynchronization of gearing waiting ("MC_GearOut")
	5	Desynchronization of camming waiting ("MC_CamOut")
<TO>.StatusSynchronizedMotion.ActualMaster	When a synchronous operation job is started, the number of the technology data block of the currently used leading axis is displayed.	
	0	Synchronous operation inactive
<TO>.StatusSynchronizedMotion.ActualCam	Currently used cam for camming	

Status displays	
Tag	**Description**
<TO>.StatusSynchronizedMotion.MasterOffset	Current offset of the leading value range of the cam
<TO>.StatusSynchronizedMotion.MasterScaling	Current scaling of the leading value range of the cam
<TO>.StatusSynchronizedMotion.SlaveOffset	Current offset of the following value range of the cam
<TO>.StatusSynchronizedMotion.SlaveScaling	Current scaling of the following value range of the cam
<TO>.Position	Setpoints of the axis
<TO>.Velocity	
<TO>.Acceleration	
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Position	Effective leading value including an additive leading value with an "MC_LeadingValueAdditive" job
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Velocity	
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Acceleration	
<TO>.StatusSynchronizedMotion.PhaseShift	Current absolute leading value offset with an "MC_PhasingAbsolute" or "MC_PhasingRelative" job
<TO>.StatusSynchronizedMotion.FunctionLeadingValue.Position	Leading value of the synchronous operation function after a leading value offset with an "MC_PhasingAbsolute" job or "MC_PhasingRelative" job including an additive leading value with a "MC_LeadingValueAdditive" job
<TO>.StatusSynchronizedMotion.FunctionFollowingValue.Position	Following value of the synchronous operation function before a following value offset with an "MC_OffsetAbsolute" job or "MC_OffsetRelative" job
<TO>.StatusSynchronizedMotion.FunctionFollowingValue.Velocity	
<TO>.StatusSynchronizedMotion.FunctionFollowingValue.Acceleration	
<TO>.StatusSynchronizedMotion.Offset	Current absolute following value offset with an "MC_OffsetAbsolute" or "MC_OffsetRelative" job
<TO>.StatusSynchronizedMotion.StatusWord.X0 (MaxVelocityExceeded)	Set to the value "TRUE" when the maximum velocity configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X1 (MaxAccelerationExceeded)	Set to the value "TRUE" when the maximum acceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X2 (MaxDecelerationExceeded)	Set to the value "TRUE" when the maximum deceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusWord.X21 (Synchronizing)	Set to the value "TRUE" when the synchronous axis synchronizes to a leading value.
<TO>.StatusWord.X22 (Synchronous)	Set to the value "TRUE" when the synchronous axis is synchronized and moves synchronously to the leading axis.
<TO>.StatusWord2.X1 (DesynchronizingCommand)	Set to the value "TRUE" when the synchronous axis desynchronizes.
<TO>.StatusWord.X24 (PhasingCommand)	Set to the value "TRUE" if a job for leading value offset is active ("MC_PhasingAbsolute", "MC_PhasingRelative").
<TO>.StatusWord2.X3 (PhasingCommandWaiting)	Set to the value "TRUE" if a job for leading value offset is pending ("MC_PhasingAbsolute", "MC_PhasingRelative").

Status displays	
Tag	**Description**
<TO>.StatusWord2.X4 (OffsetCommand)	Set to the value "TRUE" if a job for following value offset is active ("MC_OffsetAbsolute", "MC_OffsetRelative").
<TO>.StatusWord2.X5 (OffsetCommandWaiting)	Set to the value "TRUE" if a job for following value offset is waiting ("MC_OffsetAbsolute", "MC_OffsetRelative").
<TO>.ErrorWord.X14 (SynchronousError)	Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.

Cam

Status displays	
Tag	**Description**
<TO>.StatusWord.X6 (Interpolated)	Set to the value "TRUE" when the job for interpolatation of the cam has been completed ("MC_InterpolateCam").
<TO>.StatusWord.X9 (CamRangeScaled)	Set to the value "TRUE" if at least one area of the cam is scaled via a "MC_SetCamRangeScaling" job is scaled.

Other synchronous operation functions 10

10.1 Simulate synchronous operation

An active synchronous operation connection is disconnected when axis enables are removed or for motion jobs on a following axis. By simulating synchronous operation, you can keep the synchronous operation active without canceling the synchronous operation relationship. You can set an active synchronous operation with the Motion Control instruction "MC_SynchronizedMotionSimulation (Page 337)" in simulation.

The synchronous operation only acts on the following axis. Setpoint changes from the synchronous operation are no longer taken into consideration at the axis and no longer forwarded to the drive. The setpoints output to the drive continue to come from any active superimposed motions of the following axis. This also applies to single-axis jobs on the following axis, while synchronous operation is in simulation mode.

NOTICE
Machine damage due to possible setpoint jumps If superimposed motions are or were active on the following axis due to the Motion Control instructions "MC_MoveSuperimposed", "MC_MotionInSuperimposed", "MC_MotionInSuperimposedAxes" or "MC_HaltSuperimposed", the following axis follows the leading axis after simulation is ended without the position offset by the superimposed motion. Setpoint jumps can occur as a result. To avoid setpoint jumps, note the following: • For superimposed motions, do not set a synchronous operation to simulation. • To move following values on the following axis, use the "MC_OffsetAbsolute" or "MC_OffsetRelative" instructions instead of the instructions for superimposed motions. • To set a synchronous operation with an active "MC_MotionInSuperimposedAxes" motion to simulation at the following axis, consider the conditions and procedure in the FAQ entry 109994585 (https://support.industry.siemens.com/cs/ww/en/view/109994585).

Starting the simulation

Requirement

- The technology object has been configured correctly.
- The following axis is a synchronous axis.
- Synchronous operation is active on the technology object in status "Synchronous" (<TO>.StatusWord.X22 = TRUE).

Procedure

To set a synchronous operation on a following axis in simulation mode, follow these steps:

1. At the "Slave" parameter of the "MC_SynchronizedMotionSimulation" job, specify the following axis on which the synchronous operation is active.
2. Bring the leading axis to a standstill, e.g. with an "MC_Halt" job.
3. Start the simulation of the synchronous operation on the following axis with "Enable" = TRUE parameter. The leading axis must be stopped at this time.

   As soon as the synchronous operation is active, this is indicated in the Motion Control instruction by the parameter "InSimulation" = TRUE and in the "<TO>.StatusSynchronizedMotion.StatusWord.X3 (InSimulation)" tag of the technology object.

   The synchronous operation remains active during the simulation, including the motions through single axis jobs or with disabling the leading axis and/or following axis with "MC_Power.Enable" = FALSE or a "MC_Stop" job, for example by opening a protective door. The synchronous operation in "synchronous" status ("MC_GearIn.InGear" = TRUE, "MC_GearInPos.InSync" = TRUE or "MC_CamIn.InSync" = TRUE, but "<TO>.StatusWord.X22" = FALSE).

End simulation

NOTICE
Machine damage due to possible setpoint jumps If the position of the following axis at the end of the simulation differs from the position at the start of the simulation, this triggers a setpoint step-change which can lead to machine damage. Therefore, make sure that the setpoints of the following axis correspond to the setpoints from the synchronous operation relationship when simulation is ended.

Requirement

- The set position of the following axis coincides with the setpoint from the synchronous relationship.
- The technology object has been enabled ("MC_Power.Enable" = TRUE).

Procedure

To end a synchronous operation on a following axis, follow these steps:

1. End the synchronous operation with the parameter "Enable" = FALSE of the "MC_SynchronizedMotionSimulation" job.

   The setpoints of the synchronous operation are directly effective on the following axis. The following axis does not have to be synchronized again after the synchronous operation has been completed.

10.1.1 Tags: Synchronous operation is being simulated

The following tags of the technology object are relevant for simulation:

Status indicators		
Tag	**Description**	
<TO>.StatusSynchronizedMotion.StatusWord.X3 (InSimulation)	Simulation of synchronous operation on a following axis with a "MC_SynchronizedMotionSimulation" job	
	FALSE	Not simulated
	TRUE	Simulated

10.2 Specify additive leading value

To superimpose the leading value of a synchronous operation from the application, use the Motion Control instruction "MC_LeadingValueAdditive" in addition to the active leading value to cyclically specify an additive leading value on the following axis. The additive leading value consists of position, velocity and acceleration.

You can find an overview in the section "Mode of operation of the instructions in synchronous operation (Page 34)".

Parameter inputs

With the following parameters of the Motion Control instruction "MC_LeadingValueAdditive (Page 347)" you can determine the additive leading value:

- At the "Axis" parameter, specify the following axis on which the additive leading value acts.
- With the "Position" parameter, you can define the additive position value.
- With the "Velocity" parameter, you can define the additive velocity value.
- With the "Acceleration" parameter, you can define the additive acceleration value.

Start additive leading value specification

With the "Enable" parameter = TRUE of the "MC_LeadingValueAdditive" job, set the additive leading value to effective. The additive leading value becomes effective directly and without dynamic limitation on the following axis.

You can start an "MC_LeadingValueAdditive" job independently of the synchronous operation job. Only one "MC_LeadingValueAdditive" job can be active on a following axis at any time.

During the additive leading value specification

The default values for position, velocity and acceleration are valid as long as the "Busy" parameter = TRUE. Changes in the specified values are directly effective without consideration of the dynamic limits. The active additive leading value specification is displayed in of the "<TO>.StatusSynchronizedMotion.StatusWord.X4 (LeadingValueAdditiveCommand)" tag of the technology object.

The effect of a "MC_LeadingValueAdditive" job depends on the status of the synchronous operation:

Status of synchronous operation	Effect on:
Not active or pending	• Start position of synchronization • Following axis dynamic response
Synchronization	• Synchronous position • Phase position • Following axis dynamic response
Synchronous motion	• Phase position • Following axis dynamic response
Desynchronization	• Stop position of following axis • Phase position • Following axis dynamic response

With a leading value switchover, the additive leading value still remains effective.

Ending the additive leading value specification

As soon as you end the leading value specification with the parameter "Enable" = FALSE of the "MC_LeadingValueAdditive" job, the additive leading value directly becomes ineffective.

10.2.1 Tags: Additive leading value

The following technology object tags are relevant for the additive leading value:

Status indicators		
Tag	**Description**	
<TO>.StatusSynchronizedMotion.StatusWord.X4 (LeadingValueAdditiveCommand)	Additive leading value with a "MC_LeadingValueAdditive" job	
	FALSE	Additive leading value not active
	TRUE	Additive leading value active
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Position	Effective leading value position of the synchronous operation function	
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Velocity	Effective leading value velocity of the synchronous operation function	
<TO>.StatusSynchronizedMotion.EffectiveLeadingValue.Acceleration	Effective leading value acceleration of the synchronous operation function	

Cross-PLC synchronous operation 11

With cross-PLC synchronous operation, you realize synchronous operations between axes that are on different CPUs. All following axes of a leading value are hereby synchronous to one another with consideration of the respective synchronous operation function. All following axes receive the same leading value at the same time.

You can configure and operate the following axes on different CPUs. You can also configure the leading axis on any CPU.

The S7-1500 and S7-1500T CPUs can make the leading value available for a cross-PLC synchronous operation. You need to use an S7-1500T CPU as the CPU that receives the leading value.

Leading axis, leading axis proxy and virtual leading axis

The leading axis can be interconnected with local following axes on the same CPU to a synchronous operation. The leading axis also provides the leading value for cross-PLC synchronous operation. You can use a positioning axis, synchronous axis or external encoder technology object as the leading axis.

Recommendation: Use a virtual axis as leading axis.

On a CPU that receives the leading value, a technology object leading axis proxy reads the leading value. A following axis on the CPU can be interconnected directly to the leading axis proxy as a leading value to a synchronous operation.

Recommendation: Use an additional virtual leading axis, which you interconnect with the following axes to a synchronous operation. If, for example, the leading value of CPU 1 is not provided or fails, you can stop or move the following axes in the group via the additional virtual leading axis.

The figure below shows the operating principle based on an example with one following axis per CPU:

Leading value delay that can be configured at the leading axis (delay time)

Delay time caused by the processing and transfer of the leading value

Gearing (example)

The leading axis and a local following axis 1 are located on CPU 1. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

The leading value of the CPU 1 is transferred to the CPUs 2 to n by means of a leading value telegram via PROFINET IO with IRT. On CPUs 2 to n, a leading axis proxy reads the leading value. A following axis is locally interconnected with a virtual leading axis.

All following axes 1 to n are synchronous and follow the same leading value.

Communication options

The CPUs can communicate with each other in the following ways:

- Communication via the direct data exchange (Page 213)

  If all CPUs are in the same project, use the direct data exchange.

  This is useful, for example, if the machine modules represented by the respective CPUs are always present in the machine.

- Communication via a PN/PN coupler (Page 220)

  For the communication of the CPUs via different PROFINET subnets, use a PN/PN coupler in ISO mode. ISO mode is possible as of firmware version 6.0 of the PN/PN coupler.

  The CPUs can be in the same project or in different projects:

  – If all CPUs are in the same project, you can configure a PN/PN reduction ratio, for example. This structure can also be useful for net separation.

    Note that online routing via the PN/PN coupler is not possible.

  – If the CPUs are in different projects, you can easily integrate option modules with their own CPU into the machine, for example.

    You can also connect machines from different manufacturers without having to disclose the know-how of your own project.

- Communication using isochronous I-device (Page 230)

  If multiple PROFINET interfaces of a CPU support the "PROFINET with IRT" functionality, you can operate the CPU as an isochronous I-device.

  The PROFINET interface configured as an I-device is used for isochronous data exchange with the higher-level IO Controller, through which you can realize cross-PLC synchronous operation. The other PROFINET interface can synchronize with the I-device interface and operate connected IO devices isochronously.

  The CPUs can be in the same project or in different projects:

  – If all CPUs are in the same project, you can temporarily deactivate the I-device, for example. This may be useful in order to temporarily operate a machine without a machine module equipped with a CPU.

    For more information on deactivating an I-device, refer to the "SIMATIC PROFINET with STEP 7" function manual (https://support.industry.siemens.com/cs/ww/en/view/49948856).

  – If the CPUs with the same PROFINET cycle are in different projects, you can easily integrate option modules with their own CPU into the machine or connect machines from different manufacturers, for example.

More information

For more information on the setup and diagnostics of a cross-PLC synchronous operation including sample projects, refer to the Siemens Industry Online Support FAQ entry 109770938 (https://support.industry.siemens.com/cs/ww/en/view/109770938).

More information on PROFIsafe sample configurations can be found in Siemens Industry Online Support in the FAQ entry 109740240 (https://support.industry.siemens.com/cs/ww/en/view/109740240).

11.1 Time response in cross-PLC synchronous operation

In the processing and transfer of the leading value, a delay time occurs between the generation of the leading value on the leading axis one on CPU and the provision of the leading value for the following axes at the leading axis proxy on the other CPUs. The following axes of the other CPUs receive the leading value with a time delay. The delay time depends on the route of the leading value.

To achieve synchronicity between the local following axes of the CPU of the leading axis and the following axes of other CPUs without extrapolating the leading value at the leading axis proxy, the leading value output can be delayed at the leading axis for the local following axes. The delay time can be compensated for with these configurable delay times.

Delay time

You can calculate and view the delay times in the interconnection overview (Page 242). The application cycles of the leading axis proxy and any cascading present are included in the calculation of the delay times.

Alternatively, you can manually configure the delay times on the leading axis and on the virtual following axes. In this way, you can consider additional requirements from your specific application, for example.

Depending on the set delay time, the leading value at the leading axis proxy is automatically interpolated or extrapolated. The automatic interpolation and extrapolation guarantees the synchronicity of all following axes. In the interconnection overview, an indication of whether the leading value is interpolated or extrapolated is provided for each route of a leading value (Page 244).

NOTE

Deviations in the following values

With an extrapolation, deviations in the following values can occur in the event of velocity changes.

With an interpolation, no deviations of the following values occur in the event of velocity changes.

If you increase the delay time of the leading axis in the leading value settings, this leads to a lower extrapolation time at the leading axis proxy or to a higher interpolation time of the leading value at the leading axis proxy. This reduces the deviations in the following values that arise during extrapolation in the acceleration and deceleration phases.

If the delay time at the leading axis proxy is increased, this results in a higher extrapolation time or to a lower interpolation time.

Recursive interconnection

When all axes are active, the leading axis becomes the following axis of its own leading value with a recursive interconnection. During the configuration, recursive interconnections are displayed in the interconnection overview. No delay times can be calculated for recursive interconnections.

Even if different synchronized groups are active at different times, recursive interconnections may still occur during interconnection. Recursive interconnections over multiple CPUs are not detected during runtime.

A recursive interconnection that is in effect during runtime is not permitted.

11.2 Compatible versions for synchronous operation across PLCs

Firmware and technology versions

A cross-PLC synchronous operation is possible as of firmware version V2.8 and as of technology version V5.0.

Leading value telegram and technology versions

The following table shows the possible combinations of technology versions depending on the leading value telegram version:

Technology version		Leading value telegram version
Leading value source	Recipient	
≤ V8.0	≤ V8.0	V1
	V9.0	-
	≥ V10.0	V1
V9.0	≤ V8.0	-
	V9.0	V2
	≥ V10.0	V2
≥ V10.0	≤ V8.0	V1
	V9.0	V2
	≥ V10.0	V1, V2

If the combination of the leading value telegram and technology versions is incompatible, technology alarm 901 is output on the leading axis proxy.

The leading value telegram version is indicated in the "<TO>.CrossPlcSynchronousOperation.Interfaces[1..32].TelegramVersion" tag of the technology object of the leading axis or following axis.

NOTE

Upgrade to technology version V10.0

Note the information on leading value telegram version 2 in the section "Upgrading to technology version V10.0 (Page 21)".

Reduction ratio

Cross-PLC synchronous operation between CPUs with different PROFINET send clocks requires the use of a PN/PN coupler.

Clock reduction of the subnets is supported as of technology version V9.0 and control value telegram version V2. If you use communication via a PN/PN coupler and technology objects with technology versions V5.0 to V8.0, do not use a reduction ratio of the subnets.

A reduction ratio of the application cycles of MC_Servo and MC_Interpolator to the send clock is possible.

Switching setpoint output cams/cam tracks

If you are operating cross-PLC synchronous operation with a PN/PN coupler and a reduction ratio of the send clocks, the technology objects receive the setpoints with a time offset. Nevertheless, the setpoints become effective on the drives at the same time.

You can find more information on the behavior of setpoint output cams and setpoint cam tracks in cross-PLC synchronous operation in Siemens Industry Online Support in the FAQ entry 109975409 (https://support.industry.siemens.com/cs/ww/en/view/109975409).

11.3 Preparing cross-PLC synchronous operation

For a cross-PLC synchronous operation, a leading axis proxy technology object on each additional CPU is required in addition to the technology objects for leading and following axes.

When you create a technology object, an "MC_Servo" organization block is automatically created. This is required when you set up communication via direct data exchange on each CPU.

Requirements

- You have created a CPU S7-1500 or S7-1500T for the leading axis.
- You have created one or more CPUs S7-1500T for additional following axes.

Procedure

To prepare the cross-PLC synchronous operation, follow these steps:

1. On the first CPU, create one of the following technology objects as the leading axis.
   - Positioning axis
   - Synchronous axis
   - External encoder (S7-1500T)

   Recommendation: Use a virtual axis as leading axis.
2. If necessary, create one or more synchronous axis technology objects as local following axes on the first CPU.
3. Create a leading axis proxy technology object on each additional CPU.
4. Create one or more synchronous axis technology objects as following axes on each additional CPU.

5. Configure the configuration parameters of the leading and following axes that are not specific for synchronous operation. You can find a description of the configuration parameters in the "S7-1500/S7-1500T Axis functions" documentation.
6. Set up the communication:
   – Communication via direct data exchange (Page 216)
   – Communication via PN/PN coupler (Page 223)
   – Communication using isochronous I-device (Page 233)
7. Configure the provision of leading value. (Page 238)
8. Configure the tolerance time (Page 241).
9. Set the delay times (Page 245).

11.4 Communication via direct data exchange

11.4.1 Cross-PLC synchronous operation with direct data exchange

In a cross-PLC synchronous operation, the leading value is transferred via PROFINET IO with IRT. Direct data exchange is used for the communication between the CPUs within a project. With communication by means of direct data exchange, the leading value is made available once within a project and can then by received by multiple CPUs on the same bus. Leading axis proxies that are interconnected with the same leading value can be configured on different CPUs. CPUs with a second IRT interface can be configured in multiple subnets within a project.

In addition, it is possible to make multiple leading values of different leading axes available on different CPUs via the same bus. The CPUs must be on a bus and belong to the same sync domain.

Within a subnet

The figure below shows the operating principle based on an example with two following axes on two CPUs:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

The CPUs 1 and 2 are interconnected via a subnet. The leading value of CPU 1 is transferred to CPU 2 by means of a leading value telegram via PROFINET IO with IRT.

On CPU 2, a leading axis proxy reads the leading value. A following axis 2 is interconnected locally as leading value with the leading axis proxy. The following axes 1 and 2 are synchronous and follow the same leading value.

Cross-network

In order to configure a CPU cross-network within a project, an additional IRT interface to the CPU is required.

The figure below shows the operating principle based on an example with three following axes on two CPUs:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

The CPUs 1 and 2 are interconnected via the subnet 1. The leading value of CPU 1 is transferred to CPU 2 by means of a leading value telegram via PROFINET IO with IRT.

On CPU 2, a leading axis proxy reads the leading value. The following axes 2 and 3 are interconnected locally as leading value with the leading axis proxy. The following axis 2 provides the setpoint for a drive within subnet 1. The following axis 3 provides the setpoint for a drive within subnet 2.

Subnet 2 is interconnected via the PROFINET interface X2 of the CPU 2. The PROFINET interfaces X1 and X2 of the CPU 2 are in coupled mode. The PROFINET cycle is identical in both subnets.

The following axes 1, 2 and 3 are synchronous and follow the same leading value.

11.4.2 Setting up communication via direct data exchange

You use communication via the direct data exchange for cross-PLC synchronous operation, in which all CPUs are in the same project.

For the required communication directions between the connected CPUs, you must first set up transfer areas. You then create input and output tags which reference the relevant transfer areas. You can then select these tags for the transfer area when configuring the leading axis and the leading axis proxy.

Hereafter, the sender CPU is the CPU on which a leading axis provides a leading value. The receiver CPU is the CPU on which a leading axis proxy reads the leading value.

Requirement

- You have set up a network via PROFINET IO with IRT.
- You have connected the IRT ports of the CPUs in the network view and in the topology view.
- You have assigned the same sync domain to all CPUs.
- You have configured a CPU as sync master.
- You have configured all other CPUs as sync slaves.
- You have created at least one technology object on all CPUs.

  NOTE
  "MC_Servo" organization block
  When you create a technology object, an MC_Servo OB is created automatically.

- On all CPUs, you have configured the "Synchronous to bus" property as the cycle time for the "MC_Servo" under "General > Cycle time".

Adding communication directions

To add the communication directions, proceed as follows:

1. Open the "I/O communication" tab in the network view.
2. To create a communication direction from the sender CPU to the receiver CPU, select the sender CPU.
3. Drag-and-drop the receiver CPU into the "Drop or select the device here" field of the "Partner 2" table column of the corresponding PROFINET interface.

   The communication direction from sender CPU to receiver CPU is created.
4. Repeat steps 2 and 3 for all communication directions required between the interconnected CPUs.

NOTE
Communication direction from the receiver CPU to the sender CPU
If necessary, also set up a communication direction from the receiver CPU to the sender CPU, e.g. to transfer application-specific status information.

Configuring transfer areas

To configure the transfer areas, follow these steps:

1. In the "I/O communication" tab in the network view, select a communication direction of a selected CPU.
2. Add a transfer area in the Inspector window under "Properties > General > Direct data exchange" by entering a name.
3. Repeat steps 1 and 2 for all created configuration directions.
4. Configure the created transfer area in the Inspector window "Properties > General > Direct data exchange > <Name of transfer area>":
   - In the "Start address" fields, define the start address of the assigned logical address area of the sender and of the receiver.

     NOTE
     Multiple receiver CPUs in the same cascade (1:n relationship)
     If multiple receiver CPUs receive the same leading value of the sender CPU, select in each case for the receiver CPU the same address area for the transfer area between the sender CPU and the receiver CPU n that you defined between the sender CPU and the receiver CPU 1 under "Properties > General > Direct data exchange" in the "Partner address" table column.

   - In the "Organization block" fields, select the MC_Servo OB of the respective CPU.
   - Define a data length of 48 bytes in the "Data length [byte]" field.
5. Repeat step 4 for all created transfer areas.
6. If you use a SIMATIC Drive Controller, set the clock system of the SINAMICS Integrated:
   - Select PROFIdrive Integrated in the network view.
   - In the Inspector window, select the entry "Send clock of the PROFINET interface [X150]" under "Properties > General > Constant bus cycle time" in the "Cycle time" selection list.

Creating tags

To create the output tag of a sender CPU and the input tag of a receiver CPU, proceed as follows:

1. Open the PLC tags of a CPU via the project tree "<Name of CPU> > PLC tags > Show all tags".

   The "PLC tags" table opens.
2. Enter the name of the new tag in the "Name" column.

3. In the "Data type" column, manually enter the "DX_TEL_SyncOp" data type.

NOTE
Data type "DX_TEL_SyncOp"
If the data type "DX_TEL_SyncOp" is not available, it was deleted with the last compilation.
To restore the "DX_TEL_SyncOp" data type, add a ≥ V5.0 technology object. After you have used the data type in the "PLC tags" table, you can delete the technology object again.

4. Enter the configured start address of the transfer area in the "Address" column with the following prefix:
   – "%Q" for an output tag on the sender CPU
   – "%I" for an input tag on the receiver CPU
5. Repeat steps 1 to 4 for the respective sender and receiver CPUs of all configured transfer areas.

Result

You have set up communication via direct data exchange. During the configuration of the leading axis and the leading axis proxy, you can now select the configured tags for the transfer areas in the table column or in the "Transfer area" selection list under "Technology object > Configuration > Leading value settings".

If no technology object is created on a CPU, the MC_Servo OB is deleted when the software is compiled. To be able to check the set communication in this case, compile the hardware only.

More information

For more information on the subject of "Direct data exchange" refer to the "SIMATIC PROFINET with STEP 7" function manual (https://support.industry.siemens.com/cs/ww/en/view/49948856).

11.4.3 Cascaded interconnection with direct data exchange

The CPUs communicate with each other via the direct data exchange. With a cascaded interconnection, a following axis makes a cross-PLC leading value available to a leading axis proxy again. Use a virtual axis for this purpose. In the following figure, this is shown as a "Virtual leading axis":

Leading value delay that can be configured at the leading axis (delay time)

Delay time caused by the processing and transfer of the leading value

Gearing (example)

The figure shows two cascades:

- The CPUs 1, 2 and 4 form the first cascade. The CPUs 2 and 4 receive the same leading value from the CPU 1 via the leading value telegram 1. The same address range is configured for transfer areas between CPUs 1 and 2 and between CPUs 1 and 4.
- The CPUs 2 and 3 as well as CPUs 4 and 5 each form a second cascade. However, CPUs 3 and 5 do not receive the same leading value. The CPU 3 receives the leading value of the CPU 2 via the leading value telegram 2. The CPU 5 receives the leading value of the CPU 4 via the leading value telegram 3. Different address ranges are therefore configured for the transfer areas between CPUs 2 and 3 and between CPUs 4 and 5.

Time response

In principle, the delay time per cascade is:

Delay time = 2 × application cycle of the CPU of the leading axis proxy

In the figure shown above, a delay time is set on the leading axis on CPU 1, which delays the leading value output to the local following axis 1. In addition, a delay time is set on each virtual leading axes 1 and 2 on CPUs 2 and 4, since CPUs 3 and 5 are present in a cascade. All following axes 1 to 5 thus receive the same leading value at the same time.

11.5 Communication via PN/PN coupler

11.5.1 Cross-PLC synchronous operation with PN/PN coupler

In a cross-PLC synchronous operation, the leading value is transferred via PROFINET IO with IRT. For communication between CPUs via different PROFINET subnets, use a PN/PN coupler in ISO mode to implement isochronous data transfer via PROFINET IO with IRT. ISO mode is possible as of firmware version 6.0 of the PN/PN coupler.

A PN/PN coupler couples two subnets together. The subnets can either be in the same project or in different projects. There can be multiple PN/PN couplers within a subnet.

With communication via multiple PN/PN couplers, the leading value is made available once and can then be received by multiple CPUs within the subnet. Leading axis proxies that are interconnected with the same leading value can be configured on different CPUs. A PN/PN coupler can only transfer a leading value from one CPU to another CPU. A transfer to multiple CPUs is not possible.

In addition, it is possible to make multiple leading values of different leading axes available on different CPUs via the same bus. The CPUs must be located in the coupled subnets and belong to the same sync domains.

Within a project

The figure below shows the operating principle based on an example with two following axes on two CPUs:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

The subnets 1 and 2 are interconnected via a PN/PN coupler. The leading value of CPU 1 is transferred to CPU 2 by means of a leading value telegram via PROFINET IO with IRT.

On CPU 2, a leading axis proxy reads the leading value. A following axis 2 is interconnected locally as leading value with the leading axis proxy. The following axes 1 and 2 are synchronous and follow the same leading value.

Cross-project

You can also implement cross-PLC synchronous operation cross-project. You can configure and operate the following axes on different CPUs in various projects. You can also configure the leading axis on a CPU in any project. All following axes of a leading value are hereby synchronous to one another with consideration of the respective synchronous operation function. All following axes receive the same leading value at the same time.

The figure below shows the operating principle based on an example with three following axes on three CPUs, each of which is configured in its own project:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1 in project A. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

The subnets 1 and 2 are interconnected via the PN/PN coupler 1. The subnets 1 and 3 are interconnected via the PN/PN coupler 2. The leading value of CPU 1 is transferred to CPUs 2 in project B and 3 in project C by leading value telegrams via PROFINET IO with IRT.

Both on CPU 2 in project B an on CPU 3 in project C, a leading axis proxy reads the leading value. The following axes 2 and 3 are locally interconnected to the respective leading axis proxy as leading value. The following axes 1, 2 and 3 are synchronous and follow the same leading value.

11.5.2 Set communication via PN/PN coupler

For the required communication directions between the connected CPUs, you must first set up transfer areas. A leading value can be provided over a maximum of 32 different transfer areas. You then create input and output tags which reference the relevant transfer areas. You can then select these tags for the transfer area when configuring the leading axis and the leading axis proxy.

When interconnecting via different projects, export one of the PROFINET interfaces of the PN/PN coupler to the other project and implement further settings there. Below, the PROFINET interface X2 is exported as an example.

Reduction ratios of 1, 2, 4, 8 and 16 are possible between projects. The send clock on the PROFINET interface X1 of the PN/PN coupler is equal to or a multiple of the send clock on the PROFINET interface X2.

Hereafter, the sender CPU in subnet 1 is the CPU on which a leading axis provides a leading value. The receiver CPU in subnet 2 is the CPU on which a leading axis proxy reads the leading value. If interconnected within the same project, both subnets 1 and 2 are in project A. If interconnected across different projects, subnet 1 is in project A and subnet 2 is in project B.

Requirement

A project

If you are running subnets 1 and 2 in the same project A, the following requirements apply:

- You have set up a network via PROFINET IO with IRT.
- You have connected the IRT ports of the CPUs in the network view and in the topology view with the IRT ports of the PN/PN coupler.
- You have assigned the same sync domain 1 to the CPU in subnet 1 and to the PROFINET interface X1 of the PN/PN coupler.
- You have assigned the same sync domain 2 to the CPU in subnet 2 and to the PROFINET interface X2 of the PN/PN coupler.
- You have configured the sender CPU as a sync master in sync domain 1.
- In sync domain 2, you have configured the PROFINET interface X2 of the PN/PN coupler as a sync master.
- You have configured the recipient CPU in subnet 2 and the PROFINET interface X1 of the PN/PN coupler as a sync slave in the corresponding sync domain.
- You have created at least one technology object on all CPUs.

NOTE

"MC_Servo" organization block

When you create a technology object, an MC_Servo OB is created automatically.

- On all CPUs, you have configured the "Synchronous to bus" property as the cycle time for the "MC_Servo" under "General > Cycle time".

Different projects

If you are running subnets 1 and 2 in different projects A and B, the following requirements apply:

- You have set up a network via PROFINET IO with IRT in both projects A and B.
- In project A, you have connected the IRT ports of the CPU in the network view and in the topology view with the IRT ports of the PROFINET interface X1 of the PN/PN coupler.
- In project A, you have assigned the same sync domain 1 to the CPU in subnet 1 and to the PROFINET interface X1 of the PN/PN coupler.
- In project B, you have assigned sync domain 2 to the CPU in subnet 2.
- In project A, you have configured the sender CPU as a sync master in the sync domain 1.
- In project A, you have configured the PROFINET interface X1 of the PN/PN coupler as a sync slave in sync domain 1.
- You have created at least one technology object on all CPUs in both projects A and B.

  NOTE

  "MC_Servo" organization block

  When you create a technology object, an MC_Servo OB is created automatically.

- In bot projects A and B, you have configured the property "Synchronous to the bus" as cycle time on all CPUs for the "MC_Servo" under "General > Cycle time".

Configuring communication directions and transfer areas

To configure the transfer areas, follow these steps:

1. In project A, in the network view, select the left coupler side with the PROFINET interface X1.
2. Configure the Ethernet connection in the Inspector window under "Properties > General > PROFINET interface [X1] > Ethernet addresses".
3. Activate the ISO mode in the Inspector window under "Properties > General > Module parameter > Operating mode".
4. Set the transfer areas in the Inspector window under "Properties > General > Module parameter > Transfer mapping". To add a new transfer area, select the value "Isochronous IN" or "Isochronous OUT" from the selection list of the "Type" column.

   The transfer area automatically has the appropriate communication direction.

   The "Isochronous control/status" transfer area is created automatically.
5. Repeat step 4 for all necessary transfer areas. You can set up to 14 transfer areas.
6. Configure the created transfer areas in the Inspector window under "Properties > General > Module parameter > Transfer mapping > Isochronous module":
   - Specify a data length in the "Length" fields. The data length of 48 bytes is preset.

     A maximum data length of 192 bytes is possible for the first two transfer areas. As of the third transfer area, the maximum possible data length is 48 bytes. In total, a maximum data length of 960 bytes for all transfer areas is possible.

- If necessary, in the "Start address" fields, define the start address of the assigned logical address area of the sender and of the receiver. Free areas are automatically preselected.
- In the "Organization block" fields, select the MC_Servo OB of the respective CPU.

7. Repeat step 6 for all created transfer areas.
8. If you use a SIMATIC Drive Controller, set the clock system of the SINAMICS Integrated:
   - Select PROFIdrive Integrated in the network view.
   - In the Inspector window, select the entry "Send clock of the PROFINET interface [X150]" under "Properties > General > Constant bus cycle time" in the "Cycle time" selection list.

Creating tags

To create the output tag of the sender CPU and the input tag of the receiver CPU, proceed as follows:

1. In project A, open the PLC tags of a CPU via the project tree "<Name of CPU> > PLC tags > Show all tags".

   The "PLC tags" table opens.
2. Enter the name of the new tag in the "Name" column.
3. In the "Data type" column, manually enter the "DX_TEL_SyncOp" data type.

   NOTE
   Data type "DX_TEL_SyncOp"
   If the data type "DX_TEL_SyncOp" is not available, it was deleted with the last compilation.
   To restore the "DX_TEL_SyncOp" data type, add a ≥ V5.0 technology object. After you have used the data type in the "PLC tags" table, you can delete the technology object again.

4. Enter the configured start address of the transfer area in the "Address" column with the following prefix:
   - "%Q" for an output tag on the sender CPU
   - "%I" for an input tag on the receiver CPU
5. Repeat steps 1 to 4 for the respective sender and receiver CPUs of all configured transfer areas.

   If you are running subnets 1 and 2 in the same project A, skip the following steps and continue reading under "Result."

Transferring the PROFINET interface X2 of the PN/PN coupler from project A to project B

This procedure is only relevant if you operate subnets 1 and 2 in different projects A and B.

To import the PROFINET interface X2 of the PN/PN coupler in project B, follow these steps:

1. In project A, in the network view, select the left coupler side with the PROFINET interface X1.
2. In the Inspector window under "Properties > General > Module parameters > Shared devices", select the "Outside the project" value for the PROFINET interface X2 in the selection list in the "Access" column.
3. Export the PROFINET interface X2 of the PN/PN coupler as a GSD file:
   - In the Inspector window under "Properties > General > Module parameter > Transfer mapping" in the "Export device description file (GSD)" area, click on the "Export" button.

     The "Export device description files (GSD)" dialog opens.
   - Select the "Export X2 (right coupler side)" option.
   - If necessary, adjust the name.

     The name is displayed in the hardware catalog after import.
   - Specify a storage location in the "Path" field.
   - Click "Export".

     The GSD file is being created.
4. Open the project B.
5. Import the GSD file of the PROFINET interface X2 of the PN/PN coupler:
   - Select the "Options > Manage general station description files (GSD)" menu.

     The "Manage device description files" dialog opens.
   - Select the storage location of the exported GSD file in the "Source path" field.
   - Select the exported GSD file in the table.
   - Click "Install".

     The GSD file is being installed. A success message then opens.
   - Click "Close".

     The hardware catalog is updated.
6. Open the network view.
7. From the hardware catalog, under "Other field devices > PROFINET IO > Gateway > Siemens Aktiengesellschaft > PN/PN coupler", drag and drop the imported PROFINET interface X2 of the PN/PN coupler in to the network view.
8. Create the tags. To do this, repeat steps 1 to 5 of the "Creating tags" procedure for project B.

Configuring PROFINET interface X2 in project B

This procedure is only relevant if you operate subnets 1 and 2 in different projects A and B.

To configure the PROFINET interface X2 of the PN/PN coupler in project B, follow these steps:

1. In project B, in the network view, select the right coupler side with the PROFINET interface X2.
2. Select subnet 2 in the Inspector window under "Properties > General > PROFINET interface [X2] > Ethernet addresses" in the "Interface connected with" area.
3. In the "Internet Protocol Version 4 (IPv4)" section, set the IP address.
4. Configure the sync domain 2:
   - Assign the sync domain 2 to the PROFINET interface X2 of the PN/PN coupler.
   - In the network view, select Sync domain 2.
   - Open the Inspector window under "Properties > General > PROFINET subnets > Domain management > Sync domains > <Sync domain 2> > Devices".
   - In the table in the "IO devices" section, select the "IRT" value for the PROFINET interface X2 of the PN/PN coupler in the "RT class" column.
   - For the PROFINET interface X2 of the PN/PN coupler, select the "Sync Master" value in the "Synchronization role" column.
   - For the recipient CPU, select the "Sync slave" value in the "Synchronization role" column.
5. In the topology view, connect the IRT ports of the CPU to the IRT ports of the PROFINET interface X2 of the PN/PN coupler.
6. Configure the transfer areas in the device view of the PN/PN coupler:
   - In the network view, select a transfer area.
   - Open the Inspector window under "Properties > General > I/O addresses".
   - Depending on the communication direction, set the start address of the incoming or outgoing address range.
   - Select the MC_Servo-OB of the corresponding CPU in the "Organization block" field.
7. Repeat step 6 for all transfer areas.

Result

You have set up the communication via the PN/PN coupler. During the configuration of the leading axis and the leading axis proxy, you can now select the configured tags for the transfer areas in the table column or in the "Transfer area" selection list under "Technology object > Configuration > Leading value settings".

If no technology object is created on a CPU, the MC_Servo OB is deleted when the software is compiled. To be able to check the set communication in this case, compile the hardware only.

More information

Via the "Isochronous control/status" transfer area, you control the isochronous mode between the PROFINET interfaces X1 and X2 of the PN/PN coupler.

If the coupled networks are not synchronized, for example because a CPU is in the "STOP" mode, a status error message is displayed if the diagnostic messages on the PN/PN coupler are enabled. The PN/PN coupler is also highlighted in red in the project tree.

You can find more information about the "PN/PN coupler" topic in the Installation and Operating Manual "SIMATIC Bus Coupler PN/PN Coupler" (https://support.industry.siemens.com/cs/ww/en/view/44319532).

11.5.3 Cascaded interconnection with PN/PN coupler

With a cascaded interconnection, a following axis makes a cross-PLC leading value available to a leading axis proxy again. Use a virtual axis for this purpose. In the following figure, this is shown as a "Virtual leading axis":

Leading value delay that can be configured at the leading axis (delay time)

Delay time caused by the processing and transfer of the leading value

Gearing (example)

The figure shows two cascades:

- The CPUs 1 and 2 in projects A and B are interconnected via a PN/PN coupler and form the first cascade.
- In Project B, CPUs 2 and 3 form the second cascade via the direct data exchange.

More than one cascade with a PN/PN coupler and multiple subnets is not permitted. Further cascades within the subnets are possible.

Time response

Regardless of whether the PN/PN coupler is interconnected within a project or cross-project, the delay time when interconnected via a PN/PN coupler is:

Delay time = 2 × application cycle of the CPU of the leading axis proxy + 2 × PROFINET cycle

In the case of a reduction ratio of the PROFINET cycle, the faster PROFINET cycle is relevant.

In the figure shown above, a delay time is set on the leading axis on CPU 1, which delays the leading value output to the local following axis 1. In addition, a delay time at the virtual leading axis 1 on CPU 2 is set, because CPU 3 is present in a cascade. All following axes 1 to 3 thus receive the same leading value at the same time.

Example

In the figure shown above, a cross-project interconnection via a PN/PN coupler (cascade 1) and an interconnection via the direct data exchange (cascade 2) are combined.

The total delay time is:

Delay time cascade 1 = 2 × application cycle of the CPU 2 + 2 × PROFINET cycle

Delay time cascade 2 = 2 × application cycle of the CPU 3

Total delay time = delay time cascade 1 + delay time cascade 2 = 2 × application cycle of the CPU 2 + 2 × PROFINET cycle + 2 × application cycle of the CPU 3

11.6 Communication using isochronous I-device

11.6.1 Cross-PLC synchronous operation with isochronous I-device

In a cross-PLC synchronous operation, the leading value is transferred via PROFINET IO with IRT in isochronous mode. For communication between CPUs, use the "I-device" functionality to implement isochronous data transfer via PROFINET IO with IRT.

An IO controller provides the leading value, which can then be received by multiple isochronous I-devices. The I-device can either be in the same project or in a different project. Leading axis proxies that are interconnected with the same leading value can be configured on different CPUs.

In addition, it is possible to make multiple leading values of different leading axes available on different CPUs via the same bus. The CPUs must be located in the same sync domains in each case.

Within a project

The figure below shows the operating principle based on an example with two following axes on two CPUs:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

CPU 2 is assigned as I-device of CPU 1 as IO controller. The leading value of CPU 1 is transferred to CPU 2 by means of a leading value telegram via PROFINET IO with IRT. The PROFINET interfaces X1 and X2 of CPU 2 are operated coupled with synchronized send clock.

On CPU 2, a leading axis proxy reads the leading value. A following axis 2 is interconnected locally as leading value with the leading axis proxy. The following axes 1 and 2 are synchronous and follow the same leading value.

Cross-project

You can also implement cross-PLC synchronous operation cross-project. You can configure and operate the following axes on different CPUs in various projects. You can also configure the leading axis on a CPU in any project. All following axes of a leading value are hereby synchronous to one another with consideration of the respective synchronous operation function. All following axes receive the same leading value at the same time.

The figure below shows the operating principle based on an example with three following axes on three CPUs, each of which is configured in its own project:

⇨ Leading value

The leading axis and a local following axis 1 are located on CPU 1 in project A. The leading axis and the following axis 1 are interconnected to a synchronous operation. The leading axis also makes the leading value available for cross-PLC synchronous operation.

CPUs 2 and 3 are assigned as I-devices of CPU 1 as IO controller. The leading value of CPU 1 is transferred to CPU 2 in project B and CPU 3 in project C by a leading value telegram via PROFINET IO with IRT. The PROFINET interfaces X1 and X2 of CPUs 2 and 3 are operated coupled with synchronized send clock.

Both on CPU 2 in project B an on CPU 3 in project C, a leading axis proxy reads the leading value. The following axes 2 and 3 are locally interconnected to the respective leading axis proxy as leading value. The following axes 1, 2 and 3 are synchronous and follow the same leading value.

11.6.2 Setting up communication using an isochronous I-device

For the required communication directions between the connected CPUs, you must first set up transfer areas. The leading value is provided via the transfer areas. You then create input and output tags which reference the relevant transfer areas. You can then select these tags for the transfer area when configuring the leading axis and the leading axis proxy.

When interconnecting via different projects, export the I-device into the project containing the IO controller and make additional settings there. Configuring I-device and IO controller in the same project is also possible.

For more information on the subject of "I-device", refer to the "SIMATIC PROFINET with STEP 7" function manual (https://support.industry.siemens.com/cs/ww/en/view/49948856).

Hereinafter, the sender CPU is the IO controller on which a leading axis provides a leading value. The sender CPU is configured in the "IO controller" project. The receiver CPU is the isochronous I-device on which a leading axis proxy reads the leading value. The receiver CPU is configured in the "I-device" project.

Requirement

- You have created the sender CPU in the "IO controller" project.
- You have created the receiver CPU in the "I-device" project.
- You have configured a PROFINET interface of the receiver CPU as I-device in the "I-device" project:
  - You have selected the "Parameter assignment of PN interface by higher-level controller" check box.
  - You have selected the "Unknown" entry in the "Higher-level IO controller" drop-down list.
- You have created at least one technology object on all CPUs in both projects "IO controller" and "I-device".

NOTE
"MC_Servo" organization block
When you create a technology object, an MC_Servo OB is created automatically.

Configuring communication directions and transfer areas

To configure transfer areas in the "I-device" project, follow these steps:

1. In the "I-device" project in the network view, select the PROFINET interface of the receiver CPU configured as I-device.
2. Select the "Isochronous mode" check box in the Inspector window under "Properties > General > Operating mode > Isochronous mode".

3. Set all required transfer areas in the Inspector window under "Properties > General > Operating mode > I-device communication":
   - To add a new transfer area, define a corresponding name in the "Transfer area" column.
   - Select the "Unknown" entry in the "Partner" column.
   - In the "Direction of transfer" column, select the corresponding communication direction via the arrow symbols. The I/O address is automatically updated with the "Q" prefix for an output tag and with the "I" prefix for an input tag.
   - Define a data length of 48 bytes in the "Length" column.
   - Select the check box in the "Isochronous mode" column.
4. Configure the created transfer areas in the Inspector window under "Properties > General > Operating mode > I-device communication > <Transfer area>":
   - If necessary, in the "Start address" fields, define the start address of the assigned logical address area of the sender and of the receiver. Free areas are automatically preselected.
   - In the "Organization block" fields, select the MC_Servo OB.
5. Repeat step 4 for all created transfer areas.

Transferring receiver CPU from "I-device" project to "IO controller" project

To transfer the receiver CPU from the "I-device" project to the "IO controller" project, follow these steps:

1. In the "I-device" project in the network view, select the PROFINET interface of the receiver CPU configured as I-device.
2. Export the PROFINET interface of the receiver CPU configured as I-device as a GSD file:
   - Compile the hardware configuration.
   - In the Inspector window under "Properties > General > Operating mode > I-device communication" in the "Export device description file (GSD)" area, click on the "Export" button.

     The "Export device description files (GSD)" dialog opens.
   - If necessary, adjust the name.

     The name is displayed in the hardware catalog after import.
   - Specify a storage location in the "Path" field.
   - Click "Export".

     The GSD file is being created.
3. In the "IO controller" project, import the GSD file of the PROFINET interface of the receiver CPU configured as I-device:
   - Select the "Options > Manage general station description files (GSD)" menu.

     The "Manage device description files" dialog opens.
   - Select the storage location of the exported GSD file in the "Source path" field.
   - Select the exported GSD file in the table.

- Click "Install".

  The GSD file is being installed. A success message then opens.
- Click "Close".

  The hardware catalog is updated.

4. In the network view, drag-and-drop the imported receiver CPU from the hardware catalog under "Other field devices > PROFINET IO > PLCs & CPs > Siemens Aktiengesellschaft" into the network view.
5. Connect the IRT ports of the CPUs with each other in the network view.
6. Connect the IRT ports of the CPUs with each other in the topology view.
7. In both projects "IO controller" and "I-device", configure the property "Synchronous to the bus" as cycle time on all CPUs for the "MC_Servo" under "General > Cycle time".
8. Configure the sync domain in the "IO controller" project:
   - Select the PROFINET network in the network view.
   - In the Inspector window, navigate to "PROFINET subnet > Domain management > Sync domains".
   - In the "Devices > IO devices" area, assign the synchronization role "Sync master" to the PROFINET interface of the sender CPU.
   - Select the RT class "IRT" for the receiver CPU.

     The synchronization role changes automatically from "Unsynchronized" to "Sync slave".
   - In the "Sync domain" area, select the same send clock that you specified in the I-device configuration.
9. Configure the receiver CPU (GSD file) in the "IO controller" project:
   - Open the device view of the receiver CPU.
   - On the right side, click the corresponding transfer area in the device overview.
   - Select the MC_Servo OB in the "Organization block" field in the Inspector window under "Properties > General > I/O addresses".
   - Select the "Isochronous mode" check box.

Creating tags

To create the output tag of the sender CPU and the input tag of the receiver CPU, proceed as follows:

1. In the "IO controller" project, open the PLC tags of the sender CPU via the project tree "<Name of CPU> > PLC tags > Show all tags".

   The "PLC tags" table opens.
2. Enter the name of the new tag in the "Name" column.

3. In the "Data type" column, manually enter the "DX_TEL_SyncOp" data type.

NOTE
Data type "DX_TEL_SyncOp"
If the data type "DX_TEL_SyncOp" is not available, it was deleted with the last compilation.
To restore the "DX_TEL_SyncOp" data type, add a ≥ V5.0 technology object. After you have used the data type in the "PLC tags" table, you can delete the technology object again.

4. Enter the configured start address of the transfer area in the "Address" column with the following prefix:
   – "%Q" for an output tag on the sender CPU
     The start addresses must match the addresses of the transfer areas of the GSD file.
   – "%I" for an input tag on the receiver CPU
     The start addresses must match the addresses of the transfer areas from the PROFINET interface of the I-device.
5. Repeat steps 1 to 4 for all configured transfer areas.
6. In the "I-device" project, repeat steps 1 to 4 for all configured transfer areas of the receiver CPU.

Result

You have set up communication using isochronous I-device. During the configuration of the leading axis and the leading axis proxy, you can now select the configured tags for the transfer areas in the table column or in the "Transfer area" selection list under "Technology object > Configuration > Leading value settings".

NOTE
Changes to the transfer areas
If you change transfer areas, you need to export the receiver CPU from the "I-device" project again and import it into the "IO controller" project.

If no technology object is created on a CPU, the MC_Servo OB is deleted when the software is compiled. To be able to check the set communication in this case, compile the hardware only.

11.6.3 Cascaded interconnection with isochronous I-device

With a cascaded interconnection, a following axis of a leading axis proxy provides a cross-PLC leading value again. Use a virtual axis for this purpose. In the following figure, this is shown as a "Virtual leading axis":

Leading value delay that can be configured at the leading axis (delay time)

Delay time caused by the processing and transfer of the leading value

Gearing (example)

The figure shows two cascades:

- CPU 1 in Project A and CPU 2 in Project B form the first cascade. CPU 2 is assigned as I-device of CPU 1 as IO controller.
- In Project B, CPUs 2 and 3 form the second cascade. CPU 3 is assigned as I-device of CPU 2 as IO controller.

Time response

Regardless of whether an isochronous I-device is interconnected within a project or across projects, the delay time when interconnected via an I-device is:

Delay time = 2 × application cycle of the CPU of the leading axis proxy

In the figure shown above, a delay time is set on the leading axis on CPU 1, which delays the leading value output to the local following axis 1. In addition, a delay time at the virtual leading axis 1 on CPU 2 is set, because CPU 3 is present in a cascade. All following axes 1 to 3 thus receive the same leading value at the same time.

You will find more information on the configuration in the section "Setting the delay times (Page 245)".

11.7 Configuring the provision of leading value and interconnecting axes

The following describes how to connect the leading value and the axes involved for a cross-PLC synchronous operation via one or more cascades.

Requirement

- You have prepared the cross-PLC synchronous operation (Page 212).
- For each additional cascade you have created a technology object synchronous axis as a virtual following axis that is used as the leading axis for the next cascade.
- The technology objects are configured correctly.
- You have set up the communication between the CPUs:
  - Via the direct data exchange (Page 216)
  - Via the PN/PN coupler (Page 223)
  - Via isochronous I-device (Page 233)

Provide cross-PLC leading value

To make the leading value of the leading axis available cross-PLC, proceed as follows:

1. Open the configuration window "Technology object > Configuration > Leading value settings" of the leading axis.
2. To show rows 2 to 32 in the table in the "Provision of leading value" area, select the "Show all transfer areas" check box.
3. In the "Provide" table column, select the check box of the corresponding transfer area.
4. In the "Transfer area" table column, select in the drop-down list the CPU output tag created for the communication.

5. To use the leading value telegram version 1, clear the check box of the corresponding transfer area in the "Leading value telegram V2" table column.

   The leading value telegram version depends on the technology version of the receiver. The leading value telegram version 2 is preset for technology objects with the technology version ≥ 10.0. You can find more information in the "Compatible versions for synchronous operation across PLCs (Page 211)" section.

Interconnect local following axes

To interconnect the local following axes on the CPU of the leading axis, follow these steps:

1. Open the configuration window "Technology object > Configuration > Leading value interconnections" of a local following axis.
2. In the "Possible leading values" table column, select the leading axis.
3. In the "Type of coupling" table column, select the entry "Delayed".
4. Repeat steps 1 to 3 for all local following axes.

Interconnecting leading axis proxies

To interconnect the leading axis proxies to other CPUs, follow these steps:

1. Open the configuration window "Technology object > Configuration > Leading value settings" of a leading axis proxy.
2. In the "Provision of leading value" area in the "Transfer area" drop-down list, select the input tag of the CPU created for the communication.
3. Repeat steps 1 and 2 for all leading axis proxies of the same cascade.

Interconnecting following axes of the other CPUs

To interconnect the following axes that are not configured on the CPU of the leading axis, proceed as follows:

1. Open the configuration window "Technology object > Configuration > Leading value interconnections" of a following axis.
2. In the "Possible leading values" table column, select the alternate leading axis of the CPU.

   In the table column "Leading value source", the leading axis is displayed which provides the leading value (<Name of the CPU>.<Name of the technology object>). The "Setpoint" entry is preset in the "Type of coupling" table column.
3. In the table column with the icon , select whether this leading value interconnection should be taken into consideration when calculating the delay time in the interconnection overview (Page 241).
4. Repeat steps 1 to 3 for all following axes of the same cascade.

Interconnecting virtual following axis as leading axis for the next cascade

To interconnect a virtual following axis that is used as leading axis for the next cascade, proceed as follows:

1. Open the configuration window "Technology object > Configuration > Leading value interconnections" of the virtual following axis.
2. In the "Possible leading values" table column, select the alternate leading axis of the CPU.

   In the table column "Leading value source", the leading axis is displayed which provides the leading value (<Name of the CPU>.<Name of the technology object>). The "Setpoint" entry is preset in the "Type of coupling" table column.
3. In the table column with the icon , select whether this leading value interconnection should be taken into consideration when calculating the delay time in the interconnection overview.
4. Switch to the configuration window "Technology object > Configuration > Leading value settings" of the virtual following axis.
5. To show rows 2 to 32 in the table in the "Provision of leading value" area, select the "Show all transfer areas" check box.
6. In the "Provide" table column, select the check box of the corresponding transfer area.
7. To use the leading value telegram version 1, clear the check box of the corresponding transfer area in the "Leading value telegram V2" table column.

   The leading value telegram version depends on the technology version of the receiver. The leading value telegram version 2 is preset for technology objects with the technology version ≥ 10.0. You can find more information in the "Compatible versions for synchronous operation across PLCs (Page 211)" section.
8. In the "Transfer area" table column, select in the drop-down list the CPU output tag created for the communication.
9. Repeat the steps in the section "Interconnecting leading axis proxies" for all leading axis proxy of the next cascade.
10. Repeat the steps in the section "Interconnecting following axes of the other CPUs" for all following axes of the next cascade.
11. Repeat steps 1 to 10 for all other cascades.

11.8 Configuring the tolerance time

If an external leading value becomes invalid during a cross-PLC synchronous operation or a communication error occurs, technology alarm 900 ("Leading values invalid") is output after a tolerance time. You can configure this tolerance time on the leading axis proxy technology object.

Procedure

To configure the tolerance time, follow these steps:

1. Open the configuration window "Technology object > Configuration > Leading value settings" of a leading axis proxy.
2. In the "Leading value monitoring" area, enter the tolerance time within which a valid leading value is expected in the "Tolerance time invalid leading value" input field.

   NOTE
   Extrapolation of the leading value
   Note that the leading value is still being extrapolated during the tolerance time and that the following axis continues to move.
   Therefore, set the tolerance time as brief as possible.

3. Repeat steps 1 and 2 for all other leading axis proxies.

11.9 Working with the interconnection overview table

11.9.1 Opening the interconnection overview

The interconnection overview contains an overview of the interconnected leading and following axes and their CPU assignment. In the interconnection overview, you also trigger the system calculation of the delay time.

Requirement

- You have created technology objects in the project for:
  - Leading axis
  - Following axis
  - Leading axis proxy
- You have interconnected the CPUs and technology objects with one another.

Procedure

To open the interconnection overview, follow these steps:

1. Select one of the following technology objects in the project navigation:
   - Positioning axis
   - Synchronous axis
   - External encoder
   - Leading axis proxy
2. Select the "Interconnection overview" command from the shortcut menu.

Result

The interconnection overview opens.

11.9.2 Interconnection overview

The interconnection overview contains an overview of the interconnected leading and following axes and their CPU assignment in tabular form.

Toolbar

The toolbar at the top of the interconnection overview provides the following functions via buttons:

Button	Description
	You update the view of the interconnection overview with this icon.
Calculate delay times	You trigger calculation of delay times with this button. The delay time is only calculated if the "Allow system calculation" check box is selected under "Leading value settings" when configuring the technology objects. You can only trigger the calculation of the delay times if the values are not current and the technology objects are not recursively connected. The delay time is calculated throughout the entire project. If the leading value for CPUs is provided in another project, you must manually transfer the delay times of the corresponding transfer areas (Page 245).

Filtering the view

You have the following options above the table to filter the view of the interconnection overview:

Field	Description
Enter text filter	In this field, enter a term by which the view should be filtered.
Show delay times	Select this check box to show the "Delay time" columns which contain the delay times.
Show local synchronous operations	Select this check box to display the local leading value interconnections in addition to the cross-PLC leading value interconnections.
Show cross-network transfer	Select this check box to additionally display the cross-network and cross-project leading value interconnections.

Interconnection overview table

The interconnection overview table contains the following information and functions:

Column		Description	
Leading value source			
	PLC	This column displays the CPU of the leading axis.	
	Leading axis	This column displays the name of the leading axis. You open the configuration of the technology object via the link.	
			If this icon is displayed in the "Leading axis" column, the interconnection is excluded from the system calculation of the delay time. In the configuration of the leading axis, the check box "Allow system calculation" is not selected under "Leading value settings".
	DT	This column displays the delay time in ms. This column is only displayed when the "Show delay times" check box is selected.	
	Leading value output	This column displays the type of the leading value output and the number of the transfer area.	
Recipient			
	PLC	This column displays the CPU of the following axis.	
	Following axis	This column displays the name of the following axis. You open the configuration of the technology object via the link.	
	Routes	When you select a row, the icon is displayed in this column. You open the "Routes" area with this icon.	
	Leading axis proxy	The name of the leading axis proxy is displayed in this column. You open the configuration of the technology object via the link.	
			If this icon is displayed in the "Leading axis proxy" column, the interconnection is excluded from the system calculation of the delay time. In the configuration of the leading axis proxy, the check box "Allow system calculation" is not selected under "Leading value settings".

Column		Description	
	DT	This column displays the delay time in ms. This column is only displayed when the "Show delay times" check box is selected.	
Cross-network transfer		These columns are only displayed when the "Show cross-network transfer" check box is selected.	
	Device	This column displays the PN/PN coupler.	
	Transfer area	This column displays the used transfer area.	
	DT	This column is only displayed when the "Show delay times" check box is selected.	
		Recipient	For a transfer area that receives the leading value from another project, the delay time is displayed in ms.
		Sender	For a transfer area that provides the leading value for recipients outside the project, enter the calculated delay time from the other project.
Interconnection			If this icon is displayed in the "Interconnection" column, the interconnection is affected by a recursion.
			If this icon is displayed in the "Interconnection" column, the interconnection is affected by a recursion, but at least one interconnection is excluded from the calculation of the delay time.
			If this icon is displayed in the "Interconnection" column, the interconnection is excluded from the system calculation of the delay time.
			With this icon, you open the configuration of the following axis.
		If the configured delay time corresponds to the calculated delay time, the icon ✔ is displayed in this column.	

In the "Leading value source cannot be clearly determined" area, interconnections are displayed where, for example, several leading axes are connected for a leading axis proxy and the leading value source is therefore not unique. The range is only displayed if there are interconnections without a unique leading value source.

11.9.3 Showing routes

The routes of the leading value of a selected following axis are shown in the interconnection overview in the area underneath the table. Within the project, the leading value is tracked backed from the following axis to the leading value source. If there are multiple routes, they are displayed next to one another. If the leading value source is outside the project, the route is only followed up to the interface that provides the leading value within the project.

Procedure

To display the existing routes of a following axis, follow these steps:

1. Select the row of the corresponding following axis in the table.
2. To show the routes, click the icon in the "Routes" column.

Result

All routes are displayed in the area below the table for the selected following axis. Routes affected by a recursion are not displayed.

It is indicated underneath a route whether the leading value is interpolated or extrapolated:

- If all cascades interpolate, "Interpolated" is displayed.
- If at least one cascade extrapolates, "Extrapolated" is displayed.

11.9.4 Setting the delay times

You can calculate and view the delay times in the interconnection overview. Alternatively, you can manually configure the delay times on the leading axis and on the virtual following axes. Depending on the set delay time, the leading value at the leading axis proxy is automatically interpolated or extrapolated.

The delay times are calculated within a project. If the leading value is provided in different projects, manually transfer the delay times from the other projects.

NOTE

Following axis on I-device

If a following axis is configured on an I-device, the delay time for this following axis cannot be calculated by the system. This applies to interconnections within a project as well as across projects.

To nevertheless be able to calculate the delay time on the leading axis, proceed as follows:

1. In this case, calculate the delay time of the following axis manually and configure this at the leading axis. To do this, follow the "Configure delay times" procedure.
2. Transfer the delay time of the following axis manually into the interconnection overview. To do this, follow the "Transfer delay times from other projects" procedure.

Requirements

- You have interconnected the CPUs and technology objects with one another.
- Except for the delay time, the technology objects are fully configured.
- You have selected the "Delayed" entry as the type of coupling in the "Technology object > Configuration > Leading value interconnections" configuration window of the local following axes so that the leading value for the local synchronous operation is delayed.

Calculating delay times

To calculate the delay times, follow these steps:

1. Open the configuration window "Technology object > Configuration > Leading value settings" of the leading axis.
2. In the "Delay time of local leading value" area, select the "Allow system calculation" check box.

3. Repeat steps 1 and 2 for all leading axis proxies and for all virtual following axes that are used as leading axis for additional cascades.
4. Open the configuration window "Technology object > Configuration > Leading value interconnections" of a non-local following axis.
5. For a leading axis proxy technology object of the table column with the symbol , select whether this leading value interconnection should be taken into account when calculating the delay time.
6. Repeat steps 4 and 5 for all other non-local following axes.
7. To open the interconnection overview, click on the link "Interconnection overview".
8. To calculate the delay times, click the "Calculate delay times" button in the interconnection overview.
9. Check the calculated delay times in the columns "DT" of the interconnection overview.
10. In the routes, check whether a leading value is interpolated or extrapolated at the leading axis proxy (<TO>.StatusExternalLeadingValue.AdjustmentTime).

Configuring delay times

To adjust the delay time and, for example, take into account additional requirements from your special application, follow these steps:

1. Open the configuration window "Technology object > Configuration > Leading value settings" of the leading axis.
2. Clear the "Allow system calculation" check box in the "Delay time of local leading value" area.
3. Enter the corresponding value in the "Delay time" input field.

   The entered delay time determines the output delay of the leading value for the local following axes (<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime).
4. Repeat steps 1 to 3 for all virtual following axes that are used as the leading axis for additional cascades.
5. Open the configuration window "Technology object > Configuration > Leading value settings" of a leading axis proxy.
6. Clear the "Allow system calculation" check box in the "Delay time of local leading value" area.
7. In the "Delay time" (<TO>.Parameter.LocalLeadingValueDelayTime) input field, enter the same delay time that is set on the local virtual following axis that is used as the leading axis for an additional cascade.

   The entered delay time determines the output delay of the leading value for the local following axes (<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime).
8. To open the interconnection overview, click on the link "Interconnection overview".
9. Check the delay times in the "DT" columns of the interconnection overview.
10. In the routes, check whether a leading value is interpolated or extrapolated at the leading axis proxy (<TO>.StatusExternalLeadingValue.AdjustmentTime).

Transfer delay times from other projects

This procedure is only relevant if the leading value is provided in different projects.

To transfer delay times, proceed as follows:

1. Have the delay times calculated in the project that receives the leading value.
2. Transfer the delay times of the corresponding transfer areas to the project that provides the leading value:
   - Open the interconnection overview.
   - Select the "Show delay times" option.
   - Select the "Show cross-network transfer" option.
   - In the "Cross-network transfer > VZ" column, enter the delay times for the corresponding transfer areas.
3. Have the delay times calculated in the project that provides the leading value.

11.10 Example: Analyze cross-PLC synchronous operation in various projects using the trace and instruction "GetPNWorkingClock"

In the following example, two following axes 1 and 2 are in synchronous operation. The following axes are configured on different CPUs in various projects and interconnected via a PN/PN coupler.

⇨ Leading value

You can use the trace to check whether the following axes are moving synchronously. Since there is no access between projects, carry out a measurement in each project. In order to be able to compare the two measurements afterwards, use the "GetPNWorkingClock" instruction, which provides the synchronization clock. The "GetPNWorkingClock" instruction is available as of firmware version V4.0.

For the instruction counters to have the same values at the same time, the measurements must run simultaneously in both CPUs. To do this, use the same trigger for both measurements, e.g. the velocity of the following axes.

Requirements

- You are using CPUs with firmware versions ≥ V4.0.
- You have two projects A and B available.
- Project A includes the following:
  - A CPU 1 with the leading axis and a local following axis 1
  - An interface of the PN/PN coupler
- Project B includes the following:
  - The second interface of the PN/PN coupler
  - A CPU 2 with a leading axis proxy and a following axis 2
- A cross-PLC synchronous operation with communication via the PN/PN coupler has been set up.
- The synchronous operation is active. The following axes 1 and 2 are in the "Synchronous" state.
- In both projects, you have programmed an instruction "GetPNWorkingClock" with "Mode" = 1. The instruction is called in MC_PreServo.

Create trace configuration in project A

To create a new trace configuration in project A, follow these steps:

1. Open project A.
2. Add a new "Trace 1" trace configuration.
3. Configure the trace 1:
   - Select the output tag of the "GetPNWorkingClock" instruction and the position of the following axis 1 as signals.
   - Set the recording time to an isochronous OB, such as the MC_Interpolator.
   - Select "Trigger on tag" as trigger mode.
   - Select the speed of the following axis 1 as the trigger tag.
   - Select the "Rising signal" event.
   - Enter a value greater than 50.0, for example.
   - Enter 100 measuring points as pretrigger (b), for example.
4. Load the trace 1 onto the CPU 1.
5. Start the trace 1.

   The trace 1 has the "Waiting for trigger" status.

Create trace configuration in project B

To create a new trace configuration in project B, follow these steps:

1. Open project B.
2. Add a new "Trace 2" trace configuration.
3. Configure the trace 2:
   - Select the output tag of the "GetPNWorkingClock" instruction and the position of the following axis 2 as signals.
   - Define the same recording conditions as for trace 1. Select the velocity of the following axis 2 as the trigger tag.
4. Load the trace 2 onto the CPU 2.
5. Start the trace 2.

   The trace 2 has the "Waiting for trigger" status.

Release trigger and merge measurements in project A

To trigger the trigger and merge the measurements in Project A, follow these steps:

1. Open project A.
2. Release the trigger. Start the traversing motion of the leading axis so that the following axes 1 and 2 each adopt a velocity of greater than 50.0.

   The recordings of the traces 1 and 2 are started in CPUs 1 and 2.
3. Add the recording of the trace 1 to the measurements.
4. Open project B.
5. Add the recording of the trace 2 to the measurements.
6. Export the measurement of the trace 2.
7. Open project A.
8. Import the measurement of the trace 2.

Create a superimposed measurement in project A

To create a superimposed measurement in project A, follow these steps:

1. Add a new superimposed measurement.
2. Add the measurements of traces 1 and 2 to the superimposed measurement.
3. Adjust the colors of the signals so that they are distinguishable.
4. Create a "workingclock" signal group with the two output tags of the "GetPNWorkingClock" instruction.

5. Create a "position" signal group with the two positions of the following axes 1 and 2.

   The signals are displayed superimposed.

Move and evaluate measurements relative to each other

Proceed as follows to move the measurements in relation to each other and evaluate them:

1. Zoom in on the time diagram of the "workingclock" signal group until the deviations of the signals are recognizable.

2. Measure the time delay Δt between the two signals of the "workingclock" signal group.

3. Move the measurements of the two projects relative to each other by using the time delay Δt as an offset.

   The signals are displayed in the time diagram without time delay.

4. You can now evaluate the signals in the time diagram of the "position" signal group.

11.11 Tags: Cross-PLC synchronous operation

Positioning axis, synchronous axis, external encoder

The following tags of the positioning axis, synchronous axis and external encoder are relevant for cross-PLC synchronous operation:

Tag	Description	
<TO>.CrossPlcSynchronousOperation.Interface[1..32].EnableLeadingValueOutput	Provide cross-PLC leading value	
	FALSE	No
	TRUE	Yes
<TO>.CrossPlcSynchronousOperation.Interface[1..32].AddressOut	Output address for the telegram of cross-PLC synchronous operation	
<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime	Delay time for setpoint coupling with delayed leading value	
<TO>.StatusProvidedLeadingValue.DelayedLeadingValue.Position	Position of the provided leading value	
<TO>.StatusProvidedLeadingValue.DelayedLeadingValue.Velocity	Velocity of the provided leading value	
<TO>.StatusProvidedLeadingValue.DelayedLeadingValue.Acceleration	Acceleration of the provided leading value	

Leading axis proxy

The following leading axis proxy technology object tags are relevant for cross-PLC synchronous operation:

Tag	Description	
<TO>.Position	Position of the leading value for local synchronous operation	
<TO>.Velocity	Velocity of the leading value for local synchronous operation	
<TO>.Acceleration	Acceleration of the leading value for local synchronous operation	
<TO>.Interface.AddressIn	Input address for the telegram of the external leading value	
<TO>.Parameter.LocalLeadingValueDelayTime	Delay time of leading value output on the local following axis which, in turn, provides a leading value	
<TO>.Parameter.ToleranceTimeExternalLeadingValueInvalid	Tolerance time until a technology alarm is triggered when the external leading value becomes invalid	
<TO>.StatusExternalLeadingValue.ModuloLength	Modulo length of the external leading value	
<TO>.StatusExternalLeadingValue.ModuloStartValue	Modulo start value of the external leading value	
<TO>.StatusExternalLeadingValue.AdjustmentTime	Time by which the external leading value is adjusted	
	< 0	The external leading value is interpolated by this time.
	> 0	The external leading value is extrapolated by this time.
<TO>.StatusWord.X4 (LeadingValueValid)	Validity of the external leading value	
	FALSE	Leading value does not exist or is not valid
	TRUE	Leading value exists and is valid
<TO>.StatusWord.X5 (LeadingValueModulo)	Modulo functionality	

Tag	Description	
<TO>.StatusWord.X5 (LeadingValueModulo)	FALSE	Leading value without modulo functionality
	TRUE	Leading value with modulo functionality
<TO>.StatusWord.X6 (LeadingAxisControl)	Follow-up mode or setpoint mode	
	FALSE	Leading axis in follow-up mode
	TRUE	Leading axis in setpoint operation

Diagnostics 12

The description of Motion Control diagnostics is limited to the diagnostics view of the technology objects in TIA Portal, the technology alarms and the error IDs on Motion Control instructions.

"Debug" program mode is available for testing the execution of your Interpreter program.

The following descriptions can be found in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation:

- Diagnostics concept
- Technology alarms
- Error IDs in Motion Control instructions

A comprehensive description of the system diagnostics of the S7-1500 CPU can be found in the "Diagnostics" function manual (https://support.industry.siemens.com/cs/ww/en/view/59192926).

12.1 Synchronous axis technology object

12.1.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Axis status

The following table shows the possible axis status values:

Status	Description
Simulation active	The axis is simulated in the CPU or used as the virtual axis. Setpoints are not output to the drive. (<TO>.StatusWord.X25 (AxisSimulation))
Enabled	The technology object has been enabled. You can move the axis with motion jobs. (<TO>.StatusWord.X0 (Enable))
Position-controlled mode	The axis is in position-controlled mode. (Inversion of <TO>.StatusWord.X28 (NonPositionControlled))
Homed	The technology object is homed. The relationship between the position in the technology object and the mechanical position was successfully created. (<TO>.StatusWord.X5 (HomingDone))

Status	Description
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Axis control panel enabled	The axis control panel is active. The axis control panel has master control over the technology object. You cannot control the axis from the user program. (<TO>.StatusWord.X4 (ControlPanelActive))
Drive ready	The drive is ready to execute setpoints. (<TO>.StatusDrive.InOperation)
Encoder values valid	The actual encoder values are valid. (<TO>.StatusSensor[1].State)
Encoder values valid (S7-1500T)	The actual encoder values of encoder 1, encoder 2, encoder 3 or encoder 4 are valid. (<TO>.StatusSensor[1..4].State)
Active encoder (S7-1500T)	The encoder in effect operationally is encoder 1, encoder 2, encoder 3 or encoder 4. (<TO>.OperativeSensor)
Encoder values homed	Encoder is homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment (<TO>.StatusSensor[1].Adjusted)
Encoder homed (S7-1500T)	Encoder 1, encoder 2, encoder 3 or encoder 4 is homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment (<TO>.StatusSensor[1..4].Adjusted)
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))

Status limit switch

The following table shows the possibilities for enabling the software and hardware limit switches:

Status	Description
Negative SW limit switch approached	The negative software limit switch has been approached. (<TO>.StatusWord.X15 (SWLimitMinActive))
Positive SW limit switch approached	The positive software limit switch has been approached. (<TO>.StatusWord.X16 (SWLimitMaxActive))
Negative HW limit switch approached	The negative hardware limit switch has been approached or overtraveled. (<TO>.StatusWord.X17 (HWLimitMinActive))
Positive HW limit switch approached	The positive hardware limit switch has been approached or overtraveled. (<TO>.StatusWord.X18 (HWLimitMaxActive))

Motion status

The following table shows the possible axis motion status values:

Status	Description
Done (no job running)	No job active at technology object. (<TO>.StatusWord.X6 (Done))
Homing job	The technology object executes a homing job of the Motion Control instruction "MC_Home" or from the axis control panel. (<TO>.StatusWord.X11 (HomingCommand))
Jog	The axis is being moved with a job for jog mode of Motion Control instruction "MC_MoveJog". (<TO>.StatusWord.X9 (JogCommand))
Velocity specification	The axis is traversed with a job with velocity specification of the Motion Control instruction "MC_MoveVelocity" or from the axis control panel. (<TO>.StatusWord.X10 (VelocityCommand))
Positioning job	The axis is traversed with a positioning job of the Motion Control instruction "MC_MoveAbsolute", "MC_MoveRelative", "MC_PositionProfile" or of the axis control panel (OR logic operation). (<TO>.StatusWord.X8 (PositioningCommand); <TO>.StatusWord2.X9 (PositionProfileCommand))
Constant velocity	The axis is moved with constant velocity or is stationary. (<TO>.StatusWord.X12 (ConstantVelocity))
Standstill	The axis is at a standstill. (<TO>.StatusWord.X7 (StandStill))
Accelerating	Axis is being accelerated. (<TO>.StatusWord.X13 (Accelerating))
Decelerating	The axis is being decelerated. (<TO>.StatusWord.X14 (Decelerating))

Status	Description
Torque limit active	At least the threshold value (default 90%) of the preset force/torque limitation acts on the axis. (<TO>.StatusWord.X27 (InLimitation))
Stop job active	The axis is stopped and disabled by Motion Control instruction "MC_Stop". (<TO>.StatusWord2.X0 (StopCommand))
Superimposed motion	The motion of the axis is superimposed by at least one overlapping Motion Control instruction (OR logic operation). (<TO>.StatusWord.X23 (MoveSuperimposedCommand); <TO>.StatusWord2.X6 (MotionInSuperimposedCommand); <TO>.StatusWord2.X8 (MotionInSuperimposedAxesCommand); <TO>.StatusWord2.X7 (HaltSuperimposedCommand))

Synchronous operation status

Status	Description
Synchronization	The axis is synchronized to the leading value of a leading axis. (<TO>.StatusWord.X21 (Synchronizing))
Synchronous	The axis is synchronized and moves synchronously to the leading axis. (<TO>.StatusWord.X22 (Synchronous))
Desynchronization (S7-1500T)	The axis is desynchronized from the leading value of a leading axis. (<TO>.StatusWord2.X1 (DesynchronizingCommand))
Synchronization pending (S7-1500T)	A synchronous operation is pending until the leading value reaches the start position for synchronization. (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 2 or 3)
Desynchronization pending (S7-1500T)	A desynchronization job is pending until the leading value reaches the start position for desynchronization. (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 4 or 5)
Additive leading value active (S7-1500T)	The axis receives an additive leading value with the Motion Control instruction "MC_LeadingValueAdditive". (<TO>.StatusSynchronizedMotion.StatusWord.X4 (LeadingValueAdditiveCommand))
Leading value offset (S7-1500T)	The leading value is shifted with the Motion Control instruction "MC_PhasingAbsolute" or "MC_PhasingRelative". (<TO>.StatusWord.X24 (PhasingCommand))
Leading value offset pending (S7-1500T)	A job for leading value offset is waiting. (<TO>.StatusWord2.X3 (PhasingCommandWaiting))
Following value offset (S7-1500T)	The following value is shifted with the Motion Control instruction "MC_OffsetAbsolute" or "MC_OffsetRelative". (<TO>.StatusWord2.X4 (OffsetCommand))
Following value offset is pending (S7-1500T)	A job for following value offset is waiting. (<TO>.StatusWord2.X5 (OffsetCommandWaiting))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program with a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Drive	An error occurred in the drive. (<TO>.ErrorWord.X4 (DriveFault))
Encoder	An error occurred in the encoder system. (<TO>.StatusSensor[1].Error)
Encoder (S7-1500T)	An error has occurred in the encoder system of encoder 1, encoder 2, encoder 3 or encoder 4. (<TO>.StatusSensor[1..4].Error)
Data exchange	Communication with a connected device is faulty. (<TO>.ErrorWord.X7 (CommunicationFault))
I/O	An error occurred accessing a logical address. (<TO>.ErrorWord.X13 (PeripheralError))
Job rejected	A job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled (for example, technology object not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
Homing	An error occurred during a homing process. (<TO>.ErrorWord.X10 (HomingFault))
Positioning	The positioning axis was not positioned correctly at the end of a positioning motion. (<TO>.ErrorWord.X12 (PositioningFault))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.ErrorWord.X6 (DynamicError))
Following error	The maximum permitted following error has been exceeded. (<TO>.ErrorWord.X11 (FollowingErrorFault))
SW limit switch	A software limit switch has been reached. (<TO>.ErrorWord.X8 (SWLimit))
HW limit switch	A hardware limit switch has been reached or overtraveled. (<TO>.ErrorWord.X9 (HWLimit))

Error	Description
Adapt	An error occurred during data adaption. (<TO>.ErrorWord.X15 (AdaptionError))
Synchronization	An error occurred during synchronization. The leading axis specified for the corresponding Motion Control instruction was not configured as a possible leading axis. (<TO>.ErrorWord.X14 (SynchronousError))
Superimposing	An error has occurred during the superimposing of the axis motion. The superimposing axis specified at the corresponding Motion Control instruction was not configured as a possible superimposing axis. (<TO>.ErrorWord.X16 (SuperimposingError))

Warnings

The following table shows the possible warnings:

Warning	Description
Configuration	One or several configuration parameters are adjusted internally at a certain time. (<TO>.WarningWord.X1 (ConfigWarning))
Job rejected	Job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled. (<TO>.WarningWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.WarningWord.X6 (DynamicWarning))
Synchronization	An error occurred during synchronization. The leading axis specified for the corresponding Motion Control instruction was not configured as a possible leading axis. (<TO>.WarningWord.X14 (SynchronousWarning))

Alarm display

For more information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

More information

An option for evaluating the individual status bits can be found in the section "Evaluating StatusWord, ErrorWord and WarningWord" of the "S7-1500/S7-1500T Motion Control overview" documentation.

12.1.2 Motion status

You use the "Technology object > Diagnostics > Motion status" diagnostic function in the TIA Portal to monitor the motion status of the axis. The diagnostics function is available in online operation.

"Setpoints" area

The following table shows the meaning of the status data:

Status	Description
Target position	Current target position of an active positioning job The target position value is only valid during execution of a positioning job. (<TO>.StatusPositioning.TargetPosition)
Position setpoint	Setpoint position of the axis (<TO>.Position)
Velocity setpoint	Velocity setpoint of the axis (<TO>.Velocity)
Velocity override	Percentage correction of the velocity specification The velocity setpoint specified in Motion Control instructions or set by the axis control panel is superimposed with an override signal and corrected as a percentage. Valid velocity correction values range from 0.0 % to 200.0 %. (<TO>.Override.Velocity)

"Current values" area

The following table shows the meaning of the status data:

Status	Description
Operative encoder	Operative encoder of the axis (<TO>.OperativeSensor)
Actual position	Actual position of the axis If the technology object is not homed, then the value is displayed relative to the position that existed when the technology object was enabled. (<TO>.ActualPosition)
Actual velocity	Actual velocity of the axis (<TO>.ActualVelocity)
Following error	Following error of the axis (<TO>.StatusPositioning.FollowingError)

"Dynamic limits" area

This area displays the limit values for the dynamic parameters.

The following table shows the meaning of the status data:

Status	Description
Velocity	Configured maximum velocity (<TO>.DynamicLimits.MaxVelocity)
Acceleration	Configured maximum acceleration (<TO>.DynamicLimits.MaxAcceleration)
Deceleration	Configured maximum deceleration (<TO>.DynamicLimits.MaxDeceleration)
Jerk	Configured maximum jerk (<TO>.DynamicLimits.MaxJerk)

12.1.3 PROFIdrive telegram

The "Technology object > Diagnostics > PROFIdrive telegram" diagnostics function is used in the TIA Portal to monitor the PROFIdrive telegrams returned by the drive and encoder. The display of the Diagnostics function is available in online operation.

"Drive" area

This area displays the following parameters contained in the PROFIdrive telegram from the drive to the controller:

- Status words "ZSW1" and "ZSW2"
- The speed setpoint (NSET) that was output to the drive
- The actual speed that was signaled from the drive (NACT)

"Encoder" area

This area displays the following parameters contained in the PROFIdrive telegram from the encoder to the controller:

- Status word "Gx_ZSW"
- The actual position value "Gx_XIST1" (cyclic actual encoder value)
- The actual position value "Gx_XIST2" (absolute encoder value)

Areas "Encoder 1" to "Encoder 4" (S7-1500T)

The "Encoder 1" to "Encoder 4" areas display the following parameters from the PROFIdrive telegram of the corresponding encoder to the controller:

- Status word "Gx_ZSW"
- The actual position value "Gx_XIST1" (cyclic actual encoder value)
- The actual position value "Gx_XIST2" (absolute encoder value)

12.2 Cam technology object

12.2.1 Applications of the cam diagnostics

In the cam diagnostics you can monitor and analyze valid points and segments of a cam from the offline and online technology object data block. The values are shown in tables and graphics and correspond to the interpolated offline or online parameters of the technology object data block.

The cam diagnostics in TIA Portal interpolates the current technology object data block parameters independently. In contrast to the cam editor, the diagnostics does not depend on the interpolation in the SIMATIC S7-1500T. The interpolation always refers to the current values in the technology object data block, the so-called snapshot.

The following parameters are taken into account during interpolation.

- <TO>.Point[i]
- <TO>.Segment[i]
- <TO>.VaildPoint[i]
- <TO>.ValidSegment[i]
- <TO>.InterpolationSettings

NOTE

The term "cam" used in this chapter applies to the technology objects of the "TO_Cam" and "TO_Cam_10k" types.

Calling the diagnostics

You can call the diagnostics as follows:

- Project tree > Project> Technology objects > Cam > Diagnostics

Possible offline applications

Valid start values of the cam in the project are displayed in a list and represented graphically.

NOTE

After you have changed values in the cam editor, you must compile the cam. The cam is automatically interpolated, even without a controller or PLCSIM.

Offline, you can:

- Check the interpolation of cams
- Identify points and segments for the same leading value
- Check the calculated velocity, acceleration and jerk
- View and compare saved snapshots
- Check transitions between cams, such as the continuity when changing cams

Possible online applications

Valid start values of the cam from the project and the actual values are displayed in a list and graphically represented online.

Online you can also:

- Check the algorithms for calculating the cams in the user program, e.g. the calculation of the coefficients for segments
- Compare a curve generated during runtime with the expected curve
- Monitor status bits and error bits
- Sort points and segments according to the leading value range, even if they are not defined in ascending order according to index in the technology object data block.
- Take, save and compare snapshots. You can use the snapshots later for documentation and additional diagnostics, when you close the TIA Portal project or change the elements of the cam.

12.2.2 Structure of the diagnostics

The cam diagnostics consists of four areas:

① List of valid points and segments with toolbar

② Curve diagram with toolbar

③ Element comparison

④ Inspector window

List of valid points and segments

In the list you can find all valid points and segments from the offline and online DB and the saved snapshots. Since you can display the values of the offline configuration and several snapshots, they are provided with expandable headers.

The list consists of the following columns:

Table column	Description
Type	In this column, the type of symbol is displayed with a symbol that corresponds to the symbol in the cam editor. The following element types are recognized: • Point • Line • Sine • Polynomial
Element	points or segments are shown in this column.
Start value	The x values for points and the x min. values for segments are shown in this column.
Value	The y values for points are shown in this column. When you expand the segments, the following details are shown: • x min. • x max. • a0 • a1 • a2 • a3 • a4 • a5 • a6 • sineAmplitude • sinePeriod • sinePhase
	In this column, you can select points or segments for comparison (Page 271).

Sorting

You can sort the points and segments in ascending or descending order using the "Element" and "Start value" columns.

Toolbar

The toolbar at the top of the list of valid points and segments provides the following functions via buttons:

Symbol	Function	Description
	Monitoring On/Off	Monitoring of the cam is started or ended.
	Update online curve	The online snapshot is updated.
	Print	The "Print (Page 275)" dialog will open.

Symbol	Function	Description
	Link list and graphic display for the selected objects	If coupling is enabled and an element is selected in the curve diagram, this element is automatically scrolled to in the list of valid points and segments. Note: This is only relevant if the list has so many entries that they are not all visible.
<No filter>	Select filter	You can select a defined filter.
	Defining filter	The "Define filter (Page 270)" dialog opens.

Curve diagram

Offline, online and saved snapshots are displayed in the curve diagram.
All valid data from the technology object data block are graphically displayed as a curve. In the curve diagram you can display curves that reflect the position specification, position, velocity, acceleration and jerk. You set the parameters of the displayed curves in the inspector window. You can show or hide the legend using the icon on the toolbar.

NOTE

Refresh the curve displayed in the offline view

If you change the values in the offline technology object data block, the offline snapshot is automatically reloaded. After you have changed parameters in the cam editor, you must compile the cam. The parameters are then automatically transferred to the technology object data block.

Toolbar

The toolbar at the top of the curve diagram provides the following functions via buttons:

Symbol	Function	Description
	Move view	Moving the view using the drag-and-drop feature To switch from any tool to the "Move view" tool, press the <Esc> key.
	Activate zoom selection	Zoom into selected area
	Activate vertical zoom	Vertical zoom into selected area without horizontal scaling Alternative: <Ctrl> +drag to ordinate keeping mouse button pressed
	Activate horizontal zoom	Horizontal zoom into selected area without vertical scaling Alternative: <Ctrl> +drag to abscissa keeping mouse button pressed
	Zoom in	Enlargement of the display Alternative: <Ctrl> + mouse wheel up in curve diagram

Symbol	Function	Description
	Zoom out	Reduction of the display Alternative: <Ctrl> + mouse wheel down in curve diagram
	Show all	Display of entire definition and value range
	Zoom into curve	Zoom to the following value range of the curve that you selected in the legend of the chart
	View: A chart with positions	Display of one chart with the following curves of the cam opened in the diagnostics: • Position specification • Effective position
	View: A chart with all curves	Display of one chart with the following curves of the cam opened in the diagnostics: • Position specification • Effective position • Effective velocity • Effective acceleration • Effective jerk
	View: Four charts with all curves	Display of four charts with the following curves of the cam opened in the diagnostics: • Chart with position specification and effective position • Chart with effective velocity • Chart with effective acceleration • Chart with effective jerk
	Vertical measuring lines	Displaying and moving of vertical measuring lines Hold down the left mouse button and drag to draw a measuring range. The vertical position of the measuring lines can be moved. The function values for the positions of the measuring lines are displayed in the chart. The difference is displayed between the measuring lines.
	Horizontal measuring lines	Displaying and moving of horizontal measuring lines Hold down the left mouse button and drag to draw a measuring range. The horizontal position of the measuring lines can be moved. The function values for the positions of the measuring lines are displayed in the chart. The difference is displayed between the measuring lines.
	Show legend	Showing or hiding of the legend in the curve diagram. To display values for a specific curve on the ordinate, click on the name of the corresponding curve in the legend.

Symbol	Function	Description
	Show status and error bits	Show and hide the diagnostics window "Status and error bits (Page 267)" You monitor the status of the technology object using the "Status and error bits" diagnostics window.
	Show scaling range	Showing and hiding the "Scaling range" diagnostic window Use the "Range scaling" diagnostics window to monitor the status of the scaling ranges.
	Save window settings	Saves of the display settings.

Element comparison

The element comparison is located below the curve diagram. You can select individual points and segments and thus Analyze and compare elements (Page 271):

Inspector window

In the inspector window you can manage the Manage snapshots (Page 273) in the "General" tab. You can set the decimal places separately in the list of valid points and segments and in the curve diagram.

12.2.3 Online view

Use the "Monitoring on/off" icon on the toolbar of the cam diagnostics to switch to the online view.

Online view of the list with valid points and segments

In the list with valid points and segments you can find the current online values under "Online snapshot". The start values and values of the elements are highlighted in orange.

Online view of the curve diagram

In the curve diagram you can monitor changes to the status of the online cam in the "Status and error bits (Page 267)" diagnostics window. You can show and hide the window using the icon.

Online view of the Inspector window

In the list of the current snapshots you can see the online snapshot, whose display you can manage and save under "Saved snapshots" (Page 273).

12.2.4 Status and error bits

You monitor the status of the technology object using the "Status and error bits" diagnostics window. The diagnostics function is available in online operation.

You can show and hide the diagnostics window using the icon on the toolbar. You can move the window to a desired position within the curve diagram using drag-and-drop.

The meaning of the status and error bits is described in the following tables.

Cam status

The following table shows the possible statuses of the cam:

Status	Description
In use	The cam is used. (<TO>.StatusWord.X0 (Control))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Definition changed	The definition range of the cam has changed in the technology data block. (<TO>.StatusWord.X4 (CamDataChanged))
Interpolated	The cam is interpolated. (<TO>.StatusWord.X5 (Interpolated))
In interpolation	The cam is interpolated. (<TO>.StatusWord.X6 (InInterpolation))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))
Copy operation active	A copy operation of an "MC_CopyCamData" job is active. (<TO>.StatusWord.X7 (CopyCamDataActive))
Range scaling in calculation	The range scaling of a "MC_SetCamRangeScaling" job is calculated. (<TO>.StatusWord.X8 (SetCamRangeScalingActive))
Range scaling active	At least one range scaling is active. (<TO>.StatusWord.X9 (CamRangeScaled))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error in a Motion Control instruction or during its use has occurred in the user program. (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled. (<TO>.ErrorWord.X3 (CommandNotAccepted))

You can access the alarm display via the icon.

Warnings

The following table shows the possible warnings:

Warning	Description
System	A system-internal error has occurred. (<TO>.WarningWord.X0 (SystemWarning))
Configuration	One or more configuration parameters will be temporarily adjusted internally. (<TO>.WarningWord.X1 (ConfigWarning))
User program	An error in a Motion Control instruction or during its use has occurred in the user program. (<TO>.WarningWord.X2 (UserWarning))
Job rejected	Job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled. (<TO>.WarningWord.X3 (CommandNotAccepted))

You can access the alarm display via the icon.

12.2.5 Range scaling

The configured scaling ranges are indicated by markers at the edge of the curve diagram. The scaling factor is displayed in the tooltip of the area selection. If the scaling ranges overlap, the effective scaling factor is displayed.

Use the "Scaling range" diagnostics window to monitor the status of the scaling ranges. The diagnostics function is available in online operation.

You can show and hide the diagnostics window using the icon on the toolbar. You can move the window to a desired position within the curve chart using drag-and-drop.

The following table describes the meaning of the parameters.

Scaling range 1 and 2

The following table shows the values for scaling ranges 1 and 2:

Parameters	Description
Scaling mode	This field shows whether the scaling range refers to the leading value range or the following value range. (<TO>.StatusRangeScaling.Range[1..2].Mode)
Start point	The start value of the scaling range is displayed in this field. (<TO>.StatusRangeScaling.Range[1..2].StartPoint)
End point	The final value of the scaling range is displayed in this field. (<TO>.StatusRangeScaling.Range[1..2].EndPoint)
Scaling factor	The scaling factor of the scaling range is displayed in this field. (<TO>.StatusRangeScaling.Range[1..2].Scaling)

12.2.6 "Definition changed" and "Interpolated" status bits

Depending on the change in the online technology object data block, the associated status bits are displayed in green.

If you change values in the online technology object data block and they do not match the interpolated values displayed in the curve diagram, the "Definition changed" status bit is displayed in green.

The following message is displayed in the upper part of the cam diagnostics:

"The online values do not correspond to the active interpolated curve. Interpolate the cam and then reload the curve in the graphic display."

Refresh graphic display

To display the current values, follow these steps:

1. Interpolate the curve.

   After the interpolation, the "Definition changed" bit is no longer set.

   The "Interpolated" bit is set.

   The note in the banner changes:

   "The curve shown is not current. Update."

2. Click on the "Refresh" icon on the toolbar or, alternatively, on the "Refresh" link in the message.

   The online snapshot is updated. You can save the online snapshots under "Saved snapshots (Page 273)".

NOTE

You can also update the diagnostics without re-interpolating the cam after making changes in the technology object data block. The last interpolated cam then remains active in the controller and during camming. The "Interpolated" bit remains set. Before interpolation, you can then analyze the interpolated cam with the new technology object data block parameters in the controller. The "Definition changed" bit then remains TRUE.

12.2.7 Filter by segments and points

To analyze the relevant elements in extensive cams, you can filter them according to the following criteria:

- Filter segments by index in the technology data block
- Filter segments by segment type
- Filter points by index in the technology data block
- Filter the displayed leading value range

Elements that do not meet the filter criteria are hidden in the list of points and segments and displayed in a lighter shade in the curve diagram than elements that meet the criteria. The filter criteria are applied to all displayed snapshots.

Defining and saving filters

To define and save a filter, follow these steps:

1. Click on the icon in the cam diagnostics toolbar.

   The "Define filter" dialog opens.
2. Set the desired filter criteria.
3. Name the filter in the drop-down list.
4. Click "OK".

   The filter is saved and applied.

Adding other filters

To add additional filters, proceed as follows:

1. Click on the icon in the cam diagnostics toolbar.

   The "Define filter" dialog opens.
2. Click the symbol .
3. Set the desired filter criteria.
4. Name the filter in the drop-down list.
5. Click "OK".

   The additional filter is saved, applied and displayed with existing filters in the drop-down list of the toolbar.

Adapting existing filters

To adjust existing filters, follow these steps:

1. Click on the icon in the cam diagnostics toolbar.
   The "Define filter" dialog opens.
2. Select the filter to be adjusted from the drop-down list.
3. Adjust the filter criteria.
4. Click "OK".
   The changes are saved and applied.

Delete filter

Proceed as follows to delete filter:

1. Click on the icon in the cam diagnostics toolbar.
   The "Define filter" dialog opens.
2. In the drop-down list, select the filter to deleted.
3. Click the symbol .
4. Click "OK".
   The filter is deleted.

Cancel filter

To cancel a filter, select the "No filter" entry in the drop-down list in the toolbar.

The filter settings are terminated.

12.2.8 Comparing elements

You can select individual points and segments from various snapshots and compare them in detail.

Select elements to compare

You can select items to compare in the following two ways:

- In the " " column, select valid points or segments.
- In the curve diagram in the shortcut menu, select the element "Show in element comparison".

Parameters in the element comparison

For each selected element, the parameters are displayed in a separate window.

NOTE

You can change the order of the window using the drag-and-drop feature.

Each window contains three expandable areas:

- Element type with mapping in the upper part

  You can expand and collapse the image of the element with the arrow next to the element type.

- Basic parameters

  The basic parameters are read out directly from the technology object data block of the cam.

  For points, the x and y values are displayed.

  The following values are displayed for segments:

  – x min.
  – x max.
  – a0
  – a1
  – a2
  – a3
  – a4
  – a5
  – a6
  – sineAmplitude
  – sinePeriod
  – sinePhase

- Extended parameters

  The extended parameters are not saved directly in the technology object data block. They are calculated by the diagnostics in the TIA Portal.

  For points, the values are displayed depending on the interpolation:

  – With linear interpolation, the velocity in the points is discontinuous. The velocity is displayed to the left (v left) and right (v right) of the point. Acceleration and jerk are not displayed.
  – With cubic interpolation, the jerk in the points is discontinuous. The jerk is displayed to the left (j left) and right (j right) of the point.
  – When interpolating with Bézier splines, the values "y", "v", "a" and "j" from the interpolation result are displayed.

The following values are displayed for segments:

- x start
- x end
- y min.
- y max.
- v start
- v end
- v min.
- v max.
- a start
- a end
- a min.
- a max.
- j start
- j end
- j min.
- j max.

NOTE

The expanding and collapsing of the individual areas and the scrolling are synchronized for all segments and points.

12.2.9 Managing snapshots

You can manage the displayed curves and snapshots in the inspector window under "Properties > General> Snapshots and curves". In the "Current snapshot" area you can see snapshots that contain valid points and segments from the technology object data block in the following order:

1. Offline configuration
2. Online configuration
3. Saved snapshot

Settings of the snapshots

You can expand the snapshots and make the following settings:

Control element/display element	Meaning
	Show and hide the respective snapshot in the curve diagram and in the list of valid points and segments
	Save the snapshot under "Saved snapshot"

Control element/display element	Meaning
	Export the snapshot (Page 274)
	Delete the saved snapshot
	Show and hide individual curves in the curve diagram and in the legend You can select the color and line shape for each curve.

The date and time of the recording, the number of segments and points and the type of interpolation are displayed for each snapshot.

You can change the name of saved snapshots.

12.2.10 Exporting and importing snapshots

You can export and import snapshots.

A list with all snapshots and the "Import snapshot" button can be found in the Inspector window > General tab > Snapshots and curves.

The following formats are supported:

- MCD exchange format
- SIMOTION SCOUT CamTool format
- Binary format

A description of the individual formats can be found in the "Exporting a cam (Page 135)" and "Importing a cam (Page 136)" sections.

Export snapshot

To export snapshots, follow these steps:

1. For the snapshot you want to export, click the icon .

   The "Export snapshot" dialog opens.
2. Select the export format and the delimiter.
   - When you select the "Comma" delimiter, the snapshot is exported as CSV file.
   - When you select the "Tabulator" delimiter, the snapshot is exported as TXT file.
3. Enter a file name.
4. Select the target directory.
5. Click the "Export" button.

NOTE

You can import into the cam configuration a snapshot exported in binary format.

Import snapshot

To import snapshots, follow these steps:

1. Click "Import snapshot".

   The "Cam import" dialog opens.
2. Select the format.
3. Select the file.
4. Click the "Open" button.

   The snapshot is displayed in the "Saved snapshots" area.
5. To display the snapshot in the list of valid points and segments and in the curve diagram, select the check box.
6. For the display in the curve diagram, select the color and line shape for the curves.

NOTE

Exports from the cam configuration can contain elements that are not supported in the cam diagnostics (see "Structure of the diagnostics (Page 262)" section). These elements are then displayed as a group of points.

12.2.11 Printing curve diagram

You have the possibility to print the displayed curves.

Procedure

To print the curves displayed in the curve diagram, follow these steps:

1. Show all curves to be printed out.
2. On the toolbar, click the icon .
3. Select the printer and the document layout.

   To preview the resulting document, click the "Preview" button.
4. Click "Press".

12.3 Leading axis proxy technology object

12.3.1 Status and error bits

You use the "Technology object > Diagnostics > Status and error bits" diagnostic function in the TIA Portal to monitor the status and error messages for the technology object. The diagnostics function is available in online operation.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

Leading axis proxy status

The following table shows the possible states of the leading axis proxy:

Status	Description
In operation	The technology object is in operation. (<TO>.StatusWord.X0 (Control))
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO.>StatusWord.X3 (OnlineStartValuesChanged))
External leading value valid	The external leading value exists and is valid. (<TO>.StatusWord.X4 (LeadingValueValid))
External leading value with modulo	The external leading value has modulo functionality. (<TO>.StatusWord.X5 (LeadingValueModulo))
Leading axis in setpoint operation	The leading axis is in setpoint operation. (<TO>.StatusWord.X6 (LeadingAxisControl))

Warnings

The following table shows the possible warnings:

Warning	Description
System	A system-internal error has occurred. (<TO>.WarningWord.X0 (SystemWarning))
Configuration	One or more configuration parameters are being internally adapted temporarily. (<TO>.WarningWord.X1 (ConfigWarning))

Warning	Description
User program	An error has occurred in the user program. (<TO>.WarningWord.X2 (UserWarning))
Job rejected	Job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled. (<TO>.WarningWord.X3 (CommandNotAccepted))
Data exchange	An error in the communication has occurred. (<TO>.WarningWord.X7 (CommunicationWarning))

Error

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))
User program	An error occurred in the user program at a Motion Control instruction or its use. (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. You cannot execute a Motion Control instruction because necessary requirements are not fulfilled (for example, technology object not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
Data exchange	Communication with a connected device is faulty. (<TO>.ErrorWord.X7 (CommunicationFault))

Alarm display

For additional information and to acknowledge the error, go to the Inspector window by clicking on the "Alarm display" link.

12.3.2 Motion status

You use the "Technology object > Diagnostics > Motion status" diagnostic function in the TIA Portal to monitor the leading value of the leading axis proxy. The diagnostics function is available in online operation.

Leading value for local synchronous operation

The following table shows the meaning of the status data:

Status	Description
Position	Adapted leading value for local synchronous operation (<TO>.Position)
Velocity	Leading value velocity for local synchronous operation (<TO>.Velocity)
Acceleration	Leading value acceleration for local synchronous operation (<TO>.Acceleration)

External leading value

The following table shows the meaning of the status data:

Status	Description
Modulo length	Modulo length of the external leading value (<TO>.StatusExternalLeadingValue.ModuloLength)
Modulo start value	Modulo start value of the external leading value (<TO>.StatusExternalLeadingValue.ModuloStartValue)
Adjustment time	Time by which the external leading value is adapted (<TO>.StatusExternalLeadingValue.AdjustmentTime)

Instructions 13

13.1 Synchronous motion

13.1.1 MC_GearIn V10

13.1.1.1 MC_GearIn: Start gearing V10

Description

With the Motion Control instruction "MC_GearIn", you start a gearing (Page 49) operation between a leading axis and a following axis. You can start synchronous operation when the leading axis is at a standstill or when it is in motion.

The Motion Control instruction offers you the following:

- Defining gear ratio (Page 50)
- Synchronizing following axis using dynamic parameters (Page 52)
- Synchronous travel in gearing (Page 53)

Applies to

- Synchronous axis

Requirement

- The technology objects of the leading axis and the following axis have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis under "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.

Override response

The override response for "MC_GearIn" jobs is described in section "Override response V10: Synchronous operation jobs".

With a "MC_GearOut" job, the following axis is desynchronized, and synchronous operation is terminated (S7-1500T).

Disabling the following axis with "MC_Power.Enable" = FALSE aborts the synchronous operation in every status.

Disabling the leading axis with an "MC_Power" job, in contrast, does not abort synchronous operation. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled and traversing again.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GearIn":

Parameters	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder (S7-1500T) TO_LeadingAxisProxy (S7-1500T)	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
RatioNumerator	INPUT	DINT	1	Gear ratio numerator (Page 50) Permitted integer values: -2147483648 to 2147483647 (value 0 not permitted)	
RatioDenominator	INPUT	DINT	1	Gear ratio denominator (Page 50) Permitted integer values: 1 to 2147483647	
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 52)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 52)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)

Parameters	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	Jerk (Page 52)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
InGear	OUTPUT	BOOL	FALSE	TRUE	Synchronous operation reached The following axis is synchronized and moves synchronously to the leading axis.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.1.2 MC_GearIn: Function chart V10

Function chart: Synchronizing and switching the leading value

Using "Exe_1", an "MC_GearIn" job (A1) is initiated. The following axis (TO_FollowingAxis) is synchronized to the leading axis (TO_LeadingAxis_1). "InGear_1" signals at time ① that the following axis is synchronized and moves synchronously to the leading axis.

At time ②, synchronous operation is overridden by another "MC_GearIn" job (A2). The abort is signaled via "Abort_1". The following axis is synchronized to the new leading axis (TO_LeadingAxis_2). "InGear_2" signals at time ③ that the following axis is synchronized and moves synchronously to the leading axis.

13.1.2 MC_GearInPos V10

13.1.2.1 MC_GearInPos: Start gearing with specified synchronous positions V10

Description

With the Motion Control instruction "MC_GearInPos", you start gearing (Page 67) between a leading axis and a following axis. The following axis is synchronized depending on the synchronization mode and the specified synchronous positions for the leading and following axis. You can start synchronous operation when the leading axis is at a standstill or when it is in motion.

The Motion Control instruction offers you the following:

- Defining gear ratio (Page 55)
- Defining direction of synchronization (Page 59)
- Define synchronous positions and type of synchronization:
  - Synchronization in advance using dynamic parameters (Page 61)
  - Synchronization in advance using leading value distance (Page 63)
  - Subsequent synchronization using leading value distance (Page 65)
  - Subsequent synchronization using leading value distance starting from current leading value position with calculated synchronous position of the following axis (Page 67)
  - Subsequent synchronization using leading value distance with calculated synchronous position of the following axis (Page 69)
- Synchronous travel in gearing (Page 72)

Different parameters are relevant depending on the synchronization profile. You can find an overview in the "Parameter overview for synchronizing with "MC_GearInPos" (Page 58)" section.

Applies to

- Synchronous axis

Requirement

- The technology objects of the leading axis and the following axis have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis under "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.

- The following axis is homed.
- With synchronization in advance using leading value distance, the leading axis must be at least the specified distance ("MasterStartDistance") from the synchronization position ("MasterSyncPosition") when starting the job.

Override response

The override response for "MC_GearInPos" jobs is described in section "Override response V10: Synchronous operation jobs".

With a "MC_GearOut" job, the following axis is desynchronized and synchronous operation is terminated.

Disabling the following axis with "MC_Power.Enable" = FALSE aborts the synchronous operation in every status.

Disabling the leading axis with "MC_Power", in contrast, does not abort synchronous operation. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled again.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GearInPos":

Parameters	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
RatioNumerator	INPUT	DINT	1	Gear ratio numerator (Page 55) Permitted integer values: -2147483648 to 2147483647 (value 0 not permitted)	
RatioDenominator	INPUT	DINT	1	Gear ratio denominator (Page 55) Permitted integer values: 1 to 2147483647	
MasterSyncPosition	INPUT	LREAL	0.0	Synchronous position of leading axis	
				When "SyncProfileReference" = 0, 1: Position of the leading axis from which the axes are synchronous and the synchronization is completed.	
				When "SyncProfileReference" = 3, 5: Position of the leading axis from which synchronization starts	
				When "SyncProfileReference" = 4: Not relevant	
SlaveSyncPosition	INPUT	LREAL	0.0	Synchronous position of following axis	

Parameters	Declaration	Data type	Default value	Description	
SlaveSyncPosition	INPUT	LREAL	0.0	When "SyncProfileReference" = 0, 1: Position of the following axis from which the axes are synchronous and the synchronization is completed.	
				When "SyncProfileReference" = 3: Position of the following axis, which is assigned to the synchronous position of the leading axis.	
				When "SyncProfileReference" = 4, 5: Not relevant	
SyncProfileReference	INPUT	DINT	1	Type of synchronization	
				0	Synchronization in advance using dynamic parameters (Page 61)
				1	Synchronization in advance using leading value distance (Page 63)
				2	Reserved
				3	Subsequent synchronization using leading value distance (Page 65)
				4	Subsequent synchronization using leading value distance starting from current leading value position with calculated synchronous position of the following axis (Page 67)
				5	Subsequent synchronization using leading value distance with calculated synchronous position of the following axis (Page 69)
MasterStartDistance	INPUT	LREAL	1.0	When "SyncProfileReference" = 1, 3, 4, 5: Leading value distance Distance of the leading axis during synchronization	
				> 0.0	The specified value is used.
				≤ 0.0	Not permitted
				When "SyncProfileReference" = 0: Not relevant	
Velocity	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Velocity	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Velocity)
				When "SyncProfileReference" = 1, 3, 4, 5: Not relevant	
Acceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Acceleration	
				> 0.0	The specified value is used.

Parameters	Declaration	Data type	Default value	Description	
Acceleration	INPUT	LREAL	-1.0	= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
				When "SyncProfileReference" = 1, 3, 4, 5: Not relevant	
Deceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Deceleration	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
				When "SyncProfileReference" = 1, 3, 4, 5: Not relevant	
Jerk	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Jerk	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
				When "SyncProfileReference" = 1, 3, 4, 5: Not relevant	
SyncDirection	INPUT	DINT	3	Direction of synchronization (Page 59) (in effect for following axes with activated Modulo setting)	
				1	Positive direction The following axis may only travel in positive direction during synchronization.
				2	Negative direction The following axis may only travel in negative direction during synchronization.
				3	Shortest distance Changes in direction are permitted for the following axis during synchronization.
StartSync	OUTPUT	BOOL	FALSE	TRUE	The following axis is synchronized to the leading axis.

Parameters	Declaration	Data type	Default value	Description	
InSync	OUTPUT	BOOL	FALSE	TRUE	Synchronous operation reached The following axis is synchronized and moves synchronously to the leading axis.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Gearing with "MC_GearInPos" (Page 54)

13.1.2.2 MC_GearInPos: Function chart V10

Function chart: Synchronization in advance using dynamic parameters and leading value distance

Section A

Using "Exe", an "MC_GearInPos" job (A1) is initiated. The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized in advance to the leading axis (TO_LeadingAxis) by means of the specified dynamic parameters. The distance required for synchronization is calculated by the system. When the specified reference positions "MasterSyncPosition" and "SlaveSyncPosition" are reached, "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

Section B

Using "Exe", an "MC_GearInPos" job (A1) is initiated. The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized to the leading axis (TO_LeadingAxis) by means of the specified leading value distance "MasterStartDistance". The dynamic response required for synchronization is calculated by the system. When the specified reference positions "MasterSyncPosition" and "SlaveSyncPosition" are reached, "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

Function chart: Synchronization in advance and subsequent synchronization using leading value distance

Section A

Using "Exe", an "MC_GearInPos" job (A1) is initiated. The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized to the leading axis (TO_LeadingAxis) by means of the specified leading value distance "MasterStartDistance". The dynamic response required for synchronization is calculated by the system. When the specified reference positions "MasterSyncPosition" and "SlaveSyncPosition" are reached, "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

Section B

Using "Exe", an "MC_GearInPos" job (A1) is initiated. When the specified reference position "MasterSyncPosition" is reached, the start of synchronization is indicated via "StartSync". The following axis (TO_FollowingAxis) is synchronized subsequently to the leading axis (TO_LeadingAxis) by means of the specified leading value distance "MasterStartDistance". The dynamic response required for synchronization is calculated by the system. "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

Function chart: Subsequent synchronization using leading value distance starting from current or specified leading value position with calculated synchronous position of the following axis

Section A

Using "Exe", an "MC_GearInPos" job (A1) is initiated. The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized subsequently from the leading value position to the leading axis (TO_LeadingAxis) by means of the specified leading value distance "MasterStartDistance". The synchronous position of the following axis and the dynamic response required for synchronization are calculated by the system. "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis at the end of the leading value distance.

Section B

Using "Exe", an "MC_GearInPos" job (A2) is initiated. When the specified reference position "MasterSyncPosition" is reached, the start of synchronization is indicated via "StartSync". The following axis (TO_FollowingAxis) is synchronized subsequently to the leading axis (TO_LeadingAxis) by means of the specified leading value distance "MasterStartDistance". The synchronous position of the following axis and the dynamic response required for synchronization are calculated by the system. "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

13.1.3 MC_GearInVelocity V10

13.1.3.1 MC_GearInVelocity: Start velocity synchronous operation V10

Description

With the Motion Control instruction "MC_GearInVelocity", you can start velocity synchronous operation (Page 94) between a leading axis and a following axis. The following axis is synchronized to the velocity of the leading axis depending on the specified gear ratio. You can start velocity synchronous operation when the leading axis is at a standstill or when it is in motion.

The Motion Control instruction offers you the following:

- Defining gear ratio (Page 95)
- Specify gear ratio once or dynamically (Page 96)
- Defining position control of the following axis (Page 97)
- Synchronizing following axis using dynamic parameters (Page 99)
- Synchronous travel in velocity synchronous operation (Page 100)

Applies to

- Synchronous axis

Requirement

- The technology objects of the leading axis and the following axis have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis under "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.
- The leading value is valid.

Override response

The override response for "MC_GearInVelocity" jobs is described in section "Override response V10: Synchronous operation jobs".

Disabling the following axis with "MC_Power.Enable" = FALSE aborts the synchronous operation in every status.

Disabling the leading axis with "MC_Power", in contrast, does not abort synchronous operation. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled again.

Homing jobs on the following axis are rejected in the non-position-controlled mode of the following axis. Active homing of the following axis with "MC_Home.Mode" = 3 or 5 aborts synchronous operation in every status.

Jobs for leading value or following value offset are rejected.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GearInVelocity":

Parameter	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ContinuousUpdate	INPUT	BOOL	FALSE	Mode for specifying the gear ratio (Page 96)	
				TRUE	Specify gear ratio continuously
				FALSE	Specify gear ratio once at the start of the job with a positive edge
RatioNumerator	INPUT	DINT	1	Gear ratio numerator (Page 95) Permitted integer values: -2147483648 to 2147483647 (value 0 not permitted)	
RatioDenominator	INPUT	DINT	1	Gear ratio denominator (Page 95) Permitted integer values: 1 to 2147483647	
Acceleration	INPUT	LREAL	-1.0	Acceleration for the synchronization (Page 99)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration for the synchronization (Page 99)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted

Parameter	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk for the synchronization (Page 99)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
PositionControlled	INPUT	BOOL	FALSE	Position control of the following axis (Page 97)	
				TRUE	Position-controlled mode
				FALSE	Non-position-controlled operation
StartSync	OUTPUT	BOOL	FALSE	TRUE	The following axis is synchronized to the leading axis.
InSync	OUTPUT	BOOL	FALSE	TRUE	Synchronous operation reached The following axis is synchronized and moves synchronously to the leading axis.
ContinuousUpdateActive	OUTPUT	BOOL	FALSE	TRUE	The gear ratio is transferred continuously. Changes of the parameter values "RatioNumerator" and "RatioDenominator" are effective immediately.
				FALSE	The gear ratio is transferred once at the start of the job with a positive edge.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.3.2 MC_GearInVelocity: Function chart V10

Function chart: Synchronization and adjustment of the gear ratio

At time ①, an "MC_GearInVelocity" job (A1) with "ContinuousUpdate" = TRUE is initiated via "Exe". The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized to the leading axis (TO_LeadingAxis) by means of the specified dynamic parameters. When reaching the velocity of the leading axis multiplied by

the specified gear ratio, "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

The denominator of the gear ratio is changed continuously after that. Because "ContinuousUpdateActive" = TRUE, the velocity of the following axis changes immediately.

At time ②, "ContinuousUpdate" is set to FALSE. "ContinuousUpdateActive" = FALSE is displayed. The gear ratio specified last is still valid. The changes of the gear ratio are no longer effective.

"ContinuousUpdate" is once again set to TRUE. For this change to become effective, job A1 is once again triggered with "Exe" at time ③. "ContinuousUpdateActive" = TRUE is displayed. The renewed synchronization of the following axis is displayed via "StartSync".

"ContinuousUpdate" is reset to FALSE. At time ④, "ContinuousUpdate" is once again set to TRUE. Because job A1 is not triggered again via "Exe", the changes of the gear ratio are not taken into account.

13.1.4 MC_PhasingRelative V10

13.1.4.1 MC_PhasingRelative: Relative shift of leading value on the following axis V10

Description

With the Motion Control instruction "MC_PhasingRelative", you offset the effective leading value relative on a following axis. A relative leading value offset is added to an already existing leading value offset. A relative leading value offset is possible in gearing with "MC_GearIn" or "MC_GearInPos" or in camming with "MC_CamIn". The position of the leading axis is not affected. A simultaneous following value offset is not permitted.

Gearing

The Motion Control instruction offers you the following in gearing:

- Shift leading value on the following axis
  - Using dynamic parameters (Page 72)
  - Leading value offset using leading value distance starting at current leading value position (Page 74)
  - Using leading value distance starting at specific leading value position (Page 75)
- Defining the direction of the leading value distance (Page 77)
- Canceling a pending leading value offset (Page 78)

Camming

The Motion Control instruction offers you the following in camming:

- Shift leading value on the following axis
  - Leading value offset using leading value distance starting at current leading value position (Page 183)
  - Using leading value distance starting at specific leading value position (Page 184)
- Defining the direction of the leading value distance (Page 185)
- Canceling a pending leading value offset (Page 187)

Applies to

- Synchronous axis

Requirement

- The technology objects of the leading axis and the following axis have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis in "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.
- By means of the Motion Control instruction "MC_GearIn", "MC_GearInPos" or "MC_CamIn", the following axis is synchronized to the leading axis ("MC_GearIn.InGear" = TRUE, "MC_GearInPos.InSync" = TRUE or "MC_CamIn.InSync" = TRUE).
- No "MC_OffsetAbsolute" or "MC_OffsetRelative" job is active or waiting.

Override response

The override response for "MC_PhasingRelative" jobs is described in section "Override response V10: Synchronous operation jobs".

Disabling the leading axis with "MC_Power.Enable" = FALSE does not abort the leading value offset. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled again.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_PhasingRelative":

Parameters	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
PhaseShift	INPUT	LREAL	0.0	Relative leading value offset	
Velocity	INPUT	LREAL	-1.0	Velocity of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.

Parameters	Declaration	Data type	Default value	Description	
Velocity	INPUT	LREAL	-1.0	= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
ProfileReference	INPUT	DINT	0	Type of the leading value offset	
				0	Only with gearing: Leading value offset using dynamic parameters
				1	Leading value offset using leading value distance as of current leading value position
				2	Leading value offset using leading value distance as of leading value position "StartPosition"
				3 ... 4	Reserved

Parameters	Declaration	Data type	Default value	Description	
ProfileReference	INPUT	DINT	0	5	Cancel pending job for leading value offset
PhasingDistance	INPUT	LREAL	0.0	When "ProfileReference" = 1, 2: Leading value distance Distance of the leading axis during leading value offset	
StartPosition	INPUT	LREAL	0.0	When "ProfileReference" = 2: Leading value position as of which the leading value is offset	
Direction	INPUT	DINT	3	When "ProfileReference" = 1, 2: Direction of the leading value distance	
				1	The leading value distance is in the positive direction of motion of the leading value.
				2	The leading value distance is in the negative direction of motion of the leading value.
				3	The leading value distance is in the current direction of motion of the leading value.
Done	OUTPUT	BOOL	FALSE	TRUE	The leading value offset is finished.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
CoveredPhaseShift	OUTPUT	LREAL	0.0	Display of the absolute leading value share that has already been offset	
StartPhasing	OUTPUT	BOOL	FALSE	TRUE	The following axis offsets the effective leading value.

13.1.4.2 MC_PhasingRelative: Function chart V10

Function chart: Relative shift of the leading value in gearing

At time ①, an "MC_PhasingRelative" job (A2) is initiated with "ProfileReference" = 0 via "Exe" during an active gearing with "MC_GearInPos" (A1) . The "StartPhasing" parameter shows that the following axis traverses the leading value offset with the dynamics specified additively to the synchronous operation motion. The absolute leading value offset traversed via the job is indicated in "CoveredPhaseShift". "Done" indicates that the leading value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_PhasingRelative" job (A2) is initiated again via "Exe". The leading value offset via dynamic parameters is moved out again with the dynamics specified in addition to the synchronous movement. The absolute leading value offset traversed via the job is indicated in "CoveredPhaseShift". "Done" indicates that the leading value was successfully shifted.

The absolute leading value offset is indicated in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

Function chart: Relative shift of the leading value in camming

At time ①, an "MC_PhasingRelative" job (A2) is triggered with "ProfileReference" = 1 via "Exe" during an active camming with "MC_CamIn" (A1) . The "StartPhasing" parameter shows that the leading value offset traverses from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute leading value offset traversed via the job is indicated in "CoveredPhaseShift". "Done" indicates that the leading value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_PhasingRelative" job (A2) is initiated again via "Exe" with "ProfileReference" = 2. The status "Waiting" is displayed at the following axis until the leading value reaches the start position (<TO>.StatusWord2.X3 = TRUE (PhasingCommandWaiting)).

At time ③ the leading value reaches the specified start position. The "StartPhasing" parameter shows that the following axis traverses the leading value offset via the specified leading value distance. The required dynamic response is calculated by the system. The absolute leading value offset traversed via the job is indicated in "CoveredPhaseShift". "Done" indicates that the leading value was successfully shifted.

The absolute leading value offset is indicated in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

13.1.5 MC_PhasingAbsolute V10

13.1.5.1 MC_PhasingAbsolute: Absolute shift of leading value on the following axis V10

Description

With the Motion Control instruction "MC_PhasingAbsolute", you perform an absolute shift of the effective leading value on the following axis. An absolute leading value offset is possible in gearing with "MC_GearIn" or "MC_GearInPos" or in camming with "MC_CamIn". The position of the leading axis is not affected by this. A simultaneous following value offset is not permitted.

Gearing

The Motion Control instruction offers you the following in gearing:

- Shift leading value on the following axis
  - Using dynamic parameters (Page 72)
  - Leading value offset using leading value distance starting at current leading value position (Page 74)
  - Using leading value distance starting at specific leading value position (Page 75)
- Defining the direction of the leading value distance (Page 77)
- Canceling a pending leading value offset (Page 78)

Camming

The Motion Control instruction offers you the following in camming:

- Shift leading value on the following axis
  - Leading value offset using leading value distance starting at current leading value position (Page 183)
  - Using leading value distance starting at specific leading value position (Page 184)
- Defining the direction of the leading value distance (Page 185)
- Canceling a pending leading value offset (Page 187)

Applies to

- Synchronous axis

Requirement

- The technology objects of the leading axis and the following axis have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis in "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.
- By means of the Motion Control instruction "MC_GearIn", "MC_GearInPos" or "MC_CamIn", the following axis is synchronized to the leading axis ("MC_GearIn.InGear" = TRUE, "MC_GearInPos.InSync" = TRUE or "MC_CamIn.InSync" = TRUE).
- No "MC_OffsetAbsolute" or "MC_OffsetRelative" job is active or waiting.

Override response

The override response for "MC_PhasingAbsolute" jobs is described in section "Override response V10: Synchronous operation jobs".

Disabling the leading axis with "MC_Power.Enable" = FALSE does not abort the leading value offset. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled again.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_PhasingAbsolute":

Parameters	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
PhaseShift	INPUT	LREAL	0.0	Absolute leading value offset	
Velocity	INPUT	LREAL	-1.0	Velocity of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Velocity)

Parameters	Declaration	Data type	Default value	Description	
Acceleration	INPUT	LREAL	-1.0	Acceleration of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk of the following axis during leading value offset (added to synchronous operation motion)	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
ProfileReference	INPUT	DINT	0	Type of the leading value offset	
				0	Only with gearing: Leading value offset using dynamic parameters
				1	Leading value offset using leading value distance as of current leading value position
				2	Leading value offset using leading value distance as of leading value position "StartPosition"
				3 ... 4	Not permitted
				5	Cancel pending job for leading value offset
PhasingDistance	INPUT	LREAL	0.0	When "ProfileReference" = 1, 2: Leading value distance Distance of the leading axis during leading value offset	

Parameters	Declaration	Data type	Default value	Description	
StartPosition	INPUT	LREAL	0.0	When "ProfileReference" = 2: Leading value position as of which the leading value is offset	
Direction	INPUT	DINT	3	When "ProfileReference" = 1, 2: Direction of the leading value distance	
				1	The leading value distance is in the positive direction of motion of the leading value.
				2	The leading value distance is in the negative direction of motion of the leading value.
				3	The leading value distance is in the current direction of motion of the leading value.
Done	OUTPUT	BOOL	FALSE	TRUE	The leading value offset is finished.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
AbsolutePhaseShift	OUTPUT	LREAL	0.0	Display of the absolute leading value share that has already been offset	
StartPhasing	OUTPUT	BOOL	FALSE	TRUE	The following axis offsets the effective leading value.

13.1.5.2 MC_PhasingAbsolute: Function chart V10

Function chart: Absolute shift of the leading value in gearing

At time ①, an "MC_PhasingAbsolute" job (A2) is initiated with "ProfileReference" = 0 via "Exe" during an active gearing with "MC_GearInPos" (A1). The "StartPhasing" parameter shows that the following axis traverses the leading value offset with the dynamics specified additively to the synchronous operation motion. The absolute leading value offset traversed via the job is indicated in "AbsolutePhaseShift". "Done" indicates that the leading value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_PhasingAbsolute" job (A2) is initiated again via "Exe". Because the absolute leading value offset (<TO>.StatusSynchronizedMotion.PhaseShift) is already 90.0, the leading value is not shifted.

The absolute leading value offset is indicated in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

Function chart: Absolute shift of the leading value in camming

At time ①, an "MC_PhasingAbsolute" job (A2) is triggered with "ProfileReference" = 1 via "Exe" during an active camming with "MC_CamIn" (A1) . The "StartPhasing" parameter shows that the leading value offset traverses from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute leading value offset traversed via the job is indicated in "AbsolutePhaseShift". "Done" indicates that the leading value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_PhasingAbsolute" job (A2) is initiated again via "Exe" with "ProfileReference" = 2. The status "Waiting" is displayed at the following axis until the leading value reaches the start position (<TO>.StatusWord2.X3 = TRUE (PhasingCommandWaiting)).

At time ③ the leading value reaches the specified start position. The "StartPhasing" parameter shows that the following axis traverses the leading value offset via the specified

leading value distance. The required dynamic response is calculated by the system. The absolute leading value offset traversed via the job is indicated in "AbsolutePhaseShift". "Done" indicates that the leading value was successfully shifted.

The absolute leading value offset is indicated in the "<TO>.StatusSynchronizedMotion.PhaseShift" tag of the technology object.

13.1.6 MC_OffsetRelative V10

13.1.6.1 MC_OffsetRelative: Relative shift of following value on the following axis V10

Description

With the Motion Control instruction "MC_OffsetRelative", you shift the following value on a following axis relative to the existing following value offset. A relative following value offset is possible in gearing with "MC_GearIn" or "MC_GearInPos" or in camming with "MC_CamIn". The position of the leading axis is not affected by this. A simultaneous leading value offset is not permitted.

Gearing

The Motion Control instruction offers you the following in gearing:

- Shift following value on the following axis:
  - Leading value offset using leading value distance starting at current leading value position (Page 79)
  - Using leading value distance starting at specific leading value position (Page 80)
- Defining the direction of the leading value distance (Page 82)
- Canceling a pending following value offset (Page 83)

Camming

The Motion Control instruction offers you the following in camming:

- Shift following value on the following axis:
  - Leading value offset using leading value distance starting at current leading value position (Page 188)
  - Using leading value distance starting at specific leading value position (Page 189)
- Defining the direction of the leading value distance (Page 191)
- Canceling a pending following value offset (Page 192)

Applies to

- Synchronous axis

Requirements

- The technology object of following axis has been configured correctly.
- The following axis is a synchronous axis.
- The following axis is enabled.
- By means of the Motion Control instruction "MC_GearIn", "MC_GearInPos" or "MC_CamIn", the following axis is synchronized to the leading axis ("MC_GearIn.InGear" = TRUE, "MC_GearInPos.InSync" = TRUE or "MC_CamIn.InSync" = TRUE).
- No "MC_PhasingAbsolute" or "MC_PhasingRelative" job is active or waiting.

Override response

The override response for "MC_OffsetRelative" jobs is described in section "Override response V10: Synchronous operation jobs".

Parameter

The following table shows the parameters of the Motion Control instruction "MC_OffsetRelative":

Parameter	Declaration	Data type	Default value	Description	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Offset	INPUT	LREAL	0.0	Relative following value offset	
ProfileReference	INPUT	DINT	1	Type of the following value offset	
				0	Reserved
				1	Following value offset using leading value distance as of current effective leading value position
				2	Following value offset using leading value distance as of effective leading value position "StartPosition"
				3 ... 4	Reserved
				5	Cancel pending job for following value offset
OffsetDistance	INPUT	LREAL	0.0	When "ProfileReference" = 1, 2: Leading value distance Effective leading value distance during following value offset	
StartPosition	INPUT	LREAL	0.0	When "ProfileReference" = 2: Effective leading value position as of which the following value is offset	
Direction	INPUT	DINT	3	When "ProfileReference" = 1, 2: Direction of the leading value distance	

Parameter	Declaration	Data type	Default value	Description	
Direction	INPUT	DINT	3	1	The leading value distance is in the positive direction of motion of the effective leading value.
				2	The leading value distance is in the negative direction of motion of the effective leading value.
				3	The leading value distance is in the current direction of motion of the effective leading value.
Done	OUTPUT	BOOL	FALSE	TRUE	The leading value offset is finished.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for the parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
CoveredOffset	OUTPUT	LREAL	0.0	Display of the absolute following value share that has already been offset	
StartOffset	OUTPUT	BOOL	FALSE	TRUE	The following axis offsets the following value.

13.1.6.2 MC_OffsetRelative: Function chart V10

Function chart: Relative shift of the following value in gearing

At time ①, an "MC_OffsetRelative" job (A2) is initiated with "ProfileReference" = 1 via "Exe" during an active gearing with "MC_GearInPos" (A1). The "StartOffset" parameter shows that the following axis traverses the following value offset from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated In "CoveredOffset". "Done" indicates that the following value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_OffsetRelative" job (A2) is initiated again via "Exe". The "StartOffset" parameter shows that the following axis traverses the following value offset via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated In "CoveredOffset". "Done" indicates that the following value was successfully shifted.

The absolute following value offset is indicated in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

Function chart: Relative shift of the following value in camming

At time ①, an "MC_OffsetRelative" job (A2) is triggered with "ProfileReference" = 1 via "Exe" during an active camming with "MC_CamIn" (A1) . The "StartOffset" parameter shows that the following axis traverses the following value offset from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated In "CoveredOffset". "Done" indicates that the following value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_OffsetRelative" job (A2) is initiated again via "Exe" with "ProfileReference" = 2. The status "Waiting" is displayed at the following axis until the leading value reaches the start position (<TO>.StatusWord2.X5 = TRUE (OffsetCommandWaiting)).

At time ③ the leading value reaches the specified start position. The "StartOffset" parameter shows that the following axis traverses the following value offset via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated In "CoveredOffset". "Done" indicates that the leading value was successfully shifted.

The absolute following value offset is indicated in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

13.1.7 MC_OffsetAbsolute V10

13.1.7.1 MC_OffsetAbsolute: Absolute shift of following value on the following axis V10

Description

With the Motion Control instruction "MC_OffsetAbsolute", you shift the following value on a following axis with an absolute offset. An absolute following value offset is possible in gearing with "MC_GearIn" or "MC_GearInPos" or in camming with "MC_CamIn". The position of the leading axis is not affected by this. A simultaneous leading value offset is not permitted.

Gearing

The Motion Control instruction offers you the following in gearing:

- Shift following value on the following axis:
  - Leading value offset using leading value distance starting at current leading value position (Page 79)
  - Using leading value distance starting at specific leading value position (Page 80)
- Defining the direction of the leading value distance (Page 82)
- Canceling a pending following value offset (Page 83)

Camming

The Motion Control instruction offers you the following in camming:

- Shift following value on the following axis:
  - Leading value offset using leading value distance starting at current leading value position (Page 188)
  - Using leading value distance starting at specific leading value position (Page 189)
- Defining the direction of the leading value distance (Page 191)
- Canceling a pending following value offset (Page 192)

Applies to

- Synchronous axis

Requirements

- The technology object of following axis has been configured correctly.
- The following axis is a synchronous axis.
- The following axis is enabled.
- By means of the Motion Control instruction "MC_GearIn", "MC_GearInPos" or "MC_CamIn", the following axis is synchronized to the leading axis ("MC_GearIn.InGear" = TRUE, "MC_GearInPos.InSync" = TRUE or "MC_CamIn.InSync" = TRUE).
- No "MC_PhasingAbsolute" or "MC_PhasingRelative" job is active or waiting.

Override response

The override response for "MC_OffsetAbsolute" jobs is described in section "Override response V10: Synchronous operation jobs".

Parameter

The following table shows the parameters of the Motion Control instruction "MC_OffsetAbsolute":

Parameter	Declaration	Data type	Default value	Description	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Offset	INPUT	LREAL	0.0	Absolute following value offset	
ProfileReference	INPUT	DINT	1	Type of the following value offset	
				0	Reserved
				1	Following value offset using leading value distance as of current effective leading value position
				2	Following value offset using leading value distance as of effective leading value position "StartPosition"
				3 ... 4	Reserved
				5	Cancel pending job for following value offset
OffsetDistance	INPUT	LREAL	0.0	When "ProfileReference" = 1, 2: Leading value distance Effective leading value distance during following value offset	
StartPosition	INPUT	LREAL	0.0	When "ProfileReference" = 2: Effective leading value position as of which the following value is offset	
Direction	INPUT	DINT	3	When "ProfileReference" = 1, 2: Direction of the leading value distance	

Parameter	Declaration	Data type	Default value	Description	
Direction	INPUT	DINT	3	1	The leading value distance is in the positive direction of motion of the effective leading value.
				2	The leading value distance is in the negative direction of motion of the effective leading value.
				3	The leading value distance is in the current direction of motion of the effective leading value.
Done	OUTPUT	BOOL	FALSE	TRUE	The leading value offset is finished.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for the parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
AbsoluteOffset	OUTPUT	LREAL	0.0	Display of the absolute following value share that has already been offset	
StartOffset	OUTPUT	BOOL	FALSE	TRUE	The following axis offsets the following value.

13.1.7.2 MC_OffsetAbsolute: Function chart V10

Function chart: Absolute shift of the following value in gearing

At time ①, an "MC_OffsetAbsolute" job (A2) is initiated with "ProfileReference" = 1 via "Exe" during an active gearing with "MC_GearInPos" (A1). The "StartOffset" parameter shows that the following axis traverses the following value offset from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated in "AbsoluteOffset". "Done" indicates that the following value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_OffsetAbsolute" job (A2) is initiated again via "Exe". Because the absolute following value offset (<TO>.StatusSynchronizedMotion.Offset) is already 90.0, the following value is not shifted.

The absolute following value offset is indicated in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

Function chart: Absolute shift of the following value in camming

At time ①, an "MC_OffsetAbsolute" job (A2) is triggered with "ProfileReference" = 1 via "Exe" during an active camming with "MC_CamIn" (A1) . The "StartOffset" parameter shows that the following axis traverses the following value offset from the current position via the specified leading value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated in "AbsoluteOffset". "Done" indicates that the following value was successfully shifted. The motion of the leading axis is not affected.

At time ② the "MC_OffsetAbsolute" job (A2) is initiated again via "Exe" with "ProfileReference" = 2. The status "Waiting" is displayed at the following axis until the leading value reaches the start position (<TO>.StatusWord2.X5 = TRUE (OffsetCommandWaiting)).

At time ③ the leading value reaches the specified start position. The "StartOffset" parameter shows that the following axis traverses the following value offset via the specified leading

value distance. The required dynamic response is calculated by the system. The absolute following value offset traversed via the job is indicated in "AbsoluteOffset". "Done" indicates that the following value was successfully shifted.

The absolute following value offset is indicated in the "<TO>.StatusSynchronizedMotion.Offset" tag of the technology object.

13.1.8 MC_CamIn V10

13.1.8.1 MC_CamIn: Start camming V10

Description

With the Motion Control instruction "MC_CamIn", you start a camming (Page 102) operation between a leading axis and a following axis. The following axis is synchronized depending on the specified synchronous position of the leading axis.

The synchronous position of the leading axis and the corresponding position of the following axis from the cam represent the relationship of the two axes to one another. The synchronous position of the leading axis is determined by the following parameters:

- Start position of the cam (<TO_Cam>.StatusCam.StartLeadingValue)
- Scaling the leading values of the cam ("MasterScaling")
- Offset or location of the cam ("MasterOffset")
- Start point within the cam ("MasterSyncPosition")

The synchronous position is calculated as follows:

Synchronous position = (Start position of the cyclic cam x "MasterScaling") + "MasterOffset" + "MasterSyncPosition"

The start of movement of the following axis is defined depending on the selected synchronization mode.

The Motion Control instruction offers you the following:

- Scaling and shifting cam (Page 150)
- Defining application mode of the cam (Page 157)
- Defining direction of synchronization (Page 161)
- Define synchronous position and type of synchronization:
  - Synchronization in advance using dynamic parameters (Page 163)
  - Synchronization in advance using leading value distance (Page 164)
  - Synchronization in advance using leading value distance starting from current leading value position (Page 167)
  - Subsequent synchronization using leading value distance (Page 171)
  - Subsequent synchronization using leading value distance starting from current leading value position (Page 173)
  - Directly set the following axis synchronously (Page 175)

  - Directly set the following axis synchronously at end of the cam (Page 176)
  - Directly set the following axis synchronously at specific leading value position (Page 177)
- Synchronous travel in camming (Page 179)

Different parameters are relevant depending on the synchronization profile. You can find an overview in the "Parameter overview for synchronizing with "MC_CamIn" (Page 160)" section.

Applies to

- Cam
- Synchronous axis

Requirement

- The technology objects of the leading axis, following axis, and cam have been configured correctly.
- The leading axis is a positioning axis, a synchronous axis, an external encoder or a leading axis proxy.
- The following axis is a synchronous axis.
- The leading axis is specified as possible leading axis in the configuration of the following axis under "Technology object > Configuration > Leading value interconnections".
- The following axis is enabled.
- The following axis is homed.
- The cam is interpolated with "MC_InterpolateCam".
- With synchronization in advance using leading value distance, the leading axis must be at least the specified distance ("MasterStartDistance") from the synchronization position ("MasterSyncPosition") when starting the job.
- With direct synchronous setting at the end of the cam, camming must already be active ("InSync" = TRUE).

Override response

The override response for "MC_CamIn" jobs is described in section "Override response V10: Synchronous operation jobs".

With a "MC_CamOut" job, the following axis is desynchronized and synchronous operation is terminated.

Disabling the following axis with "MC_Power.Enable" = FALSE aborts the synchronous operation in every status.

Disabling the leading axis with "MC_Power", in contrast, does not abort synchronous operation. The following axis follows the leading axis even during the braking ramp and after the leading axis is enabled again.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_CamIn":

Parameter	Declaration	Data type	Default value	Description	
Master	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading axis technology object	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
MasterOffset	INPUT	LREAL	0.0	When "SyncProfileReference" = 0, 1, 3, 4, 7: Offset of the leading values of the cam (Page 150) The cam technology object is not changed.	
				When "SyncProfileReference" = 2, 5, 6: Not relevant	
SlaveOffset	INPUT	LREAL	0.0	When "SyncProfileReference" = 0, 1, 3, 4, 6: Offset of the following values of the cam (Page 150) The cam technology object is not changed.	
				When "SyncProfileReference" = 2, 5, 7: Not relevant	
MasterScaling	INPUT	LREAL	1.0	Scaling of the leading values of the cam (Page 150) The cam technology object is not changed.	
				0.0	Not permitted
SlaveScaling	INPUT	LREAL	1.0	Scaling of the following values of the cam (Page 150) The cam technology object is not changed.	
MasterSyncPosition	INPUT	LREAL	0.0	Synchronous position of leading axis	
				When "SyncProfileReference" = 0, 1, 6: Position of the leading axis (relative to the start position of the cam), from which the axes are synchronous and synchronization is complete. The value must be within the definition of the cam.	
				When "SyncProfileReference" = 3: Position of the leading axis (relative to the start position of the cam) from which the synchronization begins The value must be within the definition of the cam.	
				When "SyncProfileReference" = 4: Not relevant	

Parameter	Declaration	Data type	Default value	Description	
MasterSyncPosition	INPUT	LREAL	0.0	When "SyncProfileReference" = 2, 5, 7: Position of the leading axis (relative to the start position of the cam to be changed), from which the axes are synchronous. The value must be within the definition of the cam to be changed.	
SyncProfileReference	INPUT	DINT	1	Synchronization profile	
				0	Synchronization in advance using dynamic parameters (Page 163)
				1	Synchronization in advance using leading value distance (Page 164)
				2	Direct synchronous setting (Page 175)
				3	Subsequent synchronization using leading value distance (Page 171)
				4	Subsequent synchronization using leading value distance starting from current leading value position (Page 173)
				5	Direct synchronous setting at the end of the cam (Page 176)
				6	Synchronization in advance using leading value distance starting from current leading value position (Page 167)
				7	Direct synchronous setting at specific leading value position (Page 177)
MasterStartDistance	INPUT	LREAL	0.0	When "SyncProfileReference" = 1, 3, 4, 6: Leading value distance Distance of the leading axis during the synchronization	
				> 0.0	The specified value is used.
				≤ 0.0	Not permitted
				When "SyncProfileReference" = 0, 2, 5, 7: Not relevant	
Velocity	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Velocity	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Velocity)
				When "SyncProfileReference" = 1, 2, 3, 4, 5, 6, 7: Not relevant	
Acceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Acceleration	
				> 0.0	The specified value is used.

Parameter	Declaration	Data type	Default value	Description	
Acceleration	INPUT	LREAL	-1.0	= 0.0	Not permitted
				< 0.0	The acceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Acceleration)
				When "SyncProfileReference" = 1, 2, 3, 4, 5, 6, 7: Not relevant	
Deceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Deceleration	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
				When "SyncProfileReference" = 1, 2, 3, 4, 5, 6, 7: Not relevant	
Jerk	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Jerk	
				> 0.0	Constant acceleration velocity profile The specified value is used.
				= 0.0	Trapezoid velocity profile
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
				When "SyncProfileReference" = 1, 2, 3, 4, 5, 6, 7: Not relevant	
ApplicationMode	INPUT	DINT	0	Application of the cam (Page 157)	
				0	Once, non-cyclic
				1	Cyclic (absolute application on the following value side)
				2	Cyclic appending (continuously appending on the following value side)
SyncDirection	INPUT	DINT	3	When "SyncProfileReference" = 0, 1, 3, 4, 6: Direction of synchronization (Page 161) In effect for following axes with activated Modulo setting.	
				1	Positive direction The following axis may only travel in positive direction during synchronization.
				2	Negative direction The following axis may only travel in negative direction during synchronization.

Parameter	Declaration	Data type	Default value	Description	
SyncDirection	INPUT	DINT	3	3	Shortest distance Changes in direction are permitted for the following axis during synchronization.
				When "SyncProfileReference" = 2, 5, 7: Not relevant	
StartSync	OUTPUT	BOOL	FALSE	TRUE	The following axis is synchronized to the leading axis.
InSync	OUTPUT	BOOL	FALSE	TRUE	Synchronous operation reached The following axis is synchronized and moves synchronously to the leading axis.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
EndOfProfile	OUTPUT	BOOL	FALSE	TRUE	The end of the cam has been reached. Displayed for at least one call of "MC_CamIn" in the user program when the cam is used cyclically.

13.1.8.2 MC_CamIn: Function chart V10

Function chart: Synchronization in advance using dynamic parameters and leading value distance as well as switching of the cam

Using "Exe_1", an "MC_CamIn" job (A1) is initiated. The start of the synchronization is displayed with "StartSync_1". The following axis (TO_FollowingAxis) is synchronized in advance to the cam (Cam_1) within the range "Sync_1" by means of the specified dynamic parameters. The distance required for synchronization is calculated by the system. When the specified reference position "MasterSyncPosition" relative to the start of the cam is reached,

"InSync_1" signals that the following axis is synchronized and moves synchronously to the leading axis.

The synchronous operation is overridden by another "MC_CamIn" job (A2). The abort is signaled via "Abort_1". The start of the synchronization is displayed with "StartSync_2". The following axis is synchronized in advance to the new cam (Cam_2) within the range "Sync_2" by means of the specified leading value distance "MasterStartDistance". Within the range "Sync_2", the axis does not follow the cam "Cam_1" The dynamic response required for synchronization is calculated by the system. When the specified reference position "MasterSyncPosition" relative to the start of the cam is reached, "InSync_2" signals that the following axis is synchronized and moves synchronously to the leading axis.

Function chart: Synchronization in advance and subsequent synchronization using leading value distance and switching of the cam

Using "Exe_1", an "MC_CamIn" job (A1) is initiated. The start of the synchronization is displayed with "StartSync_1". The following axis (TO_FollowingAxis) is synchronized in advance to the cam (Cam_1) within the range "Sync_1" by means of the specified leading value distance "MasterStartDistance". The dynamic response required for synchronization is calculated by the system. When the specified reference position "MasterSyncPosition" relative

to the start of the cam is reached, "InSync_1" signals that the following axis is synchronized and moves synchronously to the leading axis.

The synchronous operation is overridden by another "MC_CamIn" job (A2). The abort is signaled via "Abort_1". When the specified reference position "MasterSyncPosition" in relation to the start of the cam is reached, the start of synchronization is indicated via "StartSync_2". The following axis is synchronized subsequently to the new cam (Cam_2) within the range "Sync_2" by means of the specified leading value distance "MasterStartDistance". Within the range "Sync_2", the axis does not follow the cam "Cam_1" The dynamic response required for synchronization is calculated by the system. "InSync_2" signals that the following axis is synchronized and moving synchronously to the leading axis.

Function chart: Synchronization in advance and subsequent synchronization using leading value distance starting from current leading value position

Section A

At time ①, an "MC_CamIn" job (A1) with "SyncProfileReference" = 4 is initiated via "Exe". The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized subsequently as of the current leading value position 270° to the cam (Cam_1) by means of the specified leading value distance "MasterStartDistance" = 180°. The dynamic response required for synchronization is calculated by the system.

At time ②, "InSync" signals at the leading value position 90° that the following axis is synchronized and moves synchronously to the leading axis.

Section B

At time ③, the "MC_CamIn" job (A1) with "SyncProfileReference" = 6 is initiated via "Exe". The start of the synchronization is displayed with "StartSync". The following axis (TO_FollowingAxis) is synchronized in advance as of the current leading value position 270° to the cam (Cam_1) by means of the specified leading value distance "MasterStartDistance" = 180°. The dynamic response required for synchronization is calculated by the system.

At time ④, the following axis reaches the following value of the specified reference position "MasterSyncPosition" = 180° at the leading value position 90° in relation to the start of the cam. The cam is automatically offset by -90° in the leading value area (<TO>.StatusSynchronizedMotion.MasterOffset). "InSync" signals that the following axis is synchronized and moving synchronously to the leading axis.

Function chart: Togging and direct synchronous setting at the end of the cam

An "MC_CamIn" job (A1) is active.

At time ① another "MC_CamIn" job (A2) is initiated via "Exe_2". The status "Waiting" is displayed at the following axis until the end of the active cam "Cam_1" has been reached (<TO>.StatusSynchronizedMotion.WaitingFunctionState = 3).

At time ② the end of the cam is reached ("Eop_1"). The cam is switched over. Since no synchronization takes place, the "Synchronous" status is retained.

13.1.9 MC_SynchronizedMotionSimulation V10

13.1.9.1 MC_SynchronizedMotionSimulation: Simulate synchronous operation V10

Description

With the Motion Control instruction "MC_SynchronizedMotionSimulation", you can simulate an active synchronous operation on a following axis. This means that a synchronous operation remains active e.g. when the following axis is disabled. The following axis does not have to be synchronized again after being enabled again.

⚠ WARNING

Machine damage

If the position of the following axis at the end of the simulation differs from the position at the start of the simulation, this leads to a setpoint jump which can result in damage to the machine.

Therefore, make sure that the setpoints of the following axis correspond to the setpoints from the synchronous operation relationship when simulation is ended.

The Motion Control instruction offers you the following:

- Simulate synchronous operation (Page 203)

Applies to

- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The following axis is a synchronous axis.
- Synchronous operation is active on the technology object in status "Synchronous" (<TO>.StatusWord.X22 = TRUE).

Override response

An "MC_SynchronizedMotionSimulation" job is not aborted by any other Motion Control job. The simulated synchronous operation remains active even when the following axis is disabled with an "MC_Power" or "MC_Stop job.

A restart of the technology object stops the simulation and aborts the synchronous operation.

A new "MC_SynchronizedMotionSimulation" job does not abort any other Motion Control jobs. With "MC_SynchronizedMotionSimulation.Enable" = TRUE, synchronous operation jobs are rejected.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SynchronizedMotionSimulation":

Parameter	Declaration	Data type	Default value	Description	
Slave	INPUT	TO_SynchronousAxis	-	Following axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Simulation of synchronous operation is started.
				FALSE	Simulation of the synchronous operation is stopped.
InSimulation	OUTPUT	BOOL	FALSE	TRUE	The synchronous operation is in simulation.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.10 MC_GearOut V10

13.1.10.1 MC_GearOut: Desynchronize gearing V10

Description

With the Motion Control instruction "MC_GearOut" end gearing (Page 49) operation between a leading axis and a following axis. With an active gearing, the following axis is desynchronized and comes to a standstill at the specified stop position. A pending gearing is canceled.

The Motion Control instruction offers you the following:

- Defining direction of desynchronization (Page 88)
- Define the stop position of the following axis and the type of desynchronization:
  - Desynchronizing following axis using dynamic parameters (Page 84)
  - Desynchronizing following axis using leading value distance (Page 85)
- Canceling pending gearing (Page 91)

Applies to

- Synchronous axis

Requirement

- The following axis is enabled.
- Gearing with "MC_GearIn" or "MC_GearInPos" is active or pending on the following axis.
- No "MC_Stop" job is active on the following axis.

Override response

The override response for "MC_GearOut" jobs is described in section "Override response V10: Synchronous operation jobs".

An "MC_GearOut" job with "SyncProfileReference" = 5 aborts a pending "MC_GearInPos" or a pending "MC_GearOut" job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GearOut":

Parameter	Declaration	Data type	Default value	Description	
Slave	INPUT	TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
SlavePosition	INPUT	LREAL	0.0	Stop position of following axis	
SyncProfileReference	INPUT	DINT	1	Type of desynchronization	
				0	Desynchronize using dynamic parameters (Page 84)
				1	Desynchronize using leading value distance (Page 85)
				2 ... 4	Reserved
				5	Canceling pending gearing (Page 91)
MasterStopDistance	INPUT	LREAL	0.0	When "SyncProfileReference" = 1: Leading value distance (Page 85)	
Deceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Deceleration (Page 84)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Jerk (Page 84)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation

Parameter	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
SyncOutDirection	INPUT	DINT	3	Desynchronization direction (Page 88)	
				1	Positive direction The following axis may only travel in positive direction during desynchronization.
				2	Negative direction The following axis may only travel in negative direction during desynchronization.
				3	Current direction The following axis is desynchronized in the direction in which the following axis is currently traveling.
StartSyncOut	OUTPUT	BOOL	FALSE	TRUE	The following axis is desynchronized.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.10.2 MC_GearOut: Function chart V10

Function chart: Desynchronization using dynamic parameters and leading value distance

Section A

With an "MC_GearInPos" job (A1) the following axis (TO_FollowingAxis) travels synchronously to the leading axis (TO_LeadingAxis). "Synchronous" status is displayed via "InSync_1".

At time ① an "MC_GearOut" job (A2) is initiated via "Exe_2". The start of the desynchronization is displayed with "SyncOut_2" ②. The following axis is desynchronized using the specified dynamic parameters. The distance required for desynchronization is calculated by the system. When the specified stop position "SlavePosition" is reached, "Done_2" signals that the following axis is desynchronized and at standstill ③.

Section B

With an "MC_GearInPos" job (A1) the following axis travels synchronously to the leading axis. "Synchronous" status is displayed via "InSync_1".

At time ④ an "MC_GearOut" job (A2) is initiated via "Exe_2". The start of the desynchronization is displayed with "SyncOut_2" ⑤. The following axis is desynchronized using the specified leading value distance "MasterStopDistance". The dynamics required for desynchronization is calculated by the system. When the specified stop position "SlavePosition" is reached, "Done_2" signals that the following axis is desynchronized and at standstill ⑥.

13.1.11 MC_CamOut V10

13.1.11.1 MC_CamOut: Desynchronize camming V10

Description

With the Motion Control instruction "MC_CamOut" end a Camming (Page 102) operation between a leading axis and a following axis. With an active camming, the following axis is desynchronized and comes to a standstill at the specified stop position. A pending camming is canceled.

The Motion Control instruction offers you the following:

- Defining direction of desynchronization (Page 197)
- Define the stop position of the following axis and the type of desynchronization:
  - Desynchronizing following axis using dynamic parameters (Page 193)
  - Desynchronizing following axis using leading value distance (Page 194)
- Canceling pending camming (Page 200)

Applies to

- Synchronous axis

Requirement

- The following axis is enabled.
- A camming with "MC_CamIn" is active or pending on the following axis.
- No "MC_Stop" job is active on the following axis.

Override response

The override response for "MC_CamOut" jobs is described in section "Override response V10: Synchronous operation jobs".

An "MC_CamOut" job with "SyncProfileReference" = 5 aborts a pending "MC_CamIn" or a pending "MC_CamOut" job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_CamOut":

Parameter	Declaration	Data type	Default value	Description	
Slave	INPUT	TO_SynchronousAxis	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
SlavePosition	INPUT	LREAL	0.0	Stop position of following axis	
SyncProfileReference	INPUT	DINT	1	Type of desynchronization	
				0	Desynchronize using dynamic parameters (Page 193)
				1	Desynchronize using leading value distance (Page 194)
				2 ... 4	Reserved
				5	Canceling pending camming (Page 200)
MasterStopDistance	INPUT	LREAL	0.0	When "SyncProfileReference" = 1: Leading value distance (Page 194)	
Deceleration	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Deceleration (Page 193)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The deceleration configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Deceleration)
Jerk	INPUT	LREAL	-1.0	When "SyncProfileReference" = 0: Jerk (Page 193)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation
				< 0.0	The jerk configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Jerk)
SyncOutDirection	INPUT	DINT	3	Desynchronization direction (Page 197)	
				1	Positive direction The following axis may only travel in positive direction during desynchronization.
				2	Negative direction The following axis may only travel in negative direction during desynchronization.
				3	Current direction The following axis is desynchronized in the direction in which the following axis is currently traveling.
StartSyncOut	OUTPUT	BOOL	FALSE	TRUE	The following axis is desynchronized.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.

Parameter	Declaration	Data type	Default value	Description	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.11.2 MC_CamOut: Function chart V10

Function chart: Desynchronization using leading value distance

With a "MC_CamIn" job (A1) the following axis (TO_FollowingAxis) travels over a cyclically running cam (Cam_1) synchronous to the leading axis (TO_LeadingAxis). "Synchronous" status is displayed via "InSync_1".

At time ① an "MC_CamOut" job (A2) is initiated via "Exe_2". The following axis should only be desynchronized in negative direction ("SyncOutDirection" = 2). The start of the desynchronization is displayed with "SyncOut_2" ②. The following axis is desynchronized using the specified leading value distance "MasterStopDistance". The dynamics required for desynchronization is calculated by the system. When the specified stop position "SlavePosition" or the configured position window is reached, "Done_2" signals following setpoint interpolation that the following axis is desynchronized and at standstill ③.

13.1.12 MC_LeadingValueAdditive V10

13.1.12.1 MC_LeadingValueAdditive: Specify additive leading value V10

Description

With the Motion Control instruction "MC_LeadingValueAdditive", you specify an additive leading value cyclically in addition to the active leading value of a following axis. The additive leading value consists of position, velocity and acceleration. Changes to the specified values are effective immediately without consideration of the dynamic limits.

The Motion Control instruction offers you the following:

- Specify additive leading value (Page 205)

Applies to

- Synchronous axis

Requirement

- The technology object has been configured correctly.
- The technology object is enabled or is in simulation with an "MC_SynchronizedMotionSimulation" job.

Override response

The override response for "MC_LeadingValueAdditive" jobs is described in section "Override response V10: Synchronous operation jobs".

If a synchronous operation is overridden by another synchronous operation, the additive leading value remains valid.

If a synchronous operation is desynchronized, the additive leading value remains valid. Desynchronization refers to the effective leading value.

An "MC_LeadingValueAdditive" job is aborted by an "MC_Reset" job with "Restart" = TRUE.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_LeadingValueAdditive":

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SynchronousAxis	-	Technology object on which the additive values act.	
Enable	INPUT	BOOL	FALSE	TRUE	The leading value is adapted.
				FALSE	The leading value is not adapted.

Parameter	Declaration	Data type	Default value	Description	
Position	INPUT	LREAL	0.0	Additive position value Recommendation: To avoid setpoint jumps, only change the additive position value during an active job in small steps.	
Velocity	INPUT	LREAL	0.0	Additive velocity value Observe the dynamic limits.	
Acceleration	INPUT	LREAL	0.0	Additive acceleration value Observe the dynamic limits.	
Busy	OUTPUT	BOOL	FALSE	TRUE	The additive values are valid.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

13.1.12.2 MC_LeadingValueAdditive: Function chart V10

Function chart: Specify additive leading value

Section A

Via "Exe_1" = TRUE, a "MC_GearInPos" job (A1) is started with synchronization in advance via dynamic parameters. At the same time, a "MC_LeadingValueAdditive" job (A2) is started via "Enable_2" = TRUE. The effective leading value (EffectiveLeadingValue.Position) and the time for starting the synchronization are calculated.

At time ①, the following axis (TO_FollowingAxis) starts to synchronize with the specified dynamic parameters ("StartSync_1" = TRUE). The additive leading value (AddValue_2) is

continuously increased in the user program and added to the leading value of the following axis. The effective leading value increased in this way has an effect on the increased dynamic response of the following axis. The additive leading value is then reduced and thus the dynamic response of the following axis is also reduced.

At time ②, the additive leading value is back at "0.0" and the effective leading value is equal to the leading value of the leading axis. The following axis is synchronized to the specified synchronous position ("InSync_1" = TRUE). The A2 job is terminated with "Enable_2" = FALSE.

Section B

Via "Enable_2" = TRUE, a "MC_LeadingValueAdditive" job (A2) is started before a synchronous operation job. The user program continuously increases the additive leading value to the value "90.0". With "Exe_2" = TRUE a "MC_GearInPos" job (A1) is started with synchronization in advance via leading value distance.

At time ③, the effective leading value reaches the value "180.0". The following axis starts to synchronize ("StartSync_1" = TRUE).

At time ④, the effective leading value reaches the value "270.0". The following axis is synchronized ("InSync_1" = TRUE). At this point the leading axis has reached the value "180.0". The synchronous position of the leading axis (MasterSyncPosition) is moved by the additive leading value. Subsequently, the additive leading value is continuously reduced. While the leading value of the leading axis increases from "180.0" to "270.0", the additive leading value decreases from "90.0" to "0.0". The effective leading value remains at "270.0" and the following axis does not move.

At time ⑤, the additive leading value has reached the value "0.0" and the effective leading value is equal to the leading value of the leading axis. The shift is canceled and the motion of the following axis is continued. The A2 job is terminated with "Enable_2" = FALSE.

13.2 Cam

13.2.1 MC_InterpolateCam V10

13.2.1.1 MC_InterpolateCam: Interpolate cam V10

Description

With the Motion Control instruction "MC_InterpolateCam", you interpolate a cam. The interpolation closes the gaps between the defined interpolation points and segments of the cam.

The Motion Control instruction offers you the following:

- Interpolating a cam (Page 150)

The cam is interpolated based on the configured settings of the technology object:

- Configuring transitions (Page 142)
- System interpolation (Page 144)
- Interpolation according to VDI Guideline 2143 (Page 147)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The cam is not currently being used, e.g. for camming.

Override response

- An "MC_InterpolateCam" job is not aborted by any other Motion Control job.
- A new "MC_InterpolateCam" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_InterpolateCam":

Parameters	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Done	OUTPUT	BOOL	FALSE	TRUE	The cam is interpolated.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

Interpolating a cam

To interpolate a cam with the "MC_InterpolateCam" Motion Control instruction, follow these steps:

1. Check the requirements indicated above.
2. Specify the cam to be interpolated in the "Cam" parameter.
3. Start the "MC_InterpolateCam" job with a positive edge at the "Execute" parameter.

   The cam is interpolated. When the "Done" parameter shows the value "TRUE", the interpolation is finished.

13.2.2 MC_GetCamLeadingValue V10

13.2.2.1 MC_GetCamLeadingValue: Read out leading value of a cam V10

Description

With the Motion Control instruction "MC_GetCamLeadingValue", you read the leading value that is defined for a following value from a cam.

The Motion Control instruction offers you the following:

- Reading a leading value (Page 179)
- Specifying an approach value and approach direction (Page 179)
- Specifying scaling and offset of the cam (Page 150)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The cam is interpolated.

Override response

- An "MC_GetCamLeadingValue" job is not aborted by any other Motion Control job.
- A new "MC_GetCamLeadingValue" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GetCamLeadingValue":

Parameter	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
FollowingValue	INPUT	LREAL	0.0	Following value for which the leading value is read	
ApproachLeadingValue	INPUT	LREAL	0.0	Approach value for the searched for leading value If the following value is used multiple times in the cam, it can be used to limit the searched leading value. The approach value refers to the – if applicable, offset and scaled – leading values of the cam. The approach value can lie inside or outside the scaled definition range of the cam.	
ApproachDirection	INPUT	DINT	3	Approach direction for the sought leading value	
				1	Positive direction
				2	Negative direction
				3	Nearest value
MasterOffset	INPUT	LREAL	0.0	Offset of the leading values of the cam The cam technology object is not changed.	
SlaveOffset	INPUT	LREAL	0.0	Offset of the following values of the cam The cam technology object is not changed.	
MasterScaling	INPUT	LREAL	1.0	Scaling of the leading values of the cam The cam technology object is not changed.	
				0.0	Not permitted
SlaveScaling	INPUT	LREAL	1.0	Scaling of the following values of the cam The cam technology object is not changed.	
Done	OUTPUT	BOOL	FALSE	TRUE	The leading value was read.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
Value	OUTPUT	LREAL	-	Read leading value (position) (valid when "Done" = TRUE)	

13.2.3 MC_GetCamFollowingValue V10

13.2.3.1 MC_GetCamFollowingValue: Read out following value of a cam V10

Description

With the "MC_GetCamFollowingValue" Motion Control instruction, you read the following value as well as the first, second and third derivative of the following value for a leading value from a cam depending on the specified read mode.

The Motion Control instruction offers you the following:

- Reading a following value (Page 181)
- Specifying scaling and offset of the cam (Page 150)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The cam is interpolated.

Override response

- An "MC_GetCamFollowingValue" job is not aborted by any other Motion Control job.
- A new "MC_GetCamFollowingValue" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GetCamFollowingValue":

Parameters	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
LeadingValue	INPUT	LREAL	0.0	Leading value for which the following value is read	
MasterOffset	INPUT	LREAL	0.0	Offset of the leading values of the cam The cam technology object is not changed.	

Parameters	Declaration	Data type	Default value	Description	
SlaveOffset	INPUT	LREAL	0.0	Offset of the following values of the cam The cam technology object is not changed.	
MasterScaling	INPUT	LREAL	1.0	Scaling of the leading values of the cam The cam technology object is not changed.	
				0.0	Not permitted
SlaveScaling	INPUT	LREAL	1.0	Scaling of the following values of the cam The cam technology object is not changed.	
ApplicationMode	INPUT	DINT	2	Read mode	
				0	Read out following value (position)
				1	Read out following value and first derivative (position, velocity)
				2	Read out following value, first derivative and second derivative (position, velocity, acceleration)
				3	Read out following value, first derivative, second derivative and third derivative (position, velocity, acceleration, jerk)
Done	OUTPUT	BOOL	FALSE	TRUE	The following value was read.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
Value	OUTPUT	LREAL	-	Read following value (position) (valid when "Done" = TRUE)	
FirstDerivative	OUTPUT	LREAL	-	First derivative on read out following value (velocity) (valid when "Done" = TRUE)	
SecondDerivative	OUTPUT	LREAL	-	Second derivative on read out following value (acceleration) (valid when "Done" = TRUE)	
ThirdDerivative	OUTPUT	LREAL	-	Third derivative on read following value (jerk) (valid when "Done" = TRUE)	

13.2.4 MC_GetCamFollowingValueCyclic V10

13.2.4.1 MC_GetCamFollowingValueCyclic: Cyclically read out following value of a cam V10

Description

With the "MC_GetCamFollowingValueCyclic" Motion Control instruction, you read the following value as well as the first, second and third derivative of the following value for a leading value from a cam cyclically depending on the specified read mode.

The Motion Control instruction offers you the following:

- Reading a following value cyclically (Page 182)
- Specifying scaling and offset of the cam (Page 150)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The cam is interpolated.

Override response

- An "MC_GetCamFollowingValueCyclic" job is not aborted by any other Motion Control job.
- A new "MC_GetCamFollowingValueCyclic" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GetCamFollowingValueCyclic":

Parameters	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The following value is read out cyclically.
				FALSE	The following value is not read out.
LeadingValue	INPUT	LREAL	0.0	Leading value for which the following value is read	

Parameters	Declaration	Data type	Default value	Description	
MasterOffset	INPUT	LREAL	0.0	Offset of the leading values of the cam The cam technology object is not changed.	
SlaveOffset	INPUT	LREAL	0.0	Offset of the following values of the cam The cam technology object is not changed.	
MasterScaling	INPUT	LREAL	1.0	Scaling of the leading values of the cam The cam technology object is not changed.	
				0.0	Not permitted
SlaveScaling	INPUT	LREAL	1.0	Scaling of the following values of the cam The cam technology object is not changed.	
ApplicationMode	INPUT	DINT	2	Read mode	
				0	Read out following value (position)
				1	Read out following value and first derivative (position, velocity)
				2	Read out following value, first derivative and second derivative (position, velocity, acceleration)
				3	Read out following value, first derivative, second derivative and third derivative (position, velocity, acceleration, jerk)
Valid	OUTPUT	LREAL	FALSE	TRUE	The following value that is read out is valid.
				FALSE	The following value that is read out is invalid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
Value	OUTPUT	LREAL	0.0	Read following value (position) (valid when "Valid" = TRUE)	
FirstDerivative	OUTPUT	LREAL	0.0	First derivative on read out following value (velocity) (valid when "Valid" = TRUE)	
SecondDerivative	OUTPUT	LREAL	0.0	Second derivative on read out following value (acceleration) (valid when "Valid" = TRUE)	
ThirdDerivative	OUTPUT	LREAL	-	Third derivative on read following value (jerk) (valid when "Valid" = TRUE)	

13.2.5 MC_CopyCamData V10

13.2.5.1 MC_CopyCamData: Copy calculated cam elements V10

Description

You use the instruction "MC_CopyCamData" to copy calculated cam elements from one array each for points and segments to the data block technology object of the cam. You use the copy mode to specify whether the existing defined cam elements remain valid or are set as invalid.

The Motion Control instruction offers you the following:

- Changing the synchronous operation function of the cam online (Page 137)
- Copy calculated cam elements (Page 139)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The data to be copied is available in a data block with one array each for points and segments:
  - For points: ARRAY[*] OF TO_Cam_Struct_PointData
  - For segments: ARRAY[*] OF TO_Cam_Struct_SegmentData
- The "Optimized block access" option is activated in the properties of the data block under "General > Attributes".

Override response

- An "MC_CopyCamData" job is not aborted by any other Motion Control job.
- A new "MC_CopyCamData" job does not abort any active Motion Control job.

  Cam elements can also be copied during active camming.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_CopyCamData":

Parameter	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	0	Copy mode	
				0	All existing defined cam elements are set as invalid before the copying procedure. ("ValidPoint" = FALSE, "ValidSegment" = FALSE)
				1	All existing defined cam elements remain valid. ("ValidPoint" = TRUE, "ValidSegment" = TRUE)
StartPointCam	INPUT	DINT	1	Index of the start point of the points to be copied in the cam	
				Permitted values for "TO_Cam": 1 ≤ "StartPointCam" ≤ 1 000	
				Permitted values for "TO_Cam_10k": 1 ≤ "StartPointCam" ≤ 10 000	
StartSegmentCam	INPUT	DINT	1	Index of the start segment of the segments to be copied in the cam	
				Permitted values: 1 ≤ "StartSegmentCam" ≤ 50	
StartPointArray	INPUT	DINT	1	Index of the start point of the points to be copied from "ArrayOfPoints"	
				Permitted values: Low limit of "ArrayOfPoints" ≤ "StartPointArray" ≤ high limit of "ArrayOfPoints"	
StartSegmentArray	INPUT	DINT	1	Index of the start segment of the segments to be copied from "ArrayOfSegments"	
				Permitted values: Low limit of "ArrayOfSegments" ≤ "StartSegmentArray" ≤ high limit of "ArrayOfSegments"	
NumberOfPoints	INPUT	DINT	0	Number of points to be copied	
				Permitted values for "TO_Cam": "NumberOfPoints" ≤ number of points from "ArrayOfPoints" and 0 ≤ "NumberOfPoints" ≤ 1 001 - "StartPointCam"	

[1] The size of the array depends on your application.

Parameter	Declaration	Data type	Default value	Description	
NumberOfPoints	INPUT	DINT	0	Permitted values for "TO_Cam_10k": "NumberOfPoints" ≤ number of points from "ArrayOfPoints" and 0 ≤ "NumberOfPoints" ≤ 10 001 - "StartPointCam"	
NumberOfSegments	INPUT	DINT	0	Number of segments to be copied	
				Permitted values: "NumberOfSegments" ≤ number of segments in the "ArrayOfSegments" and 0 ≤ "NumberOfSegments" ≤ 51 - "StartSegmentCam"	
ArrayOfPoints	INOUT	ARRAY[*] OF TO_Cam-_Struct_PointData[1]	-	Array that contains the points to be copied	
ArrayOfSegments	INOUT	ARRAY[*] OF TO_Cam-_Struct_SegmentData[1]	-	Array that contains the segments to be copied	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

[1] The size of the array depends on your application.

13.2.6 MC_SetCamRangeScaling V10

13.2.6.1 MC_SetCamRangeScaling: Scaling the cam range V10

Description

Use the Motion Control instruction "MC_SetCamRangeScaling" to scale a cam range. The scaling range refers to the interpolated cam. The configuration of the cam technology object is not changed.

Up to two scaling ranges are possible for one cam.

The Motion Control instruction offers you the following:

- Scaling a cam range (Page 153)

Applies to

- Cam

Requirement

- The technology object has been configured correctly.
- The cam is interpolated (<TO>.StatusWord.X5 (Interpolated) = TRUE).

Override response

- An "MC_SetCamRangeScaling" job is not aborted by any other Motion Control job.
- A new "MC_SetCamRangeScaling" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetCamRangeScaling":

Parameters	Declaration	Data type	Default value	Description	
Cam	INPUT	TO_Cam TO_Cam_10k TO_Cam_600Seg TO_Cam_6kSeg	-	Cam technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	1	Scaling mode	
				1	Range scaling in the leading value range[1)]
				2	Range scaling in the following value range[2)]
RangeNumber	INPUT	DINT	1	Number of the scaling range	
				1	Scaling range 1
				2	Scaling range 2
RangeStartPoint	INPUT	LREAL	0.0	Start point Start point ≤ End point	
RangeEndPoint	INPUT	LREAL	0.0	End point Start point ≤ End point	
RangeScaling	INPUT	LREAL	1.0	Scaling factor	
				> 0.0	The specified value is used.
				≤ 0.0	Not permitted
Done	OUTPUT	BOOL	FALSE	TRUE	The cam range is scaled.

1) If the cam is used with the Motion Control instruction "MC_PositionProfile", the range scaling refers to the time values.

2) If the cam is used with the Motion Control instruction "MC_PositionProfile", the range scaling refers to the axis values.

Parameters	Declaration	Data type	Default value	Description	
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

1) If the cam is used with the Motion Control instruction "MC_PositionProfile", the range scaling refers to the time values.

2) If the cam is used with the Motion Control instruction "MC_PositionProfile", the range scaling refers to the axis values.

13.2.6.2 MC_SetCamRangeScaling: Function chart V10

Function chart: Scaling the cam during active camming

Camming with "MC_CamIn" (A1) is active ("InSync" = 1).

At time ①, "Exe" is used to initiate a "MC_SetCamRangeScaling" job (A2) with "RangeNumber" = 1. The cam is scaled in the scaling range from "RangeStartPoint" = 0.0 to "RangeEndPoint" = 360.0 by the scaling factor "Factor" = 2.0 in the following value range ("Mode" = 2). The scaling takes effect immediately.

At time ②, the "Exe" of the "MC_SetCamRangeScaling" job (A2) is initiated again with "RangeNumber" = 2. The cam is scaled in the scaling range from "RangeStartPoint" = 0.0 to "RangeEndPoint" = 360.0 by the scaling factor "Factor" = 0.5 in the leading value range ("Mode" = 1). The scaling in addition to the first scaling takes effect immediately.

13.3 Override response of Motion Control jobs V10

13.3.1 Override response V10: Homing and motion jobs

The following table shows how a new Motion Control job affects active homing and motion jobs:

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 0, 1 active MC_Move-Velocity MC_MoveJog	MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_Move-Super-imposed MC_Motion-InSuper-imposed MC_Motion-InSuper-imposed-Axes MC_Halt-Super-imposed	MC_Motion-InVelocity MC_Motion-InPosition
MC_Home[1)] "Mode" = 3, 5	A	A	A	A	A	N	A	A
MC_Home "Mode" = 9	A	-	-	-	-	N	-	-
MC_Halt "Mode" = 1	-	A	A	A	-	N	-	A
MC_Halt "Mode" = 0 **MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity MC_MoveJog**	-	A	A	A	A	N	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 0, 1 active MC_MoveVelocity MC_MoveJog	MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_MoveSuperimposed MC_MotionInSuperimposed MC_MotionInSuperimposedAxes MC_HaltSuperimposed	MC_MotionInVelocity MC_MotionInPosition

MC_GearOut MC_CamOut waiting[4]	N	N	N	N	N	N	-	N
MC_GearOut MC_CamOut active[5]	N	N	N	N	N	N	A	N

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

NOTE

Override response with active fixed stop

With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

13.3.2 Override response V10: Synchronous operation jobs

The following table shows how a new Motion Control job affects the motion of the axis on active synchronous operation jobs:

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_Home[1] "Mode" = 3, 5	A	A	-	N	-	-	-	-	A
MC_Halt "Mode" = 0, 1 **MC_MoveAbsolute/ MC_MoveRelative** "BufferMode" = 0 Active **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog**	A	A	-	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_MoveAbsolute/-MC_MoveRelative "BufferMode" = 1 active, waiting **MC_PositionProfile** "BufferMode" = 1 active, waiting	N	N	-	N	N	N	-	N	N

MC_Stop	A	A	A	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_GearIn MC_GearInVelocity	A	A	A	A	A	A	-	A	A
MC_GearInPos MC_CamIn waiting[2]	-	-	A	-	-	-	-	A	-

MC_GearOut MC_CamOut active[5]	A[7]	N	A[7] [8]	A[7]	A	A	-	A[7]	N

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

NOTE

Override response with active fixed stop

With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

13.3.3 Override response V10: Measuring input jobs

The following table shows which new Motion Control jobs will override active measuring input jobs:

⇒ **Active job** ⇓ **New job**	**MC_MeasuringInput**	**MC_MeasuringInputCyclic**
MC_Home "Mode" = 2, 3, 5, 8, 9, 10	B	B
MC_Home "Mode" = 0, 1, 6, 7, 11, 12	-	-
MC_MeasuringInput **MC_MeasuringInputCyclic** **MC_AbortMeasuringInput**	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B The running job is aborted with "ErrorID" = 16#80A3.

- No effect. Running job continues to be executed.

13.3.4 Override response V10: Kinematics motion commands

Single axis jobs are not overridden by kinematics jobs.

The following table shows how a new Motion Control job affects active kinematics motion jobs:

⇒ **Active job** ⇓ **New job**	**MC_MoveLinearAbsolute** **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt** **MC_DefineWorkspaceZone** **MC_DefineKinematicsZone** **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive** **MC_SetOcsFrame**	**MC_GroupInterrupt**	**MC_GroupStop**
MC_Home **MC_MoveSuperimposed** **MC_GearOut** **MC_CamOut**	N	N	N
MC_Halt **MC_MoveAbsolute/** **MC_MoveRelative/** **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog** **MC_Stop** **MC_GearIn** **MC_GearInPos** **MC_GearInVelocity** **MC_CamIn** **MC_MotionInVelocity** **MC_MotionInPosition**	A	A	A
MC_GroupStop	A	A	N
MC_GroupInterrupt **MC_GroupContinue**	B	A	N
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt**	-	-	N

⇒ Active job ⇓ New job	MC_MoveLinearAbsolute MC_MoveLinearRelative MC_MoveCircularAbsolute MC_MoveCircularRelative MC_MoveDirectAbsolute MC_MoveDirectRelative MC_TrackConveyorBelt MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive MC_SetOcsFrame	MC_GroupInterrupt	MC_GroupStop
MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive			
MC_SetOcsFrame	C, -	-	N

A The running job is aborted with "CommandAborted" = TRUE.

B Running job is interrupted or resumed.

C Synchronization of the OCS with the conveyor belt is aborted with "MC_SetOcsFrame" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed. A new kinematics job is added to the job sequence.

13.3.5 Override response V10: Interpreter jobs

The following table shows how a new Motion Control job affects running Interpreter jobs:

⇒ Active job ⇓ New job	MC_LoadProgram	MC_RunProgram	MC_StopProgram
MC_LoadProgram	N	N	N
MC_RunProgram	-[1]	N	N
MC_StopProgram	A	A	A[2]
MC_Reset	-/N[3]	-/N[3]	-/N[3]

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) The new job is also executed.

2) A new "MC_StopProgram" job with "Mode" = 0 cancels a running "MC_StopProgram" job with "Mode" = 1 or 2. A new "MC_StopProgram" job with "Mode" = 1 aborts a current "MC_StopProgram" job with "Mode" = 2.

3) An "MC_Reset" job with "Restart" = TRUE is rejected. Running job continues to be executed.

Override response for technology objects controlled by the Interpreter

The following table shows how a new Motion Control job acts in relation to a technology object controlled by the Interpreter during the execution of an Interpreter program ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)):

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_Power disable/enable with technology object	✓	✓
MC_Reset with "Restart" = TRUE	✓	✓
MC_Reset with "Restart" = FALSE	✓	-
MC_Home **MC_Halt** **MC_Stop**	✓	✓
MC_MoveAbsolute **MC_MoveRelative** **MC_MoveVelocity** **MC_MoveJog**	✓	✓
MC_SetAxisSTW **MC_WriteParameter**	✓	-
MC_MoveSuperimposed **MC_MotionInSuperimposed** **MC_MotionInSuperimposedAxes** **MC_HaltSuperimposed**	-	-
MC_MotionInVelocity **MC_MotionInPosition**	✓	✓
MC_GearIn **MC_GearInPos** **MC_GearInVelocity** **MC_GearOut** **MC_CamIn** **MC_CamOut**	✓	✓[1)]
MC_PhasingRelative **MC_PhasingAbsolute**	-	-
MC_LeadingValueAdditive	✓	-
MC_OffsetRelative **MC_OffsetAbsolute**	-	-
MC_TorqueAdditive **MC_TorqueRange**	✓	-
MC_TorqueLimiting	✓	-/✓[2)]
MC_SynchronizedMotionSimulation	✓	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative**	-	-
MC_GroupInterrupt **MC_GroupContinue**	-	-
MC_GroupStop	✓	✓
MC_KinematicsMotionSimulation	✓	-
MC_TrackConveyorBelt	-	-
MC_DefineTool **MC_SetTool** **MC_SetOcsFrame**	-	-
MC_KinematicsTransformation **MC_InverseKinematicsTransformation**	✓	-
MC_DefineWorkspaceZone **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_DefineKinematicsZone** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive**	-	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

NOTE

MC_Power

Note that a "MC_Power" request with "Enable" = FALSE always locks the specified technology object, even if the technology object was enabled via an Interpreter program with "powerOn()".

Mixed operation of MC_Power (SCL) and powerOn() (MCL) is not permitted.

NOTE

MC_Stop

Note that when starting a motion controlled by the Interpreter no "MC_Stop" job may be active, otherwise the motion job will be aborted.

NOTE

MC_GroupStop

Note that when starting a kinematics motion controlled by the Interpreter, no "MC_GroupStop" job may be active, otherwise the motion job will be aborted.

A "MC_GroupStop" job only affects active kinematics motions or if the kinematics technology object is controlled by the Interpreter ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)).

Tags of the technology object data blocks 14

14.1 Legend

Tag	Name of the tag	
Data type	Data type of the tag	
Values	Value range of the tag - minimum value to maximum value (L - linear specification R - rotary specification) If no specific value is shown, the value range limits of the relevant data type apply or the information under "Description".	
W	Effectiveness of changes in the technology data block	
	DIR	Direct: Values are changed via direct assignment and take effect at the start of the next MC_Servo.
	CAL	At call of Motion Control instruction: Values are changed directly and take effect at the start of the next MC_Servo after the call of the corresponding Motion Control instruction in the user program.
	RES	Restart: Changes to the start value in the load memory are made using the extended instruction "WRIT_DBL" (write to DB in load memory). Changes will not take effect until after restart of the technology object.
	RON	Read only: The tag cannot and must not be changed during runtime of the user program.
Description	Description of the tag	

Access to the tags is with "<TO>.<tag name>". The placeholder <TO> represents the name of the technology object.

14.2 Tags of the synchronous axis technology object

14.2.1 Actual values and setpoints (synchronous axis)

The following tags indicate the setpoint and actual values of the technology object.

Tags

Legend

Tag	Data type	Values	W	Description
Position	LREAL	-	RON	Position setpoint
Velocity	LREAL	-	RON	Setpoint velocity or speed setpoint
ActualPosition	LREAL	-	RON	Actual position
ActualVelocity	LREAL	-	RON	Actual velocity

Tag	Data type	Values	W	Description	
ActualSpeed	LREAL	-	RON	For PROFIdrive drives	Actual speed of the motor
				For drives with analog setpoint interface	0.0
				For drives with linear motor	0.0
Acceleration	LREAL	-	RON	Setpoint acceleration	
ActualAcceleration	LREAL	-	RON	Actual acceleration	
OperativeSensor	UDINT	1 ... 4	RON	Operative encoder	
ModuloCycle	DINT	-2147483648 ... 2147483647	RON	Number of modulo cycles of the setpoint	
ActualModuloCycle	DINT	-2147483648 ... 2147483647	RON	Number of modulo cycles of the actual value	
VelocitySetpoint	LREAL	-1.0E12 ... 1.0E12	RON	Output setpoint velocity or setpoint rpm	

14.2.2 "Simulation" tag (synchronous axis)

The tag structure "<TO>.Simulation.<tag name>" contains the configuration of the simulation mode. In simulation mode, you can simulate axes without a real drive in the CPU.

Tags

Legend

Tag	Data type	Values	W	Description	
Simulation.	TO_Struct_AxisSimulation				
Mode	UDINT	0, 1	RES[1)]	Simulation mode	
				0	No simulation, normal operation
				1	Simulation mode

1) Technology version V2.0: RON

14.2.3 "VirtualAxis" tag (synchronous axis)

The tag structure "<TO>.VirtualAxis.<tag name>" contains the configuration of the virtual operation of the axis. A virtual axis is often used as a virtual leading axis in order to generate the setpoints for several real following axes in synchronous operation.

Tags

Legend

Tag	Data type	Values	W	Description	
VirtualAxis.	TO_Struct_VirtualAxis				
Mode	UDINT	0, 1	RON	Virtual axis	
				0	No virtual axis

Tag	Data type	Values	W	Description	
Mode	UDINT	0, 1	RON	1	Technology version ≤ V7.0: The behavior of a virtual axis is identical to the behavior of an axis in simulation. The actual values are generated via the control loop and a simplified drive model. Technology version ≥ V8.0: In technology version V8.0, the behavior of the virtual axis has been changed. The behavior of a virtual axis is no longer identical to the behavior of an axis in simulation. The position and velocity setpoints are directly adopted as actual values with an application cycle delay. The feedback loop and the drive model are not simulated. The dynamic filter is effective. To maintain compatibility with virtual axes of technology versions ≤ V7.0 for an axis: 1. Switch on the axis in simulation (<TO>.Simulation.Mode = 1). 2. Deactivate the virtual axis (<TO>.VirtualAxisMode = 0).

14.2.4 "Actor" tag (synchronous axis)

The tag structure "<TO>.Actor.<tag name>" contains the controller-side configuration of the drive.

Tags

				1	Automatic transfer of values configured in the drive to the configuration of the technology object
ActualVelocityMode	DINT	0, 1	RES	Type of calculation for actual speed value or actual velocity value	
				0	Actual value calculation from differentiation of the position change
				1	Actual value calculation with NACT value from the PROFIdrive telegram
Interface.	TO_Struct_SensorInterface				
AddressIn	VREF	0 to 65535	RON	Input address for the PROFIdrive telegram	
AddressOut	VREF	0 to 65535	RON	Output address for the PROFIdrive telegram	
Number	UDINT	1 to 2	RON	Number of the encoder in the telegram	
Parameter.	TO_Struct_SensorParameter				
Resolution	LREAL	1.0E-12 ... 1.0E12	RES	Resolution of a linear encoder (offset between two encoder pulses)	
StepsPerRevolution	UDINT	1 to 8388608	RES	Increments per rotary encoder revolution	
FineResolutionXist1	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST1" (cyclic actual encoder value)	
FineResolutionXist2	UDINT	0 to 31	RES	Number of bits for fine resolution "Gx_XIST2" (absolute value of the encoder)	
DeterminableRevolu-tions	UDINT	0 to 8388608	RES	Number of differentiable encoder revolutions for a multi-turn absolute encoder (For a single-turn absolute encoder = 1; for an incremental encoder = 0)	
DistancePerRevolution	LREAL	0.0 to 1.0E12	RES	For technology objects < V8.0: Load distance per revolu-tion of an externally mounted encoder For technology objects >= V8.0: Load travel per measuring wheel revolution of an externally mounted encoder	

Tag	Data type	Values	W	Description	
BehaviorGx_XIST1	DINT	0, 1	RES	Evaluation of "Gx_XIST1" bits.	
				0	Based on the bits of the encoder resolution. The incremental actual value "Gx_XIST1" is transmitted with less than 32 bits in the PROFIdrive telegram. For example: At 16 bits, the value ranges from 0 to 65,535.
				1	32-bit value of the encoder value The "Gx_XIST1" incremental actual value is transferred with 32 bits of 0 to 4,294,967,295 in the PROFIdrive telegram.
ReferenceSpeed	LREAL	0.0 to 1.0E12	RES	Reference speed for NACT in PROFIdrive telegram with rotary encoder Only relevant for "ActualVelocityMode" = 1	
ReferenceVelocity	LREAL	0.0 to 1.0E12	RES	Reference velocity for NACT in the PROFIdrive telegram with linear encoder Only relevant for "ActualVelocityMode" = 1	
Backlash.	TO_Struct_Backlash				
Enable	BOOL	-	DIR	Enable backlash compensation	
				FALSE	Disabled
				TRUE	Enabled
				If you enable or disable backlash compensation at runtime, you must home the axis again.	
Size	LREAL	0.0 to 1.0E12	DIR	Size of backlashes	
				If you change the size of backlashes during runtime, you have to home the axis again.	
Velocity	LREAL	0.0 to 1.0E12	DIR	Velocity for traversing of backlashes	
				0.0	Motor traverses backlashes within one servo cycle.
				> 0.0	Motor traverses backlash with the specified velocity.
DirectionAbsolute-Homing	DINT	0, 1	DIR	Direction of movement during or before absolute encoder adjustment	
				0	Positive
				1	Negative
ActiveHoming.	TO_Struct_SensorActiveHoming				
Mode	DINT	0 to 2	RES	Homing mode	
				0	Use zero mark via PROFIdrive telegram

Units of measure (Page %getreference)

14.2.14 "Mechanics" tag (synchronous axis)

The tag structure "<TO>.Mechanics.<tag name>" contains the configuration of the mechanics.

Tags

Legend

Tag	Data type	Value range	W	Description
Mechanics.	TO_Struct_Mechanics			
LeadScrew	LREAL	1.0E-12 to 1.0E12	RES	Leadscrew pitch

14.2.15 "Modulo" tag (synchronous axis)

The tag structure "<TO>.Modulo.<tag name>" contains the configuration of the modulo function.

Tags

Legend

Tag	Data type	Values	W	Description	
Modulo.	TO_Struct_Modulo				
Enable	BOOL	-	RES	FALSE	Modulo conversion disabled
				TRUE	Modulo conversion enabled
Length	LREAL	0.001 to 1.0E12	RES	Modulo length When modulo conversion is enabled, a check is made for modulo length > 0.0	
StartValue	LREAL	-1.0E12 to 1.0E-12	RES	Modulo start value	

14.2.16 "DynamicLimits" tag (synchronous axis)

The tag structure "<TO>.DynamicLimits.<tag name>" contains the configuration of the dynamic limits. During Motion Control, no dynamic values greater than the dynamic limits are permitted. If you specify greater values in a Motion Control instruction, then motion is performed using the dynamic limits, and a warning is indicated (alarm 501 to 503 - Dynamic values are limited).

Tags

Legend

Tag	Data type	Values	W	Description
DynamicLimits.	TO_Struct_DynamicLimits			
MaxVelocity	LREAL	0.0 to 1.0E12	RES	Maximum permissible velocity of the axis
Velocity	LREAL	0.0 to 1.0E12	DIR	Current maximum velocity of the axis The minimum from "MaxVelocity" and "Velocity" is effective for motion control.
MaxAcceleration	LREAL	0.0 to 1.0E12	DIR	Maximum permissible acceleration of the axis
MaxDeceleration	LREAL	0.0 to 1.0E12	DIR	Maximum permissible deceleration of the axis
MaxJerk	LREAL	0.0 to 1.0E12	DIR	Maximum permissible jerk on the axis

14.2.17 "DynamicDefaults" tag (synchronous axis)

The tag structure "<TO>.DynamicDefaults.<tag name>" contains the configuration of the dynamic defaults. These settings will be used when you specify a dynamic value less than 0.0 in a Motion Control instruction (exceptions: "MC_MoveJog.Velocity", "MC_MoveVelocity.Velocity"). Changes to the default dynamic values will be applied at the next positive edge at the "Execute" parameter of a Motion Control instruction.

Tags

Legend

Tag	Data type	Values	W	Description
DynamicDefaults.	TO_Struct_DynamicDefaults			
Velocity	LREAL	0.0 to 1.0E12	CAL	Default velocity

ReferencingVelocity	LREAL	Linear: 0.0 to 1000.0 mm/s	CAL	Homing velocity Velocity during active homing at which the home position is approached.	
		Rotary: 0.0 to 36000.0 °/s			
HomePosition	LREAL	-1.0E12 to 1.0E12	CAL	Home position	

14.2.21 "Override" tag (synchronous axis)

The tag structure "<TO>.Override.<tag name>" contains the configuration of override parameters. The override parameters are used to apply a correction percentage to default values. An override change takes effect immediately, and is performed with the dynamic settings in effect in the Motion Control instruction.

Tags

Legend

Tag	Data type	Values	W	Description
Override.	TO_Struct_Override			
Velocity	LREAL	0.0 to 200.0%	DIR	Velocity or speed override Percentage correction of the velocity or speed

14.2.22 "PositionControl" tag (synchronous axis)

The tag structure "<TO>.PositionControl.<tag name>" contains the settings of position control.

Tags

Legend

Tag	Data type	Values	W	Description
PositionControl.	TO_Struct_PositionControl			
Kv	LREAL	0.0 to 2147480.0	DIR	Proportional gain of the closed loop position control ("Kv" > 0.0)
Kpc	LREAL	0.0 to 150.0%	DIR	Velocity precontrol of the position control Recommended setting: • Isochronous drive connection via PROFIdrive: 100.0% • Non-isochronous drive connection via PROFIdrive: 0.0 to 100.0% • Analog drive connection: 0.0 to 100.0%
EnableDSC	BOOL	-	RES	Dynamic Servo Control (DSC) FALSE: DSC disabled TRUE: DSC activated DSC is only possible with one of the following PROFIdrive telegrams: • Standard telegram 5 or 6 • SIEMENS telegram 105 or 106
SmoothingTimeByChangeDifference	LREAL	0.0 to 1.0E12 s	DIR	Smoothing time for the manipulated variable for switching operations, for example: • Encoder switchover • Change in P-gain ("Kv") • Switchover to emergency stop ramp
InitialOperativeSensor	UDINT	1 to 4	RES	Active sensor after initialization of the axis (sensor number 1 to 4) This encoder is used after startup of the CPU and after a restart of the technology object. At an operating mode transition from STOP → RUN of the CPU (without restart of the technology object), the encoder that was also active before the STOP is still being used.
ControlDifferenceQuantization.	TO_Struct_PositionDifferenceQuantification			
Mode	DINT	-	RES	Type of quantification Configuration of a quantization when a drive with stepper motor interface is connected 0: No quantification 1: Quantization corresponding to encoder resolution 2: Quantization to a direct value

Tag	Data type	Values	W	Description
Mode	DINT	-	RES	(configuration is performed using the parameter view (data structure))
Value	LREAL	0.001 to 1.0E12	RES	Value of quantification Configuration of a value for quantization to a direct value ("<TO>.PositionControl.ControlDifferenceQuantization.Mode" = 2) (configuration is performed using the parameter view (data structure))
VelocityModePowerOn	DINT	0 to 1	RES	Behavior of the velocity setpoint when the axis is enabled
				0 Velocity is set to "0" with maximum dynamic values of the axis (ramp).
				1 Velocity is immediately set to "0" without ramp.

14.2.23 "TorquePreControl" tag (synchronous axis)

The tag structure "<TO>.TorquePreControl.<tag name>" contains the settings of the torque precontrol.

Tags

Legend

Tag	Data type	Values	W	Description
TorquePreControl.	TO_Struct_TorquePreControl			
Mode	DINT	0 ... 1	RES	Mode of torque precontrol (effect only in position-controlled mode)
				0 Torque precontrol not in effect
				1 Torque precontrol based on the acceleration of the axis
Scale	LREAL	0.0 ... 150.0	DIR	Weighting factor for the value of the torque precontrol [%]

14.2.24 "SetpointFilter" tag (synchronous axis)

The tag structure "<TO>.SetpointFilter.<tag name>" contains the settings of the setpoint filter.

Tags

Legend

Tag	Data type	Values	W	Description
SetpointFilter.	TO_Struct_SetpointFilter			
DynamicFilter.	TO_Struct_DynamicFilter			
Mode	DINT	0 to 2	RES	Dynamic filter mode

1) The dead time T_t is internally limited to sixteen times the value from the application cycle of the MC_Servo. No alarm is output at higher values.

Tag			Data type	Values	W	Description	
		Mode	DINT	0 to 2	RES	0	Dynamic filter not active
						1	PT1/PT2 filter + dead time
						2	Sliding window demand + dead time
		T1	LREAL	0.0 to 1.0E12	DIR	First time constant of the sliding window demand The value is internally limited to the 16-fold servo clock.	
		T2	LREAL	0.0 to 1.0E12	DIR	Second time constant of the sliding window demand The value is internally limited to the 16-fold servo clock.	
		Tt	LREAL	0.0 to 1.0E12[1)]	DIR	Additional dead time of the dynamic filter in time unit of the axis	

1) The dead time T_t is internally limited to sixteen times the value from the application cycle of the MC_Servo. No alarm is output at higher values.

14.2.25 "DynamicAxisModel" tag (synchronous axis)

The tag structure "<TO>.DynamicAxisModel.<tag name>" contains the balancing filter settings.

Tags

Legend

Tag		Data type	Values	W	Description
DynamicAxisModel.		TO_Struct_DynamicAxisModel			
	VelocityTimeConstant	LREAL	0.0 to 1.0E12	DIR	Speed control loop substitute time [s]
	AdditionalPositionTime-Constant	LREAL	0.0 to 1.0E12	DIR	Additive position control loop substitute time [s]
	CurrentTimeConstant	LREAL	0.0 to 1.0E12	DIR	Current control loop substitute time in time unit of the axis

14.2.26 "FollowingError" tag (synchronous axis)

The tag structure "<TO>.FollowingError.<tag name>" contains the configuration of the dynamic following error monitoring.

If the permissible following error is exceeded, then technology alarm 521 is output, and the technology object is disabled (alarm reaction: remove enable).

When the warning level is reached, a warning is output (technology alarm 522).

Tags

Legend

Tag		Data type	Values	W	Description	
FollowingError.		TO_Struct_FollowingError				
	EnableMonitoring	BOOL	-	RES	FALSE	Following error monitoring deactivated
					TRUE	Following error monitoring enabled

Tag	Data type	Values	W	Description
MinValue	LREAL	Linear: 0.0 to 1.0E12 Rotary: 0.001 to 1.0E12	DIR	Permissible following error at velocities below the value of "MinVelocity"
MaxValue	LREAL	Linear: 0.0 to 1.0E12 Rotary: 0.002 to 1.0E12	DIR	Maximum permissible following error, which may be reached at the maximum velocity.
MinVelocity	LREAL	0.0 to 1.0E12	DIR	"MinValue" is permissible below this velocity and is held constant.
WarningLevel	LREAL	0.0 to 100.0	DIR	Warning level Percentage value relative to the valid maximum following error
AdditionalSetpointDelay-Time	LREAL	0.0 to 1.0E12	DIR	Time constant for additional deceleration of position set-point to calculate the following error in the time unit of the axis

14.2.27 "PositioningMonitoring" tag (synchronous axis)

The tag structure "<TO>.PositioningMonitoring.<tag name>" contains the configuration of position monitoring at the end of a positioning motion.

If the actual position value at the end of a positioning motion is reached within the tolerance time and remains in the positioning window for the minimum dwell time, then "<TO>.StatusWord.X6 (Done)" is set in the technology data block. This completes a Motion Control job.

If the tolerance time is exceeded, then technology alarm 541 "Positioning monitoring" with supplemental value 1: "Target range not reached" is displayed.

If the minimum dwell time is not met, then technology alarm 541 "Positioning monitoring" with supplemental value 2: "Exit target range again" is displayed.

Tags

Legend

Tag	Data type	Values	W	Description
PositioningMonitoring.	TO_Struct_PositionMonitoring			
ToleranceTime	LREAL	0.0 to 1.0E12	DIR	Tolerance time Maximum permitted duration from reaching of velocity setpoint zero until entrance into the positioning window
MinDwellTime	LREAL	0.0 to 1.0E12	DIR	Minimum dwell time in positioning window
Window	LREAL	0.001 to 1.0E12	DIR	Positioning window

14.2.28 "StandstillSignal" tag (synchronous axis)

The tag structure "<TO>.StandstillSignal.<tag name>" contains the configuration of the standstill signal.

If the actual velocity value is below the velocity threshold, and does not exceed it during the minimum dwell time, then the standstill signal "<TO>.StatusWord.X7 (Standstill)" is set.

Tags

Legend

Tag	Data type	Values	W	Description
StandstillSignal.	TO_Struct_StandstillSignal			Configuration for the standstill signal
VelocityThreshold	LREAL	0.0 to 1.0E12	DIR	Velocity threshold If velocity is below this threshold, the minimum dwell time begins.
MinDwellTime	LREAL	0.0 to 1.0E12	DIR	Minimum dwell time

14.2.29 "StatusPositioning" tag (synchronous axis)

The tag structure "<TO>.StatusPositioning.<tag name>" indicates the status of a positioning motion.

Tags

Legend

Tag	Data type	Values	W	Description
StatusPositioning.	TO_Struct_StatusPositioning			
Distance	LREAL	-1.0E12 ... 1.0E12	RON	Distance to target position
TargetPosition	LREAL	-1.0E12 ... 1.0E12	RON	Target position
TargetPositionModulo-Cycle	DINT	-2147483648 ... 2147483647	RON	Number of modulo cycles to target position with positioning motions
FollowingError	LREAL	-1.0E12 ... 1.0E12	RON	Current following error
SetpointExecutionTime	LREAL	0 ... 1.0E12	RON	Setpoint execution time of the axis (Results from T_{lpo}, T_{vtc} or 1/kv, T_{Send} and T_O of the axis)
SuperimposedDistance	LREAL	0 ... 1.0E12	RON	Use the instructions "MC_MoveSuperimposed", "MC_MotionInSuperimposed", "MC_MotionInSuperimposedAxes" and "MC_HaltSuperimposed" to move the distance. The value is reset when the basic motion and the superimposed motion are completed or the basic motion is aborted.

14.2.30 "StatusDrive" tag (synchronous axis)

The tag structure "<TO>.StatusDrive.<tag name>" indicates the status of the drive.

Tags

Legend

Tag	Data type	Values	W	Description	
StatusDrive.	TO_Struct_StatusDrive				
InOperation	BOOL	-	RON	Operation status of the drive	
				FALSE	Drive not ready Setpoints will not be executed.
				TRUE	Drive ready Setpoints can be executed.
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and drive	
				FALSE	Cyclic communication not established. Fault ZSW1.X3 (FaultPresent) is present. Possible causes: • The CPU is in STOP. • The drive has failed. • The "ControlRequested" bit in the status word of the drive has the value "FALSE". • The drive signals an error using the status word. • For isochronous configuration, the dynamic sign of life in the telegram has failed or is not supplied by the drive.
				TRUE	Cyclic communication OK and no fault effective
Error	BOOL	-	RON	FALSE	No drive error
				TRUE	Drive error
AdaptionState	DINT	0 to 4	RON	Status of automatic data transfer of drive parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer

14.2.31 "StatusServo" tag (synchronous axis)

The tag structure "<TO>.StatusServo.<tag name>" indicates the status for the balancing filter.

Tags

Legend

Tag	Data type	Values	W	Description
StatusServo.	TO_Struct_StatusServo			
BalancedPosition	LREAL	-	RON	Position setpoint after the balancing filter
ControlDifference	LREAL	-	RON	Control deviation
PositionAfterDynamicFilter	LREAL	-	RON	Position setpoint after the dynamic filter

14.2.32 "StatusProvidedLeadingValue" tag (synchronous axis)

The tag structure "<TO>.StatusProvidedLeadingValue.<tag name>" contains the provided leading value with leading value delay of the cross-PLC synchronous operation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusProvidedLeadingValue.	TO_Struct_StatusProvidedLeadingValue			Provided leading value
DelayedLeadingValue	TO_Struct_ProvidedLeadingValue			Leading value with leading value delay

Velocity	LREAL	-1.0E12 to 1.0E-12	RON	Velocity
Acceleration	LREAL	-1.0E12 to 1.0E-12	RON	Acceleration

14.2.33 "StatusSensor[1..4]" tags (synchronous axis)

The tag structure "<TO>.StatusSensor[1..4].<tag name>" indicates the status of the measuring system.

Tags

Legend

Tag	Data type	Values	W	Description
StatusSensor[1..4].	Array [1..4] OF TO_Struct_StatusSensor			
State	DINT	0 to 2	RON	Status of the actual encoder value

Tag	Data type	Values	W	Description	
State	DINT	0 to 2	RON	0	"NOT_VALID" Invalid
				1	"WAITING_FOR_VALID" Waiting for "Valid" status
				2	"VALID" Valid
CommunicationOK	BOOL	-	RON	Cyclic BUS communication between controller and encoder	
				FALSE	Not established
				TRUE	Established
Error	BOOL	-	RON	FALSE	No error in the measuring system
				TRUE	Error in the measuring system.
AbsEncoderOffset	LREAL	-	RON	Home position offset for value of an absolute value encoder. The value will be retentively stored in the CPU.	
Control	BOOL	-	RON	FALSE	Encoder is not active
				TRUE	Encoder is active
Position	LREAL	-	RON	Encoder position	
Velocity	LREAL	-	RON	Encoder velocity	
AdaptionState	DINT	0 to 4	RON	Status of automatic data transfer of encoder parameters	
				0	"NOT_ADAPTED" Data not transferred
				1	"IN_ADAPTION" Data transfer in progress
				2	"ADAPTED" Data transfer complete
				3	"NOT_APPLICABLE" Data transfer not selected, not possible
				4	"ADAPTION_ERROR" Error during data transfer
ModuloCycle	DINT	-2147483648 to 2147483647	RON	Number of modulo cycles	
Adjusted	DINT	0, 1	RON	Homing status of the encoder	
				0	Encoder not homed
				1	Encoder homed with one of the following homing types: • Active homing • Passive homing • Absolute encoder adjustment • Incremental encoder adjustment

14.2.34 "StatusExtrapolation" tag (synchronous axis)

The tag structure "<TO>.StatusExtrapolation.<tag name>" indicates the status of the actual value extrapolation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusExtrapolation.	TO_Struct_StatusExtrapolation			
FilteredPosition	LREAL	-1.0E12 to 1.0E-12	RON	Position after position filter
FilteredVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Velocity after velocity filter and tolerance band
ExtrapolatedPosition	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated position
ExtrapolatedVelocity	LREAL	-1.0E12 to 1.0E-12	RON	Extrapolated velocity

14.2.35 "StatusSynchronizedMotion" tag (synchronous axis)

The tag structure "<TO>.StatusSynchronizedMotion.<tag name>" indicates the status of synchronous operation.

Tags

Legend

Tag	Data type	Value range	W	Description

14.2.36 "StatusKinematicsMotion" tag (synchronous axis)

The "<TO>.StatusKinematicsMotion" tag contains status information of the technology object with regard to usage as kinematics axis.

Information on evaluating individual bits (e.g. bit 2 "MaxDecelerationExceeded") can be found in the "Evaluating StatusWord, ErrorWord, and WarningWord" section of the "S7-1500/S7-1500T Motion Control overview" documentation.

Tag

Legend

Tag	Data type	Values	W	Description
StatusKinematicsMotion	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"MaxVelocityExceeded"

Tag	Data type	Values	W	Description	
Bit 0	-	-	-	0	The kinematics technology object calculated a lower velocity setpoint than the maximum velocity on the axis.
				1	The kinematics technology object calculated a higher velocity setpoint than the maximum velocity on the axis.
Bit 1	-	-	-	"MaxAccelerationExceeded"	
				0	The kinematics technology object calculated a lower setpoint acceleration calculated than the maximum acceleration of the axis.
				1	The kinematics technology object calculated a higher setpoint acceleration than the maximum acceleration of the axis.
Bit 2	-	-	-	"MaxDecelerationExceeded"	
				0	The kinematics technology object calculated a lower setpoint deceleration than the maximum deceleration of the axis.
				1	The kinematics technology object calculated a lower setpoint deceleration than the maximum deceleration of the axis.

14.2.37 "StatusTorqueData" tag (synchronous axis)

The tag structure "<TO>.StatusTorqueData.<tag name>" shows the status of the force/torque data.

Tags

Legend

Tag	Data type	Value range	W	Description	
StatusTorqueData.	TO_Struct_StatusTorqueData				
CommandAdditiveTorqueActive	DINT	0, 1	RON	Additive setpoint torque or additive setpoint force	
				0	Inactive
				1	Active
CommandTorqueRangeActive	DINT	0, 1	RON	Force/torque limits B+, B-	
				0	Inactive
				1	Active
ActualTorque	LREAL	-1.0E12 ... 1.0E12	RON	Actual torque of the axis

				2	"MC_MotionInPosition" active
ActualSuperimposingAxis	DB_ANY	0 to 65535	RON	At the start of a "MC_MotionInSuperimposedAxes" job, the number of the technology data block of the currently used superimposing axis is displayed.	
				0	"MC_MotionInSuperimposedAxes" job inactive
StatusWord.	DWORD	-	RON	-	
Bit 0	Bool	-	RON	"MaxVelocityExceeded" The configured maximum velocity is exceeded during a MotionIn movement.	
Bit 1 ... Bit 31	Bool	-	RON	Reserved	

14.2.39 "StatusInterpreterMotion" tag (synchronous axis)

The tag structure "<TO>.StatusInterpreterMotion.<tag name>" contains status information on motion jobs controlled by a technology object Interpreter.

Tags

Legend

Tag	Data type	Values	W	Description
StatusInterpreterMotion.	TO_Struct_StatusInterpreterMotion			
Interpreter	DB_ANY	0 to 65535		Controlling Interpreter technology object
StatusWord.	DWORD	-	RON	Status information
Bit 0	-	-	-	"ControlledByInterpreter" An MCL job is processed or active or the bit is set via the MCL instruction "setControlledByInterpreter()".
Bit 1	-	-	-	"MotionByInterpreter" An MCL motion job is in effect.
Bit 2 to Bit 31	-	-	-	Reserved

14.2.40 "StatusWord" tag (synchronous axis)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 5 "HomingDone") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Enable" Enable status The technology object has been enabled.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"ControlPanelActive" The axis control panel is active.
Bit 5	-	-	-	"HomingDone" Homing status The technology object is homed.
Bit 6	-	-	-	"Done" No motion job is in progress and the axis control panel is deactivated.
Bit 7	-	-	-	"Standstill" Standstill signal The axis is at a standstill.
Bit 8	-	-	-	"PositioningCommand" A positioning job is active ("MC_MoveRelative","MC_MoveAbsolute").
Bit 9	-	-	-	"JogCommand" An "MC_MoveJog" job is running.
Bit 10	-	-	-	"VelocityCommand" An "MC_MoveVelocity" job is running.
Bit 11	-	-	-	"HomingCommand" An "MC_Home" job is being processed.

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using MC_TorqueRange without SIEMENS telegram 10x, compare the values from telegram 750:
<InLimit> = ActualTorque (M_ACT) * 0.9 > UpperTorqueLimit (M_LIMIT_POS) OR ActualTorque (M_ACT) * 0.9 < LowerTorqueLimit (M_LIMIT_NEG)

Tag	Data type	Values	W	Description
Bit 12	-	-	-	"ConstantVelocity" The velocity setpoint is reached. A constant velocity setpoint is output.
Bit 13	-	-	-	"Accelerating" An acceleration operation is active.
Bit 14	-	-	-	"Decelerating" A deceleration operation is active.
Bit 15	-	-	-	"SWLimitMinActive" A negative software limit switch has been approached or exceeded.
Bit 16	-	-	-	"SWLimitMaxActive" A positive software limit switch has been approached or exceeded.
Bit 17	-	-	-	"HWLimitMinActive" A negative hardware limit switch has been approached or exceeded.
Bit 18	-	-	-	"HWLimitMaxActive" A positive hardware limit switch has been approached or exceeded.
Bit 19	-	-	-	Reserved
Bit 20	-	-	-	Reserved
Bit 21	-	-	-	"Synchronizing" The axis synchronizes to a leading value.
Bit 22	-	-	-	"Synchronous" The axis moves synchronously to a leading value.
Bit 23	-	-	-	"MoveSuperimposedCommand" An "MC_MoveSuperimposed" job is running.
Bit 24	-	-	-	"PhasingCommand" An "MC_PhasingAbsolute" or "MC_PhasingRelative" job for the leading value offset is active.
Bit 25	-	-	-	"AxisSimulation" The technology object is in simulation.
Bit 26	-	-	-	"TorqueLimitingCommand" An "MC_TorqueLimiting" job is running.
Bit 27	-	-	-	"InLimitation"[1] The drive operates at least at the threshold value (default setting 90%) of the force/torque limit.
Bit 28	-	-	-	"NonPositionControlled" The axis is not in position-controlled mode.

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using MC_TorqueRange without SIEMENS telegram 10x, compare the values from telegram 750:
<InLimit> = ActualTorque (M_ACT) * 0.9 > UpperTorqueLimit (M_LIMIT_POS) OR ActualTorque (M_ACT) * 0.9 < LowerTorqueLimit (M_LIMIT_NEG)

Tag	Data type	Values	W	Description
Bit 29	-	-	-	"KinematicsMotionCommand" The axis is used for a kinematics job.
Bit 30	-	-	-	"InClamping" The axis is clamped at a fixed stop.
Bit 31	-	-	-	"MotionInCommand" An "MC_MotionInVelocity" job or an "MC_MotionInPosition" job is active.

[1] The bit is correctly displayed only when using SIEMENS telegram 10x. When using MC_TorqueRange without SIEMENS telegram 10x, compare the values from telegram 750:
<InLimit> = ActualTorque (M_ACT) * 0.9 > UpperTorqueLimit (M_LIMIT_POS) OR ActualTorque (M_ACT) * 0.9 < LowerTorqueLimit (M_LIMIT_NEG)

14.2.41 "StatusWord2" tag (synchronous axis)

The "<TO>.StatusWord2" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 0 "StopCommand") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Value range	W	Description
StatusWord2	DWORD	-	RON	Status information of the technology object
Bit 0	BOOL	-	RON	"StopCommand" An "MC_Stop" job is running. The technology object is disabled.
Bit 1	BOOL	-	RON	"DesynchronizingCommand" An "MC_GearOut" job or "MC_CamOut" job is active. The following axis is desynchronized.
Bit 2	BOOL	-	RON	"PassingBacklash" The backlash is traversed. "<TO>.ActualPosition" does not hereby change.
Bit 3	BOOL	-	RON	"PhasingCommandWaiting" An "MC_PhasingAbsolute" or "MC_PhasingRelative" job for leading value offset is waiting.
Bit 4	BOOL	-	RON	"OffsetCommand" An "MC_OffsetAbsolute" or "MC_OffsetRelative" job for following value offset is active.
Bit 5	BOOL	-	RON	"OffsetCommandWaiting" An "MC_OffsetAbsolute" or "MC_OffsetRelative" job for following value offset is waiting.
Bit 6	BOOL	-	RON	"MotionInSuperimposedCommand" An "MC_MotionInSuperimposed" job is running.
Bit 7	BOOL	-	RON	"HaltSuperimposedCommand" An "MC_HaltSuperimposed" job is running.

Tag		Data type	Value range	W	Description
	Bit 8	BOOL	-	RON	"MotionInSuperimposedAxesCommand" An "MC_MotionInSuperimposedAxes" job is running.
	Bit 9	BOOL	-	RON	"PositionProfileCommand" An "MC_PositionProfile" job is running.
	Bit 10	BOOL	-	RON	"OnProfile" An "MC_PositionProfile" job is running and the axis traverses the setpoint values of the time-based position profile.
	Bit 11 ... Bit 31	BOOL	-	RON	Reserved

14.2.42 "ErrorWord" tag (synchronous axis)

The "<TO>.ErrorWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the alarms requiring acknowledgment and serious errors alarm classes into consideration.

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

	Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
	Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
	Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
	Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
	Bit 4	-	-	-	"DriveFault" Error in drive
	Bit 5	-	-	-	"SensorFault" Error in encoder system
	Bit 6	-	-	-	"DynamicError" Specified dynamic values are limited to permissible values.

Tag	Data type	Values	W	Description
Bit 7	-	-	-	"CommunicationFault" Communication error Missing or faulty communication.
Bit 8	-	-	-	"SWLimit" Software limit switch reached or overtraveled.
Bit 9	-	-	-	"HWLimit" Hardware limit switch reached or overtraveled.
Bit 10	-	-	-	"HomingError" Error during homing operation The homing cannot be completed.
Bit 11	-	-	-	"FollowingErrorFault" Following error limits exceeded
Bit 12	-	-	-	"PositioningFault" Positioning error
Bit 13	-	-	-	"PeripheralError" Error accessing a logical address
Bit 14	-	-	-	"SynchronousError" Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.
Bit 15	-	-	-	"AdaptionError" Error in automatic data transfer
Bit 16	-	-	-	"SuperimposingError" Error in the superimposition of the axis The superimposing axis specified at the corresponding Motion Control instruction was not configured as a possible superimposing axis.
Bit 16 ... Bit 31	-	-	-	Reserved

14.2.43 "ErrorDetail" tag (synchronous axis)

The "<TO>.ErrorDetail" tag structure contains the alarm number and the effective local alarm response of the technology alarm pending on the technology object with the highest priority.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all technology alarms pending on the technology object.

					0	No reaction
					1	Stop with current dynamic values
					2	Stop with maximum dynamic values
					3	Stop with emergency stop ramp
					4	Remove enable
					5	Track setpoints

14.2.44 "WarningWord" tag (synchronous axis)

The "<TO>.WarningWord" tag shows the error groups in which there is at least one technology alarm for the technology object. The tag takes technology alarms of the acknowledgeable warnings alarm class into consideration.

You can find information on evaluating the individual bits, e.g. bit 13 "PeripheralWarning", in the chapter"Evaluating StatusWord, ErrorWord and WarningWord" in the "S7-1500/S7-1500T Motion Control Overview" documentation.

You can use the "Get_Alarm" instruction, for example, to evaluate all warnings pending on the technology object.

Bit 13	-	-	-	"PeripheralWarning" Error accessing a logical address
Bit 14	-	-	-	"SynchronousWarning" Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.
Bit 15	-	-	-	"AdaptionWarning" Error in automatic data transfer
Bit 16	-	-	-	"SuperimposingWarning" Error in the superimposition of the axis The superimposing axis specified in the Motion Control instruction was not configured as a possible superimposing axis.
Bit 16... Bit 31	-	-	-	Reserved

14.2.45 "ControlPanel" tag (synchronous axis)

The tag structure "<TO>.ControlPanel.<tag name>" contains no relevant data for you. This tag structure is internally used.

14.2.46 "InternalToTrace" tag (synchronous axis)

The tag structure "<TO>.InternalToTrace.<tag name>" contains no relevant data for you. This tag structure is internally used.

14.3 Tags of the cam technology object

14.3.1 "Point[1..i]" tag (cam)

The "<TO>.Point[1..i].<tag name>" tag structure contains the defined points of the cam.

The array size depends on the type of cam:

Cam type	Array size
TO_Cam	i = 1 000
TO_Cam_10k	i = 10 000
TO_Cam_600Seg	i = 50
TO_Cam_6kSeg	

Tags

Legend

Tag		Data type	Values	W	Description
Point[1..i].		ARRAY [1..i] OF TO_Cam_Struct_PointData			
	x	LREAL	-1.0E12 ... 1.0E12	CAL	Value of the point in the definition range
	y	LREAL	-1.0E12 ... 1.0E12	CAL	Value of the point in the range of the function

14.3.2 "ValidPoint[1..i]" tag (cam)

The "<TO>.ValidPoint[1..i]" tag structure indicates the validity of the defined points of the cam.

The array size depends on the type of cam:

Cam type	Array size
TO_Cam	i = 1 000
TO_Cam_10k	i = 10 000
TO_Cam_600Seg	i = 50
TO_Cam_6kSeg	

Tags

Legend

Tag	Data type	Values	W	Description	
ValidPoint[1..i]	ARRAY [1..i] OF BOOL	-	CAL	Indicates whether the defined point is valid.	
				FALSE	Invalid
				TRUE	Valid

14.3.3 "Segment[1..i]" tag (cam)

The "<TO>.Segment[1..i].<tag name>" tag structure contains the defined segments of the cam.

The array size depends on the type of cam:

Cam type	Array size
TO_Cam	i = 50
TO_Cam_10k	
TO_Cam_600Seg	i = 600
TO_Cam_6kSeg	i = 6 000

Tags

Legend

Tag	Data type	Values	W	Description
Segment[1..i].	ARRAY [1..i] OF TO_Cam_Struct_SegmentData			
xmin	LREAL	-1.0E12 ... 1.0E12	CAL	Start coordinates of the segment
xmax	LREAL	-1.0E12 ... 1.0E12	CAL	End coordinates of the segment
a0	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A0 for x^0 of the polynomial for the segment

Tag	Data type	Values	W	Description
a1	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A1 for x^1 of the polynomial for the segment
a2	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A2 for x^2 of the polynomial for the segment
a3	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A3 for x^3 of the polynomial for the segment
a4	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A4 for x^4 of the polynomial for the segment
a5	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A5 for x^5 of the polynomial for the segment
a6	LREAL	-1.0E12 ... 1.0E12	CAL	Coefficient A6 for x^6 of the polynomial for the segment
sineAmplitude	LREAL	-1.0E12 ... 1.0E12	CAL	Amplitude of the sine element
sinePeriod	LREAL	-1.0E12 ... 1.0E12	CAL	Period length of the sine element [rad]
sinePhase	LREAL	-1.0E12 ... 1.0E12	CAL	Phase offset of the sine element [rad]

14.3.4 "ValidSegment[1..i]" tag (cam)

The "<TO>.ValidSegment[1..i]" tag structure indicates the validity of the defined segments of the cam.

The array size depends on the type of cam:

Cam type	Array size
TO_Cam	i = 50
TO_Cam_10k	
TO_Cam_600Seg	i = 600
TO_Cam_6kSeg	i = 6 000

Tags

Legend

Tag	Data type	Values	W	Description	
ValidSegment[1..i]	ARRAY [1..i] OF BOOL	-	CAL	Indicates whether the defined segment is valid.	
				FALSE	Invalid
				TRUE	Valid

14.3.5 "InterpolationSettings" tag (cam)

The tag structure "<TO>.InterpolationSettings.<tag name>" contains the configuration for the interpolation of the cam.

Tags

Legend

Tag	Data type	Values	W	Description	
InterpolationSettings.	TO_Cam_Struct_InterpolationSet-tings				
InterpolationMode	DINT	0 ... 2	CAL	Interpolation type	
				0	Linear
				1	Cubic splines (C splines)
				2	Bézier splines (B splines)
BoundaryConditions	DINT	0, 1	CAL	Characteristics of the boundary points	
				0	No profile start or profile end conditions
				1	First derivative equal at profile start and end

14.3.6 "StatusCam" tag (cam)

The "<TO>.StatusCam.<tag name>" tag structure indicates the status of the cam.

Tags

Legend

Tag	Data type	Values	W	Description
StatusCam.	TO_Cam_Struct_StatusCam			
StartLeadingValue	LREAL	-1.0E12 ... 1.0E12	RON	When "<TO>.StatusWord.X5 (Interpolated)" = TRUE: First defined interpolation point or start of the first seg-ment of the cam (Start value of the definition range of the cam) The value can be changed by range scaling with a "MC_SetCamRangeScaling".
EndLeadingValue	LREAL	-1.0E12 ... 1.0E12	RON	When "<TO>.StatusWord.X5 (Interpolated)" = TRUE: Last defined interpolation point or end of the last seg-ment of the cam (End value of the definition range of the cam) The value can be changed by range scaling with a "MC_SetCamRangeScaling".
StartFollowingValue	LREAL	-1.0E12 ... 1.0E12	RON	When "<TO>.StatusWord.X5 (Interpolated)" = TRUE: First defined interpolation point or start of the first seg-ment of the cam (Associated following value of the start value of the definition range of the cam) The value can be changed by range scaling with a "MC_SetCamRangeScaling".

Tag	Data type	Values	W	Description
EndFollowingValue	LREAL	-1.0E12 ... 1.0E12	RON	When "<TO>.StatusWord.X5 (Interpolated)" = TRUE: Last defined interpolation point or end of the last segment of the cam (Associated following value of the end value of the definition range of the cam) The value can be changed by range scaling with a "MC_SetCamRangeScaling".
NumberOfValidPoints	DINT	With "TO_Cam": 0 ... 1 000	RON	Number of valid points ("ValidPoint" = TRUE)
		With "TO_Cam_10k": 0 ... 10 000		
		With "TO_Cam_600Seg" or "TO_Cam_6kSeg": 0 ... 50		
NumberOfValidSegments	DINT	With "TO_Cam" or "TO_Cam_10k": 0 ... 50	RON	Number of valid segments ("ValidSegment" = TRUE)
		With "TO_Cam_600Seg": 0 ... 600		
		With "TO_Cam_6kSeg": 0 ... 6 000		

14.3.7 "StatusRangeScaling" Tag (cam)

The tag structure "<TO>.StatusRangeScaling.<tag name>" shows the status of the scaling range of the cam.

Tags

Legend

Tag	Data type	Values	W	Description	
StatusRangeScaling.	TO_Cam_Struct_StatusRangeScaling				
Range.	ARRAY [1..2] TO_Cam_Struct_Range				
Mode	DINT	1, 2	RON	Scaling mode	
				1	Range scaling in the leading value range
				2	Range scaling in the following value range
StartPoint	LREAL	-1.0E12 ... 1.0E12	RON	Start point	
EndPoint	LREAL	-1.0E12 ... 1.0E12	RON	End point	
Scaling	LREAL	-1.0E12 ... 1.0E12	RON	Scaling factor	

14.3.8 "StatusWord" tag (cam)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 4 "CamDataChanged") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Control" Use status The cam is in use.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"CamDataChanged" The definition range of the cam has changed in the technology data block.
Bit 5	-	-	-	"Interpolated" The cam is interpolated.
Bit 6	-	-	-	"InInterpolation" The cam is in interpolation.
Bit 7	-	-	-	"CopyCamDataActive" A copy operation of an "MC_CopyCamData" job is active.
Bit 8	-	-	-	"SetCamRangeScalingActive" The scaling of a range of the cam is calculated ("MC_SetCamRangeScaling.Busy" = TRUE).
Bit 9	-	-	-	"CamRangeScaled" At least one cam range is scaled via a "MC_SetCamRangeScaling" job.
Bit 10 ... Bit 31	-	-	-	Reserved

14.3.9 "ErrorWord" tag (cam)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Bit 2	-	-	-	"UserWarning" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4 ... Bit 31	-	-	-	Reserved

14.4 Tags of the leading axis proxy technology object

14.4.1 Leading value (leading axis proxy)

The following tags indicate the leading value parameters of the technology object for local synchronous operation.

Tags

Legend

Tag	Data type	Values	W	Description
Position	LREAL	-	RON	Adapted leading value for local synchronous operation
Velocity	LREAL	-	RON	Leading value velocity for local synchronous operation
Acceleration	LREAL	-	RON	Leading value velocity for local synchronous operation

14.4.2 "Interface" tag (leading axis proxy)

The tag structure "<TO>.Interface.<Tag name>" contains the input address of the telegram.

Tags

Legend

Tag		Data type	Values	W	Description
Interface.		TO_Struct_LeadingAxisProxy_Interface			
	AddressIn	VRef	-	RON	Input address for the telegram of the external leading value

14.4.3 "Parameter" tag (leading axis proxy)

The tag structure "<TO>.Parameter.<tag name>" contains parameters for leading value adaptation.

Tags

Legend

Tag		Data type	Values	W	Description
Parameter.		TO_Struct_LeadingAxisProxy_Parameter			
	LocalLeadingValueDelayTime	LREAL	0.0 ... 1.0E9	DIR	Delay time of virtual local following axis which, in turn, provides a cross-PLC leading value with a cascade (<TO>.CrossPlcSynchronousOperation.LocalLeadingValueDelayTime)
	ToleranceTimeExternalLeadingValueInvalid	LREAL	0.0 ... 1.0E12	DIR	Tolerance time until a technology alarm is triggered when the external leading value becomes invalid

14.4.4 "StatusExternalLeadingValue" tag (leading axis proxy)

The tag structure "<TO>.StatusExternalLeadingValue.<Tag name>" contains the parameter values of the external leading value.

Tags

Legend

Tag		Data type	Values	W	Description
StatusExternalLeadingValue.		TO_Struct_LeadingAxisProxy_StatusData			
	ModuloLength	LREAL	0.0 ... 1.0E12	RON	Modulo length of the external leading value
	ModuloStartValue	LREAL	-1.0E12 ... 1.0E12	RON	Modulo start value of the external leading value

Tag	Data type	Values	W	Description	
AdjustmentTime	LREAL	-1.0E12 ... 1.0E12	RON	Time by which the external leading value is adjusted	
				< 0	The external leading value is interpolated by this time.
				> 0	The external leading value is extrapolated by this time.

14.4.5 "StatusWord" tag (leading axis proxy)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 4 "LeadingValueValid") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
StatusWord	DWORD	-	RON	Status information of the technology object
Bit 0	-	-	-	"Control" Use status The leading axis proxy is in operation.
Bit 1	-	-	-	"Error" An error is present.
Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
Bit 4	-	-	-	"LeadingValueValid" The leading value exists and is valid.
Bit 5	-	-	-	"LeadingValueModulo" The leading value is with modulo functionality.
Bit 6	-	-	-	"LeadingAxisControl" The leading axis is in setpoint operation.
Bit 7 ... Bit 31	-	-	-	Reserved

14.4.6 "'ErrorWord" tag (leading axis proxy)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Tags

Legend

Tag	Data type	Values	W	Description
ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" System error
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
Bit 4 ... Bit 7	-	-	-	Reserved
Bit 7	-	-	-	"CommunicationFault" Communication error Missing or faulty communication.
Bit 8 ... Bit 31	-	-	-	Reserved

14.4.7 "ErrorDetail" tag (leading axis proxy)

The tag structure "<TO>.ErrorDetail.<tag name>" contains the alarm number and the effective local alarm response for the technology alarm that is currently pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Tags

Legend

Tag	Data type	Values	W	Description	
ErrorDetail.	TO_Struct_ErrorDetail				
Number	UDINT	-	RON	Alarm number	
Reaction	DINT	0, 13	RON	Effective alarm response	
				0	No reaction
				13	Invalid leading value

14.4.8 "WarningWord" tag (leading axis proxy)

The "<TO>.WarningWord" tag indicates pending warnings at the technology object.

Information on the evaluation of the individual bits (e.g. bit 1 "ConfigWarning") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

5.1 Kinematics systems for handling tasks 22

5.2 Kinematics technology object with up to 4 interpolating kinematics axes 22

5.3 Motion control instructions for kinematics control 24

5.4 Functions in STEP 7 25

5.5 Configuration limits for kinematics systems 26

6 S7-1500T Motion Control KinPlus 27

6.1 Product description "S7-1500T Motion Control KinPlus" 27

6.2 Kinematics technology object with more than 4 interpolating kinematics axes 30

6.3 SIMATIC Memory Card S7-1500T Motion Control KinPlus 33

7 Mapping kinematics in the project 36

7.1 Term definition 36

7.2 Legend for representation of the kinematics 38

7.3 Coordinate systems and frames 39
7.3.1 Kinematics types with up to four interpolating kinematics axes 41
7.3.2 Kinematics types with more than four kinematics axes 43

7.4 Supported kinematics types 46

7.5 Units of measure 47

7.6 Configuring and interconnecting kinematics axes 49

7.6.1 Configuring kinematics axes ... 49
7.6.1.1 Modulo setting ... 50
7.6.1.2 Axis in simulation/virtual axis ... 50
7.6.2 Interconnecting kinematics axes ... 50

7.7 Mechanical axis coupling ... 51
7.7.1 Mechanical axis coupling for kinematics types with up to four interpolating kinematics axes. ... 51
7.7.2 Mechanical axis coupling for kinematics types with more than four interpolating kinematics axes ... 51
7.7.3 Tags: Mechanical axis coupling ... 53

7.8 Joints ... 54
7.8.1 Joint coordinate system (JCS) ... 54
7.8.2 Configuring joints ... 55
7.8.2.1 Inverting the joint direction ... 55
7.8.2.2 Define joint traversing range ... 56
7.8.2.3 Monitoring of the joint traversing range ... 56
7.8.2.4 Defining an offset ... 57
7.8.3 Tags: Joints ... 57

7.9 Kinematics types ... 58
7.9.1 Cartesian portal ... 58
7.9.1.1 Cartesian portal 2D ... 58
7.9.1.2 Cartesian portal 2D with orientation ... 60
7.9.1.3 Cartesian portal 3D ... 62
7.9.1.4 Cartesian portal 3D with orientation ... 65
7.9.1.5 Cartesian portal 3D with 2 orientations A, B ... 68
7.9.1.6 Tags: Cartesian portal ... 71
7.9.2 Roller picker ... 73
7.9.2.1 Roller picker 2D ... 73
7.9.2.2 Roller picker 2D with orientation ... 75
7.9.2.3 Roller picker 3D (vertical) ... 77
7.9.2.4 Roller picker 3D with orientation (vertical) ... 80
7.9.2.5 Roller picker 3D with orientation (horizontal) ... 83
7.9.2.6 Tags: Roller picker ... 86
7.9.3 SCARA ... 87
7.9.3.1 SCARA 2D with orientation ... 87
7.9.3.2 SCARA 3D with orientation ... 90
7.9.3.3 Tags: SCARA ... 95
7.9.4 Articulated arm ... 96
7.9.4.1 Articulated arm 2D ... 96
7.9.4.2 Articulated arm 2D with orientation ... 99
7.9.4.3 Articulated arm 3D ... 103
7.9.4.4 Articulated arm 3D with orientation ... 108
7.9.4.5 6-axis articulated arm with central wrist ... 115
7.9.4.6 6-axis articulated arm with offset wrist ... 127
7.9.4.7 Tags: Articulated arm ... 139
7.9.5 Delta picker ... 141
7.9.5.1 Delta picker 2D ... 141
7.9.5.2 Delta picker 2D with orientation ... 144
7.9.5.3 Delta picker 3D ... 146
7.9.5.4 Delta picker 3D with orientation ... 149
7.9.5.5 Delta picker 3D with 2 orientations A, B ... 152

7.9.5.6 Permissible joint position for delta picker 157
7.9.5.7 Tags: Delta picker 158
7.9.6 Cylindrical robot 159
7.9.6.1 Cylindrical robot 3D 159
7.9.6.2 Cylindrical robot 3D with orientation 163
7.9.6.3 Tags: Cylindrical robot 167
7.9.7 Tripod 168
7.9.7.1 Tripod 3D 168
7.9.7.2 Tripod 3D with orientation 172
7.9.7.3 Tags: Tripod 175
7.9.8 User-defined kinematics systems 176
7.9.8.1 Tags: User-defined kinematics systems 176

7.10 Kinematics transformation 177
7.10.1 Transformation for predefined kinematics systems 177
7.10.1.1 Reference points 177
7.10.1.2 Traversing range and transformation area 178
7.10.1.3 Joint position spaces (kinematics-dependent) 179
7.10.1.4 Singularities 183
7.10.2 Transformation for user-defined kinematics systems 190
7.10.2.1 User transformation without JCS 190
7.10.2.2 User transformation with JCS 192
7.10.2.3 MC_Transformation [OB98] 194
7.10.2.4 Program example for a user-defined kinematics systems 197
7.10.3 Tags: Kinematics transformation 201

8 Kinematics functions 202

8.1 Offset and rotation of the coordinate system 202
8.1.1 Define KCS/OCS frame 204
8.1.2 Define tool frames 206
8.1.3 Tags: Coordinate systems and frames 208

8.2 Zone monitoring 208
8.2.1 Defining zones 211
8.2.1.1 Structure of the "Zones" configuration window 211
8.2.1.2 Defining workspace zones 211
8.2.1.3 Defining kinematics zones 212
8.2.1.4 Defining a zone number for a zone 214
8.2.1.5 Defining the zone type for a workspace zone 214
8.2.1.6 Defining a reference coordinate system for a zone 215
8.2.1.7 Defining the zone geometry 216
8.2.1.8 Defining the offset and rotation in the reference coordinate system 219
8.2.1.9 Activating zone monitoring 219
8.2.1.10 Deactivating zone monitoring 220
8.2.2 Zone violation 221
8.2.3 Retracting after a zone violation 222
8.2.4 Tags: Zone monitoring 223

8.3 Overview of kinematics motions 223
8.3.1 Introduction to the programming of the kinematics motions 225
8.3.2 Define target position 226
8.3.3 Motion status and remaining distance 230
8.3.4 Interrupting, continuing and stopping kinematics motions 234

8.3.5 Interaction of kinematics motions and single axis motions 235
8.3.6 Tags: Kinematics motions 235

8.4 Motion dynamics 240
8.4.1 Dynamic settings and dynamic limits 240
8.4.2 Considering dynamics in path planning 241
8.4.3 Defining dynamic limits at the kinematics axes 242
8.4.4 Defining dynamic limits at the kinematics technology object 242
8.4.5 Configuring dynamics for the kinematics and the orientation motion 243
8.4.6 Configuring dynamics for the sPTP motion 244
8.4.7 Dynamic adaptation 244
8.4.8 Preparing dynamics at the motion job 247
8.4.9 Display of currently effective dynamic limits 247
8.4.10 Override 249

8.5 Motion preparation using multiple jobs 250
8.5.1 Job sequence 250
8.5.2 Blending kinematics motions with maximum rounding clearance 252
8.5.3 Dynamic behavior when motions are appended/blended 256
8.5.4 Preliminary motion preparation 256
8.5.5 Setting the motion preparation 257

8.6 Moving a kinematics in a linear manner 258
8.6.1 Defining the target position of the linear motion 258
8.6.2 Defining the dynamic response of the linear motion 259
8.6.3 Defining the transition of linear motion 261
8.6.4 Starting a linear motion job 263
8.6.5 Tags: Linear motion 263

8.7 Moving a kinematics in a circular manner 265
8.7.1 Defining the circular path of the circular motion 265
8.7.1.1 Defining the circular path via intermediate point and target position 265
8.7.1.2 Defining the circular path via center point and angle 267
8.7.1.3 Define circular path via radius and target position 269
8.7.2 Define the dynamic response of the circular motion 272
8.7.3 Define the transition of circular motion 273
8.7.4 Starting a circular motion job 276
8.7.5 Tags: Circular motion 276

8.8 Moving a kinematics with a synchronous "point-to-point" motion 278
8.8.1 Defining the target position of the sPTP motion 279
8.8.1.1 Defining the axis target position of the sPTP motion 279
8.8.1.2 Define joint target positions of the sPTP motion 280
8.8.1.3 Defining the Cartesian target coordinates of the sPTP motion 281
8.8.2 Defining the dynamics factors of the sPTP motion 283
8.8.3 Defining the transition of the sPTP motion 284
8.8.4 Starting the sPTP motion job 286
8.8.5 Tags: sPTP motion 287

8.9 Conveyor Tracking 288
8.9.1 Configuring and starting conveyor tracking 290
8.9.2 Phases of conveyor tracking 291
8.9.3 Behavior of the "TrackingState" tag 295
8.9.4 Motion between two tracked OCS 298
8.9.5 Dynamics in the phases of the conveyor tracking 299

8.9.5.1 Dynamic adaptation during conveyor tracking 299
8.9.5.2 Dynamic reserve 301
8.9.6 Stopping behavior with "MC_GroupStop" and "MC_GroupInterrupt" 306
8.9.7 Blending behavior 307

8.10 Set kinematics to simulation mode 307
8.10.1 Starting simulation mode 307
8.10.2 Ending simulation mode 308
8.10.3 Tags: Kinematics to simulation 308

8.11 Setting a tool to active 309

9 3D visualization 310

9.1 Structure of the 3D visualization 310

9.2 Working with the 3D display 311

9.3 Operating the zone display 313

9.4 Operating the directional pad 314

9.5 Monitoring and comparing position values 315

10 Commissioning 317

10.1 Control panel status 317

10.2 Taking over master control and enabling kinematics 318

10.3 Selecting an active tool 322

10.4 Operator controls for jogging and homing 323

10.5 Setting the home position of a kinematics axis 330

10.6 Active homing of the kinematics axis 330

10.7 Specifying dynamics in the kinematics control panel 331

10.8 Jogging the kinematics 333
10.8.1 Jogging the kinematics axes in the MCS 334
10.8.2 Jogging joints in the JCS 335
10.8.3 Cartesian kinematics jogging in WCS/OCS 336

10.9 Disabling kinematics and handing over master control 338

11 Diagnostics 339

11.1 Kinematics technology object 339
11.1.1 Structure of the diagnostics 339
11.1.2 Status and error bits 340
11.1.3 Zones status 342
11.1.4 Motion and tools 343
11.1.5 Positions 345

12 Kinematics trace 347

12.1 Defining parameter values for recording 347

12.2 List of recordings 350

12.3 Recording and playing kinematics motions 350

12.4 Saving and deleting recordings 352

12.5 Importing and exporting recordings 353

13 Calibration 355

13.1 Using 3D display for the calibration 355

13.2 Moving the kinematics for calibration 356

13.3 Display progress and status 357

13.4 Setting points 357

13.5 Apply or reset values 359

13.6 Calibrate object coordinate systems 359
13.6.1 Configuring calibration of an object coordinate system 359
13.6.2 Move OCS with the "Two-point" calibration method 360
13.6.3 Move OCS and rotate around the y axis 361
13.6.4 Move OCS with the "One-point" calibration method 361
13.6.5 Move OCS and rotate around one axis or two axes 361
13.6.6 Move OCS and rotate around the z axis 363
13.6.7 Examples 363
13.6.7.1 Introduction 363
13.6.7.2 Move OCS 1 368
13.6.7.3 Move OCS 1 and rotate around the y axis 370
13.6.7.4 Move OCS 1 and rotate around z axis 372
13.6.7.5 Move OCS 1 and rotate it around the z axis and y axis 374

13.7 Calibrate workspace zones 378
13.7.1 Configuring calibration of a workspace zone 378
13.7.2 Calibrate cuboid zone with corner points 379
13.7.3 Calibrate cylindrical zone with surface line 380
13.7.4 Calibrate cylindrical zone with circular plane 381
13.7.5 Calibrate spherical zone with diameter 382
13.7.6 Calibrate spherical zone with radius 383

14 Instructions 384

14.1 Kinematics motions 384
14.1.1 MC_GroupInterrupt V10 384
14.1.1.1 MC_GroupInterrupt: Interrupt motion execution V10 384
14.1.2 MC_GroupContinue V10 385
14.1.2.1 MC_GroupContinue: Continue motion execution V10 385
14.1.2.2 MC_GroupContinue: Function chart V10 387
14.1.3 MC_GroupStop V10 389
14.1.3.1 MC_GroupStop: Stop motion V10 389
14.1.3.2 MC_GroupStop: Function chart V10 391
14.1.4 MC_MoveLinearAbsolute V10 392
14.1.4.1 MC_MoveLinearAbsolute: Position kinematics with linear path motion V10 392

14.1.4.2 MC_MoveLinearAbsolute: Function chart V10 396
14.1.5 MC_MoveLinearRelative V10 397
14.1.5.1 MC_MoveLinearRelative: Relative positioning of kinematics with linear path motion V10 397
14.1.5.2 MC_MoveLinearRelative: Function chart V10 401
14.1.6 MC_MoveCircularAbsolute V10 402
14.1.6.1 MC_MoveCircularAbsolute: Position kinematics with circular path motion V10 402
14.1.6.2 MC_MoveCircularAbsolute: Function chart V10 406
14.1.7 MC_MoveCircularRelative V10 408
14.1.7.1 MC_MoveCircularRelative: Relative positioning of kinematics with circular path motion V10 408
14.1.7.2 MC_MoveCircularRelative: Function chart V10 412
14.1.8 MC_MoveDirectAbsolute V10 414
14.1.8.1 MC_MoveDirectAbsolute: Absolute movement of kinematics with synchronous "point-to-point" motion V10 414
14.1.8.2 MC_MoveDirectAbsolute: Function chart V10 420
14.1.9 MC_MoveDirectRelative V10 422
14.1.9.1 MC_MoveDirectRelative: Relative movement of kinematics with synchronous "point-to-point" motion V10 422
14.1.9.2 MC_MoveDirectRelative: Function chart V10 427
14.1.10 MC_TrackConveyorBelt V10 429
14.1.10.1 MC_TrackConveyorBelt: Start conveyor tracking V10 429
14.1.10.2 MC_TrackConveyorBelt: Function chart V10 431
14.1.11 MC_KinematicsMotionSimulation V10 433
14.1.11.1 MC_KinematicsMotionSimulation: Start/end simulation of kinematics V10 433

14.2 Zones 435
14.2.1 MC_DefineWorkspaceZone V10 435
14.2.1.1 MC_DefineWorkspaceZone: Define workspace zone V10 435
14.2.2 MC_DefineKinematicsZone V10 437
14.2.2.1 MC_DefineKinematicsZone: Define kinematics zone V10 437
14.2.3 MC_SetWorkspaceZoneActive V10 438
14.2.3.1 MC_SetWorkspaceZoneActive: Activate workspace zone V10 438
14.2.4 MC_SetWorkspaceZoneInactive V10 440
14.2.4.1 MC_SetWorkspaceZoneInactive: Deactivate workspace zone V10 440
14.2.5 MC_SetKinematicsZoneActive V10 442
14.2.5.1 MC_SetKinematicsZoneActive: Activate kinematics zone V10 442
14.2.6 MC_SetKinematicsZoneInactive V10 443
14.2.6.1 MC_SetKinematicsZoneInactive: Deactivate kinematics zone V10 443

14.3 Tools 445
14.3.1 MC_DefineTool V10 445
14.3.1.1 MC_DefineTool: Redefine tool V10 445
14.3.2 MC_SetTool V10 446
14.3.2.1 MC_SetTool: Change active tool V10 446

14.4 Coordinate systems 448
14.4.1 MC_SetOcsFrame V10 448
14.4.1.1 MC_SetOcsFrame: Redefine object coordinate systems V10 448
14.4.2 MC_KinematicsTransformation V10 449
14.4.2.1 MC_KinematicsTransformation: Convert axis coordinates to Cartesian coordinates V10 449
14.4.3 MC_InverseKinematicsTransformation V10 452
14.4.3.1 MC_InverseKinematicsTransformation: Convert Cartesian coordinates to axis coordinates V10 452

14.5 Override response of Motion Control jobs V10 456
14.5.1 Override response V10: Homing and motion jobs 456
14.5.2 Override response V10: Synchronous operation jobs 459
14.5.3 Override response V10: Measuring input jobs 462
14.5.4 Override response V10: Kinematics motion commands 463
14.5.5 Override response V10: Interpreter jobs 464

Introduction 1

Purpose of the documentation

This documentation provides important information that you need to configure and commission the integrated Motion Control functionality of the S7-1500 Automation systems.

Required basic knowledge

In order to understand this documentation, the following knowledge is required:

- General knowledge in the field of automation
- General knowledge in the field of drive engineering and motion control

Validity of the documentation

This documentation is valid for the S7-1500 product range.

Conventions

- The path specifications in the project tree assume that the "Technology objects" folder is open in the subtree of the CPU. The "Technology object" placeholder represents the name of the technology object.

  Example: "Technology object > Configuration > Basic parameters".
- The <TO> placeholder represents the name set in tags for the respective technology object.

  Example: <TO>.Actor.Type
- This documentation contains pictures of the devices described. The pictures may differ in minor details from the devices supplied.

You should also observe the notes that are marked as follows:

NOTE

A note contains important information about the product described in the documentation, about the handling of the product, and about sections in this documentation demanding your particular attention.

Industry Mall

The Industry Mall is the catalog and ordering system of Siemens Aktiengesellschaft for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

1.1 S7-1500 Motion Control Documentation Guide

Product information

Please also note the supplementary information on the Motion Control documentation:

- Product information on the S7-1500/1500T Motion Control documentation
  https://support.industry.siemens.com/cs/ww/en/view/109794046
  (https://support.industry.siemens.com/cs/ww/en/view/109794046)

Documentation

The documentation of the Motion Control functions is divided into the following documents:

- S7-1500/S7-1500T Motion Control Overview
  https://support.industry.siemens.com/cs/en/view/109990070
  (https://support.industry.siemens.com/cs/ww/en/view/109990070)

  This document describes the innovations in the technology versions, how to upgrade the technology version, functions that are used for all technology objects, and the operational sequence of Motion Control applications.
- S7-1500/S7-1500T Motion Control alarms and error IDs
  https://support.industry.siemens.com/cs/ww/en/view/109990076
  (https://support.industry.siemens.com/cs/ww/en/view/109990076)

  This document describes the technology alarms of the technology objects and the error identifications of the Motion Control instructions.
- S7-1500/S7-1500T Axis functions
  https://support.industry.siemens.com/cs/en/view/109990072
  (https://support.industry.siemens.com/cs/ww/en/view/109990072)

  This document describes the drive and encoder connection and functions for single-axis movements.
- S7-1500/S7-1500T Synchronous operation functions
  https://support.industry.siemens.com/cs/ww/en/view/109990074
  (https://support.industry.siemens.com/cs/ww/en/view/109990074)

  This document describes gearing, velocity synchronous operation and camming as well as cross-PLC synchronous operation.

- S7-1500/S7-1500T Measuring input and output cam functions
  https://support.industry.siemens.com/cs/ww/en/view/109990075
  (https://support.industry.siemens.com/cs/ww/en/view/109990075)
  This document describes the detection of the actual position via a measuring input and the output of switching signals via output cam or cam track.
- S7-1500T kinematics functions
  https://support.industry.siemens.com/cs/ww/en/view/109990073
  (https://support.industry.siemens.com/cs/ww/en/view/109990073)
  This document describes the control of kinematics with up to 6 interpolating axes.
- S7-1500T Interpreter functions
  https://support.industry.siemens.com/cs/ww/en/view/109990077
  (https://support.industry.siemens.com/cs/ww/en/view/109990077)
  This documentation describes the control of technology objects via an Interpreter program.

1.2 Function Manuals documentation guide

1.2.1 Information classes Function Manuals

The documentation for the SIMATIC S7-1500 automation system, for the 1513/1516pro-2 PN, SIMATIC Drive Controller CPUs based on SIMATIC S7-1500 and the SIMATIC ET 200MP, ET 200SP, ET 200AL and ET 200eco PN distributed I/O systems is arranged into three areas.

This arrangement enables you to access the specific content you require.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742705).

Basic information

The system manuals and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, SIMATIC Drive Controller, ET 200MP, ET 200SP, ET 200AL and ET 200eco PN systems. Use the corresponding operating instructions for 1513/1516pro-2 PN CPUs.

The STEP 7 online help supports you in the configuration and programming.

Examples:

- Getting Started S7-1500
- System manuals
- Operating instructions ET 200pro and 1516pro-2 PN CPU
- Online help TIA Portal

Device information

Equipment manuals contain a compact description of the module-specific information, such as properties, wiring diagrams, characteristics and technical specifications.

Examples:

- Equipment manuals for CPUs
- Equipment manuals for interface modules
- Equipment manuals for digital modules
- Equipment manuals for analog modules
- Equipment manuals for communication modules
- Equipment manuals for technology modules
- Equipment manuals for power supply modules
- Equipment manuals for BaseUnits

General information

The function manuals contain detailed descriptions on general topics relating to the SIMATIC Drive Controller and the S7-1500 automation system.

Examples:

- Function Manual Diagnostics
- Function Manual Communication
- Function Manuals Motion Control
- Function Manual Web Server
- Function Manual Cycle and Response Times
- PROFINET Function Manual
- PROFIBUS Function Manual

Product Information

Changes and supplements to the manuals are documented in a Product Information. The Product Information takes precedence over the device and system manuals.

You will find the latest Product Information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/de/en/view/68052815)
- SIMATIC Drive Controller (https://support.industry.siemens.com/cs/de/en/view/109772684/en)
- Motion Control (https://support.industry.siemens.com/cs/de/en/view/109794046/en)
- ET 200SP (https://support.industry.siemens.com/cs/de/en/view/73021864)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109765611)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP/SIMATIC Drive Controller (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109781058)

1.2.2 Basic tools

Tools

The tools described below support you in all steps: from planning, over commissioning, all the way to analysis of your system.

TIA Selection Tool

The TIA Selection Tool tool supports you in the selection, configuration, and ordering of devices for Totally Integrated Automation (TIA).

As successor of the SIMATIC Selection Tools , the TIA Selection Tool assembles the already known configurators for automation technology into a single tool.

With the TIA Selection Tool , you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/109767888)

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to perform commissioning and maintenance activities on various SIMATIC S7 stations as bulk operations independent of TIA Portal.

The SIMATIC Automation Tool offers a wide range of functions:

- Scanning of a PROFINET/Ethernet system network and identification of all connected CPUs
- Assignment of addresses (IP, subnet, Gateway) and device name (PROFINET device) to a CPU
- Transfer of the date and the programming device/PC time converted to UTC time to the module
- Program download to CPU
- RUN/STOP mode switchover
- CPU localization through LED flashing
- Reading out of CPU error information
- Reading the CPU diagnostic buffer
- Reset to factory settings
- Firmware update of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/98161300)

PRONETA

SIEMENS PRONETA (PROFINET network analysis) is a commissioning and diagnostic tool for PROFINET networks. PRONETA Basic has two core functions:

- In the network analysis, you get an overview of the PROFINET topology. Compare a real configuration with a reference installation or make simple parameter changes, e.g. to the names and IP addresses of the devices.
- The "IO test" is a simple and rapid test of the wiring and the module configuration of a plant, including documentation of the test results.

You can find SIEMENS PRONETA Basic on the Internet:
(https://support.industry.siemens.com/cs/ww/en/view/67460624)

SIEMENS PRONETA Professional is a licensed product that offers you additional functions. It offers you simple asset management in PROFINET networks and supports operators of automation systems in automatic data collection/acquisition of the components used through various functions:

- The user interface (API) offers an access point to the automation cell to automate the scan functions using MQTT or a command line.
- With PROFIenergy diagnostics, you can quickly detect the current pause mode or the readiness for operation of devices that support PROFIenergy and change these as needed.
- The data record wizard supports PROFINET developers in reading and writing acyclic PROFINET data records quickly and easily without PLC and engineering.

You can find SIEMENS PRONETA Professional on the Internet.
(https://www.siemens.com/proneta-professional)

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and the optimal use of resources

You can find SINETPLAN on the Internet (https://new.siemens.com/global/en/products/automation/industrial-communication/profinet/sinetplan.html).

1.2.3 SIMATIC Technical Documentation

Additional SIMATIC documents will complete your information. You can find these documents and their use at the following links and QR codes.

The Industry Online Support gives you the option to get information on all topics. Application examples support you in solving your automation tasks.

Overview of the SIMATIC Technical Documentation

Here you will find an overview of the SIMATIC documentation available in Siemens Industry Online Support:

Industry Online Support International (https://support.industry.siemens.com/cs/ww/en/view/109742705)

Watch this short video to find out where you can find the overview directly in Siemens Industry Online Support and how to use Siemens Industry Online Support on your mobile device:

Quick introduction to the technical documentation of automation products per video (https://support.industry.siemens.com/cs/us/en/view/109780491)

YouTube video: Siemens Automation Products - Technical Documentation at a Glance (https://youtu.be/TwLSxxRQQsA)

Retention of the documentation

Retain the documentation for later use.

For documentation provided in digital form:

1. Download the associated documentation after receiving your product and before initial installation/commissioning. Use the following download options:
   - Industry Online Support International: (https://support.industry.siemens.com)

     The article number is used to assign the documentation to the product. The article number is specified on the product and on the packaging label. Products with new, non-compatible functions are provided with a new article number and documentation.
   - ID link:

     Your product may have an ID link. The ID link is a QR code with a frame and a black frame corner at the bottom right. The ID link takes you to the digital nameplate of your product. Scan the QR code on the product or on the packaging label with a smartphone camera, barcode scanner, or reader app. Call up the ID link.
2. Retain this version of the documentation.

Updating the documentation

The documentation of the product is updated in digital form. In particular in the case of function extensions, the new performance features are provided in an updated version.

1. Download the current version as described above via the Industry Online Support or the ID link.
2. Also retain this version of the documentation.

mySupport

With "mySupport" you can get the most out of your Industry Online Support.

Registration	You must register once to use the full functionality of "mySupport". After registration, you can create filters, favorites and tabs in your personal workspace.
Support requests	Your data is already filled out in support requests, and you can get an overview of your current requests at any time.
Documentation	In the Documentation area you can build your personal library.
Favorites	You can use the "Add to mySupport favorites" to flag especially interesting or frequently needed content. Under "Favorites", you will find a list of your flagged entries.
Recently viewed articles	The most recently viewed pages in mySupport are available under "Recently viewed articles".
CAx data	The CAx data area gives you access to the latest product data for your CAx or CAe system. You configure your own download package with a few clicks: • Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files • Manuals, characteristics, operating manuals, certificates • Product master data

You can find "mySupport" on the Internet. (https://support.industry.siemens.com/My/ww/en)

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You can find the application examples on the Internet.
(https://support.industry.siemens.com/cs/ww/en/ps/ae)

Safety instructions 2

2.1 General safety instructions

The safety instructions can be found in section "Safety instructions" in the System Manual "SIMATIC S7-1500, ET 200MP Automation System" (https://support.industry.siemens.com/cs/ww/en/view/59191792) document.

Cybersecurity-relevant information can be found in the Industrial Cybersecurity section.

2.2 Warnings in this document

You can find explanations of the warnings used in this document in the "Legal information" section.

Industrial cybersecurity 3

Due to the digitalization and increasing networking of machines and industrial plants, the risk of cyber attacks is also growing. Appropriate protective measures are therefore mandatory, particularly in the case of critical infrastructure facilities.

3.1 Cybersecurity information

Siemens provides products and solutions with industrial cybersecurity functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial cybersecurity concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial cybersecurity measures that may be implemented, please visit
https://www.siemens.com/cybersecurity-industry.

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Cybersecurity RSS Feed under
https://new.siemens.com/cert.

New features V10.0

4

4.1 New kinematics functions V10.0

Technology version V10.0 contains the following new features:

Kinematics control panel

- The traversing velocity can only be set with active master control via "Adjust > Velocity" in the kinematics control panel, but not via <TO>.Override.Velocity in the user program.

S7-1500T Motion Control KinPlus

- The Motion Control package "S7-1500T Motion Control KinPlus" V10.0 supports the technology versions V9.0 and V10.0 also on the CPU 1516T/TF-3 PN and CPU 1517T/TF-3 PN with CPU firmware version V4.1.
- The configuration of the kinematics type "6-axis articulated arm with central wrist" has been extended by the parameter length L6. This supports kinematics with horizontal offset of the central wrist in relation to the A1 axis.
- The predefined kinematics types have been expanded to include the "6-axis articulated arm with offset wrist (Page 127)" kinematics type.

Overview of functions 5

5.1 Kinematics systems for handling tasks

Kinematics are user-programmable mechanical systems in which multiple mechanically coupled axes produce the motion of a working point. The S7-1500T technology CPUs provide functions for controlling kinematics systems, e.g. for handling tasks, with the kinematics technology object. Typical applications include:

- Pick & Place
- Installation
- Palletizing

The kinematics control panel and extensive online and diagnostic functions support straightforward commissioning of kinematics systems. The kinematics technology object is fully integrated in the system diagnostics of the S7-1500T CPU.

5.2 Kinematics technology object with up to 4 interpolating kinematics axes

The kinematics technology object calculates motion setpoints for the tool center point (TCP) of the kinematics taking into account the dynamic settings. The kinematics technology object calculates the motion setpoints for the individual axes of the kinematics and vice versa from the current values of the axes using the kinematics transformation. The kinematics technology object outputs the axis-specific motion setpoints to the interconnected positioning axes.

The kinematics technology object provides the kinematics transformation (Page 177) for the predefined kinematics types on the system level. In the case of user-defined kinematics systems, you must provide the user transformation (Page 190) in a separate program.

You create the individual axes of the kinematics in the TIA Portal as "Positioning axis" or "Synchronous axis" technology objects. When you configure the kinematics technology object, you interconnect the axes in accordance with the configured kinematics type.

You can find an overview of the functions of the kinematics technology object in the section "Motion control instructions for kinematics control (Page 24)".

The graphic below shows the basic principle of operation of the kinematics technology object with up to four interpolating kinematics axes:

Configuration

The following configurations are available in the kinematics technology object:

- Basic parameters
  - Kinematics (Page 46)
  - Units of measure (Page 47)
- Interconnections
  - Interconnecting kinematics axes (Page 49)
  - Mechanical axis coupling (Page 51)
- Geometry (Page 58)
- Conveyor tracking (Page 288)
- Dynamics
  - Presets and limits (Page 240)
  - Dynamic adaptation (Page 244)
- Kinematics coordinate system, object coordinate systems and tools
  - Coordinate systems and frames (Page 39)
  - Kinematics types with up to four interpolating kinematics axes (Page 41)
  - Offset and rotation of the coordinate system (Page 202)
- Zones (Page 208)
- Job sequence (Page 250)

5.3 Motion control instructions for kinematics control

You execute the functions of the kinematics technology object using the Motion Control instructions in your user program or the TIA Portal (under "Technology object > Commissioning").

The following table shows the motion control instructions that are supported by the kinematics technology object:

Motion control instruction	Brief description
Kinematics motions	
"MC_GroupInterrupt"	Interrupt motion execution
"MC_GroupContinue"	Continue motion execution
"MC_GroupStop"	Stop motion
"MC_MoveLinearAbsolute"	Position kinematics with linear path motion
"MC_MoveLinearRelative"	Relative positioning of kinematics with linear path motion
"MC_MoveCircularAbsolute"	Position kinematics with circular path motion
"MC_MoveCircularRelative"	Relative positioning of kinematics with circular path motion
"MC_MoveDirectAbsolute"	Absolute movement of kinematics with synchronous "point-to-point" motion

Motion control instruction	Brief description
"MC_MoveDirectRelative"	Relative movement of kinematics with synchronous "point-to-point" motion
"MC_TrackConveyorBelt"	Start conveyor tracking
"MC_KinematicsMotionSimulation"	Start/end simulation of kinematics
Zones	
"MC_DefineWorkspaceZone"	Define workspace zone
"MC_DefineKinematicsZone"	Define kinematics zone
"MC_SetWorkspaceZoneActive"	Activate workspace zone
"MC_SetWorkspaceZoneInactive"	Deactivate workspace zone
"MC_SetKinematicsZoneActive"	Activate kinematics zone
"MC_SetKinematicsZoneInactive"	Deactivate kinematics zone
Tools	
"MC_DefineTool"	Redefine tool
"MC_SetTool"	Change active tool
Coordinate systems	
"MC_SetOcsFrame"	Redefine object coordinate systems
"MC_KinematicsTransformation"	Convert axis coordinates to Cartesian coordinates
"MC_InverseKinematicsTransformation"	Convert Cartesian coordinates to axis coordinates

5.4 Functions in STEP 7

The following table shows the functions supported by the kinematics technology object in STEP 7:

Functions in the TIA Portal	Brief description
Kinematics control panel (Page 317)	• Active homing of the kinematics axes • Jog kinematics in WCS or OCS • Jog individual kinematics axes in MCS • Jog joints in the JCS
Diagnostics (Page 339)	Monitor and observe status and error messages of the kinematics technology object
Kinematics trace (Page 347)	• 3D visualization of the current motion of the tool center point (TCP) and the object coordinate systems (OCS) • Record, play back and save kinematics motions • Exporting and importing recordings
Calibration (Page 355)	• Determine exact position of object coordinate systems • Define workspace zones • Move tool center point offline in the 3D view using the directional pad • Move real kinematics online with the kinematics control panel

5.5 Configuration limits for kinematics systems

Motion control resources

Each CPU offers a defined set of "Motion Control resources". For information on the total Motion Control resources available, refer to the technical specifications of the utilized CPU.

You can find an overview of the Motion Control resources of a CPU in the TIA Portal under "Tools > Resources".

Extended Motion Control resources (S7-1500T)

In addition to the Motion Control resources of the interconnected axes, a kinematics technology object utilizes 30 "Extended Motion Control resources". For information on the maximum number of usable kinematics systems, refer to the technical specifications of the utilized CPU.

You can find the technical specifications of the S7-15xxT CPUs in the respective manual.

Application cycle

As the number of technology objects used increases, the computing time needed by the CPU to process the technology objects increases. The Motion Control application cycle can be adapted according to the number of technology objects used.

S7-1500T Motion Control KinPlus

6

6.1 Product description "S7-1500T Motion Control KinPlus"

The Motion Control package "S7-1500T Motion Control KinPlus" enables you to control kinematics with 5 or 6 interpolating axes. These functions are not included in the firmware of a technology CPU due to export law.

Principle of operation

The Motion Control package "S7-1500T Motion Control KinPlus" contains the full Motion Control firmware with the function extensions. The Motion Control functions for kinematics with up to 4 axes and all other Motion Control functions, such as homing or synchronous operation, are also loaded from the Motion Control package "S7-1500T Motion Control KinPlus".

The Motion Control package must be copied to a SIMATIC Memory Card of the type "S7-1500T Motion Control KinPlus". The firmware with the function extensions is loaded from this card in runtime.

Supported kinematics types

"S7-1500T Motion Control KinPlus" extends the kinematics technology object to include the following kinematics types:

- Cartesian portal with 2 orientations A, B
- 6-axis articulated arm with central wrist
- 6-axis articulated arm with offset wrist
- Delta picker with 2 orientations A, B
- User-defined kinematics 3D with 3 orientations

Using versions

You use the "S7-1500T Motion Control KinPlus" Motion Control package depending on the CPU firmware version.

The following table shows you the CPUs with which you can use the "S7-1500T Motion Control KinPlus" Motion Control package depending on versions and which technology versions are supported.

Version Motion Control package "S7-1500T Motion Control KinPlus"	CPU firmware version	Supported CPUs	Technology version			
			V7.0	V8.0	V9.0	V10.0
V10.0	V4.1	• CPU 1516T-3 PN • CPU 1516TF-3 PN • CPU 1517T-3 PN • CPU 1517TF-3 PN • CPU 1518T-3 PN • CPU 1518TF-3 PN	-	-	✓	✓
V9.0	V4.0	• CPU 1518T-3 PN • CPU 1518TF-3 PN	-	-	✓	-
V8.0	V3.1	• CPU 1507D TF with SINAMICS S120 Integrated • CPU 1518T-4 PN/DP • CPU 1518TF-4 PN/DP	✓	✓	-	-
V7.0	V3.0	• CPU 1507D TF with SINAMICS S120 Integrated • CPU 1518T-4 PN/DP • CPU 1518TF-4 PN/DP	✓	-	-	-

Simulation with PLCSIM and PLCSIM Advanced is not supported.

Type of delivery

The SIMATIC Memory Card for "S7-1500T Motion Control KinPlus" is available with the following storage capacity:

Product	Article number
S7-1500T Motion Control KinPlus **2 GB**	6ES7 954-8LP80-0AA0
S7-1500T Motion Control KinPlus **32 GB**	6ES7 954-8LT80-0AA0

The Motion Control package "S7-1500T Motion Control KinPlus" is available as follows:

Product	Article number
S7-1500T Motion Control KinPlus package V10.0 as software download (initially only available in EU countries, planned for other countries in 2026)	6ES7 823-0KE03-1AA0
S7-1500T Motion Control KinPlus package V10.0 on USB flash drive	6ES7 823-0KU03-1AA0

NOTE

Reusing the "S7-1500T Motion Control KinPlus" Motion Control package

You need one SIMATIC Memory Card and one "S7-1500T Motion Control KinPlus" Motion Control package per CPU.
The "S7-1500T Motion Control KinPlus" Motion Control package cannot be used multiple times. It is not permissible to order it once and then duplicate it.

Important export information

Due to existing export restrictions for software, with respect to certain controller functions (more than 4 interpolating axes), the European/German export list classifies the product "S7-1500T Motion Control KinPlus" as a dual-use good with label AL=2D002 and ECCN=N.

When using "S7-1500T Motion Control KinPlus", special attention must be paid to the fact that the obligation to obtain authorization also exists when components requiring authorization are exported as part of service delivery, spare parts delivery and software upgrade/software update delivery. This applies, in particular, when the software has been exported by the machine manufacture after installation in the machine.

This can lead to severe restrictions on providing services due to the length of the official authorization process.

General information:

For certain components, an obligation exists to obtain authorization for reexport according to U.S. law. This must also be heeded. Information on the obligation to obtain authorization for delivered components can be found in the delivery documents:

Goods labeled with AL not equal to N are subject to European or German export authorization when being exported from the EU. Goods labeled with ECCN not equal to N are subject to U.S. reexport authorization.

Even without a label, or with label AL=N or ECCN=N, authorization may be required due to the final whereabouts and purpose for which the goods are to be used.

In the event of a purchase agreement, the fulfillment of the agreement on the part of Siemens is subject to there being no obstacle to fulfillment due to national or international foreign trade law or embargos and/or other sanctions.

Customers are subsequently responsible for the lawful handling.

6.2 Kinematics technology object with more than 4 interpolating kinematics axes

If a SIMATIC Memory Card with the Motion Control package "S7-1500T Motion Control KinPlus" is plugged into the CPU, the kinematics technology object calculates the motion setpoints for the tool center point for kinematics with more than 4 kinematics axes. The kinematics technology object calculates the motion setpoints for the individual axes of the kinematics and vice versa from the current values of the axis using the kinematics transformation. The dynamic specifications are included in all calculations. The kinematics technology object outputs the axis-specific motion setpoints to the interconnected positioning or synchronous axes.

For the predefined kinematics types, the kinematic transformation (Page 177) is part of the kinematics technology object. For the user-defined kinematics 3D with 3 orientations, you need to provide the kinematics transformation in a separate program.

You create the individual axes of the kinematics in the TIA Portal as "Positioning axis" or "Synchronous axis" type technology objects. When you configure the kinematics technology object, you interconnect the axes in accordance with the configured kinematics type.

The following graphic shows the basic function of the kinematics technology object when using S7-1500T Motion Control KinPlus:

① Mechanical axis couplings

② Offsets
Inverted direction of movement
Transformation

③ Status, joint traversing range limits

For kinematics with more than 4 kinematics axes, the joint coordinate system (JCS) represents the mechanical positions of the kinematics joints, while the MCS displays the axis positions. The joint coordinates can be specified as target coordinates for sPTP motions.

Configuration

In the kinematics technology object, the following configurations are available for kinematics types with more than 4 kinematics axes:

- Basic parameters
  - Kinematics (Page 46)
  - Units of measure (Page 47)
- Interconnections
  - Interconnecting kinematics axes (Page 49)
  - Mechanical axis coupling (Page 51)
  - Joints (Page 54)
- Geometry (Page 216)
- Conveyor tracking (Page 288)
- Dynamics
  - Presets and limits (Page 243)
  - Dynamic adaptation (Page 244)
- Kinematics coordinate system, object coordinate systems and tools
  - Coordinate systems and frames (Page 39)
  - Kinematics types with more than four kinematics axes (Page 43)
  - Offset and rotation of the coordinate system (Page 202)
- Zones (Page 211)
- Job sequence (Page 250)

Motion Control instructions

All Motion Control instructions supported by the kinematics technology object can also be used for kinematics with more than 4 interpolating axes.

You can find more information under Motion control instructions for kinematics control (Page 24).

Functions in STEP 7

The following table shows the functions supported by S7-1500T Motion Control KinPlus in STEP 7:

Functions in the TIA Portal	Brief description
Kinematics control panel (Page 317)	• Active homing of the kinematics axes • Jog kinematics in WCS or OCS • Jog individual kinematics axes in MCS • Jog joints in the JCS

Functions in the TIA Portal	Brief description
Diagnostics (Page 339)	Monitor and observe status and error messages of the kinematics technology object
Kinematics trace (Page 347)	• 3D visualization of the current motion of the tool center point (TCP) and the object coordinate systems (OCS) • Record, play back and save kinematics motions • Exporting and importing recordings
Calibration (Page 355)	• Determine exact position of object coordinate systems • Define workspace zones • Move tool center point offline in the 3D view using the directional pad • Move real kinematics online with the kinematics control panel

6.3 SIMATIC Memory Card S7-1500T Motion Control KinPlus

The SIMATIC Memory Card with the Motion Control package "S7-1500T Motion Control KinPlus" is marked with "S7-1500T MC KinPlus".

① Slider for setting write protection:
- Slider up: not write-protected
- Slider down: write-protected

② Memory size

③ Article number

④ Serial number

⑤ Production version

The card can contain the Motion Control package "S7-1500T Motion Control KinPlus" and all files that are also stored on a normal SIMATIC Memory Card. You can only use a Motion Control package "S7-1500T Motion Control KinPlus" on a SIMATIC Memory Card "S7-1500T MC KinPlus".

You can find more information about using the SIMATIC Memory Card in the function manual "Structure and Use of the CPU Memory (https://support.industry.siemens.com/cs/ww/en/view/59193101)".

Enable Motion Control package "S7-1500T Motion Control KinPlus"

The SIMATIC Memory Card "S7-1500T MC KinPlus" does not contain a Motion Control package "S7-1500T Motion Control KinPlus" in the following situations:

- The card is still unused.
- All versions have been deleted.
- The card has been formatted via the TIA Portal or the CPU display.

Requirement

You have downloaded the Motion Control package "S7-1500T Motion Control KinPlus" as a software download or have it available on a USB flash drive.

Procedure

1. Create the "\MCRC\" folder on the "SIMATIC" Memory Card "S7-1500T MC KinPlus".
2. Copy the UPD file from the Motion Control package "S7-1500T Motion Control KinPlus" into the "\MCRC\" folder ("Motion Control Runtime Component") on the SIMATIC Memory Card.

   Copy the UPD file to the SIMATIC Memory Card using a card reader or the SIMATIC web server.
3. To activate the Motion Control package on the CPU, insert the SIMATIC Memory Card into the SIMATIC CPU. After POWER OFF → POWER ON of the CPU, the firmware extension is loaded and can be used as long as the card is inserted.

Show loaded Motion Control package

To check if the firmware extension "S7-1500T Motion Control KinPlus" has been loaded successfully, check the current Motion Control package.

You can find the version and type of the loaded Motion Control package via the following options:

- Under "Online and Diagnostics > General" in the Motion Control Package Information area
- In the diagnostic buffer in the event description for the loaded version
- In the display of the CPU under Overview > Motion Control Package Information
- In the web server on the page Diagnostics > Motion Control Package Information

If the Motion Control package "S7-1500T Motion Control KinPlus" is successfully loaded, "Package name: MC KinPlus" is displayed. The version and internal version of the Motion Control package are also displayed. If "Package name: MC Base" is displayed, the Motion Control package "S7-1500T Motion Control KinPlus" is not loaded.

Upgrade the Motion Control package

To upgrade the Motion Control package, copy the new UPD file into the folder "\MCRC\". The UPD file with the highest version from the folder "\MCRC\" is always loaded during the startup of the CPU. The version of the Motion Control package is included in the file name. The newest version is always loaded if there are several versions of the Motion Control package "S7-1500T Motion Control KinPlus" on the card.

Delete data on the card

To preserve the possibility of restoring an earlier version, save the existing file on another data medium before deleting it.

To free up memory on the SIMATIC Memory Card, delete Motion Control package files with earlier versions if you have copied different versions of the Motion Control package to the card.

Format SIMATIC Memory Card

Formatting the SIMATIC Memory Card deletes the Motion Control package "S7-1500T Motion Control KinPlus".

Before formatting the SIMATIC Memory Card, save the Motion Control package file on an external data medium.

WARNING

Memory card unusable

Formatting the SIMATIC Memory Card via Windows applications makes it unusable.

Format the memory card exclusively via the TIA Portal or the display of the CPU.

NOTICE

Motion Control package "S7-1500T Motion Control KinPlus" deleted

If you select the option to format the SIMATIC Memory Card when restoring the factory settings for the module, the Motion Control package "S7-1500T Motion Control KinPlus" is deleted.

Before you restore the factory settings for the module and format the SIMATIC Memory Card, save the Motion Control package file on an external data medium.

CPU replacement

If you replace the CPU, you only have to plug the SIMATIC Memory Card "S7-1500T Motion Control KinPlus" into a new device with compatible firmware. You can find the version overview in the "Product description "S7-1500T Motion Control KinPlus" (Page 27)" section.

Mapping kinematics in the project 7

7.1 Term definition

Kinematics

Kinematics are user-programmable mechanical systems in which multiple mechanically coupled axes produce the motion of a working point.

Kinematics axes

Kinematics axes are the axes of the kinematics motion. You connect each kinematics axis with a positioning axis/synchronous axis technology object.

Wrist point

The axes A4, A5 and A6 form the central wrist with the kinematics types "6-axis articulated arm with central wrist". This means that the axes A4, A5 and A6 intersect at one point. This point is referred to as the wrist point. The axis A5 forms the wrist point with the kinematics type "6-axis articulated arm with offset wrist".

Kinematics zero point (KZP)

The coordinate origin of the kinematics coordinate system (KCS) is the KZP. You configure the geometry parameters of the kinematics starting from the KZP.

Zero point of the flange coordinate system (FZP)

The coordinate origin of the flange coordinate system (FCS) is the FZP. Starting from the FZP, you define, for example, the flange zones of the kinematics.

Tool center point (TCP)

The coordinate origin of the tool coordinate system (TCS) is the tool center point or TCP. The TCP is the operating point of the kinematics.

Degrees of freedom of kinematics

The degrees of freedom of kinematics are the dimensions in which the tool can move. 2D kinematics systems move the tool in the xz plane and thus have 2 translational degrees of freedom. 3D kinematics systems move the tool in xyz space and thus have 3 translational degrees of freedom. The optional orientation of the tool is 1 to 3 more degrees of freedom (rotations around the z, y and x axes).

Machine coordinate system (MCS)

The MCS contains the position data of the interconnected kinematics axes and thus combines up to six one-dimensional systems in one system.

Joint coordinate system (JCS)

The JCS contains the geometric positions of the kinematics joints. Joints can perform linear or rotary movements.

Job sequence

The job sequence of the kinematics technology object is the memory to which motion-related Motion Control jobs are entered as pending, waiting jobs. The job sequence allows the calculation of a velocity profile over several jobs.

AxesGroup

Kinematics-related Motion Control instructions have the input parameter "AxesGroup". Because the kinematics technology object groups the kinematics axes, you assign the kinematics technology object directly to the input parameter "AxesGroup".

Joint position space

Depending on the kinematics type, a kinematics can reach Cartesian coordinates via various joint positions. The kinematics type (Page 58) defines the possible joint positions and the positive and negative joint position spaces. The joint positioning spaces are limited by the respective transformation areas.

Joint traversing range

The joint traversing range defines the minimum and maximum traversing position of a joint.

Target joint position range

A target joint position range defines the number of revolutions of a joint.

7.2 Legend for representation of the kinematics

The following table shows the graphic elements and symbols used in the display of kinematics and coordinate systems:

Graphic element	Meaning
	Basis of kinematics
	Kinematics arm
	Kinematics deflected from zero position
	Active rotary axis
	• Passive joint • Axis guide
	Active linear axis
	Rotary axis on the tool adapter
	Swivel axis
	Tool adapter
	Tool (gripper)
	Coordinate axis set up out of the mapping plane
	Coordinate axis set up into the mapping plane
	Color x axis
	Color y axis
	Color z axis

7.3 Coordinate systems and frames

A handling task involves many objects, e.g. kinematics systems, tools, pallets and products. You describe these objects and their relative positions with coordinate systems and frames. The kinematics technology object calculates all motions for the tool center point (TCP).

Coordinate systems

The kinematics technology object uses the following right-handed Cartesian coordinate systems according to DIN 66217:

- World coordinate system (WCS)
- Kinematics coordinate system (KCS)
- Flange coordinate system (FCS)
- Tool coordinate system (TCS)
- Object coordinate systems (OCS)

The following graphic shows the relative position of the coordinate systems using a workspace example:

The position of the FCS and the TCS in the zero position of the kinematics is defined differently for the following kinematics types:

- Kinematics types with up to four interpolating kinematics axes (Page 41)
- Kinematics types with more than four kinematics axes (Page 43)

World coordinate system (WCS)

The WCS is the fixed coordinate system of the environment or workspace of the kinematics. The zero point of the WCS is the reference point for objects and motions on the kinematics technology object. Starting from the zero point of the WCS (e.g. corner of a workspace), you define the position of the objects using frames.

Kinematics coordinate system (KCS)

The KCS is connected to the kinematics. The position of the KCS within the kinematics is specified for each predefined kinematics type. The coordinate origin of the KCS is the kinematics zero point (KZP). You configure the geometry parameters of the kinematics starting from the KZP.

You configure the position of the KCS in the WCS using the KCS frame.

Object coordinate system (OCS)

The OCS is a user-defined coordinate system. With an OCS, for example, you define the position of a pallet in the workspace. You define the position of the OCS in the WCS with an OCS frame. You can define up to 3 OCS frames which are active at the same time.

① OCS frame

Frames

Frames specify the offset and rotation of one coordinate system relative to another coordinate system.

The following table shows the frames for the kinematics technology object:

Frame	Description
KCS frame	Position of the kinematics coordinate system (KCS) in the world coordinate system (WCS)
Transformation frame	Position of the flange coordinate system (FCS) in the KCS The transformation frame results from the kinematics transformation and is displayed in the "<TO>.FlangeInKcs" tag of the technology object.
Tool frame	Position of the tool coordinate system (TCS) in the FCS
OCS1..3 frame	Position of the object coordinate systems 1 to 3 (OCS1..3) in the WCS

7.3.1 Kinematics types with up to four interpolating kinematics axes

Flange coordinate system (FCS)

The FCS is attached to the tool adapter (flange) of the kinematics. As a result, the position of the FCS changes with kinematics motions.

The position of the FCS in the zero position of the kinematics results from the configuration of the geometry parameters of the kinematics. The kinematics technology object calculates the transformation frame from the geometry parameters.

The transformation frame describes the position of the FCS in the KCS. The z axis of the FCS always points in the negative z direction of the KCS. A rotation of the FCS around z of the KCS is possible for kinematics types with orientation.

The following graphic shows the positions of the FCS, KCS and the transformation frame using the "Cylindrical robot" kinematics example:

① KCS frame

② Transformation frame

Tool coordinate system (TCS) and tool center point (TCP)

The TCS is attached to the FCS and defines the tool center point (TCP) in the coordinate origin. The TCP is the operating point of the tool. The kinematics motions always refer to the TCP (with reference to WCS/OCS). You define the position of the TCS in the FCS using a tool frame.

You can define tool frames for up to three tools, of which only one tool and one tool frame is active at the same time. The procedure for the definition of tool frames is described in the section "Defining tool frames" (Page 206).

The position of the TCS is defined at the target position reached for kinematics types with up to 4 interpolating axes as follows:

- The x direction of the TCS is the same as the x direction of the target position.
- The y direction of the TCS is opposite to the y direction of the target position.
- The z direction of the TCS always points in the negative z direction of the target position.

The following graphic shows the position of the TCS and the TCP in the workspace:

① Tool frame

The following graphic shows the position of the TCS before and after a kinematics motion:

① TCS at initial position

② Kinematics motion to target position

③ TCS at the target position reached

For kinematics types with orientation, the orientation is negative relative to the TCS and positive relative to the TCP or WCS.

7.3.2 Kinematics types with more than four kinematics axes

Flange coordinate system (FCS)

The FCS is attached to the tool adapter (flange) of the kinematics. As a result, the position of the FCS changes with kinematics motions.

The position of the FCS in the zero position of the kinematics results from the configuration of the geometry parameters of the kinematics. The kinematics technology object calculates the transformation frame from the geometry parameters.

The x axis of the FCS is defined in the outward direction of the flange normal vector. This means that the x axis of the FCS is also in the direction of the tool length vector if the tool frame of the TCS is defined without rotation.

In contrast to kinematics with up to four interpolating kinematics axes, the z axis of the FCS does not always point in the negative direction of the KCS.

The following graphic shows the positions of the FCS and KCS and the transformation frame of a kinematics with five kinematics axes using the "Delta picker 3D with 2 orientations A, B" kinematics as an example:

① KCS frame

② Transformation frame

The following graphic show the alignment of the FCS at other joint positions of the kinematics:

① KCS frame
② Transformation frame

① KCS frame
② Transformation frame
③ Pivot

Tool coordinate system (TCS) and tool center point (TCP)

The TCS is attached to the FCS and defines the tool center point (TCP) in the coordinate origin. The TCP is the operating point of the tool. The kinematics motions always refer to the TCP (with reference to WCS/OCS). You define the position of the TCS in the FCS using a tool frame.

You can define tool frames for up to three tools, of which only one tool and one tool frame is active at the same time. The procedure for the definition of tool frames is described in the section "Defining tool frames" (Page 206).

The position of the TCS is defined at the target position reached for kinematics types with more than 4 interpolating axes as follows:

- The x direction of the TCS is the same as the x direction of the target position.
- The y direction of the TCS is the same as the y direction of the target position.
- The z direction of the TCS is the same as the z direction of the target position.

The following graphic shows the position of the TCS and the TCP in the workspace:

① Tool frame

The following graphic shows the position of the TCS before and after a kinematics motion:

① TCS at initial position

② Kinematics motion to target position

③ TCS at the target position reached

7.4 Supported kinematics types

The type of the mechanical system and the number of the axes determine the kinematics type. The mechanically coupled axes produce the motion of the tool center point (TCP). Depending on the kinematics type, you configure the kinematics using appropriate geometry parameters.

The kinematics technology object supports the following kinematics types:

Category	Kinematics type
Predefined kinematics systems	
Cartesian portal (Page 58)	Cartesian portal 2D
	Cartesian portal 2D with orientation
	Cartesian portal 3D
	Cartesian portal 3D with orientation
	Cartesian portal 3D with 2 orientations A, B [1]

7.5 Units of measure

Select the units of measure available for the technology object from the drop-down lists.

Setting or changing the units of measurement affects the parameter values:

- Display of parameter values in the technology data block
- Assignment of parameters in the user program
- Input and display of the position and velocity in the TIA Portal

All information and displays correspond to the selected unit of measure.

The set units are displayed in the "<TO>.Units" tag structure of the technology object. The tag structure is described in the ""Units" tag (kinematics) (Page 499)" section.

Position and velocity

The following table shows the supported units of measure for position and velocity of linear axes:

Position	Velocity
nm, µm, mm[1], m, km	mm/s[1], mm/min, mm/h, m/s, m/min, m/h, km/min, km/h
in, ft, mi	in/s, in/min, ft/s, ft/min, mi/h

[1] Six decimal places when the option box "Use position values with higher resolution" is selected.

The following table shows the supported units of measure for angle and angular velocity of rotational axes:

Angle	Angular velocity
°[1], rad	°/s[1], °/min, rad/s, rad/min

[1] Six decimal places when the option box "Use position values with higher resolution" is selected.

Acceleration

The acceleration is set accordingly as the position/s^2 (angle/s^2) unit of measure.

Jerk

The jerk is set as the position/s^3 (angle/s^3) unit of measure.

Units of measure of the axes and the kinematics technology object

The technology objects always transfer values without units of measure.

For example, if you set [mm] for an axis and [m] for the kinematics technology object, the kinematics technology object miscalculates the position values of the linear axis in [m]. If, in this example, the kinematics technology object outputs a setpoint for a one-meter motion, the axis only moves by one millimeter.

The kinematics technology object outputs linear and rotary setpoints to the interconnected axes according to the kinematics type. The kinematics technology object does not check the axis type of the interconnected axis (linear or rotary).

Configure the units of measure as follows:

- Configure the interconnected technology objects as linear or rotary axes according to the kinematics type.
- Configure the same linear/rotary units of measure for the axes interconnected according to the kinematics type as for the kinematics technology object.
- Configure the same units of measure on the interconnected axes for all linear axes and for all rotary axes.

Position values with higher resolution

If you select the "Use position values with higher resolution" check box in the configuration of the positioning axis, synchronous axis, external encoder and kinematics technology objects, six decimal places are available in the selected unit, instead of the standard three. Due to the LREAL format, the representable position and angle range in [mm] and [°] is limited to +/- 1.0E09. You can then only use the units mm, mm/s, ° and °/s. If you have previously configured other units, these will automatically be changed to the unit "mm, mm/s, ° or °/s".

The following values are reduced by a factor of 1000 for position values with a higher resolution:

- Displayable position range
- Displayable angular range
- Mechanical gear ratio
- Numerical traversing range with regard to long-term stability
- Dynamic values for velocity, acceleration and deceleration

7.6 Configuring and interconnecting kinematics axes

You can interconnect a kinematics technology object with positioning axes and synchronous axes. There must be a clear reference between the kinematics technology object and the interconnected axes. You cannot use a second kinematics technology object with already interconnected axes.

Depending on the kinematics type, you need 2 to 6 positioning axes or synchronous axes, which you interconnect with the kinematics.

Depending on the kinematics type, the following kinematics axes are relevant:

Kinematics type	Kinematics axis					
	A1	A2	A3	A4	A5 [1]	A6 [1]
2D	✓	✓	-	-	-	-
2D with orientation	✓	✓	-	✓	-	-
3D	✓	✓	✓	-	-	-
3D with orientation	✓	✓	✓	✓	-	-
3D with 2 orientations A, B [1]	✓	✓	✓	✓	✓	-
3D with 3 orientations [1]	✓	✓	✓	✓	✓	✓
6-axis articulated arm with central wrist [1]						
6-axis articulated arm with offset wrist [1]						

✓ Relevant

- Not relevant

[1] Only with S7-1500T Motion Control KinPlus

7.6.1 Configuring kinematics axes

Configure the following basic parameters of the axes depending on the kinematics used:

- Select the axis type according to the kinematics axes for the kinematics type (Page 58) used
- Set Modulo setting (Page 50) according to the kinematics type used or the interconnected kinematics axis

The following additional basic parameters are relevant for the interconnected kinematics axes:

- Axis in simulation/virtual axis (Page 50)
- Units of measure (Page 47)

7.6.1.1 Modulo setting

The kinematics technology object itself has no modulo setting. When you interconnect axes with active modulo setting to the kinematics technology object, the modulo range of the axes must cover at least the traversing range of the kinematics.

For the kinematics types with up to 4 interpolating axes, the zero position of the axis must correspond to the zero position of the kinematics axis. The Modulo range of the kinematics axes A1, A2 and A3 cannot be changed during a kinematics motion.

For the Cartesian orientations, you can specify an angle greater than 360°. A relative motion traverses this angle. An absolute motion maps this angle in the following ranges:

- A = -180° to 179.999°

The following ranges for the orientation are defined in addition for kinematics types with more than four interpolating kinematics axes:

- B = -90° to 90°
- C = -180° to 179,999°

For kinematics types with more than four interpolating kinematics axes, the "Modulo" setting should not be enabled for the axes A4, A5 and A6.

7.6.1.2 Axis in simulation/virtual axis

You can also interconnect the kinematics technology object with axes in simulation and virtual axes.

7.6.2 Interconnecting kinematics axes

Interconnect the axes of kinematics in the "Interconnections" configuration window.

Kinematics axes

In the drop-down lists, select the desired axes depending on the kinematics type (Page 58). Positioning axes and synchronous axes which are already created in the project are shown in the drop-down lists. Axes that are already interconnected are also visible in the drop-down lists but cannot be interconnected twice.

No provision is made for changing the interconnection of the axes during operation.

You directly call the configuration of the selected technology object using the button. Configure the interconnected technology objects according to the kinematics type (Page 49).

7.7 Mechanical axis coupling

7.7.1 Mechanical axis coupling for kinematics types with up to four interpolating kinematics axes.

If the position of a kinematics axis changes due to the motion of another kinematics axis, these two axes are mechanically coupled. Mechanical couplings between two kinematics axes can arise for reasons of construction. For example, if the kinematics axis A4 of the "SCARA" kinematics is coupled to the spindle of a linear axis, the orientation changes due to the motion of the linear axis.

NOTE

If you set a mechanical axis coupling for a first axis to a second axis, the setting "Modulo" must not be activated for the first axis.

The kinematics transformation compensates for the mechanical couplings with a compensation factor. You specify the mechanical couplings and respective compensation factor depending on the kinematics type during configuration of the kinematics.

You can configure the mechanical axis coupling for the following kinematics types:

- SCARA 2D with orientation (Page 87)
- SCARA 3D with orientation (Page 90)
- Articulated arm 2D (Page 96)
- Articulated arm 2D with orientation (Page 99)
- Articulated arm 3D (Page 103)
- Articulated arm 3D with orientation (Page 108)
- Cylindrical robot 3D with orientation (Page 163)

You can find additional information on the setting and the compensation factor in the description of the kinematics type used.

7.7.2 Mechanical axis coupling for kinematics types with more than four interpolating kinematics axes

Mechanical axis couplings of two axes mean that when the "<TO>.AxisCoupling.N[1].CausingAxis" axis moves by a distance or an angle, the position of another joint also changes without the coupled axis "<TO>.AxisCoupling.N[1].AffectedAxis" or the motor of the axis. The motor encoder of the coupled axis "<TO>.AxisCoupling.N[1].AffectedAxis" does not detect any change in position.

Configuring the mechanical axis coupling

If there are mechanical axis couplings, configure them in the "Interconnections" configuration window of the kinematics.

The coupling factor defines the position change of the tracked joint in relation to the position change of the moved axis.

The coupling factor <TO>.AxisCoupling.N[1..5].Factor defines the position change of the coupled axis "<TO>.AxisCoupling.N[1].AffectedAxis" in relation to the position change of the coupled axis "<TO>.AxisCoupling.N[1].CausingAxis".

The coupling factor is defined as a quotient, but the two position items do not need to be identical. The position changes are specified in a numerical value (without unit) of the position unit of the kinematics axis.

$$\text{Coupling factor} = \frac{\text{Position change coupled axis}}{\text{Position change causing axis}}$$

Example 1

When the axis A4 is moved by +90°, the joint J4 is moved by +90° and joint J5 is moved by 9° along with it, even though axis A5 does not move. This results in a coupling factor between axis A4 and axis A5 of:

$$\text{Coupling factor} = \frac{9}{90} = 0.1$$

Example 2

When the axis A4 is moved by 90°, the joint J4 is moved by 90°. The joint J5 is not affected. There is no mechanical coupling between axis A4 and axis A5.

Example 3

When the axis A4 is moved by 90°, the joint J4 is moved by 90° and joint J5 is also moved by -0.9 mm, even though axis A5 does not move. This results in a coupling factor between axis A4 and axis A5 of:

$$\text{Coupling factor} = \frac{-0.9}{90} = -0.01$$

NOTE

The coupling factor for kinematics with joint coordinate system (JCS) behaves inversely to the compensation factor of kinematics without joint coordinate system.

Determining coupling factors

You have the following options to determine the coupling factors:

- Determination based on the mechanical data of the kinematics
- Detection of the position change at the affected axis via an external measuring system with movement of the axis "<TO>.AxisCoupling.N[1..5].CausingAxis"
- Determination based on position change of the affected joint

Determination based on position change of the affected joint

Follow these steps to determine the coupling factor using the position change of the affected joint:

1. Move the affected joint into the zero position.
2. Move the coupled joint via the assigned axis by a defined distance or an angle, e.g. by 5°. The axis moves by 5° in this case when the direction of movement of the joint is not inverted.

3. Jog the axis "<TO>.AxisCoupling.N[1..5].CausingAxis" so that the coupled axis is moved again in the mechanical zero position without the motor of the affected axis moving.
4. You calculate the axis coupling factor from the moved position change of the axis "<TO>.AxisCoupling.N[1..5].CausingAxis" from step 3 and the known position change of the coupled axis "<TO>.AxisCoupling.N[1..5].AffectedAxis" (5°) from step 2.

NOTE

Traversing coupled axis with sPTP motion

For coupled axes with coupling factor ≠ 1, the traversing of joints in the JCS with an sPTP motion can result in compensation motions of the coupled axes.

NOTE

Jogging joints in the JCS

For coupled axes with coupling factor ≠ 1, the jogging of joints in the JCS can result in an unwanted position change of the coupled axes.

7.7.3 Tags: Mechanical axis coupling

For the mechanical axis coupling for kinematics types with more than four interpolating kinematics axes, the following tags of the kinematics technology object are relevant:

Tag	Description
Configuration of the mechanical axis coupling	
<TO>.AxisCoupling.N[1..5].Enable	Enabling/disabling the mechanical axis coupling
<TO>.AxisCoupling.N[1..5].CausingAxis	Coupling axis
<TO>.AxisCoupling.N[1..5].AffectedAxis	Coupled axis
<TO>.AxisCoupling.N[1..5].Factor	Coupling factor

7.8 Joints

7.8.1 Joint coordinate system (JCS)

The joint coordinate system (JCS) represents the real mechanical positions of the kinematics joints.

Functions

The JCS offers the following functions:

- Display current positions, velocities and accelerations of the joints of a kinematics
- Direct movement of the joints of a kinematics without moving mechanically coupled joints
- Traversing range limit of the joints by defining a joint traversing range (Page 56)
- Specification of the joint position ranges of a kinematics system on sPTP jobs
- Setting of zero point and counting direction of the joints

Setpoint calculation at the kinematics

The following diagram shows the kinematics transformation, the calculation of the joint coordinates (in the JCS) and the calculation of the axis coordinates (in the MCS):

7.8.2 Configuring joints

Configure the joints of the kinematics in the "Joints" configuration window.

7.8.2.1 Inverting the joint direction

The defined directions of movement of the joints of a kinematics are described in the section "Kinematics types (Page 58)". These directions of movement are used in the kinematics transformation.

The direction of movement of the joints can be defined for different mechanics inversely to the defined directions of movement of the kinematics types.

If the direction of travel of a joint of the real kinematics is inverse to the direction of travel of the joint defined in the kinematics type from Siemens, select the check box "Direction inverted" for the joint.

The inversion of the direction of movement is calculated by the technology object after the kinematics transformation.

The following diagram shows an example of a kinematics 6-axis articulated arm with central wrist, where the inverse direction of movement is required for the joint J1:

① Definition of the direction of motion on the kinematics type

② Definition of the direction of movement at the kinematics used

③ Positive direction of movement joint 1

④ Negative direction of movement joint 1

NOTE

Then check whether the direction of movement of the joint matches the direction of movement of the kinematics axis, e.g. by jogging in the MCS. If the direction of the joint and the axis direction are inverse, invert the encoder and drive direction of the kinematics axis.

7.8.2.2 Define joint traversing range

The joint traversing range defines the permitted traversing range of a kinematics joint. By defining the joint traversing range, you prevent a mechanical endstop or joint positions from being approached when these are not permitted.

In the "Joints" configuration window, define the joint traversing range by entering the lower and upper limits.

Configure the limits of the joint traversing range in such a way that the joint has a sufficient deceleration distance and comes to a standstill in the permissible traversing range.

NOTE

The software limit switches of the kinematics axes are independent of the configured joint traversing range. You can define the joint traversing range greater than, equal to or less than the axis traversing range.

7.8.2.3 Monitoring of the joint traversing range

Depending on the job, monitoring of the joint traversing range is already active when the job is issued or becomes active during the active job.

Job	Checking of the joint coordinates during the motion preparation in the MC_LookAhead	Cyclic checking of the joint coordinates during the active job
• MC_MoveLinearAbsolute • MC_MoveLinearRelative • MC_MoveCircularAbsolute • MC_MoveCircularRelative	-	✓
• MC_MoveDirectAbsolute • MC_MoveDirectRelative	✓	✓
Single axis job	-	-

Alarm response when leaving the joint position area

When a joint crosses the upper or lower limit of the joint traversing range, the 820 technology alarm is output. The kinematics motion is canceled, and the axes stop with the maximum dynamic values configured for the axes (alarm response: Stop with maximum dynamic values of the axes).

To return to the joint traversing range, move the joint via a single-axis job, e.g. with an "MC_MoveAbsolute", "MC_MoveRelative", or "MC_MoveJog" job.

7.8.2.4 Defining an offset

The offset describes the difference of the defined zero position of the joint of the kinematics type (Page 58) and the mechanical zero position of the joint at the kinematics used.

If the zero position of the mechanics axis does not match the zero position of the kinematics type, configure an offset.

Example

The joint J2 is in the mechanical zero position. This mechanical zero position deviates by 30° in positive direction of rotation from the defined zero position of the kinematics type. The defined zero position of the kinematics type used for the kinematics transformation is staggered by -30°. The offset is configured with "<TO>.Joint.J[2].Offset" = -30°.

NOTE

When homing the associated kinematics axis, ensure that the mechanical zero point of the joint matches the position 0.0 of the kinematics axis.

7.8.3 Tags: Joints

When configuring the joints for kinematics types with more than four interpolating kinematics axes, the following tags of the kinematics technology object are relevant:

Tag	Description
Configuration of joints	
<TO>.Joint.J[1..6].InverseDirection	Invert direction of movement
<TO>.Joint.J[1..6].Offset	Difference between the defined zero position of the joint of the kinematics type (Page 58) and the mechanical zero position of the joint at the kinematics used
<TO>.Joint.J[1..6].LowerLimit	Lower limit of the joint traversing range
<TO>.Joint.J[1..6].UpperLimit	Upper limit of the joint traversing range
Setpoints of the kinematics motion for the joints	
<TO>.JointData.J[1..6].Acceleration	Current acceleration setpoint
<TO>.JointData.J[1..6].Position	Current position setpoint
<TO>.JointData.J[1..6].Velocity	Current velocity setpoint

7.9 Kinematics types

7.9.1 Cartesian portal

7.9.1.1 Cartesian portal 2D

The "Cartesian portal 2D" kinematics support 2 axes and 2 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 2 orthogonal linear axes A1 and A2. The axes enclose a rectangular working range.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1 With axis A1 in the zero position:
Distance of the FCS to the KZP in x direction of the KCS

L2 With axis A2 in the zero position:
Distance of the FCS to the KZP and flange length LF in z direction of the KCS

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics

x_1 Deflection of axis A1 in the positive x direction

z_1 Deflection of axis A2 in the positive z direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at distance LF from the zero position of axis A2.

The position 0.0 on the respective interconnected technology object defines the zero position of axes A1 and A2. You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L2. You shift the FCS in the negative z direction of the KCS using length LF.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.1.2 Cartesian portal 2D with orientation

The "Cartesian portal 2D with orientation" kinematics supports 3 axes and 3 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 2 orthogonal linear axes A1 and A2
- 1 rotary axis A4 with rotation around z in the KCS

The linear axes enclose a rectangular working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1 With axis A1 in the zero position:
Distance of the FCS to the KZP in x direction of the KCS

L2 With axis A2 in the zero position:
Distance of the FCS to the KZP and flange length LF in z direction of the KCS

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics

x_1 Deflection of axis A1 in the positive x direction

z_1 Deflection of axis A2 in the positive z direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at distance LF from the zero position of axis A2.

The position 0.0 on the respective interconnected technology object defines the zero position of axes A1 and A2. You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L2. You shift the FCS in the negative z direction of the KCS using length LF. In the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.1.3 Cartesian portal 3D

The "Cartesian portal 3D" kinematics supports 3 axes and 3 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 3 orthogonal linear axes A1, A2 and A3. The linear axes enclose a rectangular working area.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the axes A1 and A3 is indicated (dashed)

Zero position of the kinematics

L1	With axis A1 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L3	With axis A3 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics

x_1	Deflection of axis A1 in the positive x direction
z_1	Deflection of axis A3 in the positive z direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The zero position of the kinematics
- The positive/negative deflection of the axes A1 and A2 is indicated (dashed)

Zero position of the kinematics

L1 With axis A1 in the zero position:
Distance of the FCS to the KZP in x direction of the KCS

L2 With axis A2 in the zero position:
Distance of the FCS to the KZP in y direction of the KCS

Deflection of the kinematics

x_1 Deflection of axis A1 in the positive x direction

y_1 Deflection of axis A2 in the negative y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at distance LF from the zero position of axis A2.

Position 0.0 on the respective interconnected technology object defines the zero position of axes A1, A2, and A3. You define the position of the FCS with axes A1, A2, and A3 in the zero position using lengths L1, L2 and L3. You shift the FCS in the negative z direction of the KCS using length LF.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.1.4 Cartesian portal 3D with orientation

The "Cartesian portal 3D with orientation" kinematics supports 4 axes and 4 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 3 orthogonal linear axes A1, A2 and A3
- 1 rotary axis A4 with rotation around z in the KCS

The linear axes enclose a rectangular working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the axes A1 and A3 is indicated (dashed)

Zero position of the kinematics

L1	With axis A1 in the zero position: Distance of the FCS to the KZP in x direction of the KCS

- The positive/negative deflection of the axes A1 and A2 is indicated (dashed)

Zero position of the kinematics

L1 With axis A1 in the zero position:
Distance of the FCS to the KZP in x direction of the KCS

L2 With axis A2 in the zero position:
Distance of the FCS to the KZP in y direction of the KCS

Deflection of the kinematics

x_1 Deflection of axis A1 in the positive x direction

y_1 Deflection of axis A2 in the negative y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at distance LF from the zero position of axis A2.

Position 0.0 on the respective interconnected technology object defines the zero position of axes A1, A2, and A3. You define the distances of the zero positions of the axes A1, A2 and A3 to the kinematics zero point using the lengths L1, L2 and L3. You shift the FCS in the negative z direction of the KCS using length LF. In the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.1.5 Cartesian portal 3D with 2 orientations A, B

The "Cartesian portal 3D with 2 orientations A, B" kinematics supports 5 axes and 5 degrees of freedom. For this kinematics type, you need the Motion Control package "S7-1500T Motion Control KinPlus" (Page 27).

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 3 orthogonal linear axes A1, A2 and A3
- One rotary axis A4 rotating around the z axis of the KCS
- One rotary swivel axis A5, which rotates around the y axis of the KCS in the kinematics zero position.

The linear axes enclose a rectangular working area.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive deflection of axes A1 and A3 and the negative deflection of axis A5 are indicated (dashed)

Zero position of the kinematics

L1	With axis A1 in the zero position: Distance of the zero position of axis A1 to the KZP in the x direction of the KCS
L3	With axis A3 in the zero position: Distance of the zero position of axis A3 to the KZP in the z direction of the KCS.
LF	Flange length before the FCS in the x direction of the FCS
L4	Distance of the joint points of rotational axis A4 and swivel axis A5 in the x direction of the KCS in the kinematics zero position

Deflection of the kinematics

x_1	Deflection of axis A1 in the positive x direction
z_1	Deflection of axis A3 in the positive z direction
α5	Negative deflection of swivel axis A5 when α5 = -45°

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the axes A1 and A2 is indicated (dashed)

Zero position of the kinematics

L1 With axis A1 in the zero position:
Distance of axis A3/A4 to the KZP in the x direction of the KCS

L2 With axis A2 in the zero position:
Distance of the FCS to the KZP in the y direction of the KCS in the kinematics zero position. If axis A4 has been moved, the distance between KZP and FCS is no longer L2.

Deflection of the kinematics

x_1 Deflection of axis A1 in the positive x direction

y_1 Deflection of axis A2 in the negative y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at a distance from axis A5 in the negative z direction of the KCS.

Position 0.0 on the respective interconnected technology object defines the zero position of axes A1, A2, and A3. You define the distances of the zero positions of axes A1, A2, and A3 to the kinematics zero point using lengths L1, L2, and L3. You can also move the zero position of axes A1, A2, and A3 and the associated joints J1, J2, and J3 with joint offsets (Page 57). You shift the FCS in the negative z direction of the KCS using length LF.

In the zero position, the FCS is aligned in the following Cartesian position:

- x = L1 + L4
- y = L2
- z = L3 - LF
- A = 0°
- B = 90°
- C = 0

In the zero position of axes A4 and A5, the x axis of the FCS points in the opposite direction of the z axis of the KCS. The y axis of the FCS points in the same direction as the y axis of the KCS. The z axis of the FCS points in the same direction as the x axis of the KCS.

Direction of travel of the joints

The following figure shows the direction of travel of the joints defined in the kinematics type.

① Front view

② Top view

Positive direction of rotation of the joints

If the direction of travel of a joint of the real kinematics is inverse to the direction of travel of the joint defined in the kinematics type from Siemens, you must invert the joint direction (Page 55) in the configuration.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.1.6 Tags: Cartesian portal

Cartesian portal 2D

You can define the 2D kinematics using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	1	Cartesian portal 2D
	2	Cartesian portal 2D with orientation

Tags	Values	Description
<TO>.Kinematics.Parameter[1]	-1.0E12 to 1.0E12	Distance L1 of the zero position of axis A1 to the kinematics zero point (KZP) in the x direction of the kinematics coordinate system (KCS)
<TO>.Kinematics.Parameter[2]	-1.0E12 to 1.0E12	Distance LF of the FCS to axis A2 in the negative z direction of the KCS
<TO>.Kinematics.Parameter[3]	-1.0E12 to 1.0E12	Distance L2 of the zero position of axis A2 to the KZP in the z direction of the KCS

Cartesian portal 3D

You can define the 3D kinematics using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	3	Cartesian portal 3D
	4	Cartesian portal 3D with orientation
	26	Cartesian portal 3D with 2 orientations A, B
<TO>.Kinematics.Parameter[1]	-1.0E12 to 1.0E12	Distance L1 of the zero position of axis A1 to the KZP in the x direction of the KCS
<TO>.Kinematics.Parameter[2]	-1.0E12 to 1.0E12	Distance L2 of the zero position of axis A2 to the KZP in the y direction of the KCS
<TO>.Kinematics.Parameter[3]	-1.0E12 to 1.0E12	• Distance LF of the FCS to axis A3 in the negative z direction of the KCS • Cartesian portal 3D with 2 orientations A, B: Distance LF of the FCS to axis A5
<TO>.Kinematics.Parameter[4]	-1.0E12 to 1.0E12	Distance L3 of the zero position of axis A3 to the KZP in the z direction of the KCS
<TO>.Kinematics.Parameter[5]	-1.0E12 to 1.0E12	Distance L4 of the joint points of rotational axis A4 and swivel axis A5 in the x direction of the KCS in the kinematics zero position[1)]

1) Only relevant for kinematics type "Cartesian portal 3D with 2 orientations A, B"

7.9.2 Roller picker

7.9.2.1 Roller picker 2D

The kinematics "Roller picker 2D" supports 2 axes and 2 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 2 rotary axes A1 and A2 and a system of guide rollers. If both axes A1 and A2 rotate with the same velocity in the same direction, the flange moves horizontally in x direction of the KCS. If both axes A1 and A2 rotate with the same velocity in opposite directions, the flange moves vertically in z direction of the KCS. The kinematics enables a rectangular working area.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L2	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
z_1	Deflection of the kinematics in the positive z direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located between axes A1 and A2.

The position 0.0 on the respective interconnected technology object defines the zero position of the axes A1 and A2. You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L2. Use the length LF to move the FCS in negative z direction of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.2.2 Roller picker 2D with orientation

The kinematics "Roller picker 2D with orientation" supports 3 axes and 3 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of a system made up of guide rollers and the following axes:

- 2 rotary axes A1 and A2
- 1 rotary axis A4 with rotation around z in the KCS

If both axes A1 and A2 rotate with the same velocity in the same direction, the flange moves horizontally in x direction of the KCS. If both axes A1 and A2 rotate with the same velocity in opposite directions, the flange moves vertically in z direction of the KCS. The kinematics enables a rectangular working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L2	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
z_1	Deflection of the kinematics in the positive z direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located between axes A1 and A2.

The position 0.0 on the respective interconnected technology object defines the zero position of the axes A1 and A2. You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L2. You shift the FCS in the negative z direction of the KCS using length LF. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.2.3 Roller picker 3D (vertical)

The kinematics "Roller picker 3D (vertical)" supports 3 axes and 3 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of a system made up of guide rollers and the following axes:

- 2 rotary axes A1 and A2
- 1 linear axis A3 in the y direction of the KCS

If both axes A1 and A2 rotate with the same velocity in the same direction, the flange moves horizontally in x direction of the KCS. If both axes A1 and A2 rotate with the same velocity in opposite directions, the flange moves vertically in z direction of the KCS. The linear portal axis A3 moves the system of guide rollers horizontally in y direction of the KCS. The kinematics enables a cuboid working area.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L3	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS
R1	Cam radius for axis A1

R2 Cam radius for axis A2

Deflection of the kinematics

x_1 Deflection of the kinematics in the positive x direction

z_1 Deflection of the kinematics in the positive z direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1 With axes A1 and A2 in the zero position:
Distance of the FCS to the KZP in x direction of the KCS

L2 With axis A3 in the zero position:
Distance of the FCS to the KZP in y direction of the KCS

R1 Cam radius for axis A1

R2 Cam radius for axis A2

Deflection of the kinematics

x_1 Deflection of the kinematics in the positive x direction

y_1 Deflection of the kinematics in the positive y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located between axes A1 and A2.

The position 0.0 on the respective interconnected technology object defines the zero position of the axes A1, A2 and A3. You define the position of the FCS for zero position of the axes A1, A2 and A3 using lengths L1, L2 and L3 . You shift the FCS in the negative z direction of the KCS using length LF.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.2.4 Roller picker 3D with orientation (vertical)

The kinematics "Roller picker 3D with orientation (vertical)" supports 4 axes and 4 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of a system made up of guide rollers and the following axes:

- 2 rotary axes A1 and A2
- 1 linear axis A3 in the y direction of the KCS
- 1 rotary axis A4 with rotation around z in the KCS

If both axes A1 and A2 rotate with the same velocity in the same direction, the flange moves horizontally in x direction of the KCS. If both axes A1 and A2 rotate with the same velocity in opposite directions, the flange moves vertically in z direction of the KCS. The linear portal axis A3 moves the system of guide rollers horizontally in y direction of the KCS. The kinematics enables a cuboid working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L3	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
z_1	Deflection of the kinematics in the positive z direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L2	With axis A3 in the zero position: Distance of the FCS to the KZP in y direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
y_1	Deflection of the kinematics in the positive y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located between axes A1 and A2.

The position 0.0 on the respective interconnected technology object defines the zero position of the axes A1, A2 and A3. You define the distance of the zero position of axis A3 to the KZP in the y direction of the KCS using length L2.

You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L3. You shift the FCS in the negative z direction of the KCS using length LF. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.2.5 Roller picker 3D with orientation (horizontal)

The kinematics "Roller picker 3D with orientation (horizontal)" supports 4 axes and 4 degrees of freedom. The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of a system made up of guide rollers and the following axes:

- 2 rotary axes A1 and A2
- 1 linear axis A3 in z direction of the KCS
- 1 rotary axis A4 with rotation around z in the KCS

If both axes A1 and A2 rotate with the same velocity in the same direction, the flange moves horizontally in x direction of the KCS. If both axes A1 and A2 rotate with the same velocity in opposite directions, the flange moves horizontally in y direction of the KCS. The linear portal axis A3 moves the system of guide rollers vertically in z direction of the KCS. The kinematics enables a cuboid working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L3	With axis A3 in the zero position: Distance of the FCS to the KZP and flange length LF in z direction of the KCS
LF	Flange length before the FCS in the z direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
z_1	Deflection of the kinematics in the positive z direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in x direction of the KCS
L2	With axes A1 and A2 in the zero position: Distance of the FCS to the KZP in y direction of the KCS
R1	Cam radius for axis A1
R2	Cam radius for axis A2

Deflection of the kinematics

x_1	Deflection of the kinematics in the positive x direction
y_1	Deflection of the kinematics in the positive y direction

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located between axes A1 and A2.

The position 0.0 on the respective interconnected technology object defines the zero position of the axes A1, A2 and A3. You define the distance of the zero position of axis A3 to the KZP in the y direction of the KCS using length L2.

You define the position of the FCS with axes A1 and A2 in the zero position using lengths L1 and L3. You shift the FCS in the negative z direction of the KCS using length LF. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the entire traversing range (Page 178) of the axes.

Joint position space

No joint position spaces for the kinematics.

7.9.2.6 Tags: Roller picker

Roller picker 2D

You define the 2D delta picker kinematics systems using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	5	Roller picker 2D
	6	Roller picker 2D with orientation
<TO>.Kinematics.Parameter[1]	-1.0E12 to 1.0E12	With zero position of the axes A1 and A2: Distance L1 of the FCS to the KZP in x direction of the kinematics coordinate system (KCS)

7.9.3 SCARA

7.9.3.1 SCARA 2D with orientation

The kinematics "SCARA 2D with orientation (swivel axis)" supports 3 axes and 3 degrees of freedom. The axes are configured as serial kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 linear axis A2 in the z direction of the KCS
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics consists of a base and an articulated arm for horizontal alignment which are connected by a revolute joint (axis A1). A linear stroke axis (axis A2) is fastened to the end of the articulated arm for the vertical alignment. The tool is fastened to the end of the linear axis. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1 Distance of the axis A1 to the KZP in z direction of the KCS

L2 Distance of the axis A1 to the FCS in x direction of the KCS

LF Distance of the FCS to the axis A1 in z direction of the FCS

Deflection of the kinematics

z_1 Deflection of the axis A2 in negative direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

Deflection of the kinematics

α1 Deflection of the axis A1 in positive direction when α1 = 30.0°
Deflection of the axis A1 in negative direction when α1 = -60.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at the end of the articulated arm.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The articulated arm points in the x direction of the KCS.
A2	The axis A2 is at the position 0.0 of the interconnected technology object.
A4	With axis A1 in the zero position, the x axis of the FCS points in the direction of the x axis of the KCS.

Compensation of mechanical axis couplings

You can configure a mechanical axis coupling of axis A4 to axis A2 for the kinematics. The kinematics transformation compensates for the configured mechanical axis coupling. The axis coupling between axis A4 and axis A2 is implemented as a leadscrew pitch. With a compensation factor of 1.0, 360.0° on axis A4 corresponds to a distance of -1.0 mm on axis A2.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: No limit
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

You can process these kinematics only with the Motion Control instructions "MC_MoveDirectAbsolute" and "MC_MoveDirectRelative" or single-axis jobs.

Joint position space

No joint position spaces for the kinematics.

7.9.3.2 SCARA 3D with orientation

The kinematics "SCARA (Selective Compliance Assembly Robot Arm) 3D with orientation" supports 4 axes and 4 degrees of freedom. The axes are configured as serial kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 rotary axis A2 at distance L2 to A1 with rotation around z of the KCS
- 1 linear axis A3 at distance L3 to A2 with motion in z direction of the KCS
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics consists of a base and two levers for horizontal alignment which are connected by revolute joints (axis A1 and A2). A linear axis (axis A3) is fastened to the end of the articulated arm for the vertical alignment. The tool is fastened to the end of the linear axis. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics

Zero position of the kinematics

L1	Distance of the axis A1 to the KZP in z direction of the KCS
L2	Distance of the axis A2 to the axis A1 in x direction of the KCS
L3	Distance of the axis A3 to the axis A2 in x direction of the KCS
LF	Distance of the FCS to the axis A2 in z direction of the FCS

Deflection of the kinematics

z_1	Deflection of the axis A3 in the positive direction

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

Deflection of the kinematics in the positive direction when α1 = 30.0° with a positive joint position when α2 = 75.0°
Deflection of the kinematics in the negative direction when α1 = -60.0° with a negative joint position when α2 = -45.0°

α1 Deflection of the axis A1 in positive direction when α1 = 30.0°
Deflection of the axis A1 in negative direction when α1 = -60.0°

α2 The deflection of axis A2 in the positive direction when α2 = 75.0° produces a positive joint position.
The deflection of axis A2 in the negative direction when α2 = -45.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. The flange coordinate system (FCS) is located at the end of the axis A3.

The following table shows the zero position of the axes:

Axis	Zero position
A1 and A2	The kinematics is elongated in the x_{KCS} direction.
A3	The FCS is located at distance L1-LF from the KCS in z direction.
A4	With axes A1 and A2 in the zero position, the x axis of the FCS points in the direction of the x axis of the KCS.

Compensation of mechanical axis couplings

You can configure the following mechanical coupled axes for the kinematics:

- Mechanical coupling of axis A1 to axis A2
- Mechanical coupling of axis A4 to axis A3

The kinematics transformation compensates for the configured mechanical axis couplings. With a compensation factor > 0.0, the kinematics transformation assumes that a positive motion of the axis A1 leads to a negative motion on the axis A2. The axis coupling between axis A4 and axis A3 is implemented as a leadscrew pitch. With a compensation factor of 1.0, 360.0° on axis A4 corresponds to a distance of -1.0 mm on axis A3.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 ≤ 180.0°
- Axis A2: -180.0° ≤ α2 ≤ 180.0°
- Axis A3: No limit
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

NOTE
Singularity
The kinematics has singularities (Page 183).

A singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). Inverse transformation is not possible in this area. This position may result, e.g. in the event of suspended installation if the lengths L2 and L3 are the same size.

The graphic below shows examples of a movement in the direction of the singularity:

Permissible joint position

Folded position
Inner singularity at L2 = L3

Joint position space

The following table shows the possible joint position spaces of the kinematics:

7.9.4 Articulated arm

7.9.4.1 Articulated arm 2D

The kinematics "Articulated arm 2D" supports 2 axes and 2 degrees of freedom. The axes are configured as serial kinematics with forced coupling of the flange system.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point
- 1 rotary axis A2 at distance L3 to axis A1

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2). Axes A1 and A2 move the articulated arm in the xz plane. Through a forced coupling between the axes and the flange system, the z axis of the FCS always points in the negative z direction of the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view:

- The position of the axes and of the forced coupler point
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

① Forced coupler point

Zero position of the kinematics

- L1 Distance of the axis A1 to the kinematics zero point (KZP) in z direction of the KCS
- L2 Distance of the axis A1 to the KZP in x direction of the KCS
- L3 Distance of the axis A2 to the axis A1 in x direction of the KCS
- L4 Distance of the forced coupler point to the axis A2 in x direction of the KCS
- LF Distance of the FCS to the forced coupler point in z direction of the FCS

Deflection of the kinematics

- α1 Positive deflection of the axis A1 when α1 = 45.0°
  Negative deflection of the axis A1 when α1 = -60.0°
- α2 The deflection of the axis A2 in the positive direction when α2 = 45.0° produces a positive joint position.
  The deflection of the axis A2 in negative direction when α2 = -15.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. You define the position of the axis A1 relative to the KZP using

lengths L1 and L2. The axis A2 is located at distance L3 in x direction of the KCS from the axis A1.

The flange coordinate system (FCS) is located at the following distances from the axis A2 and the forced coupler point:

- Distance L4 to the axis A2 in x direction of the KCS
- Distance LF to the forced coupler point in the negative z direction of the KCS

The axis A2 and the flange system are force-coupled. With the force coupling, the z axis of the FCS always points in negative z direction of the KCS. The forced coupler point is located at distance L4 in x direction of the KCS from the axis A2.

The following table shows the zero position of the axes:

Axis	Zero position
A1	Length L3 points in x direction of the KCS.
A2	At zero position of the axis A1, the length L4 points in x direction of the KCS.

Compensation of mechanical axis couplings

For the kinematics, you can configure a mechanical axis coupling of axis A1 to axis A2. The kinematics transformation compensates for the configured mechanical axis coupling. With a compensation factor > 0.0, the kinematics transformation assumes that a positive motion of the axis A1 leads to a negative motion on the axis A2.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: -180.0° ≤ α2 < 180.0°

NOTE
Singularity
The kinematics has outer singularities (Page 183).

Joint position space

The following table shows the possible joint position spaces of the kinematics:

Tag	Data type	Values	W	Description	
StatusKinematics.	TO_Struct_Kinematics_StatusKinematics				
Valid	BOOL	-	RON	Validity of the transformation values	
				FALSE	Invalid
				TRUE	Valid

7.9.4.2 Articulated arm 2D with orientation

The kinematics "Articulated arm 2D with orientation" supports 3 axes and 3 degrees of freedom. The axes are configured as serial kinematics with forced coupling of the flange system.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point
- 1 rotary axis A2 at distance L3 to axis A1
- 1 rotary axis A4 with rotation around z in the KCS at a distance L4 in x direction of the KCS to axis A2

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2). Axes A1 and A2 move the articulated arm in the xz plane. Through a forced coupling between the axes and the flange system, the z axis of the FCS always points in the negative z direction of the KCS. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view:

- The position of the axes and of the forced coupler point
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

① Forced coupler point

Zero position of the kinematics

L1 Distance of the axis A1 to the kinematics zero point (KZP) in z direction of the KCS

L2 Distance of the axis A1 to the KZP in x direction of the KCS

L3 Distance of the axis A2 to the axis A1 in x direction of the KCS

L4 Distance of the forced coupler point to the axis A2 in x direction of the KCS

LF Distance of the FCS to the forced coupler point in z direction of the FCS

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 45.0°
Negative deflection of the axis A1 when α1 = -60.0°

α2 The deflection of the axis A2 in the positive direction when α2 = 45.0° produces a positive joint position.
The deflection of the axis A2 in negative direction when α2 = -15.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the base of the kinematics. You define the position of the axis A1 relative to the KZP using lengths L1 and L2. The axis A2 is located at distance L3 in x direction of the KCS from the axis A1.

The flange coordinate system (FCS) is located at the following distances from the axis A2 and the forced coupler point:

- Distance L4 to the axis A2 in x direction of the KCS
- Distance LF to the forced coupler point in the negative z direction of the KCS

The axis A2 and the flange system are force-coupled. With the force coupling, the z axis of the FCS always points in negative z direction of the KCS. The forced coupler point is located at distance L4 in x direction of the KCS from the axis A2.

The following table shows the zero position of the axes:

Axis	Zero position
A1	Length L3 points in x direction of the KCS.
A2	At zero position of the axis A1, the length L4 points in x direction of the KCS.
A4	At the zero position of axis A1 and A2, the x axis of the FCS points in the direction of the x axis of the KCS.

Compensation of mechanical axis couplings

For the kinematics, you can configure a mechanical axis coupling of axis A1 to axis A2. The kinematics transformation compensates for the configured mechanical axis coupling. With a compensation factor > 0.0, the kinematics transformation assumes that a positive motion of the axis A1 leads to a negative motion on the axis A2.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: -180.0° ≤ α2 < 180.0°
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

Joint position space

The following table shows the possible joint position spaces of the kinematics:

Tag	Data type	Values	W	Description	
StatusKinematics.	TO_Struct_Kinematics_StatusKinematics

7.9.4.3 Articulated arm 3D

The kinematics "Articulated arm 3D" supports 3 axes and 3 degrees of freedom. The axes are configured as serial kinematics with forced coupling of the flange system.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 rotary axis A2 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point
- 1 rotary axis A3 at distance L3 to axis A2

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2 and A3). Axis A1 rotates the kinematics horizontally around the base. Axes A2 and A3 move the articulated arm. The kinematics enables an approximately spherical working area. Through a forced coupling between the axes and the flange system, the z axis of the FCS always points in the negative z direction of the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes and of the forced coupler point
- The position of coordinate systems KCS and FCS
- The zero position of the axes
- The positive/negative deflection of the axes A2 and A3 is indicated (dashed)

① Forced coupler point

Zero position of the kinematics

- L1 Distance of the axis A2 to the kinematics zero point (KZP) in z direction of the KCS
- L2 Distance of the axis A2 to the KZP in x direction of the KCS
- L3 Distance of the axis A3 to the axis A2 in x direction of the KCS
- L4 Distance of the forced coupler point to the axis A3 in x direction of the KCS
- LF Distance of the FCS to the forced coupler point in z direction of the FCS

Deflection of the kinematics

- α2 Positive deflection of the axis A2 when α2 = 45.0°
  Negative deflection of the axis A2 when α2 = -60.0°
- α3 The deflection of the axis A3 in positive direction when α3 = 45.0° produces a positive joint position.
  The deflection of the axis A3 in negative direction when α3 = -15.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 30.0°
Negative deflection of the axis A1 when α1 = -60.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. You define the position of the axis A2 relative to the KZP using lengths L1 and L2. The axis A3 is located at distance L3 in x direction of the KCS from the axis A2.

The flange coordinate system (FCS) is located at the following distances from the axis A3 and the forced coupler point:

- Distance L4 to the axis A3 in x direction of the KCS
- Distance LF to the forced coupler point in the negative z direction of the KCS

The axis A3 and the flange system are force-coupled. With the force coupling, the z axis of the FCS always points in negative z direction of the KCS. The forced coupler point is located at distance L4 in x direction of the KCS from the axis A3.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The articulated arms of the kinematics point in the x direction of the KCS.
A2	At zero position of the axis A1, the length L3 points in x direction of the KCS.
A3	At zero position of the axes A1 and A2, the length L4 points in x direction of the KCS.

Compensation of mechanical axis couplings

You can configure a mechanical axis coupling of axis A2 to axis A3 for the kinematics. The kinematics transformation compensates for the configured mechanical axis coupling. With a compensation factor > 0.0, the kinematics transformation assumes that a positive motion of the axis A2 leads to a negative motion on the axis A3.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: $-180.0° \leq \alpha 1 < 180.0°$
- Axis A2: $-180.0° \leq \alpha 2 < 180.0°$
- Axis A3: $-180.0° \leq \alpha 3 < 180.0°$

NOTE
Singularity
The kinematics has singularities (Page 183).

A singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). Inverse transformation is not possible in this area.

The graphic below shows examples of singularities and permissible joint positions:

Permissible joint position

Inner singularity

7.9.4.4 Articulated arm 3D with orientation

The kinematics "Articulated arm 3D with orientation" supports 4 axes and 4 degrees of freedom. The axes are configured as serial kinematics with forced coupling of the flange system.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 rotary axis A2 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point
- 1 rotary axis A3 at distance L3 to axis A2
- 1 rotary axis A4 with rotation around z in the KCS at a distance L4 in x direction of the KCS to axis A3

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2 and A3). Axis A1 rotates the kinematics horizontally around the base. Axes A2 and A3 move the articulated arm. The kinematics enables an approximately spherical working area. Through a forced coupling between the axes and the flange system, the z axis of the FCS always points in the negative z direction of the KCS. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

① Forced coupler point

Zero position of the kinematics

- L1 Distance of the axis A2 to the kinematics zero point (KZP) in z direction of the KCS
- L2 Distance of the axis A2 to the KZP in x direction of the KCS
- L3 Distance of the axis A3 to the axis A2 in x direction of the KCS
- L4 Distance of the forced coupler point to the axis A3 in x direction of the KCS
- LF Distance of the FCS to the forced coupler point in z direction of the FCS

Deflection of the kinematics

- α2 Positive deflection of the axis A2 when α2 = 45.0°
  Negative deflection of the axis A2 when α2 = -60.0°
- α3 The deflection of the axis A3 in positive direction when α3 = 45.0° produces a positive joint position.
  The deflection of the axis A3 in negative direction when α3 = -15.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 30.0°
Negative deflection of the axis A1 when α1 = -60.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. You define the position of the axis A2 relative to the KZP using lengths L1 and L2. The axis A3 is located at distance L3 in x direction of the KCS from the axis A2.

The flange coordinate system (FCS) is located at the following distances from the axis A3 and the forced coupler point:

- Distance L4 to the axis A3 in x direction of the KCS
- Distance LF to the forced coupler point in the negative z direction of the KCS

The axis A3 and the flange system are force-coupled. With the force coupling, the z axis of the FCS always points in negative z direction of the KCS. The forced coupler point is located at distance L4 in x direction of the KCS from the axis A3.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The articulated arms of the kinematics point in the x direction of the KCS.
A2	At zero position of the axis A1, the length L3 points in x direction of the KCS.
A3	At zero position of the axes A1 and A2, the length L4 points in x direction of the KCS.
A4	At zero position of the axes A1, A2 and A3, the x axis of the FCS points in the direction of the x axis of the KCS.

Compensation of mechanical axis couplings

You can configure a mechanical axis coupling of axis A2 to axis A3 for the kinematics. The kinematics transformation compensates for the configured mechanical axis coupling. With a compensation factor > 0.0, the kinematics transformation assumes that a positive motion of the axis A2 leads to a negative motion on the axis A3.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: -180.0° ≤ α2 < 180.0°
- Axis A3: -180.0° ≤ α3 < 180.0°
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

NOTE

Singularity

The kinematics has singularities (Page 183).

A singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). Inverse transformation is not possible in this area.

The graphic below shows examples of singularities and permissible joint positions:

Permissible joint position

Inner singularity

Joint position space

The following table shows the possible joint position spaces of the kinematics:

Tag		Data type	Values	W	Description

7.9.4.5 6-axis articulated arm with central wrist

The kinematics "6-axis articulated arm with central wrist" supports 6 axes and 6 degrees of freedom. The axes are configured as serial kinematics. For this kinematics type you need the Motion Control package "S7-1500T Motion Control KinPlus (Page 27)".

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes (output state):

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 rotary axis A2 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point with rotation around y
- 1 rotary axis A3 at a distance L3 in x direction of the KCS to the axis A2 with rotation around y
- 1 rotary axis A4 with the distance L5 in z direction of the KCS to the axis A5 and distance L6 in y direction to the axis A1
- 1 rotary axis A5 with the distances L4 in x direction of the KCS and L5 in z direction of the KCS to the axis A3 with rotation around y
- 1 rotary axis A6 with distance LF to axis A5 with rotation around x

The distances L1 to L6 and LF are shown in the following diagrams with the side view and the top view of the kinematics.

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2 and A3). Axis A1 rotates the kinematics horizontally around the base. Axes A2 and A3 move the articulated arms. The kinematics enables an approximately spherical working area.

The axes A4, A5 and A6 form the central wrist. This means that the axes A4, A5 and A6 intersect at one point. This point is referred to as the wrist point.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics

NOTE
Singularity
Note that the zero position represents a singularity.

- The positive/negative deflection of the kinematics is indicated (dashed)

α6 Negative deflection of the axis A6 when α6 = -90.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. With zero position of the axes A1, A2, A3 and A5, the kinematics is extended in x direction of the KCS.

You can use the lengths L1 to L6 and the flange length LF to define the zero position of the flange coordinate system (FCS) at zero position of the kinematics. Since there is no forced coupling between the kinematics axes and the flange system, the coordinate axes of the FCS at the zero position of the kinematics point in the same direction as the coordinate axes of the KCS.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The articulated arms of the kinematics point in the x direction of the KCS.
A2	At zero position of the axis A1, the length L3 points in x direction of the KCS.
A3	At zero position of the axes A1 and A2, the length L4 points in the x direction of the KCS and length L5 points in the z direction of the KCS.
A5	At zero position of the axes A1, A2 and A3, the length LF points in the x direction of KCS.
A4, A6	At zero position of the axes A1, A2, A3 and A5, the x, y and z axes of FCS point in the direction of the x, y and z axes of KCS.

Direction of travel of the joints

The following figure shows the direction of travel of the joints defined in the kinematics type.

Positive direction of rotation of the joints

If the direction of travel of a joint of the real kinematics is inverse to the direction of travel of the joint defined in the kinematics type from Siemens, you must invert the joint direction (Page 55) in the configuration.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A[1..6]: -180.0° ≤ α[1..6] < 180.0°

To traverse outside these traversing range definitions, you can use, for example, the Motion Control instructions "MC_MoveLinearAbsolute (Page 392)" or "MC_MoveDirectAbsolute (Page 414)" and "MC_MoveDirectRelative (Page 422)" with "TurnJoint[1..6]" ≠ 1.

NOTE

Modulo functionality

Do not use the setting "Modulo" for the axes A1 to A6.

If Length L6 ≠ 0.0 is configured, an area with the wrist point is not reachable because of the horizontal offset of the central wrist.

The not reachable area corresponds to a cylinder with the radius of Length L6 and a center axis which is collinear with the z axis of the KCS.

The flange or tool can be moved within the area but not with all possible orientations.

① Front view
② Wrist point
③ Not reachable area
④ Top view

The behavior is as follows for a motion job in which the wrist point moves to the non reachable area:

- **Dynamic adaptation is not activated.**

  If it is detected that the wrist point would move to the non reachable area during the kinematics motion, the job is canceled with the technology alarm 803 ("Error in the calculation of the transformation").

- **Dynamic adaptation is activated (with or without segmentation of the path)**

  If an invalid configuration is detected during motion preparation, the job is rejected with the technology alarm 802 ("Cannot calculate the geometry element").
  If no invalid configuration is detected during motion preparation, the behavior is like the behavior when traversing with deactivated dynamic adaptation.

If the kinematics travel with an sPTP motion job in WCS or OCS such that the target position results in the wrist point moving within the non reachable area, the job is rejected with the technology alarm 802 ("Cannot calculate the geometry element").

With the technology alarms 802 and 803, the corresponding function block also issues the error message with the "ErrorID" = 16#8001 ("A technology alarm (technology object error) occurred while processing the Motion Control instruction").

The behavior and effect of the wrist point moving close to the limited area is comparable to the behavior close to an outer singularity.
Avoid motions with the wrist point close to the limited area and implement suitable preventative measures. See section Singularities (Page 183).

NOTE

Singularity

The kinematics has singularities (Page 183).

Singularity is present in the following cases:

- Length L6 = 0.0
  - Axes of rotation A1 and A4 are collinear

    The axis A4 is located on the z axis of the KCS and rotates around the z axis of the KCS.
  - Axes of rotation A1 and A4 are collinear

    The axis A5 is located on the z axis of the KCS and rotates around the z axis of the KCS.
  - Axes of rotation A1 and A6 are collinear

    The axis A6 is located on the z axis of the KCS and rotates around the z axis of the KCS or the x axis of the FCS is located on the z axis of the KCS.
  - Axes of rotation A4 and A6 are collinear

    The axes A4 and A6 rotate in opposite directions around the same axis when α5 = 0.0°.
- Length L6 ≠ 0.0
  - Axes of rotation A4 and A6 are collinear

    The axes A4 and A6 rotate in opposite directions around the same axis when α5 = 0.0°.

Inverse transformation is not possible in these cases.

The graphic below shows examples of singularities and permissible joint positions:

Permissible joint position

Inner singularity

Joint position space

The joint position space of the kinematics "6-axis articulated arm with central wrist" is defined by the joint positions from the kinematics transformation. The joint position space thus describes the geometric joint positions of the kinematics.

When using mechanical axis couplings, inverted joint directions or joint offsets, the joint position space is not defined by the absolute joint positions "<TO>.JointData.J[1..6].Position" or the axis positions "<TO>.AxesData.A[1..6].Position".

The following example shows the geometric joint position on joint 5:

Case 1: No joint inversion and no joint offset is defined. The joint position corresponds to the geometric joint position (from the transformation), thus -45°. Bit 4 in the "<TO>StatusKinematics.LinkConstellation" tag is TRUE, because the geometric joint position is -45°.

Case 2: The inverted traversing direction is configured for joint 5. The kinematics has exactly the same geometric joint position as in Case 1. However, due to the inverted traversing direction, the joint position is +45°. Bit 4 in the "<TO>StatusKinematics.LinkConstellation" tag is thus also TRUE in this case, because the geometric joint position (from the transformation) is -45°.

Working areas

The following graphics show the overhead area ① and the standard area ②:

Example "A" shows the kinematics with joint J1 in the zero position. The wrist point is located in the standard area. In example "B", joint J1 is rotated by -180.0°. With the rotated joint J1, the standard area and the overhead area are also rotated.

The following table shows the possible joint position spaces of the kinematics:

Tag		Data type	Values	W	Description	
StatusKinematics.		TO_Struct_Kinematics_StatusKinematics				
	Valid	BOOL	-	RON	Validity of the transformation values	
					FALSE	Invalid

Tag	Data type	Values	W	Description	
Valid	BOOL	-	RON	TRUE	Valid
LinkConstellation	DWORD	0 ... n	RON	Joint position space	
Bit 0	-	-	-	Geometric joint position joint J1	
				0	The wrist point is located in the front area (standard area) or on the joint position lines for joint J1.
				1	The wrist point is located in the rear area (overhead area) of the joint position lines for joint J1.
Bit 1	-	-	-	Geometric joint position joint J2	
				0	Not relevant
				1	Not relevant
Bit 2	-	-	-	Geometric joint position joint J3	
				0	The wrist point is in one of the following positions: • On the joint position line for joint J3 • In the standard area (bit 0 = 0), above the joint position line for joint J3 • In the overhead area (bit 0 = 1), below the joint position line for joint J3
				1	The wrist point is in one of the following positions: • In the standard area (bit 0 = 0), below the joint position line for joint J3 • In the overhead area (bit 0 = 1), above the joint position line for joint J3
Bit 3	-	-	-	Geometric joint position joint J4	
				0	Not relevant
				1	Not relevant
Bit 4	-	-	-	Geometric joint position joint J5	
				0	α5 positive
				1	α5 negative or α5 = 0°
Bit 5	-	-	-	Geometric joint position joint J6	
				0	Not relevant
				1	Not relevant
Bit 6 ... 31	-	-	-	Not relevant	

Bits 1, 3, 5 and 6 ... 31 in the "<TO>StatusKinematics.LinkConstellation" tag are not programmable on the Motion Control instructions "MC_MoveDirectAbsolute" or "MC_MoveDirectRelative". A setting is reported as an impermissible value for the target joint position space ("ErrorID" = 16#80D2).

Examples

The following examples show various joint position spaces for the same Cartesian position of the kinematics "6-axis articulated arm with central wrist". There are no configured offsets or inversions in the example. The tool center point in the FCS is configured as follows:
x = 60 mm, y = 0 mm, z = -100 mm, A = 0°, B = 90°, C = 0°.

7.9.4.6 6-axis articulated arm with offset wrist

The kinematics "6-axis articulated arm with offset wrist" supports 6 axes and 6 degrees of freedom. The axes are configured as serial kinematics. For this kinematics type you need the Motion Control package "S7-1500T Motion Control KinPlus (Page 27)".

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes (output state):

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 rotary axis A2 with the distances L1 in z direction of the KCS and L2 in x direction of the KCS to the kinematics zero point with rotation around y
- 1 rotary axis A3 at a distance L3 to axis A2 with rotation around y
- 1 rotary axis A4 at a distance L5 in z direction of the KCS to the axis A3 with rotation around x
- 1 rotary axis A5 with the distances L4 in x direction of the KCS and L5 in z direction of the KCS to the axis A3 with rotation around y
- 1 rotary axis A6 with the distances L7 in y direction of the KCS and L8 in z direction of the KCS to the axis A5 with rotation around x

The distances L1 to L5, L7 to L8 and LF are shown in the following figures with the side view and the top view of the kinematics.

The kinematics consists of a base and articulated arms, which are connected by revolute joints (axes A1, A2 and A3). Axis A1 rotates the kinematics horizontally around the base. The axes A2, A3, A4 and A5 move the articulated arms. The kinematics enables an approximately spherical working area. The wrist point is the pivot point of axis A5.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics

NOTE
Singularity
Note that the zero position represents a singularity.

- The positive/negative deflection of the kinematics is indicated (dashed)

① Wrist point

② Joint position line for the joint

Zero position of the kinematics

- L1 Distance of the axis A2 to the kinematics zero point (KZP) in z direction of the KCS
- L2 Distance of the axis A2 to the KZP in x direction of the KCS
- L3 Distance of the axis A3 to the axis A2 in x direction of the KCS
- L4 Distance of the wrist point to the axis A3 in x direction of the KCS
- L5 Distance of the wrist point to the axis A3 in z direction of the KCS
- LF Distance of the FCS to the wrist point in x direction of the KCS
- L8 Distance of the axis A6 to the wrist point in z direction of the KCS

Deflection of the kinematics

α2 Positive deflection of the axis A2 when α2 = 45.0°
Negative deflection of the axis A2 when α2 = -60.0°

α3 The deflection of the axis A3 in positive direction when α3 = 45.0° produces a positive joint position.
The deflection of the axis A3 in negative direction when α3 = -15.0° produces a negative joint position.

α5 The deflection of the axis A5 in negative direction when α5 = -60.0° or α5 = -75.0°produces a negative joint position.

The graphic below shows the following in the top view (xy plane):

- The position of the axes
- The position of coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

① Wrist point

Zero position of the kinematics

L7 Distance of the axis A6 to the wrist point in y direction of the KCS

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 30.0°
Negative deflection of the axis A1 when α1 = -45.0°

α4 Positive deflection of the axis A4 when α4 = 90.0°

α6 Negative deflection of the axis A4 when α6 = -90.0°

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. With zero position of the axes A1, A2, A3 and A5, the kinematics is extended in x direction of the KCS.

You can use the lengths L1 to L8 and the flange length LF to define the zero position of the flange coordinate system (FCS) at zero position of the kinematics. Since there is no forced coupling between the kinematics axes and the flange system, the coordinate axes of the FCS at the zero position of the kinematics point in the same direction as the coordinate axes of the KCS.

The configuration of both lengths L7 and L8 with the value "= 0.0" is not permitted and is rejected with a technology alarm 101 on the kinematics technology object.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The articulated arms of the kinematics point in the x direction of the KCS.
A2	At zero position of the axis A1, the length L3 points in x direction of the KCS.
A3	At zero position of the axes A1 and A2, the length L4 points in the x direction of the KCS and length L5 points in the z direction of the KCS.
A5	At zero position of the axes A1, A2 and A3, the length LF points in the x direction of KCS.
A4, A6	At zero position of the axes A1, A2, A3 and A5, the x, y and z axes of FCS point in the direction of the x, y and z axes of KCS.

Direction of travel of the joints

The following figure shows the direction of travel of the joints defined in the kinematics type:

Positive direction of rotation of the joints

If the direction of travel of a joint of the real kinematics is inverse to the direction of travel of the joint defined in the kinematics type from Siemens, you must invert the joint direction (Page 55) in the configuration.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A[1..6]: -180.0° ≤ α[1..6] < 180.0°

To traverse outside these traversing range definitions, you can use, for example, the Motion Control instructions "MC_MoveLinearAbsolute (Page 392)" or "MC_MoveDirectAbsolute (Page 414)" and "MC_MoveDirectRelative (Page 422)" with "TurnJoint[1..6]" ≠ 1.

NOTE

Modulo functionality

Do not use the setting "Modulo" for the axes A1 to A6.

NOTE

Singularity

The kinematics has singularities (Page 183).

Singularity is present in the following cases:

- Axes of rotation A1 and A4 are collinear

  The axis A4 is located on the z axis of the KCS and rotates around the z axis of the KCS.
- Axes of rotation A1 and A5 are collinear

  The axis A5 is located on the z axis of the KCS and rotates around the z axis of the KCS.
- Axes of rotation A1 and A6 are collinear

  The axis A6 is located on the z axis of the KCS and rotates around the z axis of the KCS or the x axis of the FCS is located on the z axis of the KCS.
- Axes of rotation A4 and A6 are collinear

  The axes A4 and A6 rotate in opposite directions around the same axis when α5 = 0.0°.

Inverse transformation is not possible in these cases.

The graphic below shows examples of singularities and permissible joint positions:

Permissible joint position

Inner singularity

Joint position space

The joint position space of the kinematics "6-axis articulated arm with offset wrist" is defined by the joint positions from the kinematics transformation. The joint position space thus describes the geometric joint positions of the kinematics.

The joint position space is not defined by the absolute joint positions "<TO>.JointData.J[1..6].Position" or the axis positions "<TO>.AxesData.A[1..6].Position" when mechanical axis couplings, inverted joint directions or joint offsets are used.

The following example shows the geometric joint position on joint 5:

Case 1: No joint inversion and no joint offset is defined. The joint position corresponds to the geometric joint position (from the transformation), thus -45°. Bit 4 in the "<TO>StatusKinematics.LinkConstellation" tag is TRUE, because the geometric joint position is -45°.

Case 2: The inverted traversing direction is configured for joint 5. The kinematics has exactly the same geometric joint position as in Case 1. However, due to the inverted traversing direction, the joint position is +45°. Bit 4 in the "<TO>StatusKinematics.LinkConstellation" tag is thus also TRUE in this case, because the geometric joint position (from the transformation) is -45°.

Working areas

The following graphics show the overhead area and the standard area:

① Overhead area

② Standard area

A The kinematics with joint J1 is in the zero position. The wrist point is located in the standard area.

B Joint J1 is rotated by -180.0°. With the rotated joint J1, the standard area and the overhead area are also rotated.

The following table shows the possible joint position spaces of the kinematics:

Tag	Data type	Values	W	Description

<TO>.Kinematics.Parameter[6]	-1.0E12 to 1.0E12	Distance L5 of the wrist point to the axis A3 in z direction of the KCS
<TO>.Kinematics.Parameter[7]	-1.0E12 to 1.0E12	Distance L7 of the axis A6 to the wrist point in y direction of the KCS
<TO>.Kinematics.Parameter[8]	-1.0E12 to 1.0E12	Distance L8 of the axis A6 to the wrist point in z direction of the KCS

7.9.5 Delta picker

7.9.5.1 Delta picker 2D

The kinematics "Delta picker 2D" supports 2 axes and 2 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 2 rotary axes A1 and A2.

The kinematics is modeled suspended. The kinematics consists of an upper connecting plate, two upper arms, connecting rods and a lower connecting plate. The axes for moving the arms (axes A1, A2) are fastened to the upper connecting plate. The upper arms and the connecting rods connect the upper and lower connecting plates.

The tool is suspended from the lower connecting plate.

The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

D1 Distance of the axes from the center of the upper connecting plate (radius of the upper connecting plate)

D2 Distance of the hinge points of the connecting rods to the middle of the lower connecting plate (radius of the lower connecting plate)

L1 Length of the upper arms

L2 Length of the connecting rods

D1, D2, L1 and L2 are identical for the two arms of the kinematics.

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics
The motion of the axes in the positive direction is the outward rotation of the upper arms.

α1 Deflection of the axis A1 in the negative direction when α1 = -45.0°

α2 Deflection of the axis A2 in the positive direction when α2 = 88.0°

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The axes A1 and A2 are at distance D1 from the common center point (kinematics zero point).

The flange coordinate system (FCS) is located on the bottom of the lower connecting plate with equal distance D2 to the hinge points of each arm. You shift the FCS in the negative z direction of the KCS using length LF.

In the zero position of the axes A1 and A2, the upper arms point in the negative z direction of the KCS.

Transformation area

Only the outwardly bent joint position (Page 157) is permitted for the arms of the kinematics. You cannot traverse the axes beyond the extended position of the arms.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

7.9.5.2 Delta picker 2D with orientation

The kinematics "Delta picker 2D with orientation" supports 3 axes and 3 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 2 rotary axes A1, A2
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics is modeled suspended. The kinematics consists of an upper connecting plate, two upper arms, connecting rods and a lower connecting plate. The axes for moving the arms (axes A1, A2) are fastened to the upper connecting plate. The upper arms and the connecting rods connect the upper and lower connecting plates.

The tool is suspended from the lower connecting plate.

The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the front view:

- The position of the axes and the coordinate systems KCS and FCS
- The zero positions of the axes A1 and A4
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

D1 Distance of the axes from the center of the upper connecting plate (radius of the upper connecting plate)

D2 Distance of the joint points of the connecting rods to the middle of the lower connecting plate (radius of the lower connecting plate)

L1 Length of the upper arms

L2 Length of the connecting rods

D1, D2, L1 and L2 are identical for the two arms of the kinematics.

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics
The motion of the axes in the positive direction is the outward rotation of the upper arms.

α1 Deflection of the axis A1 in the negative direction when α1 = -45.0°

α2 Deflection of the axis A2 in the positive direction when α2 = 88.0°

Legend for representation of the kinematics (Page 38)

The kinematics coordinate system (KCS) with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The axes A1 and A2 are at distance D1 from the common center point (kinematics zero point).

The flange coordinate system (FCS) is located in the center point of the lower connecting plate with equal distance D2 to the joint points of each arm. You shift the FCS in the negative z direction of the KCS using length LF.

In the zero position of the axes A1 and A2, the upper arms point in the negative z direction of the KCS. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

Only the outwardly bent joint position (Page 157) is permitted for the arms of the kinematics. You cannot traverse the axes beyond the extended position of the arms.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

7.9.5.3 Delta picker 3D

The kinematics "Delta picker 3D" supports 3 axes and 3 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 3 rotary axes A1, A2 and A3.

The kinematics is modeled suspended. The kinematics consists of an upper connecting plate, three upper arms, connecting rods and a lower connecting plate. The axes for moving the arms (axes A1, A2 and A3) are fastened to the upper connecting plate. The upper arms and the connecting rods connect the upper and lower connecting plates.

The tool is suspended from the lower connecting plate.

The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS.

Coordinate systems and zero position

The graphic below shows the following in the top view (xy plane):

- The position of the kinematics coordinate system (KCS)
- The angles of the axes A1, A2 and A3 to one another

β1 Angle between the axes A1 and A2

β2 Angle between the axes A2 and A3

Legend for representation of the kinematics (Page 38)

The following graphic shows the top view of the position of the flange coordinate system (FCS) in the xy plane of the lower connecting plate:

The graphic below shows the following in the front view (xz plane):

- The position of the axis A1 and the coordinate systems KCS and FCS
- The zero position of the axis A1
- The positive/negative deflection of the axis A1 is indicated (dashed)

Zero position of the kinematics

D1 Distance of the axes from the center of the upper connecting plate (radius of the upper connecting plate)

D2 Distance of the hinge points of the connecting rods to the middle of the lower connecting plate (radius of the lower connecting plate)

L1 Length of the upper arms

L2 Length of the connecting rods

D1, D2, L1 and L2 are identical for the three arms of the kinematics.

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics
The motion of the axes in the positive direction is the outward rotation of the upper arms.

α1 Deflection of the axis A1 in negative direction when α1 = -50.0°
Deflection of the axis A1 in positive direction when α1 = 90.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The axes A1, A2 and A3 are at distance D1 from the common center point (kinematics zero point).

The FCS is located in the center on the bottom of the lower connecting plate with equal distance D2 to the hinge points of each arm. You shift the FCS in the negative z direction of the KCS using length LF.

In the zero position of the axes A1, A2 and A3, the upper arms point in the negative z direction of the KCS.

Transformation area

Only the outwardly bent joint position (Page 157) is permitted for the arms of the kinematics. You cannot traverse the axes beyond the extended position of the arms.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

7.9.5.4 Delta picker 3D with orientation

The kinematics "Delta picker 3D with orientation" supports 4 axes and 4 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 3 rotary axes A1 A2 and A3
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics is modeled suspended. The kinematics consists of an upper connecting plate, three upper arms, connecting rods and a lower connecting plate. The axes for moving the arms (axes A1, A2 and A3) are fastened to the upper connecting plate. The upper arms and the connecting rods connect the upper and lower connecting plates.

The tool is attached to the lower connecting plate.

The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the top view (xy plane):

- The position of the kinematics coordinate system (KCS)
- The angles of the axes A1, A2 and A3 to one another

- The zero positions of the axes A1 and A4
- The positive/negative deflection of the axis A1 is indicated (dashed)

Zero position of the kinematics

D1 Distance of the axes from the center of the upper connecting plate (radius of the upper connecting plate)

D2 Distance of the joint points of the connecting rods to the middle of the lower connecting plate (radius of the lower connecting plate)

L1 Length of the upper arms

L2 Length of the connecting rods

D1, D2, L1 and L2 are identical for the three arms of the kinematics.

LF Flange length before the FCS in the z direction of the KCS

Deflection of the kinematics
The motion of the axes in the positive direction is the outward rotation of the upper arms.

α1 Deflection of the axis A1 in negative direction when α1 = -50.0°
Deflection of the axis A1 in positive direction when α1 = 90.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The axes A1, A2 and A3 are at distance D1 from the common center point (kinematics zero point).

The FCS is located in the center point on the bottom of the lower connecting plate with equal distance D2 to the joint points of each arm. You shift the FCS in the negative z direction of the KCS using length LF.

In the zero position of the axes A1, A2 and A3, the upper arms point in the negative z direction of the KCS. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

Only the outwardly bent joint position (Page 157) is permitted for the arms of the kinematics. You cannot traverse the axes beyond the extended position of the arms.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

7.9.5.5 Delta picker 3D with 2 orientations A, B

The kinematics "Delta picker 3D with 2 orientations A, B" supports 5 axes and 5 degrees of freedom. The axes are configured as parallel kinematics. For this kinematics type, you need the Motion Control package "S7-1500T Motion Control KinPlus" (Page 27).

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 3 rotary axes A1 A2 and A3
- One rotary swivel axis A4 which rotates around the z axis of the KCS in the kinematics zero position.
- One rotary swivel axis A5, which rotates around the y axis of the KCS in the kinematics zero position.

The kinematics is modeled suspended. The kinematics consists of an upper connecting plate, three upper arms, connecting rods and a lower connecting plate. The axes for moving the arms (axes A1, A2 and A3) are fastened to the upper connecting plate. The upper arms and the connecting rods connect the upper and lower connecting plates.

The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS.

The rotary axis A4 and the swivel axis A5 are mounted on the lower connecting plate. The motors of the axes A4 and A5 can be mounted on the upper connecting plate or below the lower connecting plate. If the motors are mounted on the upper connecting plate, then the axes A4 and A5 are moved via a mechanical shaft, which is mounted between the two connecting plates.

The tool is attached to the swivel axis A5.

Coordinate systems and zero position

The graphic below shows the following in the top view (xy plane):

- The position of the kinematics coordinate system (KCS)
- The angles of the axes A1, A2 and A3 to one another

β1 Angle between the axes A1 and A2

β2 Angle between the axes A2 and A3

Legend for representation of the kinematics (Page 38)

The following graphic shows the bottom view of the position of the flange coordinate system (FCS) in the xy plane of the lower connecting plate:

The graphic below shows the following in the front view (xz plane):

- The position of the axis A1 and the coordinate systems KCS and FCS
- The zero positions of the axes A1 and A4
- The positive/negative deflection of the axis A1 is indicated (dashed)

Zero position of the kinematics

D1 Distance of the axes from the center of the upper connecting plate (radius of the upper connecting plate)

D2 Distance of the joint points of the connecting rods to the middle of the lower connecting plate (radius of the lower connecting plate)

L1 Length of the upper arms

L2 Length of the connecting rods

L3 Distance of the swivel axis from the lower connecting plate in the negative z direction of the KCS

L4 Distance of the joint points of rotary axis A4 and swivel axis A5 in the x direction of the KCS
in the kinematics zero position

D1, D2, L1 and L2 are identical for the three arms of the kinematics.

LF Distance LF from the joint point of swivel axis A5 to the FCS in the negative x direction of the FCS

Deflection of the kinematics
The motion of the axes A1, A2 and A3 in positive direction is that of the rotation outward of the upper arms.

α1 Deflection of the axis A1 in negative direction when α1 = -50.0°
Deflection of the axis A1 in positive direction when α1 = 90.0°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The axes A1, A2 and A3 are at distance D1 from the common center point (kinematics zero point).

At the zero position of the kinematics, the FCS is oriented with A = 0°, B = 90° and C = 0°.

In the zero position of the axes A1, A2 and A3, the upper arms point in the negative z direction of the KCS. At the zero position of axes A4 and A5, the x axis of the FCS points in the negative direction of the z axis of the KCS.

Direction of travel of the joints

The following figure shows the direction of travel of the joints defined in the kinematics type.

① Front view

② Side view

Positive direction of rotation of the joints

If the direction of travel of a joint of the real kinematics is inverse to the direction of travel of the joint defined in the kinematics type from Siemens, you must invert the joint direction (Page 55) in the configuration.

Transformation area

Only the outwardly bent joint position (Page 157) is permitted for the arms of the kinematics. You cannot traverse the axes beyond the extended position of the arms.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

7.9.5.6 Permissible joint position for delta picker

Only the outwardly bent joint position is permitted for the arms of the delta picker kinematics. The graphic below shows examples of permissible and impermissible joint positions for the transformation:

Permissible joint position

Invalid joint position for the transformation

1) Only relevant for kinematics type "Delta picker 3D with 2 orientations A, B"

7.9.6 Cylindrical robot

7.9.6.1 Cylindrical robot 3D

The kinematics "Cylindrical robot 3D" supports 3 axes and 3 degrees of freedom. The axes are configured as serial kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 linear axis A2 in z direction of the KCS
- 1 linear axis A3 in x direction of the KCS

The kinematics consists of a base, a supporting column and a jib. Axis A1 rotates the supporting column with jib around the base. Axis A2 moves the jib vertically. Axis A3 moves the flange system horizontally on the jib. The kinematics enables a cylindrical working area.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero positions of the axes A1 and A2
- The deflection of the kinematics is indicated (dashed)

Zero position of the axes A1 and A2

L1 At zero position of the axis A2:
Distance of the FCS to the kinematics zero point (KZP) and flange length LF in z direction of the KCS

LF Flange length before the FCS in the z direction of the KCS

x_1 Positive deflection of the axis A3
At the zero position of axis A3, the z axis of the FCS is located on the z axis of the KCS. For mechanical reasons, the kinematics shown cannot approach the zero position of the axis A3.

Deflection of the kinematics

x_2 Positive deflection of the axis A3

z_1 Positive deflection of the axis A2

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L2 Distance of the axis A3 from the KZP in y direction of the KCS (negative value here)

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 30°
Negative deflection of the axis A1 when α1 = -75°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. You define the distance of the zero position of axis A2 in z direction of the KCS from the KZP using length L1. You define the distance of the axis A3 from the KZP in y direction of the KCS using length L2.

The flange coordinate system (FCS) is located on the axis A3, shifted by the length LF in negative z direction of the KCS.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The jib with the axis A3 points in x_{KCS} direction.
A2	The axis A2 is at the position 0.0 of the interconnected technology object.
A3	The axis A3 is at the position 0.0 of the interconnected technology object.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: No limit
- Axis A3: No limit

NOTE
Singularity
The kinematics has singularity (Page 183).

A singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). Inverse transformation is not possible in this area. This position may result, e.g. if the length L2 is 0.0 due to the design.

The graphic below shows examples of permissible and impermissible joint positions for the transformation:

Permissible joint position

Singularity at L2 = 0.0

Joint position space

The following table shows the possible joint position spaces of the kinematics:

Tag	Data type	Values	W	Description	
StatusKinematics.	TO_Struct_Kinematics_StatusKinematics				
Valid	BOOL	-	RON	Validity of the transformation values	
				FALSE	Invalid
				TRUE	Valid

7.9.6.2 Cylindrical robot 3D with orientation

The kinematics "Cylindrical robot 3D with orientation" supports 4 axes and 4 degrees of freedom. The axes are configured as serial kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 1 rotary axis A1 with rotation around the z axis of the kinematics coordinate system (KCS)
- 1 linear axis A2 in z direction of the KCS
- 1 linear axis A3 in x direction of the KCS
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics consists of a base, a supporting column and a jib. Axis A1 rotates the supporting column with jib around the base. Axis A2 moves the jib vertically. Axis A3 moves the flange system horizontally on the jib. The kinematics enables a cylindrical working area. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the side view (xz plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero positions of the axes A1 and A2
- The deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L1 With axis A2 in the zero position:
Distance of the FCS to the kinematics zero point (KZP) and flange length LF in z direction of the KCS

LF Flange length before the FCS in the z direction of the KCS

x_1 Positive deflection of the axis A3
At the zero position of axis A3, the z axis of the FCS is located on the z axis of the KCS. For mechanical reasons, the kinematics shown cannot approach the zero position of the axis A3.

Deflection of the kinematics

x_2 Positive deflection of the axis A3

z_1 Positive deflection of the axis A2

Legend for representation of the kinematics (Page 38)

The graphic below shows the following in the top view (xy plane):

- The position of the axes and the coordinate systems KCS and FCS
- The zero position of the kinematics
- The positive/negative deflection of the kinematics is indicated (dashed)

Zero position of the kinematics

L2 Distance of the axis A3 to the KZP in y direction of the KCS (negative value in this case)

Deflection of the kinematics

α1 Positive deflection of the axis A1 when α1 = 30°
Negative deflection of the axis A1 when α1 = -75°

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the base of the kinematics. You define the distance of the zero position of axis A2 in z direction of the KCS from the KZP using length L1. You define the distance of the axis A3 from the KZP in y direction of the KCS using length L2.

The flange coordinate system (FCS) is located on the axis A3, shifted by the length LF in negative z direction of the KCS.

The following table shows the zero position of the axes:

Axis	Zero position
A1	The jib with the axis A3 points in x_{KCS} direction.
A2	The axis A2 is at the position 0.0 of the interconnected technology object.
A3	The axis A3 is at the position 0.0 of the interconnected technology object.
A4	With axis A1 in the zero position, the x axis of the FCS points in the direction of the x axis of the KCS.

Compensation of mechanical axis couplings

You can configure a mechanical axis coupling of axis A4 to axis A2 for the kinematics. The kinematics transformation compensates for the configured mechanical axis coupling. The axis coupling between axis A4 and axis A2 is implemented as a leadscrew pitch. With a compensation factor of 1.0, 360.0° on axis A4 corresponds to a distance of -1.0 mm on axis A2.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axis A1: -180.0° ≤ α1 < 180.0°
- Axis A2: No limit
- Axis A3: No limit
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

NOTE
Singularity
The kinematics has singularity (Page 183).

A singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). Inverse transformation is not possible in this area. This position may result, e.g. if the length L2 is 0.0 due to the design.

The graphic below shows examples of permissible and impermissible joint positions for the transformation:

Permissible joint position

Singularity at L2 = 0.0

Joint position space

The following table shows the possible joint position spaces of the kinematics:

Tag	Data type	Values	W	Description	
StatusKinematics.	TO_Struct_Kinematics_StatusKinematics				
Valid	BOOL	-	RON	Validity of the transformation values	
				FALSE	Invalid
				TRUE	Valid
LinkConstellation	DWORD	0 to n	RON	Joint position space	
Bit 0	-	-	-	Position axis 1	
				0	Not relevant
				1	Not relevant
Bit 1	-	-	-	Position axis 2	
				0	Not relevant
				1	Not relevant
Bit 2	-	-	-	Angle α3 of axis A3 positive/negative taking into consideration the mechanical axis coupling	
				0	α3 positive
				1	α3 negative
Bit 3 ... 31	-	-	-	Not relevant	

7.9.6.3 Tags: Cylindrical robot

Cylindrical robot 3D

You define the "Cylindrical robot 3D" kinematics using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	21	Cylindrical robot 3D
<TO>.Kinematics.Parameter[1]	-1.0E12 to 1.0E12	Distance L1 of the zero position of the axis A2 to the kinematics zero point in z direction of the kinematics coordinate system (KCS)
<TO>.Kinematics.Parameter[2]	-1.0E12 to 1.0E12	Distance L2 between the axes A2 and A3 in y direction of the KCS
<TO>.Kinematics.Parameter[3]	-1.0E12 to 1.0E12	Distance of the flange coordinate system from the axis A3 in the negative z direction of the KCS

Cylindrical robot 3D with orientation

You define the "Cylindrical robot 3D with orientation" kinematics using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	22	Cylindrical robot 3D with orientation
<TO>.Kinematics.Parameter[1]	-1.0E12 to 1.0E12	Distance L1 of the zero position of the axis A2 to the kinematics zero point in z direction of the KCS
<TO>.Kinematics.Parameter[2]	-1.0E12 to 1.0E12	Distance L2 between the axes A2 and A3 in y direction of the KCS
<TO>.Kinematics.Parameter[3]	-1.0E12 to 1.0E12	Distance of the flange coordinate system from the axis A3 in the negative z direction of the KCS
<TO>.Kinematics.Parameter[4]	-	Mechanical axis coupling of axis A4 to A2 present/not present
	0	Not present
	1	Present
<TO>.Kinematics.Parameter[5]	-1.0E12 to 1.0E12	Compensation factor of axis A4 to axis A2

7.9.7 Tripod

7.9.7.1 Tripod 3D

The kinematics "Tripod 3D" supports 3 axes and 3 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of 3 linear axes A1, A2 and A3.

The kinematics is modeled suspended and consists of an upper connecting plate, 3 arms and a lower connecting plate. The axes for the motion of the arms consist of rails with sliding carriages. The rails with the sliding carriages are fastened to the upper connecting plate. Connecting rods connect the sliding carriages to the lower connecting plate. The tool is suspended from the lower connecting plate. The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS.

Coordinate systems and zero position

The graphic below shows the following in the top view (xy plane):

- The position of the kinematics coordinate system (KCS)
- The angles of the axes A1, A2 and A3 to one another

β1 Angle between the axes A1 and A2

β2 Angle between the axes A2 and A3

Legend for representation of the kinematics (Page 38)

The following graphic shows the top view of the position of the flange coordinate system (FCS) in the xy plane of the lower connecting plate:

The graphic below shows the following in the front view (xz plane):

- The position of the axis A1 and the coordinate systems KCS and FCS
- The zero position of the axis A1
- The positive deflection of the axis A1 is indicated (dashed)

Zero position of the kinematics

D1	Distance of the upper hinge points of the connecting rods to the center of the upper connecting plate
D2	Distance of the lower hinge points of the connecting rods to the center of the lower connecting plate
L1	Length of the connecting rods
LF	Flange length before the FCS in the z direction of the KCS
γ	Angle between the upper connecting plate (xy plane of the KCS) and the rail of the axis A1 ($0.0° \leq \gamma < 90.0°$)

D1, D2, L1 and γ are identical for the three arms of the kinematics.

Deflection of the kinematics with deflection of the axis A1 in positive direction

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The kinematics zero point is centered relative to the zero positions of the axes A1, A2 and A3.

The FCS is located in the center point of the lower connecting plate with identical distance D2 to the joint points of each connecting rod. You shift the FCS in the negative z direction of the KCS using length LF.

At the zero position, axes A1, A2 and A3 are in the xy plane of the KCS.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axes A1, A2 and A3: 0.0 ≤ Travel distance

NOTE
Singularity
The kinematics has outer singularities (Page 183).

Joint position space

No joint position spaces for the kinematics.

7.9.7.2 Tripod 3D with orientation

The kinematics "Tripod 3D with orientation" supports 4 axes and 4 degrees of freedom. The axes are configured as parallel kinematics.

The following graphic shows the principal configuration and the typical working area of the kinematics:

The kinematics consists of the following axes:

- 3 linear axes A1, A2 and A3
- 1 rotary axis A4 with rotation around z in the KCS

The kinematics is modeled suspended and consists of an upper connecting plate, 3 arms and a lower connecting plate. The axes for the motion of the arms consist of rails with sliding carriages. The rails with the sliding carriages are fastened to the upper connecting plate. Connecting rods connect the sliding carriages to the lower connecting plate. The tool is suspended from the lower connecting plate. The parallelogram structures of the connecting rods keep the lower connecting plate parallel to the xy plane of the KCS. The kinematics axis A4 enables rotation of the tool around z in the KCS.

Coordinate systems and zero position

The graphic below shows the following in the top view (xy plane):

- The position of the kinematics coordinate system (KCS)
- The angles of the axes A1, A2 and A3 to one another

β1 Angle between the axes A1 and A2

β2 Angle between the axes A2 and A3

Legend for representation of the kinematics (Page 38)

The following graphic shows the top view of the position of the flange coordinate system (FCS) in the xy plane of the lower connecting plate:

The graphic below shows the following in the side view:

- The position of the axis A1 and the coordinate systems KCS and FCS
- The zero position of the axis A1
- The positive deflection of the axis A1 is indicated (dashed)

Zero position of the kinematics

D1	Distance of the upper joint points of the connecting rods to the center of the upper connecting plate
D2	Distance of the lower joint points of the connecting rods to the center of the lower connecting plate
L1	Length of the connecting rods
LF	Flange length before the FCS in the z direction of the KCS
γ	Angle between the upper connecting plate (xy plane of the KCS) and the rail of the axis A1 ($0.0° \leq \gamma < 90.0°$)

D1, D2, L1 and γ are identical for the three arms of the kinematics.

Deflection of the kinematics with deflection of the axis A1 in positive direction

Legend for representation of the kinematics (Page 38)

The KCS with the kinematics zero point (KZP) is located at the center point of the upper connecting plate. The kinematics zero point is centered relative to the zero positions of the axes A1, A2 and A3.

The FCS is located in the center point of the lower connecting plate with identical distance D2 to the joint points of each connecting rod. You shift the FCS in the negative z direction of the KCS using length LF.

At the zero position, axes A1, A2 and A3 are in the xy plane of the KCS. At the zero position of axis A4, the x axis of the FCS points in the direction of the x axis of the KCS.

Transformation area

The kinematics transformation covers the following traversing range (Page 178) of the axes:

- Axes A1, A2 and A3: 0.0 ≤ Travel distance
- Axis A4: No limit

  An angle greater than 360° can be defined for the orientation. But coordinate A of the tool center point (TCP) is mapped in the range -180° to +180°.

NOTE
Singularity
The kinematics has outer singularities (Page 183).

Joint position space

No joint position spaces for the kinematics.

7.9.7.3 Tags: Tripod

You define the tripod kinematics using the following tags of the technology object:

Tags	Values	Description
<TO>.Kinematics.TypeOfKinematics	23	Tripod 3D
	24	Tripod 3D with orientation
<TO>.Kinematics.Parameter[1]	0.0 to 1.0E12	Distance D1 (radius of the upper connecting plate)
<TO>.Kinematics.Parameter[2]	0.001 to 1.0E12	Length L1 of connecting rods
<TO>.Kinematics.Parameter[3]	0.0° to 89.999°	Angle γ between the linear axes and the x-y plane of the kinematics coordinate system
<TO>.Kinematics.Parameter[4]	0.0 to 1.0E12	Distance D2 (radius of the lower connecting plate)
<TO>.Kinematics.Parameter[5]	90.001° to 179.998°	Angle β1 between the axes A1 and A2
<TO>.Kinematics.Parameter[6]	90.001° to 179.998°	Angle β2 between the axes A2 and A3
<TO>.Kinematics.Parameter[7]	-1.0E12 to 1.0E12	Distance of the flange coordinate system from the lower connecting plate in the negative z direction of the kinematics coordinate system

7.9.8 User-defined kinematics systems

You can configure user-defined kinematics systems with corresponding axis interconnections:

- User-defined 2D
- User-defined 2D with orientation A
- User-defined 3D
- User-defined 3D with orientation A
- User-defined 3D with 3 orientations

The configuration supports you in a user-defined kinematics as follows:

- You interconnect the kinematics axes under "Technology object > Configuration > Interconnections".
- You define the transformation parameters under "Technology object > Configuration > Geometry". Up to 32 tags for defining the geometry of your kinematics are available on the system level.

Transformation area

The kinematics transformation covers the following traversing range of the axes:

- Axis A[4..6]: -180.0° ≤ α[4..6] < 180.0°

User transformation

You have to program the user transformation of the Cartesian positions and the axis positions and axis dynamics. Predefined interfaces are available on the system level. The function of the user transformation is different for kinematics with and without JCS:

- User transformation without JCS (Page 190)
- User transformation with JCS (Page 192)

7.9.8.1 Tags: User-defined kinematics systems

You configure the user-defined kinematics systems using the following tags of the technology object:

Tag	Values	Description
<TO>.Kinematics.TypeOfKinematics	31	User-defined 2D
	32	User-defined 2D with orientation A
	33	User-defined 3D
	34	User-defined 3D with orientation A
	36	User-defined 3D with 3 orientations
<TO>.Kinematics.Parameter[1..32]	-	Up to 32 user-specific parameters

7.10 Kinematics transformation

The kinematics transformation is the conversion between the Cartesian coordinates of the kinematics motion and the setpoints for the individual kinematics axes:

- Forward transformation

  Calculation of the Cartesian coordinates from the axis positions of the kinematics axes
- Inverse transformation

  Calculation of the axis positions of the kinematics axes from the Cartesian coordinates

The kinematics transformation converts the position values and the dynamic values (velocity, acceleration).

The kinematics technology object provides the kinematics transformation for the predefined kinematics types on the system level. In the case of user-defined kinematics systems, you must calculate the user transformation (Page 190) in its own program.

7.10.1 Transformation for predefined kinematics systems

7.10.1.1 Reference points

The kinematics transformation uses the following reference points:

- Kinematics zero point (KZP)
- Zero positions of the kinematics axes
- Tool center point (TCP)

The positive direction of the axes for the kinematics transformation is dependent on the kinematics type (Page 58). Configure the positive direction on the positioning axis/synchronous axis technology object corresponding to the positive direction of the axis in the kinematics.

Zero positions of the kinematics axes

The position 0.0 on the positioning axis/synchronous axis technology object defines the zero position of the kinematics axis. Reference the axes in such a way that the axes indicate the position 0.0 in the zero position of the kinematics. The zero position of the kinematics depends on the kinematics type (Page 58).

7.10.1.2 Traversing range and transformation area

The transformation area is the area of the axis positions that the kinematics transformation covers. The kinematics type defines the transformation area for the individual kinematics axes. You will find information on the transformation area in the description of the individual kinematics systems (Page 58).

The hardware and software limit switches of an axis define the maximum traversing range and the working area. The working area of a kinematics axis can be greater than or less than the transformation area depending on the axis configuration:

- Working area > Transformation area

  When a kinematics axis exits the transformation area during a kinematics motion, the kinematics technology object outputs the technology alarm 803. The kinematics motion is aborted and the axes stop with the maximum dynamic values configured for the axes (alarm reaction: Stop with maximum dynamic values of the axes).

- Working area ≤ Transformation area

  When a kinematics axis runs into the software limit switch, the positioning axis/synchronous axis technology object outputs the technology alarm 533. The axis stops with the maximum dynamic values configured for the axis (alarm reaction: Stop with maximum dynamic values). When the axis is stopped, the kinematics technology object outputs the technology alarm 801. The kinematics motion is aborted and the axes stop with the maximum dynamic values configured for the axes (alarm reaction: Stop with maximum dynamic values of the axes).

The following graphic shows the relationship between the working area of the axis and the transformation area:

① Mechanical end stop

② Hardware limit switch for positioning axis/synchronous axis technology object

③ Software limit switch for positioning axis/synchronous axis technology object

④ Maximum traversing range of the axis

⑤ Working area of the axis

⑥ Transformation area
(here working area > transformation area)

7.10.1.3 Joint position spaces (kinematics-dependent)

Depending on the kinematics type, a kinematics can reach Cartesian coordinates via various joint positions. The kinematics type (Page 58) defines the possible joint positions and the positive and negative joint position spaces. The joint position spaces are limited by the respective transformation areas. In addition, with the "Delta picker" kinematics type there are further limitations due to invalid joint positions and singularities (Page 183) with the kinematics types "articulated arm", "SCARA 3D" and "cylindrical robot". Also note the resulting constructional limitations due to the installation location of the kinematics.

The kinematics technology object indicates the current joint position in the "<TO>.StatusKinematics.LinkConstellation" tag.

The kinematics system cannot exit the joint position space during a linear or circular motion. You can change the joint position space using single-axis motions and synchronous "point-to-point" motion (sPTP motion).

Example: Kinematics type "SCARA 3D"

A "SCARA 3D" kinematics is to relocate an object from one pallet to another pallet. Due to a wall, the kinematics system cannot reach the second pallet without the axis A2 changing the joint position space.

The figure below shows the kinematics in the top view (xy plane):

Zero position of the kinematics

Deflection of the kinematics in the positive direction when α1 = 45.0° with positive joint position when α2 = 120.0°
Deflection of the kinematics in the negative direction when α1 = -45.0° with negative joint position when α2 = -120.0°

α1 Deflection of the axis A1 in positive direction when α1 = 45.0°
Deflection of the axis A1 in the negative direction when α1 = -45.0°

α2 The deflection of the axis A2 in the positive direction when α2 = 120.0° produces a positive joint position.
The deflection of the axis A2 in negative direction when α2 = -120.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

Example: "Articulated arm 3D" kinematics type

A kinematics "Articulated arm 3D" should move one object from one storage location to another. The kinematics cannot reach the second storage location because of the ceiling without axis A3 changing the joint position space.

The figure below shows the kinematics in the side view (xz plane):

Zero position of the kinematics

Deflection of the kinematics in the positive direction when α2 = 10.0° with positive joint position when α3 = 35.0°
Deflection of the kinematics in the negative direction when α2 = -15.0° with negative joint position when α3 = -75.0°

α2 Deflection of the axis A2 in the positive direction when α2 = 10.0°
Deflection of the axis A2 in negative direction when α2 = -15.0°

α3 The deflection of the axis A3 in positive direction when α3 = 35.0° produces a positive joint position.
The deflection of the axis A3 in negative direction when α3 = -75.0° produces a negative joint position.

Legend for representation of the kinematics (Page 38)

Example: Kinematics type "cylindrical robot"

A kinematics "Cylindrical robot" should move an object from one storage location to another. The kinematics cannot reach the second storage location without axis A3 changing the joint position space.

The figure below shows the kinematics in the top view (xy plane):

Zero position of the kinematics

Deflection of the kinematics in positive direction when α1 = 30.0°
Deflection of the kinematics in the negative direction when α1 = -75.0°

α1 Deflection of the axis A1 in positive direction when α1 = 30.0°
Deflection of the axis A1 in the negative direction when α1 = -75.0°

Legend for representation of the kinematics (Page 38)

7.10.1.4 Singularities

Depending on the kinematics type, inverse transformation Cartesian coordinates are possible, which cannot be clearly converted into axis positions of the kinematics axes. The Cartesian coordinates at which this behavior occurs are referred to as singularities.

Inner singularities

The inner singularity occurs when the zero point of the flange coordinate system (FCS) is located on the z axis of the kinematics coordinate system (KCS). The following kinematics have inner singularities:

- Articulated arm 3D
- Articulated arm 3D with orientation
- 6-axis articulated arm with central wrist
- 6-axis articulated arm with offset wrist
- SCARA 3D with orientation
- Cylindrical robot 3D
- Cylindrical robot 3D with orientation

Inner singularity using the articulated arm 3D as an example

In the vicinity of the inner singularity, a path motion without dynamic adaptation will result in an overrun of the dynamics of the kinematics axis A1 and the kinematics axis A4. This causes the entire kinematics to rotate with an overrun of the dynamics.

Outer singularities

An outer singularity occurs when one or more arms of the kinematics are completely extended or folded. The following kinematics have outer singularities:

- Articulated arm 2D
- Articulated arm 2D with orientation
- Articulated arm 3D
- Articulated arm 3D with orientation
- 6-axis articulated arm with central wrist
- 6-axis articulated arm with offset wrist
- SCARA 3D with orientation
- Delta picker 2D

- Delta picker 2D with orientation
- Delta picker 3D
- Delta picker 3D with orientation
- Delta picker 3D with 2 orientations A, B
- Tripod 3D
- Tripod 3D with orientation

In the vicinity of these singularities a path motion without dynamic adaptation will result in an overrun of the dynamics at the kinematics axes, which can result in oscillations of the entire kinematics as well as excessive forces being applied.

Extended position using the articulated arm 3D as an example

The articulated arm is fully extended and the flange is at the external limit of the maximum possible working range.

Folded position using the articulated arm 3D as an example

The articulated arm is completely folded.

Behavior in the vicinity of a singularity

In the vicinity of a singularity a path motion without dynamic adaptation results in overruns of the dynamics. This means one or more kinematics axes can move at very high speed and accelerate or decelerate with excessive force. The size of the area in which this behavior occurs depends on the kinematics used.

⚠ WARNING

Overrun of the dynamics in the vicinity of a singularity

An overrun of the dynamics in the vicinity of a singularity can result in the following damage:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damages, for example, through overload of the mechanical components

Take into account the preventive measures described in this section to prevent this behavior.

A path motion through a singularity is not possible. The technology alarm 803 "Error during calculation of the transformation" is output (alarm response: Stop with maximum dynamic values of the axes).

The kinematics system reduces the overruns of the dynamics caused by setpoints to the maximum dynamics of the axis. The reduction of the overruns of the dynamics can result in an unpredictable axis motion.

When the dynamic limits of the kinematics axes are exceeded, this is displayed at the affected kinematics axis with the tag "<TO>.StatusKinematicsMotion" and the technology alarm 511 "Dynamic limit is violated by the kinematics motion" is triggered. The technology alarm 511 does not trigger an alarm response and the kinematics motion is not stopped.

Affected kinematics motions

An overrun of the dynamics in the vicinity of a singularity only occurs for path motions without dynamic adaptation.

An overrun of the dynamics due to a singularity does not occur for the following motions:

- Synchronous point-to-point motion
- Motions in the MCS through the kinematics control panel

Dynamic adaptation in the vicinity of singularities

With movement in the vicinity of singularities with dynamic adaptation without segmentation of the path, dynamics can be significantly limited over the entire motion. Therefore, with motions in the vicinity of singularities, use the dynamic adaptation with segmentation of the path.

Preventive measures to prevent the behavior

By applying the following preventive measures, you can avoid a path motion without dynamic adaptation in the vicinity of a singularity:

1. Avoid the use of conveyor tracking in the vicinity of a singularity. When conveyor tracking is active, singularities are not handled despite active dynamic adaptation (Page 244).
2. Activate Dynamic adaptation (Page 244) for linear or circular motions that are not part of the phases of conveyor tracking.
3. To limit the working area of the kinematics, use zone monitoring or software limit switches at the kinematics axes.
4. Control with the kinematics control panel
   - Move the kinematics in the MCS.
   - In the WCS or OCS, avoid the "Jog" mode.

     The dynamic adaptation is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.

– Up to technology version V5.0 of the kinematics technology object: In the WCS or OCS, avoid using the "Jog to target position" mode.

  The dynamic adaptation is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.

– As of technology version V5.0 and higher: Move the kinematics to the "Jog to target position" mode in the WCS or OCS using the kinematics control panel.

  "Dynamic adaptation without segmentation of the path" is permanently active in the "Jog to target position" mode, and the dynamic limits of the kinematics axes are taken into account.

Determining the area with overrun of the dynamics for articulated arm 3D

To empirically determine the area in which overruns of the dynamics occur due to a singularity, use the following functions:

- Kinematics diagnostics
- Kinematics control panel
- Trace
- Virtual or simulated axes

WARNING

Deliberately traveling into the singularity

The following damage may occur due to overruns of the dynamics in the vicinity of a singularity:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damages, for example, through overload of the mechanical components

Do **not** determine the areas with overrun in the dynamics by moving the actual kinematics.

You **must** configure all kinematics axes as "virtual axis" or "axis in simulation".

Requirements

- All kinematics axes are configured as virtual or simulated axes. The kinematics are interconnected.
- The geometry of the kinematics is configured to match the real kinematics.
- The dynamics for kinematics and all kinematics axes are configured.
- The permitted dynamics are known from the application.
- The tool center point is located at the origin of the FCS.

Determining the distance to the inner singularity

1. Configure a Trace with the following signals:
   - <TOKinematics>.A[1..6].Velocity
   - <TOKinematics>.A[1..6].Acceleration
   - <TOKinematics>.FlangeInKcs.x.Position
   - <TOKinematics>.FlangeInKcs.y.Position
   - <TOKinematics>.FlangeInKcs.z.Position
2. Open the diagnostics of the kinematics and arrange it next to the kinematics control panel.
3. Set the kinematics control panel as follows:
   - Operating mode: Jog
   - Coordinate system: WCS
   - Path velocity: Maximum required path velocity for the process
4. Make sure that all kinematics axes are configured as virtual axes or axes in simulation.
5. Jog the kinematics to a position from which the inner singularity could be reached.
6. Jog the kinematics backward a little (e.g. 1 mm) in y direction so that you can jog slightly past the singularity.
7. Jog the kinematics with maximum path velocity in x direction past the inner singularity and record the signals in the Trace.

Jog forward and backward in x direction

Jog backward in y direction

8. Gradually increase the distance in y direction to the inner singularity. Repeat step 7.

The recorded Trace shows the dynamics of the axis A1 at different distances of the FCS to the inner singularity.

9. Determine the distance on the y-axis at which the dynamics of the kinematics axis A1 is permissible for your process.

   This distance corresponds to the radius of a cylinder around the z axis of the KCS in which overruns of the dynamics occur and the flange must not be moved.

NOTE

Validity of the determined distance

The determined distance only applies to a kinematics with the configured geometry and dynamics.

NOTE

Valid tool

Configure the tool once again so that the tool matches your application.

Limiting the working area with zone monitoring

The Cartesian space that must be excluded from the working area results from the determined distance.

You can find a description of the zone monitoring in section "Zone monitoring (Page 208)".

1. Define a cylindrical blocked zone or signal zone around the z axis of the KCS:
   - Length z: Entire working area of the kinematics
   - Radius: Determined distance
   - x: Position of the KZP in x direction of the WCS
   - y: Position of the KZP in y direction of the WCS

Signal zone	Blocked zone
Useful in case of a major shift of the TCP from the origin of the FCS in x or y direction and when using conveyor tracking	Useful in case of a minor shift of the TCP from the origin of the FCS in x or y direction Not very useful when using conveyor tracking
Individually programmed stop reaction when: – Flange zone violates signal zone – Signal zone violated by TCP	Automatic stop reaction when: – Flange zone violates blocked zone – Blocked zone violated by TCP

2. Define a spherical flange zone:
   - Radius: Distance required for the stop reaction
   - CS: FCS
   - x: 0.0
   - y: 0.0
   - z: 0.0

3. When you are using a signal zone, program a stop reaction for the kinematics and any other axes, if necessary.

NOTE

Extended position and folded position

You can also use this procedure to determine the area of the overruns of the dynamics in extended and folded positions and then limit the working area of the kinematics with zones.

7.10.2 Transformation for user-defined kinematics systems

7.10.2.1 User transformation without JCS

Unlike for predefined kinematics types, you must calculate the transformation for user-defined kinematics systems in your own program. Like for predefined kinematics types, the kinematics technology object performs the following tasks:

- Processing of Motion Control instructions
- Monitoring functions
- Communication with the interconnected axes

You program the user transformation of the Cartesian coordinates and the axis-specific setpoints in the MC_Transformation organization block. This programming includes the transformation of the positions and the dynamic values (velocity, acceleration). You freely define the parameters of a user-defined kinematics system in the tags of the kinematics technology object "<TO>.Kinematics.Parameter[1..32]" or under "Technology object > Configuration > Geometry".

When you add the MC_Transformation in the TIA Portal, the system data block "TransformationParameter" is automatically created under "Program blocks > System blocks > Program resources". In the properties of the organization block under "General > Transformation", the MC_Transformation indicates the number of the system data block "TransformationParameter". You write and read the axis-specific data or the Cartesian data of the kinematics to be transformed in the system data block "TransformationParameter".

With the technology version V5.0, longer runtimes of the MC_Interpolator arise during user transformation. With longer runtimes of the MC_Interpolator, the runtimes of the organization blocks with lower priority are extended.

NOTE

Disable system performance improvement

If you are using user-defined kinematics, clear the "Improve system performance" check box in the MC_LookAhead properties under "General > Multi-core processor".

Programming

The graphic below shows the interfaces and the interaction of system performance and user transformation:

Processing by user program

System performance

The kinematics technology object automatically calls the MC_Transformation. The MC_Transformation contains the following start information:

- Kinematics technology object that calls the MC_Transformation
- Required direction of the transformation (forward or inverse transformation)
- Processing context of the transformation (current motion or motion planning)
- Pointer to the system data block "TransformationParameter" (VARIANT)

You evaluate this status information in your user program. In MC_Transformation, you program the algorithms for the calculation of the axis-specific data or the Cartesian data of all user-defined kinematics systems. You read the kinematics parameters needed for this from the tags of the "<TO>.Kinematics.Parameter[1..32]" technology object. You write the result of the calculation to the "TransformationParameter" interface.

The transformation parameters are then applied automatically to the kinematics technology object and processed further. The kinematics technology object outputs the setpoints to the kinematics axes.

You can configure and apply the user-defined transformation with multiple kinematics technology objects on a PLC. To differentiate in MC_Transformation between the different kinematics technology objects, use the input "KinematicsObject".

7.10.2.2 User transformation with JCS

Unlike for predefined kinematics types, you must calculate the transformation for user-defined kinematics systems in your own program. Like for predefined kinematics types, the kinematics technology object performs the following tasks:

- Processing of Motion Control instructions
- Monitoring functions
- Communication with the interconnected axes

You program the user transformation of the Cartesian coordinates and the joint-specific setpoints in the MC_Transformation organization block without considering inversions and offsets. If the joint directions of movement or the joint zero positions of the kinematics used do not correspond to the programmed user transformation, there are two ways to adapt them:

1. Retain the user transformation. Invert the affected joint directions of movement and joint zero positions in the "Joints" configuration window of the kinematics technology object. In this case, the joint-specific parameters "AxisData" in the system data block "Transformation" are not equal to the joint coordinates ("JointData"). The technology object performs this calculation automatically through the configured offsets and inversions.
2. Change the programmed user transformation in such a way that the calculated joint-specific setpoints from the transformation correspond to the joint coordinate system of the kinematics. In this case, the "AxisData" parameters in the "Transformation" system data block are equal to the joint coordinates ("JointData"). It is not necessary to configure the joint offset.

This programming includes the transformation of the positions and the dynamic values (velocity, acceleration). You freely define the parameters of a user-defined kinematics system in the tags of the kinematics technology object "<TO>.Kinematics.Parameter[1..32]" or under "Technology object > Configuration > Geometry".

When you add the MC_Transformation in the TIA Portal, the system data block "TransformationParameter" is automatically created under "Program blocks > System blocks > Program resources". In the properties of the organization block under "General > Transformation", the MC_Transformation indicates the number of the system data block "TransformationParameter". You write and read the joint-specific data or the Cartesian data of the kinematics to be transformed in the system data block "TransformationParameter".

With the technology version V5.0, longer runtimes of the MC_Interpolator arise during user transformation. With longer runtimes of the MC_Interpolator, the runtimes of the organization blocks with lower priority are extended.

NOTE

Disable system performance improvement

If you are using user-defined kinematics, clear the "Improve system performance" check box in the MC_LookAhead properties under "General > Multi-core processor".

Programming

The graphic below shows the interfaces and the interaction of system performance and user transformation in a kinematics with used JCS:

The kinematics technology object automatically calls the MC_Transformation. The MC_Transformation contains the following start information:

- Kinematics technology object that calls the MC_Transformation
- Required direction of the transformation (forward or inverse transformation)
- Processing context of the transformation (current motion or motion planning)
- Pointer to the system data block "TransformationParameter" (VARIANT)

You evaluate this status information in your user program. In MC_Transformation, you program the algorithms for the calculation of the axis-specific data or the Cartesian data of all user-defined kinematics systems. You read the kinematics parameters needed for this from the tags of the "<TO>.Kinematics.Parameter[1..32]" technology object. You write the result of the calculation to the "TransformationParameter" interface.

The transformation parameters are then applied automatically to the kinematics technology object and processed further. The kinematics technology object outputs the setpoints to the kinematics axes.

You can configure and apply the user-defined transformation with multiple kinematics technology objects on a PLC. To differentiate in MC_Transformation between the different kinematics technology objects, use the input "KinematicsObject".

NOTE
Inverse transformation
In the inverse transformation, only the basic joint range "TurnJoint" = 0 needs to be programmed. The technology object automatically calculates the sPTP motions for the joint position ranges outside of the basic joint range "TurnJoint" ≠ 0.

7.10.2.3 MC_Transformation [OB98]

Reference declaration for system data block "TransformationParameter"

You must specify a reference to the data type for the system data block "TransformationParameter" in the MC_Transformation. For this purpose, you specify a tag with the following data type in the "Temp" area of the block interface:

"REF_TO TO_Struct_TransformationParameter_V2"

To enable access to the system data block "TransformationParameter", assign the data type "TO_Struct_TransformationParameter_V2" using the following casting command:

```
#P ?= #TransformationParameters;
```

The declaration is described in a program example (Page 197).

Block call

The MC_Transformation is called in the Motion Control application cycle according to the configured priority. When the MC_Transformation is called, the kinematics technology object assigns its parameters:

Parameter	Declaration	Data type	Default value	Description	
KinematicsObject	INPUT	DB_ANY	-	Kinematics technology object for which the MC_Transformation calculates the transformation when called.	
ExecutionContext	INPUT	DINT	-	Processing context of the MC_Transformation OB	
				0	MOTION_EXECUTION Calculation of the axis setpoints in the motion execution in the MC_Interpolator. The calculated values are necessary for the current motion control.
				1	NON_MOTION_EXECUTION The transformation is necessary for the motion planning (currently no motion).
TransformationType	INPUT	DINT	-	Calculation called for	

Parameter	Declaration	Data type	Default value	Description	
TransformationType	INPUT	DINT	-	0	Forward transformation Calculation of the Cartesian parameters from the axis positions
				1	Inverse transformation Calculation of the axis-specific parameters from the Cartesian parameters
TransformationParameters	InOut	VARIANT	-	Pointer to the system data block "TransformationParameter"	
FunctionResult	OUTPUT	DINT	-	Return value of the MC_Transformation to the kinematics technology object	
				0	Calculation performed and parameters output
				≠ 0	Error during calculation (user-defined) If an error occurs during the calculation, the kinematics technology object stops the motion. The kinematics technology object outputs a technology alarm with the error ID as an accompany value and deletes the job sequence. The value can be greater than or less than zero.

Priority

You configure the priority of the MC_Transformation in the properties of the organization block under "General > Attributes > Priority". For the priority you can set values from 17 to 25 (default setting 25):

- The priority of MC_Transformation must be at least one level lower than the priority of MC_Servo.
- The priority of MC_Transformation must be at least one level higher than the priority of MC_Interpolator.

Tags of the system data block "TransformationParameter"

The following table shows the tags in the system data block "TransformationParameter":

NOTE

If JCS is used, the "AxisData" tags are to be interpreted as joint-specific setpoints.

Tag	Data type	Description	
AxisData.	STRUCT_ Transformation AxisData_V2	JCS not used: Axis-specific parameters	JCS used: Joint-specific parameters without consideration of inversions and offsets
a1Position	LREAL	Position setpoint of the axis A1	Position setpoint of the joint J1
a1Velocity	LREAL	Velocity setpoint of the axis A1	Velocity setpoint of the joint J1
a1Acceleration	LREAL	Acceleration setpoint of the axis A1	Acceleration setpoint of the joint J1
a2Position	LREAL	Position setpoint of the axis A2	Position setpoint of the joint J2

Tag	Data type	Description	
a2Velocity	LREAL	Velocity setpoint of the axis A2	Velocity setpoint of the joint J2
a2Acceleration	LREAL	Acceleration setpoint of the axis A2	Acceleration setpoint of the joint J2
a3Position	LREAL	Position setpoint of the axis A3	Position setpoint of the joint J3
a3Velocity	LREAL	Velocity setpoint of the axis A3	Velocity setpoint of the joint J3
a3Acceleration	LREAL	Acceleration setpoint of the axis A3	Acceleration setpoint of the joint J3
a4Position	LREAL	Position setpoint of the axis A4	Position setpoint of the joint J4
a4Velocity	LREAL	Velocity setpoint of the axis A4	Velocity setpoint of the joint J4
a4Acceleration	LREAL	Acceleration setpoint of the axis A4	Acceleration setpoint of the joint J4
a5Position	LREAL	Position setpoint of the axis A5	Position setpoint of the joint J5
a5Velocity	LREAL	Velocity setpoint of the axis A5	Velocity setpoint of the joint J5
a5Acceleration	LREAL	Acceleration setpoint of the axis A5	Acceleration setpoint of the joint J5
a6Position	LREAL	Position setpoint of the axis A6	Position setpoint of the joint J6
a6Velocity	LREAL	Velocity setpoint of the axis A6	Velocity setpoint of the joint J6
a6Acceleration	LREAL	Acceleration setpoint of the axis A6	Acceleration setpoint of the joint J6
CartesianData	STRUCT_ Transformation CartesianData _V2	Cartesian parameters and joint position space	
xPosition	LREAL	x position	
xVelocity	LREAL	x velocity	
xAcceleration	LREAL	x acceleration	
yPosition	LREAL	y position	
yVelocity	LREAL	y velocity	
yAcceleration	LREAL	y acceleration	
zPosition	LREAL	z position	
zVelocity	LREAL	z velocity	
zAcceleration	LREAL	z acceleration	
aPosition	LREAL	A-position (orientation)	
aVelocity	LREAL	A velocity (orientation)	
aAcceleration	LREAL	A acceleration (orientation)	
bPosition	LREAL	B position (orientation)	
bVelocity	LREAL	B velocity (orientation)	
bAcceleration	LREAL	B acceleration (orientation)	
cPosition	LREAL	C position (orientation)	
cVelocity	LREAL	C velocity (orientation)	
cAcceleration	LREAL	C acceleration (orientation)	
LinkConstellation	DWORD	Joint position space	

7.10.2.4 Program example for a user-defined kinematics systems

An example of user transformation in the MC_Transformation (Page 194) of a 2D kinematics with the name "KinematicsUserDefined2D" is described below. For these kinematics, two transformation parameters were defined under "Technology object > Configuration > Geometry".

The interaction of system performance and user transformation is displayed in the figure in section "User transformation without JCS (Page 190)".

The following table shows the declaration of the tags used:

Tag	Declaration	Data type	Description	
KinematicsObject	Input	DB_ANY	Reference to the technology object	
TransformationType	Input	DInt	Transformation direction	
			0	Forward transformation
			1	Inverse transformation
FunctionResult	Output	DInt	Transformation result	
			0	Successful
			< 0	Error
TransformationParameters	InOut	Variant	Reference to the system data block "TransformationParameter" in the MC_Transformation	
P	Temp	REF_TO TO_Struct_TransformationParameter_V2	Temporary tag for the casting command	
GearRatioA1	Temp	LReal	Temporary tag for read the defined transformation parameters	
GearRatioA2	Temp	LReal	Temporary tag for read the defined transformation parameters	
InvalidCast	Constant	DInt	Return value for an unsuccessful casting command	

The program example is structured as follows:

- Casting command for access to the system data block "TransformationParameter"
- Evaluation of the technology object
- Read the defined transformation parameters
- Evaluation of the transformation direction
- Calculation of the Cartesian coordinates from the axis positions of the kinematics axes (forward transformation)
- Calculation of the axis positions of the kinematics axes from the Cartesian coordinates (backward transformation)

First, the example program is explained step by step. The program code is summarized in the section "Program example".

Casting command for access to the system data block "TransformationParameter"

The casting command enables access the transformation parameters defined in the configuration.

The variant pointer is passed on to the temporary tag using the casting command.

```
#P ?= #TransformationParameters;
```

It is then tested whether the casting command was successful. This means that the specified InOut tag "TransformationParameters" has the expected structure of type "TO_Struct_TransformationParameter_V1".

If the casting command was not successful, the calculation is canceled and the tag "FunctionResult" gets the value "InvalidCast".

```
IF #P = NULL THEN
    #FunctionResult := #InvalidCast;
    RETURN;
END_IF;
```

Evaluation of the technology object

An IF query is used to evaluate whether the user-defined kinematics requires the transformation defined below.

```
IF #KinematicsObject = "KinematicsUserDefined2D" THEN
```

Read the defined transformation parameters

First, the transformation parameters defined in the configuration are read out. Two gears ratios were defined in this example.

```
    #GearRatioA1 := "KinematicsUserDefined2D".Kinematics.Parameter[1];
    #GearRatioA2 := "KinematicsUserDefined2D".Kinematics.Parameter[2];
```

Evaluation of the transformation direction

The transformation direction is evaluated in the next step. If the tag "TransformationType" has the value "0", the forward transformation is calculated. If the tag has the value "1", the backward transformation is calculated.

```
    IF #TransformationType = 0 THEN
```

Calculation of the Cartesian coordinates from the axis positions of the kinematics axes (forward transformation)

In the forward transformation, Cartesian data (position, velocity and acceleration) are calculated from the axis data. The forward transformation is first calculated in x direction and then in z direction.

```
#P^.CartesianData.xPosition := #P^.AxisData.a1Position * #GearRatioA1;
#P^.CartesianData.xVelocity := #P^.AxisData.a1Velocity * #GearRatioA1;
#P^.CartesianData.xAcceleration := #P^.AxisData.a1Acceleration * #GearRatioA1;

#P^.CartesianData.zPosition := #P^.AxisData.a2Position * #GearRatioA2;
#P^.CartesianData.zVelocity := #P^.AxisData.a2Velocity * #GearRatioA2;
#P^.CartesianData.zAcceleration := #P^.AxisData.a2Acceleration * #GearRatioA2;
```

The specification of the joint position space is not required in this example. The corresponding tag is set to zero.

```
#P^.CartesianData.LinkConstellation := 16#0000;
```

If the transformation is successful, the tag "FunctionResult" receives the value "0".

```
#FunctionResult := 0;
```

Calculation of the axis positions of the kinematics axes from the Cartesian coordinates (backward transformation)

In the backward transformation, axis data (position, velocity and acceleration) are calculated from the Cartesian data. The backward transformation is first calculated for axis A1 and then for axis A2.

```
    ELSIF #TransformationType = 1 THEN

        #P^.AxisData.a1Position := #P^.CartesianData.xPosition / #GearRatioA1;
        #P^.AxisData.a1Velocity := #P^.CartesianData.xVelocity / #GearRatioA1;
        #P^.AxisData.a1Acceleration := #P^.CartesianData.xAcceleration / #GearRatioA1;

        #P^.AxisData.a2Position := #P^.CartesianData.zPosition / #GearRatioA2;
        #P^.AxisData.a2Velocity := #P^.CartesianData.zVelocity / #GearRatioA2;
        #P^.AxisData.a2Acceleration := #P^.CartesianData.zAcceleration / #GearRatioA2;
```

If the transformation is successful, the tag "FunctionResult" receives the value "0".

```
        #FunctionResult := 0;

    END_IF;
END_IF;
```

Program example

The program example is summarized with Commentary in the following section:

SCL

```
//Cast of the variant "TransformationParameters" to the referenced datatype
//"TO_Struct_TransformationParameter_V2".
//This has to be done in order to access the variant pointer, which references
//the "TransformationParameters" where the "AxisData" and "CartesianData" for
//the calculation of user transformation are stored.
#P ?= #TransformationParameters;
```

SCL

```
//Check if cast of "TransformationParameters" was successfull. Otherwise abort calculation.
IF #P = NULL THEN
    #FunctionResult := #InvalidCast;
    RETURN;
END_IF;

//Check if "KinematicsUserDefined2D" needs transformation.
IF #KinematicsObject = "KinematicsUserDefined2D" THEN

    //Read the user defined cartesian parameters.
    #GearRatioA1 := "KinematicsUserDefined2D".Kinematics.Parameter[1];
    #GearRatioA2 := "KinematicsUserDefined2D".Kinematics.Parameter[2];

    //Calculate the forward transformation "AxisData" -> "CartesianData".
    //The system fills the "AxisData" of "TransformationParameters" with values.
    //To calculate the "CartesianData" evaluate "AxisData".
    IF #TransformationType = 0 THEN

        //Calculate the position, velocity and acceleration component for the x-vector.
        #P^.CartesianData.xPosition := #P^.AxisData.a1Position * #GearRatioA1;
        #P^.CartesianData.xVelocity := #P^.AxisData.a1Velocity * #GearRatioA1;
        #P^.CartesianData.xAcceleration := #P^.AxisData.a1Acceleration * #GearRatioA1;

        //Calculate the position, velocity and acceleration component for the z-vector.
        #P^.CartesianData.zPosition := #P^.AxisData.a2Position * #GearRatioA2;
        #P^.CartesianData.zVelocity := #P^.AxisData.a2Velocity * #GearRatioA2;
        #P^.CartesianData.zAcceleration := #P^.AxisData.a2Acceleration * #GearRatioA2;

        //Link constellation can be set to 0 here, hence it is not needed.
        #P^.CartesianData.LinkConstellation := 16#0000;

        //Transformation was successfull.
        #FunctionResult := 0;

    //Calculate the backward transformation "CartesianData" -> "AxisData".
    //The system fills the "CartesianData" of "TransformationParameters" with values.
    //To calculate the "AxisData" evaluate "CartesianData".
    ELSIF #TransformationType = 1 THEN

        //Calculate the position, velocity and acceleration component for the first axis.
        #P^.AxisData.a1Position := #P^.CartesianData.xPosition / #GearRatioA1;
        #P^.AxisData.a1Velocity := #P^.CartesianData.xVelocity / #GearRatioA1;
        #P^.AxisData.a1Acceleration := #P^.CartesianData.xAcceleration / #GearRatioA1;

        //Calculate the position, velocity and acceleration component for the second axis.
        #P^.AxisData.a2Position := #P^.CartesianData.zPosition / #GearRatioA2;
        #P^.AxisData.a2Velocity := #P^.CartesianData.zVelocity / #GearRatioA2;
        #P^.AxisData.a2Acceleration := #P^.CartesianData.zAcceleration / #GearRatioA2;

        //Transformation was successfull.
        #FunctionResult := 0;

    END_IF;
END_IF;
```

Check the validity of the transformation/cartesian values

Check the "<TO>.StatusKinematics.Valid" bit cyclically, e.g. in the MC_PostServo. If "<TO>.StatusKinematics.Valid" shows the value "FALSE", then the Cartesian values are invalid. In this case, initiate a stop action, for example, with the Motion Control instruction "MC_GroupStop".

Check the setpoint specification of the Cartesian values and the programmed user transformation.

7.10.3 Tags: Kinematics transformation

The following tags of the kinematics technology object are relevant for the kinematics transformation:

Tag	Description	
Status values		
<TO>.StatusKinematics.Valid	TRUE	Transformation/Cartesian values valid
	FALSE	Transformation/Cartesian values invalid
<TO>.StatusKinematics.LinkConstellation	Joint position space	
<TO>.FlangeInKcs	Current transformation frame (with dynamics, setpoint reference)	

Kinematics functions 8

8.1 Offset and rotation of the coordinate system

You can define the following frames in the configuration for a technology object kinematics:

Frame	Description
KCS frame	Position of the kinematics coordinate system (KCS) in the world coordinate system (WCS)
OCS1..3 frame	Position of the object coordinate systems 1 to 3 (OCS1..3) in the WCS
Tool frame	Position of the tool coordinate system (TCS) in the FCS

The position of the frames is determined by the offset and the rotation in the reference coordinate system.

Offset

You use the shift to define the position of the zero point of a coordinate system or a zone within the reference coordinate system. You specify the offset in Cartesian coordinates.

The following table shows the definition of the offset:

Value in the frame	Description
x	Shift in the x direction in the reference coordinate system
y	Shift in the y direction in the reference coordinate system
z	Shift in the z direction in the reference coordinate system

Rotation

You use the rotation to define the orientation of a coordinate system or a zone within the reference coordinate system. The rotation is made up of three successive individual rotations around the axes of the coordinate system which you define using three Euler angles. The individual rotations depend on each other.

The following graphic shows the three successive rotations using a cuboid zone as an example:

① Rotation A

② Rotation B

③ Rotation C

The following table shows the definition of the rotations:

Rotation	Description
Rotation A	Euler angle of the first rotation A positive angle corresponds to a clockwise rotation around the z axis of the coordinate system. The coordinate system rotated once consists of the axes x', y' and z.
Rotation B	Euler angle of the second rotation A positive angle corresponds to a clockwise rotation around the rotated y' axis. The coordinate system rotated twice consists of the axes x'', y' and z'.
Rotation C	Euler angle of the third rotation A positive angle corresponds to a clockwise rotation around the rotated x'' axis. The coordinate system rotated three times consists of the axes x'', y'' and z''. The x'', y'' and z'' axes correspond to the x, y and z axes of the rotated coordinate system or of the rotated zone.

8.1.1 Define KCS/OCS frame

You have the following options to define KCS and OCS frames:

- Offline, you define the KCS/OCS frames in the following configuration windows:
  - You define the position of the KCS in the WCS in the "Extended parameters > Kinematics coordinate system" configuration window.
  - You define the position of the OCS in the WCS in the "Extended parameters > Object coordinate system" configuration window.
- Use the "MC_SetOcsFrame (Page 448)" Motion Control instruction to define the position of an OCS in the WCS during runtime.

Configurable coordinates and value ranges

Since the kinematics types support different numbers of degrees of freedom, enter only the values that are relevant and permissible for your kinematics type.

The following table shows you the values that you can specify during configuration (✓) and their valid value ranges.

Kinematics type	KCS/OCS frame					
	Offset			Rotation		
	x	y	z	A	B	C
2D	✓	0.0	✓	0.0	✓ -180.0° to 179.999°	0.0
2D with orientation	✓	0.0 [1]	✓	0.0[2]	0.0	0.0

[1] For the kinematics type "SCARA 2D", an offset in the y direction is permissible.

[2] For the kinematics type "SCARA 2D", a rotation around A is permissible.

Value = 0.0: Offset/rotation not permitted or not relevant

Kinematics type	KCS/OCS frame					
	Offset			Rotation		
	x	y	z	A	B	C
3D	✓	✓	✓	✓ -180.0° to 179.999°	✓ -90.0° to 90.0°	✓ -180.0° to 179.999°
3D with orientation	✓	✓	✓	✓ -180.0° to 179.999°	0.0	0.0
3D with 2 orientations A, B	✓	✓	✓	✓ -180.0° to 179.999°	0.0	0.0
3D with 3 orientations **6-axis articulated arm with central wrist, 6-axis articulated arm with offset wrist**	✓	✓	✓	✓ -180.0° to 179.999°	✓ -90.0° to 90.0°	✓ -180.0° to 179.999°

1) For the kinematics type "SCARA 2D", an offset in the y direction is permissible.

2) For the kinematics type "SCARA 2D", a rotation around A is permissible.

Value = 0.0: Offset/rotation not permitted or not relevant

Defining the KCS frame offline

To define the KCS frame, enter the offset and rotation of the kinematics zero point in the WCS in the "Kinematics coordinate system" configuration window.

Defining the OCS frame offline

You configure the OCS frames as follows in the "Extended parameters > Object coordinate systems" configuration window:

1. Select the OCS to be defined in the "Object coordinate system (OCS)" drop-down list. You can define up to three object coordinate systems.
2. To define an OCS frame, enter the values for the offset and rotation.
3. The status of the configuration is shown via the following symbols for each OCS:
   - OCS frame is not defined. (default value)
   - Configuration is valid.
   - Configuration is incomplete or incorrect.

Calibrate OCS

Calibration (Page 355) enables you to determine the exact position of an OCS in the WCS in online or offline mode or check the defined position of an OCS.

Define OCS frames with Motion Control instructions

In an "MC_SetOcsFrame (Page 448)" Motion Control instruction, you define an OCS frame with the following parameters:

- Enter the value for offset and rotation of the OCS in the WCS in the "Frame" parameter.
- Enter the object coordinate system OCS1, OCS2 or OCS3 in the "OcsNumber" parameter.

8.1.2 Define tool frames

You have the following options to define tool frames:

- You can define the tool frames for up to three tools offline in the "Extended parameters > Tools" configuration window.
- You define the tool frame for Tool 1 with the "MC_DefineTool (Page 445)" Motion Control instruction during runtime.

Configurable coordinates and value ranges

Since the kinematics types support different numbers of degrees of freedom, define only the values that are relevant and permissible for your kinematics type.

The following table shows you the values that you can specify during configuration (✓) and their valid value ranges.

Kinematics type	Tool frame					
	Offset			Rotation		
	x	y	z	A	B	C
2D	✓	0.0	✓	0.0	0.0	0.0
2D with orientation	0.0	0.0	✓	✓ -180.0° to 179.999°	0.0	0.0
3D	✓	✓	✓	0.0	0.0	0.0
3D with orientation	✓	✓	✓	✓ -180.0° to 179.999°	0.0	0.0
3D with 2 orientations A, B	✓	✓	✓	0.0	✓ -180.0° to 179.999°	0.0
3D with 3 orientations	✓	✓	✓	✓ -180.0° to 179.999°	✓ -90.0° to 90.0°	✓ -180.0° to 179.999°
6-axis articulated arm with central wrist, 6-axis articulated arm with offset wrist						

Value = 0.0: Offset/rotation not permitted

Defining tool frames offline

You configure the tool frames as follows in the "Extended parameters > Tools" configuration window:

1. Select the tool to be defined in the "Tool" drop-down list. You can define up to three tools.
2. To define a frame, enter the values for the offset and rotation.
3. The status of the configuration is shown via the following symbols for each tool:
   - Tool frame is not defined. (default value)
   - Configuration is valid.
   - Configuration is incomplete or incorrect.

Define tool frame with Motion Control instructions

Enter the values for offset and rotation of the tool frame for Tool 1 in the "Frame" parameter in an "MC_DefineTool (Page 445)" Motion Control instruction.

Example

Tool frame with a kinematics "Delta picker 3D with 2 orientations A, B"

The following example shows a possible definition of the tool frame with a kinematics "Delta picker 3D with 2 orientations A, B". The tool is rotated by B = -90° in relation to the FCS and is shifted in direction x and z.

① Tool frame

8.1.3 Tags: Coordinate systems and frames

The following tags of the kinematics technology object are relevant for coordinate systems and frames:

Tag	Description
Configuration	
<TO>.KcsFrame	KCS frame x, y, z, A, B, C
<TO>.OcsFrame[1..3]	OCS frame x, y, z, A, B, C
<TO>.Tool[1..3]	Tool frame x, y, z, A, B, C
Status values	
<TO>.Tcp	Position of the tool center point (TCP), TCP frame in the world coordinate system (WCS). x, y, z, A, B, C
<TO>.TcpInWcs	Parameter for tool center point in the world coordinate system x, y, z, A, B, C
<TO>.TcpInOcs[1..3]	Parameter for the tool center point (TCP) in the Object Coordinate Systems 1 to 3 (OCS) x, y, z, A, B, C
<TO>.FlangeInKcs	Parameter for the flange coordinate system (FCS) in the kinematics coordinate system (KCS) x, y, z, A, B, C
<TO>.StatusOcsFrame[1..3]	Display of the OCS frames x, y, z, A, B, C

8.2 Zone monitoring

The zone monitoring has the following purposes:

- Protection from collisions with mechanical installations
- Triggering of process-related actions (signal zones)

⚠ WARNING

Inappropriate use of zone monitoring

Zone monitoring is not suitable for preventing personal injury.

1. Implement suitable protective measures to prevent personal injury, e.g. protective fences or safety doors.
2. Use safety functions for safe monitoring of the kinematics, for example, with SIMATIC Safe Kinematics.

Zones

Zones are geometric bodies you can use to describe and subdivide the workspace of a kinematics system. You can configure the following zones on the kinematics technology object:

- **Workspace zones**

  Workspace zones describe the environment of a kinematics system. You can configure the following zone types as workspace zones for the kinematics technology object:

  – Work zone

    With work zones, you limit the possible travel space of the kinematics or define several possible work areas.

  – Signal zone

    Signal zones are areas within the traversing space of the kinematics. Signal zones indicate the following:

    • Kinematics zone is entering the signal zones

    • Kinematics zone is located in the signal zone

  – Blocked zone

    Blocked zones are areas within the traversing space of the kinematics in which a kinematics zone must not enter (e.g. control cabinet, protective wall).

- **Kinematics zones**

  Kinematics zones envelope the end point of a kinematics system (flange or tool).

  Kinematics zones are related to the working point/flange of a kinematics and move with the kinematics. The zone monitoring checks the kinematics zones for penetration with workspace zones. With kinematics zones, you expand the monitored area beyond the tool center point (TCP). The tool center point (TCP) is permanently defined as the first kinematics zone (<TO>.KinematicsZone[1]) and always activated.

  You can configure the following zone types as kinematics zones for the kinematics technology object:

  – Tool zone

    Tool zones envelope the tool or parts of the tool.

  – Flange zone

    Flange zones envelope the flange or parts of the flange.

The following example shows how the zone types of a kinematics are used:

Workspace zones

- Work zone
- Signal zone
- Blocked zone

Kinematics zones

- Flange zone and tool zone

8.2.1 Defining zones

8.2.1.1 Structure of the "Zones" configuration window

The "Zones" configuration window is divided into the following areas:

- Graphic view

  The workspace zones or the kinematics zones, which you define in the tabular editor, are displayed in the graphic view. You operate the 3D visualization via the toolbar. For more information about operating the toolbar and the graphic display, refer to the section "3D visualization (Page 310)".
- Tabular editor of the workspace zones

  You configure the workspace zones (Page 211)here.
- Tabular editor of the kinematics zones
- You configure the kinematics zones (Page 212)here.

Online view

When you click on the symbol, values of the workspace zones and the kinematics zones at the current point in time are read back from the CPU. When you click the icon in the "Number" column, two additional rows are displayed. The additional rows contain the following values:

- Start values of the CPU
- Start values in project

  You can edit these values. If you want to apply the change, load the changes from the project into the device.

8.2.1.2 Defining workspace zones

You have the following options to define workspace zones:

- You can define workspace zones offline in the "Extended parameters > Zones > Workspace zones (Page 211)" configuration window.
- Via the Calibration (Page 355), you can define workspace zones in online and offline mode.
- With the "MC_DefineWorkspaceZone" (Page 435) Motion Control instruction, you define workspace zones during runtime.

Parameter inputs

You define the following parameters for a workspace zone:

- Defining a zone number for a zone (Page 214)
- Defining the zone type for a workspace zone (Page 214)
- Defining a reference coordinate system for a zone (Page 215)
- Defining the zone geometry (Page 216)

- Defining the offset and rotation in the reference coordinate system (Page 219)
- Activating zone monitoring (Page 219)

8.2.1.3 Defining kinematics zones

You have the following options to define kinematics zones:

- You can define kinematics zones offline in the "Extended parameters > Zones > Workspace zones (Page 211)" configuration window.
- With the "MC_DefineKinematicsZone" (Page 437) Motion Control instruction, you define kinematics zones during runtime.

Parameter inputs

You define the following parameters for a kinematics zone:

- Defining a zone number for a zone (Page 214)
- Defining the zone geometry (Page 216)
- Defining a reference coordinate system for a zone (Page 215)
- Defining the offset and rotation in the reference coordinate system (Page 219)
- Activating zone monitoring (Page 219)

Tool changeover

If you wish to define and use more than one tool, check whether the dimensions of a tool zone are suitable for all tools and envelop them. Otherwise, create a separate zone for each of the tools dimensioned differently.

Example of tool zone

You define tool zones in the tool coordinate system (TCS). The following graphic shows a spherical tool zone:

Example of flange zone

You define flange zones in the flange coordinate system (FCS). The following graphic shows a cylindrical flange zone:

In this example, a shift by the height of the flange zone in negative z direction of the FCS has been defined.

8.2.1.4 Defining a zone number for a zone

You can define the following number of zones:

- Up to 10 workspace zones
- Up to 9 kinematics zones

Zone number in the tabular editor

If you define a zone in the kinematics configuration window under "Extended parameters > Zones > Workspace zones" or "Extended parameters > Zones > Kinematics zones", the zone number is specified by the respective line in which you define a zone.

Motion Control instructions

Specify the zone number in the "ZoneNumber" parameter in an "MC_DefineWorkspaceZone" or "MC_DefineKinematicsZone" Motion Control instruction.

8.2.1.5 Defining the zone type for a workspace zone

You can define the following zone types:

- **Work zone**

  You can specify several work zones.

  Only one work zone can be activated at a given time. If no work zone is activated, the entire traversing space of the kinematics is regarded as the work area.

  Kinematics zones must be located within work zones.
- **Signal zone**

  You can specify several signal zones. Multiple signal zones can be activated at the same time.

  Signal zones can be located outside the work zone to some extent.
- **Blocked zone**

  You can specify several blocked zones. Multiple blocked zones can be activated at the same time.

  Blocked zones can be located outside the work zone to some extent.

Selecting a zone type

Select the zone type in the "Zone type" column.

Motion Control instruction

Specify the zone type in the "ZoneType" parameter in an "MC_DefineWorkspaceZone" Motion Control instruction.

8.2.1.6 Defining a reference coordinate system for a zone

Workspace zone

You can select the following reference coordinate systems for a workspace zone:

- WCS (world coordinate system)
- OCS1 (object coordinate system 1)
- OCS2 (object coordinate system 2)
- OCS3 (object coordinate system 3)

If you create the zone in an OCS, the zone moves together with the OCS.

Kinematics zone

You can select the following reference coordinate systems for a kinematics zone:

- If you select TCS, the zone envelops the tool or parts of it and moves with the tool (TCP).
- If you select FCS, the zone envelops the flange or parts of it and moves with the flange.

Selecting a reference coordinate system

You select the reference coordinate system in the "KS" column.

Motion Control instructions

Specify the reference coordinate system in the "ReferenceSystem" parameter in an "MC_DefineWorkspaceZone" or "MC_DefineKinematicsZone" Motion Control instruction.

8.2.1.7 Defining the zone geometry

You can configure zones with the following geometric bodies:

- Sphere
- Cuboid
- Cylinder

Sphere

You define a sphere starting from the zero point using the radius:

r Radius of the sphere

Configuring a sphere

1. Select the icon in the "Geometry" column.
2. Enter the radius in the "Radius" column.

Motion Control instructions

In the Motion Control instructions "MC_DefineWorkspaceZone" and "MC_DefineKinematicsZone", specify the zone geometry in these parameters:

Parameter	Value
GeometryType	1
GeometryParameter[1]	Radius of the sphere

Cuboid

You define a cuboid starting from the zero point using the edge lengths in x, y and z direction:

Lx Edge length in x direction of the zone coordinate system

Ly Edge length in y direction of the zone coordinate system

Lz Edge length in z direction of the zone coordinate system

Configuring a sphere

1. Select the icon in the "Geometry" column.
2. Enter the edge lengths in the following columns:
   - In the "Length x" column, edge length in x direction of the zone coordinate system
   - In the "Length y" column, edge length in y direction of the zone coordinate system
   - In the "Length z" column, edge length in z direction of the zone coordinate system

Motion Control instructions

In the Motion Control instructions "MC_DefineWorkspaceZone" and "MC_DefineKinematicsZone", specify the zone geometry in these parameters:

Parameter	Value
GeometryType	0
GeometryParameter[1]	Edge length in x direction of the zone coordinate system
GeometryParameter[2]	Edge length in y direction of the zone coordinate system
GeometryParameter[3]	Edge length in z direction of the zone coordinate system

Cylinder

You define a cylinder starting from the zero point using the radius of the base and the cylinder height:

r Radius of the base of the cylinder

Lz Height of the cylinder

Configuring a cylinder

1. Select the icon in the "Geometry" column.
2. Enter the height of the cylinder in the "Length z" column.
3. Enter the radius of the base in the "Radius" column.

Motion Control instructions

In the Motion Control instructions "MC_DefineWorkspaceZone" and "MC_DefineKinematicsZone", specify the zone geometry in these parameters:

Parameter	Value
GeometryType	2
GeometryParameter[1]	Radius of the base of the cylinder
GeometryParameter[2]	Height of the cylinder

8.2.1.8 Defining the offset and rotation in the reference coordinate system

Define the offset and rotation of the geometric body starting from the zero point of the reference coordinate system as follows:

1. Define the offset of the zone by entering the following values:
   - x: Offset of the zone in the x direction
   - y: Offset of the zone in the y direction
   - z: Offset of the zone in the z direction

   In the kinematics zones, the offset of the zone to the zero point of the TCS or FCS remains constant.
2. Define the rotation of the zone by entering the following values:

   (Not relevant for a spherical zone)
   - A: Enter a value between -180.0° and 179.999° for the rotation of the zone around the z axis.
   - B: Enter a value between -90.0° and 90.0° for the rotation of the zone around the y axis.
   - C: Enter a value between -180.0° and 179.999° for the rotation of the zone around the x axis.

Enter offset and rotation

You enter the offset and rotation of the zone in the columns for the coordinates x, y, z, A, B and C.

Motion Control instructions

Specify the offset and rotation of the zone in the "Frame" parameter in an "MC_DefineWorkspaceZone" or "MC_DefineKinematicsZone" Motion Control instruction.

8.2.1.9 Activating zone monitoring

You activate zone monitoring (Page 208) for a defined zone by setting the status of the zone.

You have the following options for setting the status of a zone:

- You can set the status of a zone to active offline in the "Extended parameters > Zones" configuration window in the tabular editor.
- You activate a zone during runtime with the following Motion Control instructions:
  - MC_SetWorkspaceZoneActive: Activate workspace zone V10 (Page 438)
  - MC_SetKinematicsZoneActive: Activate kinematics zone V10 (Page 442)

Note the following when activating zone monitoring for work zones:

- Only one work zone can be active at a given time.
- If no work zone is activated, the entire traversing space of the kinematics is regarded as the work area.

Setting a zone to active offline

In the "Status" column, select whether the zone should be active or inactive after loading into the device.

Activating a defined zone with a Motion Control instruction

With the "ZoneNumber" parameter, you specify the number of the zone to be activated.

Before you issue an "MC_SetWorkspaceZoneActive" or "MC_SetKinematicsZoneActive" job, make sure that the zone specified at the "ZoneNumber" parameter is already defined and that the following conditions are therefore met:

- For an "MC_SetWorkspaceZoneActive" job
  - The "MC_DefineWorkspaceZone" job is complete ("Done" = TRUE).
  - The "StatusWorkspaceZone[1..10].Valid" tag is set to TRUE.
- For an "MC_SetKinematicsZoneActive" job
  - The "MC_DefineKinematicsZone" job is complete ("Done" = TRUE).
  - The "StatusKinematicsZone[2..10].Valid" tag is set to TRUE.

Otherwise, the job is rejected with "ErrorID" = 16#80C7.

After the start of the "MC_SetWorkspaceZoneActive" or "MC_SetKinematicsZoneActive" job with "Execute" = TRUE, the job is added to the job sequence (Page 250) and is thus effective for subsequent motion jobs.

When the job is complete ("Done" = TRUE), the tag of the data block technology object shows the status of the active zone as follows:

- Workspace zones: "<TO>.StatusWorkspaceZone[1..10].Active" = TRUE
- Kinematics zones: "<TO>.StatusKinematicsZone[2..10].Active" = TRUE

8.2.1.10 Deactivating zone monitoring

You deactivate zone monitoring (Page 208) for a defined zone by setting the status of the zone to inactive.

You have the following options for setting the status of a zone:

- You can set the status of a zone to inactive offline in the "Extended parameters > Zones" configuration window in the tabular editor.
- You set one or more zones to inactive during runtime with the following Motion Control instructions:
  - MC_SetWorkspaceZoneInactive: Deactivate workspace zone V10 (Page 440)
  - MC_SetKinematicsZoneInactive: Deactivate kinematics zone V10 (Page 443)

Setting a zone to inactive offline

In the "Status" column, select whether the zone should be active or inactive after loading into the device.

Deactivating one or more active zones with a Motion Control instruction

Deactivating an active zone

If you want to set a zone to inactive, enter the number of the zone at the "ZoneNumber" parameter.

In the "MC_SetWorkspaceZoneInactive" or "MC_SetKinematicsZoneInactive" Motion Control instruction, you choose in the "Mode" parameter with "0" that only the zone specified in the "ZoneNumber" parameter is deactivated.

Deactivating multiple active zones

If you want to set multiple active zones to inactive, enter the zones at the "Mode" parameter.

- You select the zones as follows in the "MC_SetWorkspaceZoneInactive" Motion Control instruction:
  - "Mode" = "1": All workspace zones
  - "Mode" = "2": All blocked zones
  - "Mode" = "3": All signal zones
  - "Mode" = "4": All work zones
- In the "MC_SetKinematicsZoneInactive" Motion Control instruction, you choose in the "Mode" parameter with "1" that all active kinematics zones should be set to inactive.

After the start of the "MC_SetWorkspaceZoneInactive" or "MC_SetKinematicsZoneInactive" job with "Execute" = TRUE, the job is added to the job sequence (Page 250) and is thus effective for subsequent motion jobs.

When the job is complete ("Done" = TRUE), the tag of the data block technology object shows the status of the inactive zones as follows:

- Workspace zones: "<TO>.StatusWorkspaceZone[1..10].Active" = FALSE
- Kinematics zones: "<TO>.StatusKinematicsZone[2..10].Active" = FALSE

8.2.2 Zone violation

The zone monitoring checks all activated workspace zones (work zones, signal zones, blocked zones) for collision with all activated kinematics zones (flange zones, tool zones, TCP). The zone monitoring monitors the zones for all motions of the kinematics system:

- Kinematics motions via the user program or kinematics control panel
- Single axis motions via the user program or axis control panel

The status of the zone monitoring is indicated in the diagnostics (Page 342) and in the tags (Page 223) of the kinematics technology object.

If the zone monitoring detects a zone violation by a kinematics motion, the following reactions occur:

Zone violation	Reaction	Description
Exiting the work zone	Alarm with stop	The kinematics technology object outputs technology alarm 806 (alarm response: Stop without leaving the path). The kinematics motion is stopped. The kinematics leaves the zone by the length of the deceleration distance at a minimum.
Entering a signal zone	Alarm without stop	The kinematics technology object outputs a technology alarm 807 (no alarm response). The kinematics motion will be continued.
Entering a blocked zone	Alarm with stop	The kinematics technology object outputs a technology alarm 806 (alarm response: Stop without leaving the path). The kinematics motion is stopped. The kinematics violates the zone by the length of the brake path at a minimum. All jobs in the job sequence are canceled.

The kinematics technology object outputs a technology alarm following zone violations by single axis motions. The positioning axis/synchronous axis technology object does not output a technology alarm. The single axis motion is not aborted. You can abort the single axis motion in the application.

In addition to the zones of the kinematics technology object, you can limit the travel space of the kinematics as follows:

- Software limit switches at the axes
- Joint traversing ranges

8.2.3 Retracting after a zone violation

Once you have acknowledged the technology alarm on the kinematics technology object, you can move the kinematics system again.

NOTICE

Zone monitoring for violated zone deactivated after acknowledgment

After you have acknowledged the technology alarm on the kinematics technology object, the zone monitoring is deactivated for the violated zone until the kinematics exits the violated blocked zone / signal zone or enters the violated work zone again. You can move the kinematics in all directions including again into the violated blocked zone / signal zone or from the work zone.

Take into consideration the travel direction when retracting the kinematics.

Monitor retraction in the application. The zone monitoring status is still displayed in the data block technology object.

After the kinematics has exited the violated blocked zone / signal zone again or entered the violated work zone again, zone monitoring is activated again for this zone. A new technology alarm is therefore triggered when the zone is violated again.

8.2.4 Tags: Zone monitoring

The following tags of the kinematics technology object are relevant for the zone monitoring:

Tag	Description
Zone configuration	
<TO>.WorkspaceZone[1..10]	Configuration of the workspace zones
<TO>.KinematicsZone[2..10]	Configuration of the kinematics zones The <TO>.KinematicsZone[1] zone is the tool center point (TCP) and is always activated.
Status values	
<TO>.StatusWorkspaceZone[1..10]	Status of the workspace zones
<TO>.StatusKinematicsZone[2..10]	Status of the kinematics zones
<TO>.StatusZoneMonitoring.WorkingZones	Display of violated work zones Bit numbers 0 to 9 correspond to the configured zone numbers.
<TO>.StatusZoneMonitoring.BlockedZones	Display of violated blocked zones Bit numbers 0 to 9 correspond to the configured zone numbers.
<TO>.StatusZoneMonitoring.SignalizingZones	Display of approached signal zones Bit numbers 0 to 9 correspond to the configured zone numbers.
<TO>.StatusZoneMonitoring.KinematicsZones	Display of kinematics zones that violate workspace zones Bit number 0 indicates the monitoring status of the TCP. Bit numbers 1 to 9 correspond to the configured zone numbers.

8.3 Overview of kinematics motions

With kinematics motions, you move the kinematics through the three-dimensional space and rotate the kinematics with up to three orientations. Plan the kinematics motion in advance. Take into consideration the following:

- Reachable points of the kinematics
- Zones
- Transformation areas
- Joint position spaces
- Joint traversing ranges
- Software limit switches of axes

Motion types

The following motion types are available:

- Linear motion (Page 258)

  You can move the kinematics linearly to a defined target position with a linear motion.
- Circular motion (Page 265)

  You can move the kinematics using a defined circular path with a circular motion.

- sPTP motion (Page 278)

  With a synchronous "point-to-point" motion (sPTP motion), you can move a kinematics time- and motion-optimized, bypass singularities or change joint position spaces. The kinematics does not follow a specified path. The single-axis motions, which move the kinematics axes synchronously, are calculated from the start and target positions.
- Conveyor tracking (Page 288)

  With conveyor tracking, the kinematics can follow an object on a moving conveyor belt.
- Orientation motion

  The orientation motion is the motion of the Cartesian orientation and is performed at the same time as the path motion. When the circular motion stops, the orientation motion also stops.

Blending types

The following differences apply to blending between path and orientation motions:

- **From a path motion to an orientation motion**

  Blending does not take place on transition from a path motion to an orientation motion.
- **Between orientation motions (without path motion)**

  If there is no path motion, blending takes place between the orientation motions. The blending distance is evaluated in the unit of measure for rotary axes.

If blending takes place between two motions, where there is both path motion and orientation motions, the path motion takes precedence in relation to the blending.

The following differences apply between the blending types:

- **Between linear/circular motions**

  
  Both motions are blended in a geometrically exact manner. The blending area is described by a 5th degree polynomial curve.
- **Between a linear/circular motion and an sPTP motion and vice versa**

  
  Blending takes place with an sPTP motion in the blending area. The path is not geometrically defined.
- **Between sPTP motions**

  
  Both motions are executed approximately. The blending area is described by a fifth degree polynomial segment.

Reference coordinate system

The target position and the target orientation you specify for a kinematics motion can relate to different coordinate systems, e.g. the world coordinate system (WCS) or an object coordinate system (OCS).

8.3.1 Introduction to the programming of the kinematics motions

You can use Motion Control instructions in the user program to transmit jobs to the technology object. You can find an overview of the Motion Control instructions for the kinematics technology object in the section "Motion control instructions for kinematics control (Page 24)".

You configure the job with the input parameters of the Motion Control instructions. The current job status is indicated in the output parameters.

Because the kinematics technology object groups the kinematics axes, you assign the kinematics technology object directly to the input parameter "AxesGroup".

You cannot enable the kinematics technology object itself using an "MC_Power" job or home it using an "MC_Home" job. For kinematics motions, the interconnected axes must be enabled ("MC_Power.Enable" = TRUE).

You can acknowledge errors of the kinematics technology object with an "MC_Reset" job or by restarting the technology object.

⚠ WARNING

Unexpected axis motions

The kinematics can perform unexpected motions due to the incorrect configuration of the technology objects or parameter assignment of the motion control jobs.

This can cause the following damages:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damages, for example, through overload of the mechanical components or collision between kinematics and machine components

Before you start the user program, implement the following preventive measures:

1. Check the correct configuration of all technology objects that are used for the motion sequence of the kinematics.
2. Check the correct parameter assignment of the motion control instructions.
3. Protect the configuration and user program against unauthorized access.

WARNING

Overrun of the dynamics through singularities

Overruns of the dynamics in the vicinity of a singularity (Page 183) can result in the following damages:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damages, for example, through overload of the mechanical components

To prevent overruns of the dynamics in the vicinity of a singularity, implement the following preventive measures:

1. Avoid path motions without dynamic adaptation in the vicinity of a singularity.
2. Use blocked zones or software limit switches for kinematics motions in the vicinity of a singularity.
3. Avoid the use of conveyor tracking in the vicinity of a singularity. Singularities are not handled when conveyor tracking is active.
4. Programming motions that are not part of the phases of conveyor tracking:
   - For linear or circular motions, activate the dynamic adaptation (Page 243).
   - Use synchronous "point-to-point" motions (Page 278).

8.3.2 Define target position

You define the target position in a Motion Control instruction for a kinematics motion depending on the kinematics type.

Define offset and rotation

Enter the values according to the following specifications:

Kinematics type	Target position					
	Offset			Rotation		
	x	y	z	A	B	C
2D	✓	0.0	✓	0.0	0.0	0.0
2D with orientation	✓	0.0	✓	✓ -180.0° to 179.999°	0.0	0.0
3D	✓	✓	✓	0.0	0.0	0.0
3D with orientation	✓	✓	✓	✓ -180.0° to 179.999°	0.0	0.0

✓ Value for offset/rotation configurable

Value = 0.0: Offset/rotation not permitted

Kinematics type	Target position					
	Offset			Rotation		
	x	y	z	A	B	C
3D with 2 orientations A, B	✓	✓	✓	✓ -180.0° to 179.999°	✓ -90.0° to 90.0°	✓ 0.0 / -180.0°
3D with 3 orientations	✓	✓	✓	✓ -180.0° to 179.999°	✓ -90.0° to 90.0°	✓ -180.0° to 179.999°
6-axis articulated arm with central wrist, 6-axis articulated arm with offset wrist						

✓ Value for offset/rotation configurable

Value = 0.0: Offset/rotation not permitted

Examples

The following examples of a kinematics type with more than 4 interpolating kinematics axes show 4 different positions of the TCP at the target position reached. The target positions are configured in each case with the same shift, but with different rotation.

① ... ④ Position in the WCS

Orientation in path motion jobs for 3D kinematics with 2 orientations

You can move a 3D kinematics with 2 orientations to a Cartesian position with a differently configured orientation. The following figures show the kinematics with different joint positions at the same target position with different orientation of the TCP. The effective direction of the tool in x direction of the TCP is the same in both cases. However, due to the rotation C, the tool is rotated -180° around the x axis of the TCP.

The following figure shows the orientation motion B in which joint J5 is moved beyond 0° and joint J4 is stationary. Since values greater than 90° for orientation B are not permitted, configure the Cartesian orientations as follows in order to move beyond the vertical position without rotating joint J4:

- A: By -180° (from 0° to -180° or also, e.g. from 20° to -160°)
- B: 90° when position of the TCP is vertical, decreasing to 0°
- C: -180°

Abrupt changes in orientations A and C do not lead to abrupt position changes on the joints or kinematics axes.

8.3.3 Motion status and remaining distance

You can obtain the status and the remaining distance of a motion job from the parameters of the corresponding Motion Control instruction.

Status of a motion job

You can identify the status of a motion job based on the "Busy" and "Active" parameters. When the job is transmitted, the "Busy" parameter is set to TRUE and the job is added to the job sequence. As long as the job is still in the job sequence, the "Active" parameter is set to FALSE. As soon as the job is active in the motion control, the "Active" parameter is set to TRUE. If the motion job is completed, the parameters "Busy" and "Active"are set to FALSE and the parameter "Done" to TRUE.

All inactive jobs in the job sequence are recalculated if another motion job is added to the job sequence. The current job is also included in the new calculation so that the current job can be blended with the next job.

Remaining distance of a motion job

You can obtain the remaining distance of a motion job from the "RemainingDistance" parameter. If the motion is not being blended, the "RemainingDistance" parameter contains the distance to the target position on the path. If the active motion is being blended with the next motion, the "RemainingDistance" parameter contains the distance to the beginning of the blending segment on the path. If only the Cartesian orientation of the TCP is changed in a motion task, but the TCP is at the Cartesian coordinates x, y, z, then the "RemainingDistance" parameter has the value "-1.0".

With an sPTP motion job, the execution progress is displayed with the "ExecutionTimeStatus" parameter instead of the remaining path. The parameter value starts at "0.0" and increases incrementally in the course of job execution until the job is completed at "1.0".

Distance of linear and circular motion jobs

The status tag "<TO>.StatusPath.AccumulatedPathLength" contains the distance already covered by the TCP of all completed motion jobs and the current motion job.

The status tag "<TO>.StatusPath.TotalPathLength" contains the total path length of the TCP for all jobs in the job sequence.

The total path length is the sum of:

- Distance of all completed motion jobs
- Distance travelled of the active motion job
- Remaining distance of the motion job
- Calculated distance of all jobs in the job sequence

Distances based on the following motion jobs are not taken into account:

- Synchronous "point-to-point" motions (sPTP motion)

  Exception: Blending segment between path motion and sPTP motion
- Active conveyor tracking
- Pure orientation motions

If there are no jobs in the job sequence and the last motion job is completed, then "AccumulatedPathLength" and "TotalPathLength" are equal.

Resetting distances

To reset the tags "AccumulatedPathLength" and "TotalPathLength" to zero in the user program, use one of the following instructions:

- Call "MC_Reset" with "Restart = TRUE" for the kinematics.
- Call "MC_GroupStop" for the kinematics.

The two tags are automatically reset during the following actions.

- Operating state changes from STOP to RUN
- Startup after POWER ON of the CPU

Calculate remaining distance of all jobs of the job sequence

To determine the remaining distance of all jobs in the job sequence, subtract "AccumulatedPathLength" from "TotalPathLength".

Remaining distance of the job sequence = "TotalPathLength" - "AccumulatedPathLength"

Example: Three linear motion jobs with smoothing

The starting point is point A. From point A, three linear path jobs are sent to points B, C and D. Blending is carried out in the second and third jobs. The path length is 0 mm at the beginning of the example. To simplify this, a 2D kinematics without orientation motion is used.

At time ①, the first linear motion job is started from point A to point B. The tag "AccumulatedPathLength" is 0.0 mm at the time ① because the kinematics is not yet

moving. "TotalPathLength" outputs the distance 100.0 mm between point A and point B. After the TCP moves, the "AccumulatedPathLength" tag shows the distance already moved.

When the second linear motion job is issued at time ②, the distance to point B is added, taking into account the smoothing, and displayed in "TotalPathLength". The total path length is now 281.8 mm. The second linear motion job becomes active at time ③.

At time ④, the third linear motion job is sent to point D. The total path length of 363.5 mm between point A and point D is now displayed in "TotalPathLength" . The third linear motion job becomes active at time ⑤.

At the time ⑥, the TCP reaches point D and all motion jobs are completed. The "AccumulatedPathLength" corresponds to the "TotalPathLength", as no more motion jobs are processed in the job sequence.

8.3.4 Interrupting, continuing and stopping kinematics motions

You can interrupt and continue active kinematics motions or stop them and thus also cancel queued motion jobs.

Suspend kinematics motions

With the Motion Control instruction "MC_GroupInterrupt (Page 384)", you interrupt the execution of the motion on a kinematics technology object.

With the "Mode" parameter, you specify the dynamic behavior. The kinematics can be stopped either with the dynamic response of the motion job to be interrupted ("Mode" = 0) or with the maximum dynamic response of the kinematics motion ("Mode" = 1). When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.

The current path is not exited when the kinematics is stopped. If the kinematics is already at a standstill, the motion control is also interrupted for subsequent motion jobs. New motion jobs are then arranged as pending jobs in the job sequence.

The kinematics technology object is in "Interrupted" status (<TO>.StatusWord.X17).

The interrupted kinematics motion can be resumed with a "MC_GroupContinue (Page 385)" job.

Resuming interrupted kinematics motions

With the Motion Control instruction "MC_GroupContinue (Page 385)", you continue a kinematics motion that was previously interrupted with an "MC_GroupInterrupt" job. The kinematics motion can be continued if the kinematics has come to a standstill following the "MC_GroupInterrupt" job. The "MC_GroupContinue" job only has an effect if the kinematics technology object is in "Interrupted" status (<TO>.StatusWord.X17).

Stop kinematics motions

With the Motion Control instruction "MC_GroupStop (Page 389)", you stop the Motion Control of the kinematics technology object.

With the "Mode" parameter, you specify the dynamic behavior. The kinematics can be stopped either with the dynamic response of the motion job to be stopped ("Mode" = 0) or with the maximum dynamic response of the kinematics motion ("Mode" = 1). When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.

During stopping, both the active motion job and all queued jobs in the job sequence are canceled and the job sequence is emptied. If the kinematics motion was already interrupted with an "MC_GroupInterrupt" job, this job is also canceled. As long as the "Execute" parameter is set to TRUE, the following kinematics jobs are rejected ("ErrorID" = 16#80CD).

The current path is not exited when the kinematics is stopped.

8.3.5 Interaction of kinematics motions and single axis motions

Kinematics motions are only possible if no single axis motions are active on the kinematics axes. Single axis motions have an overriding effect on kinematics motions. The motion of the corresponding axis is overridden by the single-axis motion and the job sequence is cleared. The other kinematics axes stop with the maximum dynamics. Exception: The kinematics is in simulation (Page 307).

The following functions are permitted during an active kinematics motion:

- Torque reduction on the axes/Travel to fixed stop ("MC_TorqueLimiting")

  When the fixed stop is reached, the kinematics motion is aborted.
- Setting of an additive torque ("MC_TorqueAdditive")
- Setting of the upper and lower torque limit ("MC_TorqueRange")
- Sensor switchover ("MC_SetSensor")

The following functions are rejected during an active kinematics motion:

- Overlaid motion on the axes ("MC_MoveSuperimposed")
- Homing of the axes ("MC_Home")

8.3.6 Tags: Kinematics motions

The following technology object tags are relevant for motion control:

Tag	Description
Status values	
<TO>.StatusWord	Status indicator for an active motion
<TO>.Tcp	Target coordinates x, y, z, A, B, C of the kinematics motion in the world coordinate system
<TO>.StatusPath.CoordSystem	Coordinate system of the active motion job

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

2) Not relevant with sPTP motion

3) Not relevant with orientation motion

Tag	Description		
<TO>.StatusPath.CoordSystem	0	World coordinate system	
	1, 2, 3	Object coordinate system 1, 2, 3	
	100	Machine coordinate system	
	101	Joint coordinate system[1]	
<TO>.StatusPath.Velocity	Current path velocity (setpoint reference)		
<TO>.StatusPath.Acceleration	Current path acceleration (setpoint reference)		
<TO>.StatusPath.OrientationVelocity	Resulting orientation velocity		
<TO>.StatusPath.DynamicAdaption	Dynamic adaptation		
	0	No dynamic adaptation	
	1	Dynamic adaptation with segmentation of the path	
	2	Dynamic adaptation without segmentation of the path	
<TO>.StatusPath.TotalPathLength	Total path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job • Remaining distance of the motion job • Calculated distance of all jobs in the job sequence		
<TO>.StatusPath.AccumulatedPathLength	Accumulated path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job		
<TO>.StatusPath.DynamicLimit	Dynamic limits affecting the running motion job		
	Bit 0	"LIMIT_ORIENTATION" Dynamic limits of the orientation motion [2]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the orientation motion.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the orientation motion.
	Bit 1	"LIMIT_PATH" Dynamic limits of the kinematics motion [2]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics motion.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics motion.
	Bit 16	"LIMIT_AXIS_A1" Dynamic limits of the kinematics axis A1 [3]	

[1] With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

[2] Not relevant with sPTP motion

[3] Not relevant with orientation motion

Tag	Description		
<TO>.StatusPath.DynamicLimit	Bit 16	TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics axis A1.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics axis A1.
			Dynamic adaptation is not activated. [2]
	Bit 17	"LIMIT_AXIS_A2" Dynamic limits of the kinematics axis A2 [3]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics axis A2.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics axis A2.
			Dynamic adaptation is not activated. [2]
	Bit 18	"LIMIT_AXIS_A3" Dynamic limits of the kinematics axis A3 [3]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics axis A3.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics axis A3.
			Dynamic adaptation is not activated. [2]
	Bit 19	"LIMIT_AXIS_A4" Dynamic limits of the kinematics axis A4 [3]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics axis A4.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics axis A4.
			Dynamic adaptation is not activated. [2]
	Bit 20	"LIMIT_AXIS_A5" Dynamic limits of the kinematics axis A5 [3]	
		TRUE	The dynamic response of the current motion is limited by the dynamic limits of the kinematics axis A5.
		FALSE	The dynamic response of the current motion is not limited by the dynamic limits of the kinematics axis A5.
			Dynamic adaptation is not activated. [2]

8.4 Motion dynamics

8.4.1 Dynamic settings and dynamic limits

Interaction

The following overview shows how the dynamic value for a motion job is formed from the dynamic settings and the dynamic limits.

① When a motion dynamic that affects both the path motion and the orientation motion is specified, only one of the two motions can have precedence. The other one is automatically adapted to the slower dynamic. If the orientation dynamic is slower than the path dynamic, for example, the path dynamic is reduced accordingly. This means that it may not be possible for the originally specified dynamic to be reached under certain circumstances.

Dynamic limits of the kinematics

The configured dynamic limits of the kinematics configured under "Technology object > Configuration > Extended parameters > Dynamics" are taken into account during the motion execution. The dynamics of a motion can be restricted so that the dynamic limits of the kinematics are not exceeded. When you change the dynamic limits of the kinematics, the changes take effect immediately for the kinematics motion and orientation motion. The dynamic limits of the kinematics take effect independent of the dynamic adaptation (Page 244).

Dynamic limits of the kinematics axes

When a motion job is transmitted, the dynamic limits of the kinematics axes configured under "Technology object > Configuration > Extended parameters > Limits > Dynamic limits" are only taken into account when dynamic adaptation (Page 244) is active. The dynamics of the motion can be restricted so that the dynamic limits of the kinematics axes are not exceeded.

Guidelines for defining dynamic settings

The following steps are recommended to optimize the motion dynamics:

- Configure and optimize the drive according to specifications.
- Define the torque and speed limit of the drive according to the drive train consisting of motor, gears and mechanical system.
- Avoid sharp curves in the path geometry by using the largest possible blending radii.
- Define dynamic limits at the kinematics axes.
- Define dynamic limits at the kinematics.
- Specify the dynamic response at the motion job.
- Use the dynamic adaptation.

8.4.2 Considering dynamics in path planning

To optimize the dynamics in motion control, consider the following factors in path planning:

- Sharp curves in the path geometry can lead to higher axis acceleration values and thus to higher motor torques. Therefore, if possible, avoid small radii in the path execution.
- It may not be possible to fully utilize the dynamic capability in small geometrical path segments (small traversing distance). Therefore, avoid small segments.
- Where suitable, use sPTP motions.

8.4.3 Defining dynamic limits at the kinematics axes

NOTE

Violations of dynamic limits of the kinematics axes

Despite active dynamic adaptation, there may be slight overruns of the dynamic limits of the kinematics axes.

To avoid violations, set the dynamics at the kinematics axes about 5% lower than their permitted limit.

Configure the following dynamic limits at the positioning axis/synchronous axis technology object:

- Define the limit for the velocity according to the maximum speed of the drive:
  - <TO_Axis>.DynamicLimits.Velocity

    Value can be changed in the user program and is effective immediately.
  - <TO_Axis>.DynamicLimits.MaxVelocity

    Value can only be changed after technology object is restarted.

  The lower of the two values is the effective value.
- Set the acceleration and deceleration limit according to the maximum torque of the drive train:
  - <TO_Axis>.DynamicLimits.MaxAcceleration
  - <TO_Axis>.DynamicLimits.MaxDeceleration

  If in doubt, start with low values. Measurements of the motor torque occurring during motion can help you to find a suitable setting.

The configured jerk only takes effect with single axis motions and is not considered in the dynamic adaptation.

For the configured limits to be considered in the velocity profile, enable dynamic adaptation at the kinematics technology object.

When you change the dynamic limits of the kinematics axes during an active motion, the changed values only take effect during the next preparation of a motion job.

You can find a description of the configuration parameters for the positioning axis and synchronous axis technology objects in the "S7-1500/S7-1500T Axis functions" documentation.

8.4.4 Defining dynamic limits at the kinematics technology object

For the kinematics technology object, define the following dynamic settings in the "Dynamics" configuration window:

- Default values for the dynamics and the dynamic limits of the path motion and of the orientation motion
- Default values for the dynamics of the sPTP motion
- Dynamic adaptation

8.4.5 Configuring dynamics for the kinematics and the orientation motion

Configuring dynamic defaults for the translational motion (path motion)

You can define the dynamic values for a path motion at the corresponding Motion Control instruction or under "Technology object > Configuration > Extended parameters > Dynamics".

NOTE

If you change the dynamic defaults during an active motion, the changed values take effect only in the next motion job.

Procedure

1. Select the entry "Kinematics motion" in the "Settings for" drop-down list.
2. Enter the default values of the dynamics in the "Velocity", "Acceleration", "Deceleration" and "Jerk" fields.
3. To activate the default settings, set the dynamic value at the Motion Control instructions to less than zero.
4. Define the default values of the dynamic limits in the "Maximum velocity", "Maximum acceleration", "Maximum deceleration" and "Maximum jerk" fields.
5. Enable the dynamic adaptation (Page 244).

Configuring dynamic defaults for the orientation motion

You can define the dynamic values for an orientation motion exclusively under "Technology object > Configuration > Extended parameters > Dynamics".

NOTE

If you change the dynamic defaults during an active motion, the changed values take effect only in the next motion job.

Procedure

1. Select the entry "Orientation motion" in the "Settings for" drop-down list.
2. Enter the default values of the dynamics in the "Velocity", "Acceleration", "Deceleration" and "Jerk" fields.
3. Define the default values of the dynamic limits in the "Maximum velocity", "Maximum acceleration", "Maximum deceleration" and "Maximum jerk" fields.
4. Enable the dynamic adaptation (Page 244).

8.4.6 Configuring dynamics for the sPTP motion

You can define the dynamic values for an sPTP motion at the corresponding Motion Control instruction or under "Technology object > Configuration > Extended parameters > Dynamics".

You specify the default settings of the dynamics of the synchronous "point-to-point" motion using factors. These factors each relate in percentage terms to the maximum values of velocity, acceleration, deceleration and jerk that you have configured for the individual axes under "Technology object > Configuration > Extended parameters > Limits> Dynamic limits".

Configuring dynamic defaults for the sPTP motion

NOTE

If you change the dynamic defaults during an active motion, the changed values take effect only in the next motion job.

Procedure

1. Select the entry "sPTP motion" in the "Settings for" drop-down list.
2. Enter the default values of the dynamics in the "Velocity factor", "Acceleration factor", "Deceleration factor" and "Jerk factor" fields.
3. To activate the default settings, set the dynamic factors at the Motion Control instructions "MC_MoveDirectRelative" or "MC_MoveDirectAbsolute" to less than zero.

8.4.7 Dynamic adaptation

When dynamic adaptation is activated, a velocity profile is calculated for the motion of the kinematics. In addition to the dynamic default values and dynamic limits for path motions and the dynamic default values for orientation motions, the velocity profile also considers the maximum velocity, maximum acceleration and maximum deceleration of the kinematics axes.

The "<TO>.StatusPath.DynamicAdaption" tag displays the status of the dynamic adaptation.

NOTE

Dynamic adaptation in the user program

Dynamic adaptation is only active if it is activated in the user program.

WARNING

Dynamic adaptation in "Jog" mode

The dynamic adaptation is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.

In the vicinity of a singularity (Page 183), a path motion without dynamic adaptation mostly results in overruns of the dynamics. This means one or more kinematics axes can move at very high speed and accelerate or decelerate with excessive force.

This can cause the following damages:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damage, for example, through overload of the mechanical components

To prevent dynamic overruns in the vicinity of singularities in "Jog" mode, take the following protective measures:

- In the WCS or OCS, avoid the "Jog" mode.
- Make sure that the dynamic settings in the kinematics control panel do not violate the dynamic limits of the kinematics axes or process.

NOTE

Dynamic adaptation in "Jog to target position" mode

In the kinematics control panel, the dynamic adaptation is only effective as of technology V6.0 and the dynamic limits of the kinematic axes are taken into account. "Dynamic adaptation without segmentation of the path" is always used.

NOTE

Violations of dynamic limits of the kinematics axes

Despite active dynamic adaptation, there may be slight overruns of the dynamic limits of the kinematics axes.

To avoid violations, set the dynamics at the kinematics axes about 5% lower than their permitted limit.

The graphic below shows an example of the velocity curve without and with dynamic adaptation.

A **Velocity curve without dynamic adaptation**
The combination of path curves and path velocity causes a limit violation of the maximum acceleration of kinematics axis A1 in the blending area ① at P1.

B **Velocity curve with dynamic adaptation**
With dynamic adaptation, the velocity and acceleration/deceleration curves of the kinematics axes remain within the defined limits. The path velocity v_p is reduced in the transition area ① at point P1. The accelerations $A1_{acc}$ and $A2_{acc}$ are smoothed and optimized in the area of the transition at point P1 so that the acceleration limit is not violated.

Defining the default setting for the dynamic adaptation

You set the dynamic adaptation under "Kinematics technology object > Configuration > Extended parameters > Dynamics".

Select the default for the dynamic adaptation in the drop-down list:

- **Do not limit (<TO>.DynamicDefaults.DynamicAdaption" = 0)**

  The dynamic limits of the axes are not taken into consideration. Only dynamic limits for the path and orientation motion apply.

  If the axis limits are violated, the technology alarm 511 occurs.

- **Limit with segmentation of the path (<TO>.DynamicDefaults.DynamicAdaption" = 1)**

  The path of a motion job is divided into individual equidistant segments. For each of these segments, the velocity profile is calculated taking into consideration the dynamic limits of the kinematics axes which apply for individual sections of the motion. The dynamic response is therefore adapted for individual sections of a motion and is thus more granular than the "Limit without segmentation of the path" mode.

  Dynamic adaptation in the "Limit with segmentation of the path" mode requires a higher computing time than in the "Limit without segmentation of the path" mode. The total time for the motion job may be shorter under certain circumstances in "Limit with segmentation of the path" mode.

- **Limit without segmentation of the path (<TO>.DynamicDefaults.DynamicAdaption" = 2)**

  The velocity profile is calculated with consideration of dynamic limits of the kinematics axes. The minimum possible velocity of a motion segment is used for the entire segment.

8.4.8 Preparing dynamics at the motion job

You can specify dynamic values for a motion job in a Motion Control instruction or use the dynamics configured at the kinematics technology object. If you do not specify any dynamic values for motion jobs (default value "-1.0"), the dynamic defaults configured under "Technology object > Configuration > Extended parameters > Dynamics" are used for the path motion.

Define the dynamics in the Motion Control instruction in a granular manner, if required, or use the default settings defined at the kinematics technology object.

Defining limits in a granular manner

Start with low values or gradually increase the limit values until the optimization is complete.

First define the limit for the velocity, then for acceleration/deceleration and finally for the jerk. If necessary, increase the limits in the same order.

If there are no particular requirements relating to the motion dynamics, the limits defined at the kinematics technology object under "Technology object > Configuration > Dynamics" can be used instead.

8.4.9 Display of currently effective dynamic limits

The "<TO>.StatusPath.DynamicLimit" status tag shows you whether and which dynamic limits affect the dynamic response of the running kinematics motion. In this way, you can adapt dynamic limits in a targeted manner and optimize the dynamic response of the kinematics motion.

If dynamic limits are in effect, the respective bits of the "<TO>.StatusPath.DynamicLimit" status tag are set to TRUE for the duration of the motion job, regardless of whether dynamic limits are reached.

The calculation of motion profiles takes place in multiple, consecutive steps. First, the configured dynamic limits are evaluated. If required, the dynamic curve is then smoothed by filter algorithms. Individual bits of the "<TO>.StatusPath.DynamicLimit" tag may be set by the evaluation which takes place at the start of the calculation, even though a trace of the

resulting motion signals (velocity, acceleration, etc.) would not show any limiting behavior and the signals would be below the respective limit.

If the motion profile does not meet the specified criteria and the motion is not performed in the specified time, for example, it is advisable to check the motion profile. To do this, localize the dynamic limits that affect the dynamics of the running kinematics motion. You can localize the effective dynamic limits by evaluating the bits of "<TO>.StatusPath.DynamicLimit".

If the kinematics motion is interrupted by an "MC_GroupInterrupt" Motion Control instruction or stopped by an "MC_GroupStop" Motion Control instruction, the bits of the "<TO>.StatusPath.DynamicLimit" status tag are set to FALSE.

If the kinematics motion is resumed by an "MC_GroupContinue" Motion Control instruction, the bits of the "<TO>.StatusPath.DynamicLimit" status tag are set to the previous status.

Dynamic limits of the kinematics

The following bits of the "<TO>.StatusPath.DynamicLimit" status tag are set to TRUE if the dynamic response of the current kinematics motion is limited by the dynamic limits configured on the kinematics:

- Bit 0: Dynamic limits for the orientation motion
- Bit 1: Dynamic limits for the kinematics motion

The following dynamic limits configured on the kinematics technology object are taken into consideration:

- <TO>.DynamicLimits.Path.Velocity
- <TO>.DynamicLimits.Path.Acceleration
- <TO>.DynamicLimits.Path.Deceleration
- <TO>.DynamicLimits.Path.Jerk
- <TO>.DynamicLimits.Orientation.Velocity
- <TO>.DynamicLimits.Orientation.Acceleration
- <TO>.DynamicLimits.Orientation.Deceleration
- <TO>.DynamicLimits.Orientation.Jerk

Bits 0 and 1 of the "<TO>.StatusPath.DynamicLimit" status tag are always set to FALSE during sPTP motions.

Dynamic limits of the kinematics axes

The following bits of the "<TO>.StatusPath.DynamicLimit" status tag are set to TRUE if the dynamic response of the current kinematics motion is limited by the dynamic limits configured on the kinematics axes:

- Bit 16: Dynamic limits of the axis A1
- Bit 17: Dynamic limits of the axis A2
- Bit 18: Dynamic limits of the axis A3
- Bit 19: Dynamic limits of the axis A4
- Bit 20: Dynamic limits of the axis A5
- Bit 21: Dynamic limits of the axis A6

When dynamic adaptation is deactivated, the dynamic limits of the kinematics axes are not considered in linear and circular motions, which is why the bits are set to FALSE.

The following dynamic limits configured on the kinematics axes are taken into consideration:

- <TO>.DynamicLimits.MaxVelocity
- <TO>.DynamicLimits.MaxAcceleration
- <TO>.DynamicLimits.MaxDeceleration
- <TO>.DynamicLimits.MaxJerk

  (Only taken into consideration with sPtP motions. "<TO>.DynamicLimits.MaxJerk" is not taken into consideration with linear and circular motions with active dynamic adaptation.)

8.4.10 Override

With the velocity override, you can adjust the programmed velocity of a kinematics. You define the velocity override in the "<TO>.Override.Velocity" tag in the technology object data block.

Depending on the kinematics motion, you define the value for the velocity override within the following value ranges:

- Enter a value between 0% and 200% for a path motion.
- Enter a value between 0% and 100% for an sPTP motion.

The velocity override acts on the velocity of the tool center point (TCP) along the path. A changed velocity override takes effect immediately for the kinematics motion.

The setpoint velocity of the motion is the velocity specified for the Motion Control instruction multiplied by the percentage value of the velocity override.

The axis-specific velocity override values do not take effect for kinematics motions.

With active master control, the override from the user program has no effect on the velocity when traversing with the kinematics control panel. To adjust the velocity for traversing with the kinematics control panel, define a percentage correction of the velocity in the kinematics control panel under "Adjust (Page 331)".

NOTICE
Deviating jog velocity due to velocity override with technology versions <V10.0 If the velocity override is changed by the user program while the kinematics control panel is active, undesired deviations in the jog velocity can occur. With active master control, both settings on velocity override take effect in jog mode of the kinematics. The value set under "Adapt" with the "Velocity" slider as well as the value configured in the "<TO>.Override.Velocity" tag have a multiplicative effect on the final velocity in jog mode. For example, the following settings result in a final velocity of 25 mm/s: • Jog velocity = 100 mm/s • "<TO>.Override.Velocity" is set cyclically to 50% in OB1. • The "Velocity" slider is set to 50%. The resulting final velocity is calculated as follows: 100 mm/s × 0.5 × 0.5 = 25 mm/s. To avoid undesired deviations in the resulting final velocity, make sure that both parameters are set correctly and the velocity override with active master control is not changed by the user program. With a query of the kinematics control panel status (<TO>.StatusWord.X4 (ControlPanelActive)) when the "<TO>.Override.Velocity" tag is written, you can prevent writing of the tag with an active kinematics control panel.

8.5 Motion preparation using multiple jobs

8.5.1 Job sequence

Motion-relevant jobs are entered in the job sequence of the kinematics technology object.

The following jobs enter the job sequence:

Job	Brief description
Kinematics motions	
MC_MoveLinearAbsolute (Page 392)	Position kinematics with linear path motion
MC_MoveLinearRelative (Page 397)	Relative positioning of kinematics with linear path motion
MC_MoveCircularAbsolute (Page 402)	Position kinematics with circular path motion
MC_MoveCircularRelative (Page 408)	Relative positioning of kinematics with circular path motion
MC_MoveDirectAbsolute (Page 414)	Absolute movement of kinematics with synchronous "point-to-point" motion
MC_MoveDirectRelative (Page 422)	Relative movement of kinematics with synchronous "point-to-point" motion

Job	Brief description
Zones	
MC_DefineWorkspaceZone (Page 435)	Define workspace zone
MC_DefineKinematicsZone (Page 437)	Define kinematics zone
MC_SetWorkspaceZoneActive (Page 438)	Activate workspace zone
MC_SetWorkspaceZoneInactive (Page 440)	Deactivate workspace zone
MC_SetKinematicsZoneActive (Page 442)	Activate kinematics zone
MC_SetKinematicsZoneInactive (Page 443)	Deactivate kinematics zone
Coordinate systems	
MC_SetOcsFrame (Page 448)	Redefine object coordinate systems

Define maximum number of jobs

By default, the job sequence can contain up to five jobs. You can change the maximum number of jobs in the configuration window "Technology object > Configuration > Extended parameters > Job sequence". The job sequence can contain a maximum of ten jobs.

NOTE
Multiple jobs in the job sequence
The more jobs contained in the job sequence, the longer it takes to calculate the motion jobs.

Processing of jobs in the job sequence

The jobs are processed in the same order in which they were entered in the job sequence. The order of the jobs cannot be changed subsequently. If another motion job is added to the job sequence, all jobs in the job sequence will be recalculated. The kinematics motion jobs do not cancel each other.

The job sequence allows the calculation of a velocity profile over several jobs. The number of motion jobs to be considered depends on the type of motion jobs, e. g. sPTP motion, linear motion, circular motion, conveyor tracking. The current job is also included in the new calculation so that the current job can be blended as far as possible with the next job.

Status of the job sequence

The two tags for the status of the job sequence can be used to check whether the calculation of the jobs in the job sequence has been completed and whether the corresponding programmed motion jobs are being blended. If the number of prepared commands in the job sequence ("<TO>StatusMotionQueue.NumberOfPreparedCommands") matches the number of jobs in the job sequence ("<TO>.StatusMotionQueue.NumberOfCommands"), then the preparation of the motion is complete.

Interrupting and resuming job execution

You can also interrupt execution of the jobs with a "MC_GroupInterrupt" job, fill the job sequence and then continue execution with an "MC_GroupContinue" job. The behavior of the motion processing at the "MC_GroupContinue" differs as follows:

- If a "MC_GroupInterrupt" job is transmitted before the start of the motion, the kinematics motion jobs transmitted between the "MC_GroupInterrupt" and the "MC_GroupContinue" job are prepared. If the number of prepared commands in the job sequence ("<TO>StatusMotionQueue.NumberOfPreparedCommands") matches the number of jobs in the job sequence ("<TO>.StatusMotionQueue.NumberOfCommands"), then the preparation of the motion is complete. As soon as the motion preparation is completed, the "MC_GroupContinue" job immediately releases the motion execution without renewed preparation.
- If an active kinematics motion is stopped with a "MC_GroupInterrupt" job and continued with a "MC_GroupContinue" job, the kinematics motions in the job sequence are prepared again with the "MC_GroupContinue" job.

8.5.2 Blending kinematics motions with maximum rounding clearance

Multiple motions can be appended to one another, in which case the kinematics comes to a standstill between the individual motions. To achieve an uninterrupted Motion Control without standstill between the individual motion jobs, the individual motions can be blended and thus connected via geometric transitions.

You can configure the maximum rounding clearance of the kinematics motions from 0% to 100% of the distance. You can specify and move blending distances greater than half of the shorter path length.

Determine maximum rounding clearance

The maximum rounding clearance is determined depending on the following values:

- L0: Rounding clearance of the previous motion job
- L1: Path length of the first job to the rounding point.
- L2: Path length of the second job to the rounding point

The maximum rounding clearance is the smallest of the following values:

- L1 - L0
- "<TO>.Transition.FactorBlendingLength" / 100 * L1
- "<TO>.Transition.FactorBlendingLength" / 100 * L2

Example: Equal distances between the points

The distances between points A and B and points B and C are the same length. The kinematics is at a standstill.

<TO>.Transition.FactorBlendingLength	Maximum rounding clearance ①		Description
100.0	L1		The entire motion can be blended. The maximum rounding clearance corresponds to the distance between points A and B or B and C.
50.0	L1 * 0.5		The maximum rounding clearance is reduced to half the distance between points A and B.

Example: Different distances between the points

The distances between points A and B and points B and C are different in length. The distance between points A and B is less than the distance between points B and C. The kinematics is in standstill.

<TO>.Transition.FactorBlendingLength	Maximum rounding clearance ①		Description
100.0	L1		The maximum rounding clearance corresponds to the distance L1, as this is the shorter distance.
50.0	L1 * 0.5		The maximum rounding clearance is calculated with half of L1, because L1 is the shorter distance.

Example: Previous job blended

The example builds on the previous example. A linear motion to point D should be traversed. Point C should not be approached directly. The motion to point D should be done with maximum rounding clearance to point C. The previous motion job to point C is blended with rounding clearance L0.

<TO>.Transition.FactorBlendingLength	Maximum rounding clearance ①		Description
100.0	L1 - L0		The maximum rounding clearance corresponds to the distance L1 minus the rounding clearance from the previous motion. That is the shortest distance.

<TO>.Transition.FactorBlendingLength	Maximum rounding clearance ①		Description
50.0	L2 * 0.5		Half of L2 is the shortest distance and therefore the maximum rounding clearance. The rounding clearance of the previous motion is lower by a factor of 50% and does not reduce the maximum rounding clearance of the following motion as much as it does at 100%.

Configure maximum rounding clearance

Up to technology version V5.0, the maximum rounding clearance is limited to 50% of the shorter distance. From technology version V6.0, you can configure the maximum rounding clearance. The default is 50% and therefore compatible with the technology versions < V6.0.

The factor [%] is configured in the configuration window "Technology object > Configuration > Extended parameters > Job sequence" or using the tag "<TO>.Transition.FactorBlendingLength" of the kinematics technology object. Change the factor in the user program before sending the motion jobs to the job sequence so that the change is effective.

The maximum rounding clearance is used when the value of the "TransitionParameter[1]" parameter is < 0.0 or the specified value exceeds the maximum rounding clearance. The rounding clearance is limited to the maximum rounding clearance when the value of the "TransitionParameter[1]" is > 0. If you have parameterized a smaller positive rounding clearance at the Motion Control instruction than the maximum rounding clearance, then the configured rounding clearance "TransitionParameter[1]" is effective.

The following table shows three possible configuration examples and their effect on the calculation of the maximum rounding clearance:

Configuration example "<TO>.Transition.FactorBlendingLength"	Effect
0.0	The rounding clearance is always zero. Blending is not possible with any motion.
50.0	The maximum rounding clearance is calculated from half of the shorter distance between the two motions.
100.0	The maximum rounding clearance is calculated from the shorter distance of the two motions and the rounding clearance of the previous motion. You have the option of moving the kinematics with the maximum possible rounding clearances.

8.5.3 Dynamic behavior when motions are appended/blended

You define the dynamic behavior for the transition of kinematics motions with the "BufferMode" and "DynamicAdaption" parameters.

Multiple motions can be appended to one another, in which case the kinematics comes to a standstill between the individual motions ("BufferMode" = 1). To achieve an uninterrupted motion, the individual motions can be blended with a blending segment. The consecutive motions can be blended at the lower velocity ("BufferMode" = 2) or at the higher velocity ("BufferMode" = 5).

Dynamic adaptation

With active dynamic adaptation with segmentation of the path ("DynamicAdaption" =1), the path of a motion job is divided into individual segments. For each of these segments, the velocity profile is calculated with consideration of the applicable limits. The dynamic response of the path is thus adapted for individual segments of a motion job. As a result, a higher traversing velocity can be reached section by section, thus reducing the traversing time of the motion.

With active dynamic adaptation without segmentation of the path ("DynamicAdaption"=2), the velocity profile is calculated taking into account the limitations that apply to the entire motion job.

Dynamic adaptation in the "Limit with segmentation of the path" mode requires a considerably higher computing time than in the "Limit without segmentation of the path" mode.

When dynamic adaptation is activated, a velocity profile for the motion of the kinematics is calculated, which takes into account both the dynamic specifications or dynamic presettings and dynamic limits of the kinematic motion as well as the maximum velocity, maximum acceleration and maximum deceleration of the kinematics axes. In addition, the dynamic presets and dynamic limits for velocity, acceleration and deceleration of the orientation motion are taken into account.

8.5.4 Preliminary motion preparation

With technology version V5.0, the calculation of the motion preparation has changed. The motion preparation is calculated in the organization block (OB) MC_LookAhead and no longer in MC_Interpolator.

The jobs from the job sequence are prepared in advance with MC_LookAhead. The dynamic values for path motions and orientation motions are transferred to the job sequence. The dynamic values are only active when the job is executed.

For the motion processing, the current path motion job and the following path motion jobs (for sPTP-motions only the next motion job) must be taken into account so that the blending of path motions is possible. Path motions are first processed in MC_LookAhead and then take effect in MC_Interpolator. Motions with blending require a longer lead time and a longer reaction time.

You can change the velocity override during a path motion, which immediately changes the dynamics of the path motion.

In MC_Interpolator, less time is needed for motion preparation and you can set a shorter application cycle of MC_Servo.

The description of the organization blocks MC_Interpolator and MC_LookAhead can be found in the "Organization blocks for Motion Control" section of the "S7-1500/S7-1500T Motion Control overview" documentation.

8.5.5 Setting the motion preparation

The motion preparation is influenced by various factors.

To increase the available computing time of the MC_LookAhead, adjust the following settings:

- Application cycle:
  - Set a bigger application cycle.
  - Set a longer PN send clock.
- Increase the maximum cycle load for MC_LookAhead in the properties of the organization block under "General > Multi-core processor". You can set values from 1% to 40% (default setting 20%) for the maximum cycle load.
- If you are not using user-defined kinematics, select the "Improve system performance" check box in the properties of MC_LookAhead under "General > Multi-core processor".
- Set the higher priority 16 for the MC_LookAhead.
- Reduce the percentage communication load in the CPU properties.
- If necessary for interpolation of cyclic cams, clear the "Improve system performance" check box in the properties of MC_Interpolator under "General > Multi-core processor".

You have the following options for reducing the calculation time of the motion preparation:

- Use dynamic adaptation without segmentation of the path instead of dynamic adaptation with segmentation of the path.
- Reduce the maximum number of jobs in the job sequence.

The following measures are possible during programming of the jobs:

- So that blending of a currently active job with a newly issued subsequent job is possible, sufficient computing time must be available for preparation of the subsequent job. You can increase the available computing time using the following measures:
  - Select the smallest possible rounding clearance. Since the rounding clearance shortens the currently active job, there is less time for calculation of the subsequent job.
  - Reduce the traversing velocity.
  - Use jobs with the longest possible traversing length.
- If no motion job is active and the job sequence is empty, you can interrupt the processing of the jobs with an "MC_GroupInterrupt" job and fill the job sequence. Then continue the processing with an "MC_GroupContinue" job as soon as the motion preparation is complete. As a result, the number of prepared commands (<TO>.StatusMotionQueue.NumberOfPreparedCommands) corresponds to the number of queued jobs (<TO>.StatusMotionQueue.NumberOfCommands) in the job sequence.

8.6 Moving a kinematics in a linear manner

You can move the kinematics linearly to a defined target position with a linear motion. With the Motion Control instruction "MC_MoveLinearAbsolute (Page 392)", you move a kinematics with a linear motion to an absolute position. With the Motion Control instruction "MC_MoveLinearRelative (Page 397)", you move a kinematics with a linear path relative to the position which was present at the start of the job processing.

You have the following options for the linear motion:

- Define target position (Page 258)
- Define dynamic response (Page 259)
- Define motion transition (Page 261)
- Start job (Page 263)
- Show motion status and remaining distance (Page 230)

8.6.1 Defining the target position of the linear motion

With the Motion Control instruction "MC_MoveLinearAbsolute", you move a kinematics with a linear motion to an absolute position. With the Motion Control instruction "MC_MoveLinearRelative", you move a kinematics with a linear path relative to the position which was present at the start of the job processing.

Parameter inputs

Absolute target position

You define the absolute target position of the linear motion with the following parameters of the Motion Control instruction "MC_MoveLinearAbsolute (Page 392)":

- With the "CoordSystem" parameter, you define the reference system for the target coordinates.
- With the "Position[1..4]" parameters, you define the x, y, z and A coordinates of the target position.
- With up to 4 interpolating kinematics axes:
  - With the "DirectionA" parameter, you define the direction of movement of the Cartesian orientation A.
- With more than 4 interpolating kinematics axes:
  - With the "Position[5..6]" parameters, you define the B and C coordinates of the target position.

NOTE

Orientation motion

The target orientation is always approached by the shortest distance. If the target orientation can be reached via two paths of equal length, motion is in the positive direction.

Relative target position

You define the relative target position of the linear motion with the following parameters of the Motion Control instruction "MC_MoveLinearRelative (Page 397)":

- With the "CoordSystem" parameter, you define the reference system for the target coordinates.
- With the "Distance[1..4]" parameters, you define the x, y, z and A coordinates of the target position.
- With more than 4 interpolating kinematics axes:
  - With the "Distance[5..6]" parameters, you define the B and C coordinates of the target position.

NOTE

Orientation motion

The target orientation is always approached by the shortest distance. If the target orientation can be reached via two paths of equal length, motion is in the positive direction.

8.6.2 Defining the dynamic response of the linear motion

You can define the dynamic response of the linear path motion at the corresponding Motion Control instruction. You can only define the dynamic response of the orientation motion in the configuration of the kinematics technology object.

Parameter inputs

You define the dynamics of the linear motion with the following parameters of the Motion Control instruction "MC_MoveLinearAbsolute (Page 392)" or "MC_MoveLinearRelative (Page 397)":

- With the "Velocity" parameter, you define the velocity.
- With the "Acceleration" parameter, you define the acceleration.
- With the "Deceleration" parameter, you define the deceleration.
- With the "Jerk" parameter, you define the jerk.
- With the "DynamicAdaption" parameter, you specify the dynamic adaptation of the path motion.

With the following configuration parameters under "Technology object > Configuration > Extended parameters > Dynamics", you define the dynamic response of the orientation motion:

- Select the entry "Orientation motion" in the "Settings for" drop-down list.
- Define the velocity (<TO>.DynamicDefaults.Orientation.Velocity) in the field "Velocity".
- Define the acceleration (<TO>.DynamicDefaults.Orientation.Acceleration) in the field "Acceleration".
- Define the deceleration (<TO>.DynamicDefaults.Orientation.Deceleration) in the field "Deceleration".
- Define the jerk (<TO>.DynamicDefaults.Orientation.Jerk) in the field "Jerk".

Dynamic adaptation

The dynamic adaptation limits the path dynamics to the axis dynamics. When dynamic adaptation is activated, a velocity profile for the motion of the kinematics is calculated, which takes into account not only the dynamic specifications or dynamic defaults and the dynamic limits of the kinematic motion, but also the maximum velocity, maximum acceleration and maximum deceleration of the kinematics axes. In addition, the dynamic defaults and the dynamic limits for velocity, acceleration and deceleration of the orientation motion are taken into account.

Use the configured default

With the "DynamicAdaption" < 0 parameter, the configured default is used. You configure the default value in the field "Limit path dynamics to axis dynamics" under "Technology object > Configuration > Extended parameters > Dynamics" of the kinematics technology object (<TO>.DynamicDefaults.DynamicAdaption).

Do not limit path dynamics to axis dynamics

With the "DynamicAdaption" = 0 parameter, no dynamic adaptation is used for the linear motion.

Limit path dynamics to axis dynamics with segmentation of the path

With the "DynamicAdaption" = 1 parameter, the dynamic adaptation is used for the linear motion. The path of the linear motion is divided into individual segments. For each of these segments, the velocity profile is calculated with consideration of the applicable limits. The dynamic response of the path is thus adapted for individual segments of the linear motion. As a result, a higher traversing velocity is reached section by section and the traversing time of the linear motion is reduced.

Note that dynamic adaptation with segmentation of the path requires a considerably higher computing time than dynamic adaptation without segmentation of the path.

Limit path dynamics to axis dynamics without segmentation of the path

With the "DynamicAdaption" = 2 parameter, the dynamic adaptation is used for the linear motion. The velocity profile is calculated for the entire linear motion. The limitations which apply to the entire motion job are taken into consideration.

8.6.3 Defining the transition of linear motion

Multiple motions can be appended to one another, in which case the kinematics comes to a standstill between the individual motions. To achieve an uninterrupted Motion Control without standstill between the individual motion jobs, the individual motions can be blended with geometric transitions. You define the corresponding parameters at the new motion job (A2), into which the previous job (A1) is to be blended.

In the following examples, the various motion transitions are explained using an active linear motion (A1) and a subsequent linear motion (A2).

Parameter inputs

You define the transition to the active motion with the following parameters of the Motion Control instruction "MC_MoveLinearAbsolute (Page 392)" or "MC_MoveLinearRelative (Page 397)":

- With the "BufferMode" parameter, you define the mode of the motion transition.
- With the "TransitionParameter[1]" parameter, you define the rounding clearance.

Appending motion

With the "BufferMode" = 1 parameter, the linear motion is appended to the active motion. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The linear motion (A2) is then executed.

In this case, the parameter "TransitionParameter[1]" is not relevant.

Blending motion

With the "BufferMode" = 2 parameter, the active motion is blended with the linear motion and the lower velocity of both jobs is used.

With the "BufferMode" = 5 parameter, the active motion is blended with the linear motion and the higher velocity of both jobs is used.

Rounding clearance d > 0.0

With the "TransitionParameter[1]" > 0.0 parameter, the active motion (A1) is blended with the linear motion (A2) as soon as the specified rounding clearance to the target position of the active motion is reached.

Rounding clearance d = 0.0

With the "TransitionParameter[1]" = 0.0 parameter, the linear motion is appended to the active motion as with "BufferMode" = 1. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The linear motion (A2) is then executed.

Rounding clearance d < 0.0

With the "TransitionParameter[1]" < 0.0 parameter, the active motion (A1) is blended with the linear motion (A2) as soon as the maximum rounding clearance to the target position of the active motion is reached.

You configure the factor of the maximum rounding clearance under "Technology object > Configuration > Extended parameters > Job sequence" (<TO>.Transition.FactorBlendingLength). In the following example, the maximum blending distance is limited to 50% of the shorter distance.

Blending between orientation motions

If the two orientation motions do not contain any translational motion, the blending distance is evaluated in the unit of measure for rotary axes.

8.6.4 Starting a linear motion job

After the start of the linear motion job with "Execute" = TRUE, the job is added to the job sequence (Page 250). The processing status is indicated in the Motion Control instruction "MC_MoveLinearAbsolute (Page 392)" or. "MC_MoveLinearRelative (Page 397)" with the parameter "Busy" = TRUE. If the job is active, this is indicated with the parameter "Active" = TRUE and in the "<TO>.StatusWord.X8 (LinearCommand)" tag of the technology object.

As soon as the target position is reached or the linear motion is blended to the next motion, the job is completed. The status is indicated with the parameter "Done" = TRUE.

You can find more information in the section "Motion status and remaining distance (Page 230)".

8.6.5 Tags: Linear motion

The following technology object tags are relevant for motion control:

Tag	Description	
Status values		
<TO>.StatusWord	Status indicator for an active motion	
<TO>.StatusWord.X8 (LinearCommand)	The value "TRUE" is set if a job for linear motion is active ("MC_MoveLinearAbsolute", "MC_MoveLinearRelative").	
<TO>.Tcp	Target coordinates x, y, z, A, B, C of the kinematics motion in the world coordinate system	
<TO>.StatusPath.CoordSystem	Coordinate system of the active motion job	
	0	World coordinate system
	1, 2, 3	Object coordinate system 1, 2, 3
	100	Machine coordinate system
	101	Joint coordinate system[1)]
<TO>.StatusPath.Velocity	Current path velocity (setpoint reference)	
<TO>.StatusPath.Acceleration	Current path acceleration (setpoint reference)	
<TO>.StatusPath.OrientationVelocity	Resulting orientation velocity	
<TO>.StatusPath.DynamicAdaption	Dynamic adaptation	
	0	No dynamic adaptation
	1	Dynamic adaptation with segmentation of the path
	2	Dynamic adaptation without segmentation of the path
<TO>.StatusPath.TotalPathLength	Total path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job • Remaining distance of the motion job • Calculated distance of all jobs in the job sequence	

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Tag	Description	
<TO>.StatusPath.AccumulatedPathLength	Accumulated path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job	
<TO>.StatusMotionQueue.NumberOfCommands	Number of jobs in the job sequence	
Override		
<TO>.Override.Velocity	Velocity override	
Dynamic limits		
<TO>.DynamicLimits.Path.Velocity	Dynamic limitation for the maximum velocity of the path	
<TO>.DynamicLimits.Path.Acceleration	Dynamic limitation for the maximum acceleration of the path	
<TO>.DynamicLimits.Path.Deceleration	Dynamic limitation for the maximum deceleration of the path	
<TO>.DynamicLimits.Path.Jerk	Dynamic limitation for the maximum jerk of the path	
<TO>.DynamicLimits.Orientation.Velocity	Dynamic limitation for the maximum velocity of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Acceleration	Dynamic limitation for the maximum acceleration of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Deceleration	Dynamic limitation for the maximum deceleration of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Jerk	Dynamic limitation for the maximum jerk of the Cartesian orientation	
Dynamic defaults		
<TO>.DynamicDefaults.Path.Velocity	Default setting of the velocity of the path	
<TO>.DynamicDefaults.Path.Acceleration	Default setting of the acceleration of the path	
<TO>.DynamicDefaults.Path.Deceleration	Default setting of the deceleration of the path	
<TO>.DynamicDefaults.Path.Jerk	Default setting of the jerk of the path	
<TO>.DynamicDefaults.Orientation.Velocity	Default setting of the velocity of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Acceleration	Default setting of the acceleration of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Deceleration	Default setting of the deceleration of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Jerk	Default setting of the jerk of the Cartesian orientation	
<TO>.DynamicDefaults.DynamicAdaption	Default setting of the dynamic adaptation	
	0	No dynamic adaptation
	1	Dynamic adaptation with segmentation of the path
	2	Dynamic adaptation without segmentation of the path
Rounding clearance		
<TO>.Transition.FactorBlendingLength	Factor of the maximum rounding clearance in percent [%] The configuration takes place in "Technology object > Configuration > Extended parameters > Job sequence". Change the factor in the user program before sending the motion jobs to the job sequence so that the change is effective.	

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Tag	Description	
<TO>.Transition.FactorBlendingLength	0.0	No blending possible
	50.0	Default value
	100.0	Blending possible with complete segment length or motion length

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

8.7 Moving a kinematics in a circular manner

You can move the kinematics using a defined circular path with a circular motion. With the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)", you move a kinematics with a circular motion to an absolute position. With the Motion Control instruction "MC_MoveCircularRelative (Page 408)", you move a kinematics with a circular motion relative to the position which was present at the start of the job processing.

You have the following options for the circular motion:

- Define circular path:
  - Define circular path via intermediate point and target position (Page 265)
  - Define circular path via center point and angle (Page 267)
  - Define circular path via radius and target position (Page 269)
- Define dynamic response (Page 272)
- Define motion transition (Page 273)
- Start job (Page 276)
- Show motion status and remaining distance (Page 230)

8.7.1 Defining the circular path of the circular motion

8.7.1.1 Defining the circular path via intermediate point and target position

With the Motion Control instruction "MC_MoveCircularAbsolute", you move a kinematics with a circular motion to an absolute position. With the Motion Control instruction "MC_MoveCircularRelative", you move a kinematics with a circular motion relative to the position which was present at the start of the job processing.

Specify an intermediate point on the circular path and the target position for the definition of the circular path. The circular path is calculated via the start position, the intermediate point and the target position. The kinematics can only traverse circular paths less than 360°.

With this mode of circular path definition, the kinematics can move in three-dimensional space:

① Start position

② Intermediate point ("AuxPoint")

③ Target position ("EndPoint")

When defining the intermediate point and target position, ensure that the information is consistent.

Parameter inputs

You define the circular path of the circular motion with the following parameters of the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or "MC_MoveCircularRelative (Page 408)":

- With the "CircMode" parameter, you define the mode of the circular path definition. With "CircMode" = 0, you define the circular path via an intermediate point and the target position.
- With the "CoordSystem" parameter, you define the reference coordinate system.
- With the "AuxPoint[1..3]" parameters, you define the x, y and z coordinates of the intermediate point of the circular path in the reference coordinate system.
- With the parameter "EndPoint[1..4]", you define the x, y, z and A coordinates of the target position in the reference coordinate system.
- With up to 4 interpolating kinematics axes:
  - With the "DirectionA" parameter, you define the direction of movement of the Cartesian orientation A (only with "MC_MoveCircularAbsolute").

- With more than 4 interpolating kinematics axes:
  - With the parameter "EndPoint[5..6]", you define the B and C coordinates of the target position in the reference coordinate system.

NOTE
Orientation motion
The target orientation is always approached by the shortest distance. If the target orientation can be reached via two paths of equal length, motion is in the positive direction.

8.7.1.2 Defining the circular path via center point and angle

With the Motion Control instruction "MC_MoveCircularAbsolute", you move a kinematics with a circular motion to an absolute position. With the Motion Control instruction "MC_MoveCircularRelative", you move a kinematics with a circular motion relative to the position which was present at the start of the job processing.

Specify the intermediate point of the circular path and the angle for the definition of the circular path. Also define the main plane and the orientation of the circular path. The circular path and the target position are calculated via the defaults .

With this mode of circular path definition, the kinematics can also move circular paths with more than 360° in a main plane.

When defining the circle center and angle, ensure that the information is consistent.

Parameter inputs

You define the circular path of the circular motion with the following parameters of the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or "MC_MoveCircularRelative (Page 408)":

- With the "CircMode" parameter, you define the mode of the circular path definition. With "CircMode" = 1, you define the circular path via the circle center and an angle in a main plane.
- With the "CoordSystem" parameter, you define the reference coordinate system.
- With the "AuxPoint[1..3]" parameters, you define the x, y and z coordinates of the center point of the circular path in the reference coordinate system.
- With the "EndPoint[4]" parameter, you define the A coordinates of the target position in the reference coordinate system.
- With up to 4 interpolating kinematics axes:
  - With the "DirectionA" parameter, you define the direction of movement of the Cartesian orientation A (only with "MC_MoveCircularAbsolute").

- With more than 4 interpolating kinematics axes:
  - With the parameter "EndPoint[5..6]", you define the B and C coordinates of the target position in the reference coordinate system.

NOTE
Orientation motion
The target orientation is always approached by the shortest distance. If the target orientation can be reached via two paths of equal length, motion is in the positive direction.

- With the "Arc" parameter, you define the angle of the circular path in the main plane.
- With the "CirclePlane" parameter, you define the main plane of the circular path in the reference coordinate system.
- With the "PathChoice" parameter, you define the orientation of the circular path in the reference coordinate system.

Main plane of the circular path

With the "CirclePlane" parameter, you define on which main plane of the reference coordinate system the circular path is to move:

- With the "CirclePlane" = 0 parameter, you define the xz plane of the reference coordinate system as the main plane.
- With the "CirclePlane" = 1 parameter, you define the yz plane of the reference coordinate system as the main plane.
- With the "CirclePlane" = 2 parameter, you define the xy plane of the reference coordinate system as the main plane.

Orientation of the circular path

There are two possible circular paths in the specified main plane. With the "PathChoice" parameter, you specify the direction in which the circular path should move:

- Use the positive direction of rotation with the "PathChoice" = 0 parameter.
- Use the negative direction of rotation using the "PathChoice" = 1 parameter.

In the following example, the xz plane is defined as the main plane:

① Positive direction of rotation ("PathChoice" = 0)
② Target position of positive direction of rotation
③ Circle center
④ Start position
⑤ Target position of negative direction of rotation
⑥ Negative direction of rotation ("PathChoice" = 1)
α Angle α = 135°

The figure below shows the direction of rotation depending on the main planes:

Positive direction of rotation

Negative direction of rotation

8.7.1.3 Define circular path via radius and target position

With the Motion Control instruction "MC_MoveCircularAbsolute", you move a kinematics with a circular motion to an absolute position. With the Motion Control instruction "MC_MoveCircularRelative", you move a kinematics with a circular motion relative to the position which was present at the start of the job processing.

Specify the radius of the circular path and the target position for each definition of the circular path. Also define the main plane and the orientation of the circular path. The circular path is calculated via the defaults.

With this mode of circular path definition, the kinematics can only move circular paths less than 360° in a main plane.

When defining the radius and target position, ensure that the information is consistent.

Parameter inputs

You define the circular path of the circular motion with the following parameters of the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or "MC_MoveCircularRelative (Page 408)":

- With the "CircMode" parameter, you define the mode of the circular path definition. With "CircMode" = 2, you define the circular path via the circle radius and the target position in a main plane.
- With the "CoordSystem" parameter, you define the reference coordinate system.
- With the parameter "EndPoint[1..4]", you define the x, y, z and A coordinates of the target position in the reference coordinate system.
- With up to 4 interpolating kinematics axes:
  - With the "DirectionA" parameter, you define the direction of movement of the Cartesian orientation A (only with "MC_MoveCircularAbsolute").
- With more than 4 interpolating kinematics axes:
  - With the parameter "EndPoint[5..6]", you define the B and C coordinates of the target position in the reference coordinate system.

NOTE

Orientation motion

The target orientation is always approached by the shortest distance. If the target orientation can be reached via two paths of equal length, motion is in the positive direction.

- With the "Radius" parameter, you define the radius of the circular path in the main plane.
- With the "CirclePlane" parameter, you define the main plane of the circular path in the reference coordinate system.
- With the "PathChoice" parameter, you define the orientation of the circular path in the reference coordinate system.

Main plane of the circular path

With the "CirclePlane" parameter, you define on which main plane of the reference coordinate system the circular path is to move:

- With the "CirclePlane" = 0 parameter, you define the xz plane of the reference coordinate system as the main plane.
- With the "CirclePlane" = 1 parameter, you define the yz plane of the reference coordinate system as the main plane.
- With the "CirclePlane" = 2 parameter, you define the xy plane of the reference coordinate system as the main plane.

Orientation of the circular path

Depending on the radius, up to four possible circular paths can occur in the specified main plane. With the "PathChoice" parameter, you specify how the circular path should move:

- Use the shorter positive circle segment with the "PathChoice" = 0 parameter.
- Use the shorter negative circle segment using the "PathChoice" = 1 parameter.
- Use the longer positive circle segment with the "PathChoice" = 2 parameter.
- Use the longer negative circle segment with the "PathChoice" = 3 parameter.

In the following example, the xz plane is defined as the main plane:

① Longer positive circle segment ("PathChoice" = 2)
② Shorter positive circle segment ("PathChoice" = 0)
③ Start position
④ Target position
⑤ Shorter negative circle segment ("PathChoice" = 1)
⑥ Longer negative circle segment ("PathChoice" = 3)

The following figure shows the positive and negative circle segments depending on the main planes:

8.7.2 Define the dynamic response of the circular motion

You can define the dynamic response of the circular path motion at the corresponding Motion Control instruction. You can only define the dynamic response of the orientation motion in the configuration of the kinematics technology object.

Parameter inputs

You define the dynamics of the circular motion with the following parameters of the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or "MC_MoveCircularRelative (Page 408)":

- With the "Velocity" parameter, you specify the velocity of the path motion.
- With the "Acceleration" parameter, you specify the acceleration of the path motion.
- With the "Deceleration" parameter, you specify the deceleration of the path motion.
- With the "Jerk" parameter, you specify the jerk of the path motion.
- With the "DynamicAdaption" parameter, you specify the dynamic adaptation of the path motion.

With the following configuration parameters under "Technology object > Configuration > Extended parameters > Dynamics", you define the dynamic response of the orientation motion:

- Select the entry "Orientation motion" in the "Settings for" drop-down list.
- Define the velocity of the orientation motion (<TO>.DynamicDefaults.Orientation.Velocity) in the field "Velocity".
- Define the acceleration of the orientation motion (<TO>.DynamicDefaults.Orientation.Acceleration) in the field "Acceleration".
- Define the deceleration of the orientation motion (<TO>.DynamicDefaults.Orientation.Deceleration) in the field "Deceleration".
- Define the jerk of the orientation motion (<TO>.DynamicDefaults.Orientation.Jerk) in the field "Jerk".

Dynamic adaptation

The dynamic adaptation limits the path dynamics to the axis dynamics. When dynamic adaptation is activated, a velocity profile for the motion of the kinematics is calculated, which takes into account not only the dynamic specifications or dynamic defaults and the dynamic limits of the kinematic motion, but also the maximum velocity, maximum acceleration and maximum deceleration of the kinematics axes. In addition, the dynamic defaults and the dynamic limits for velocity, acceleration and deceleration of the orientation motion are taken into account.

Use the configured default

With the "DynamicAdaption" < 0 parameter, the configured default is used. You configure the default value in the field "Limit path dynamics to axis dynamics" under "Technology object > Configuration > Extended parameters > Dynamics" of the kinematics technology object (<TO>.DynamicDefaults.DynamicAdaption).

Do not limit path dynamics to axis dynamics

With the "DynamicAdaption" = 0 parameter, no dynamic adaptation is used for the circular motion.

Limit path dynamics to axis dynamics with segmentation of the path

With the "DynamicAdaption" = 1 parameter, the dynamic adaptation is used for the circular motion. The path of the circular motion is divided into individual segments. For each of these segments, the velocity profile is calculated with consideration of the applicable limits. The dynamic response of the path is thus adapted for individual segments of the circular motion. As a result, a higher traversing velocity is reached section by section and the traversing time of the circular motion is reduced.

Note that dynamic adaptation with segmentation of the path requires a considerably higher computing time than dynamic adaptation without segmentation of the path.

Limit path dynamics to axis dynamics without segmentation of the path

With the "DynamicAdaption" = 2 parameter, the dynamic adaptation is used for the circular motion. The velocity profile is calculated for the entire circular motion. The limitations which apply to the entire motion job are taken into consideration.

8.7.3 Define the transition of circular motion

Multiple motions can be appended to one another, in which case the kinematics comes to a standstill between the individual motions. To achieve an uninterrupted Motion Control without standstill between the individual motion jobs, the individual motions can be blended with geometric transitions. You define the corresponding parameters at the new motion job (A2), into which the previous job (A1) is to be blended.

In the following examples, the various motion transitions are explained using an active linear motion (A1) and a subsequent circular motion (A2).

Parameter inputs

You define the transition to the active motion with the following parameters of the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or "MC_MoveCircularRelative (Page 408)":

- With the "BufferMode" parameter, you define the mode of the motion transition.
- With the "TransitionParameter[1]" parameter, you define the rounding clearance.

Appending motion

With the "BufferMode" = 1 parameter, the circular motion is appended to the active motion. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The circular motion (A2) is then executed.

In this case, the parameter "TransitionParameter[1]" is not relevant.

Blending motion

With the "BufferMode" = 2 parameter, the active motion is blended with the circular motion and the lower velocity of both jobs is used.

With the "BufferMode" = 5 parameter, the active motion is blended with the circular motion and the higher velocity of both jobs is used.

Rounding clearance d > 0.0

With the "TransitionParameter[1]" > 0.0 parameter, the active motion (A1) is blended with the circular motion (A2) as soon as the specified rounding clearance to the target position of the active motion is reached.

Rounding clearance d = 0.0

With the "TransitionParameter[1]" = 0.0 parameter the circular motion is appended to the active motion as with "BufferMode" = 1. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The circular motion (A2) is then executed.

Rounding clearance d < 0.0

With the "TransitionParameter[1]" < 0.0 parameter, the active motion (A1) is blended with the circular motion (A2) as soon as the maximum rounding clearance to the target position of the active motion is reached.

You configure the factor of the maximum rounding clearance under "Technology object > Configuration > Extended parameters > Job sequence" (<TO>.Transition.FactorBlendingLength). In the following example, the maximum blending distance is limited to 50% of the shorter distance.

Blending between orientation motions

If the two orientation motions do not contain any translational motion, the blending distance is evaluated in the unit of measure for rotary axes.

8.7.4 Starting a circular motion job

After the start of the circular motion job with "Execute" = TRUE, the job is added to the job sequence (Page 250). The processing status is indicated in the Motion Control instruction "MC_MoveCircularAbsolute (Page 402)" or. "MC_MoveCircularRelative (Page 408)" with the parameter "Busy" = TRUE. If the job is active, this is indicated with the parameter "Active" = TRUE and in the "<TO>.StatusWord.X9 (CircularCommand)" tag of the technology object.

As soon as the target position is reached or the circular motion is blended to the next motion, the job is completed. The status is indicated with the parameter "Done" = TRUE.

You can find more information in the section "Motion status and remaining distance (Page 230)".

8.7.5 Tags: Circular motion

The following technology object tags are relevant for motion control:

Tag	Description	
Status values		
<TO>.StatusWord	Status indicator for an active motion	
<TO>.StatusWord.X9 (CircularCommand)	The value "TRUE" is set if a job for circular motion is active ("MC_MoveCircularAbsolute", "MC_MoveCircularRelative").	
<TO>.Tcp	Target coordinates x, y, z, A, B, C of the kinematics motion in the world coordinate system	
<TO>.StatusPath.CoordSystem	Coordinate system of the active motion job	
	0	World coordinate system
	1, 2, 3	Object coordinate system 1, 2, 3
	100	Machine coordinate system
	101	Joint coordinate system[1)]
<TO>.StatusPath.Velocity	Current path velocity (setpoint reference)	
<TO>.StatusPath.Acceleration	Current path acceleration (setpoint reference)	
<TO>.StatusPath.OrientationVelocity	Resulting orientation velocity	
<TO>.StatusPath.DynamicAdaption	Dynamic adaptation	
	0	No dynamic adaptation
	1	Dynamic adaptation with segmentation of the path
	2	Dynamic adaptation without segmentation of the path
<TO>.StatusPath.TotalPathLength	Total path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job • Remaining distance of the motion job • Calculated distance of all jobs in the job sequence	

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Tag	Description	
<TO>.StatusPath.AccumulatedPathLength	Accumulated path length of linear and circular path motions Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job	
<TO>.StatusMotionQueue.NumberOfCommands	Number of jobs in the job sequence	
Override		
<TO>.Override.Velocity	Velocity override	
Dynamic limits		
<TO>.DynamicLimits.Path.Velocity	Dynamic limitation for the maximum velocity of the path	
<TO>.DynamicLimits.Path.Acceleration	Dynamic limitation for the maximum acceleration of the path	
<TO>.DynamicLimits.Path.Deceleration	Dynamic limitation for the maximum deceleration of the path	
<TO>.DynamicLimits.Path.Jerk	Dynamic limitation for the maximum jerk of the path	
<TO>.DynamicLimits.Orientation.Velocity	Dynamic limitation for the maximum velocity of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Acceleration	Dynamic limitation for the maximum acceleration of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Deceleration	Dynamic limitation for the maximum deceleration of the Cartesian orientation	
<TO>.DynamicLimits.Orientation.Jerk	Dynamic limitation for the maximum jerk of the Cartesian orientation	
Dynamic defaults		
<TO>.DynamicDefaults.Path.Velocity	Default setting of the velocity of the path	
<TO>.DynamicDefaults.Path.Acceleration	Default setting of the acceleration of the path	
<TO>.DynamicDefaults.Path.Deceleration	Default setting of the deceleration of the path	
<TO>.DynamicDefaults.Path.Jerk	Default setting of the jerk of the path	
<TO>.DynamicDefaults.Orientation.Velocity	Default setting of the velocity of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Acceleration	Default setting of the acceleration of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Deceleration	Default setting of the deceleration of the Cartesian orientation	
<TO>.DynamicDefaults.Orientation.Jerk	Default setting of the jerk of the Cartesian orientation	
<TO>.DynamicDefaults.DynamicAdaption	Default setting of the dynamic adaptation	
	0	No dynamic adaptation
	1	Dynamic adaptation with segmentation of the path
	2	Dynamic adaptation without segmentation of the path
Rounding clearance		
<TO>.Transition.FactorBlendingLength	Factor of the maximum rounding clearance in percent [%] The configuration takes place in "Technology object > Configuration > Extended parameters > Job sequence". Change the factor in the user program before sending the motion jobs to the job sequence so that the change is effective.	

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Tag	Description	
<TO>.Transition.FactorBlendingLength	0.0	No blending possible
	50.0	Default value
	100.0	Blending possible with complete segment length or motion length

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

8.8 Moving a kinematics with a synchronous "point-to-point" motion

With a synchronous "point-to-point" motion (sPTP motion), you can move a kinematics time- and motion-optimized, bypass singularities (Page 183) or change joint position spaces. The kinematics does not follow a specified path. The single-axis motions, which move the kinematics axes synchronously, are calculated from the start and target positions. All kinematics axes move simultaneously and reach the corresponding target position at the same time. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes. The movement path of the tool center point (TCP) results from the motions and dynamics of the individual axes.

Blending between sPTP motions and path motions results in the reduction of the travel time of a sequence of motion jobs, e.g.:

- Record product with a defined path motion
- Move product with sPTP motion as quickly as possible
- Place product with a defined path motion

With the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)", you move a kinematics with an sPTP motion to an absolute position. With the Motion Control instruction "MC_MoveDirectRelative (Page 422)", you move a kinematics with an sPTP motion relative to the position which was present at the start of the job processing.

NOTE

Traversing coupled axis with sPTP motion

For coupled axes with coupling factor ≠ 1, the traversing of joints in the JCS with an sPTP motion can result in compensation motions of the coupled axes.

You have the following options for the sPTP motion:

- Define target position:
  - Define axis target positions (Page 279)
  - Define joint target positions (Page 280)
  - Define Cartesian coordinates (Page 281)
- Define dynamic factors (Page 283)
- Define motion transition (Page 284)
- Start job and show execution progress (Page 286)

8.8.1 Defining the target position of the sPTP motion

8.8.1.1 Defining the axis target position of the sPTP motion

With the Motion Control instruction "MC_MoveDirectAbsolute", you move a kinematics with a synchronous "point-to-point" motion (sPTP motion) to an absolute position. With the Motion Control instruction "MC_MoveDirectRelative", you move a kinematics with an sPTP motion relative to the position which was present at the start of the job processing.

Enter axis-related target positions in the machine coordinate system (MCS). The single-axis motions are calculated from the start and target positions of the axes. The kinematics moves all single-axis motions synchronously. All kinematics axes move simultaneously and reach the given target positions at the same time. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes.

Parameter inputs

Absolute target positions

You define the absolute target position of the axes with the following parameters of the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)":

- With the "CoordSystem" = 100 parameter, you define the MCS as the reference coordinate system.
- With the "Position[1..4]" parameters, you define the absolute target joint positions of the axes A1 to A4.
- With more than 4 interpolating kinematics axes:
  - With the "Position[5..6]" parameters, you define the absolute target joint positions of the axes A5 and A6.

Relative target positions

You define the relative target position of the axes with the following parameters of the Motion Control instruction "MC_MoveDirectRelative (Page 422)":

- With the "CoordSystem" = 100 parameter, you define the MCS as the reference coordinate system.
- With the "Distance[1..4]" parameters, you define the relative target joint positions of the axes A1 to A4.
- With more than 4 interpolating kinematics axes:
  - With the "Distance[5..6]" parameters, you define the relative target joint positions of the axes A5 and A6.

8.8.1.2 Define joint target positions of the sPTP motion

With the Motion Control instruction "MC_MoveDirectAbsolute", you move a kinematics with a synchronous "point-to-point" motion (sPTP motion) to an absolute position. With the Motion Control instruction "MC_MoveDirectRelative", you move a kinematics with an sPTP motion relative to the position which was present at the start of the job processing.

Enter target positions in the joint coordinate system (JCS). The single-axis motions are calculated from the start and target positions of the joints. The kinematics moves all single-axis motions synchronously. All kinematics axes move simultaneously and reach the given target positions at the same time. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes.

With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Parameter inputs

Absolute target positions

You define the absolute target position of the joints with the following parameters of the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)":

- With the "CoordSystem" = 101 parameter, you define the JCS as the reference coordinate system.
- With the "Position[1..4]" parameters, you define the absolute target positions of joints J1 to J4.
- With more than 4 interpolating kinematics axes:
  - With the "Position[5..6]" parameters. you define the absolute target positions of joints J5 and J6.

Relative target positions

You define the relative target positions of the joints with the following parameters of the Motion Control instruction "MC_MoveDirectRelative (Page 422)":

- With the "CoordSystem" = 101 parameter, you define the JCS as the reference coordinate system.
- With the "Distance[1..4]" parameters, you define the relative target positions of joints J1 to J4.
- With more than 4 interpolating kinematics axes:
  - With the "Distance[5..6]" parameters, you define the relative target positions of joints J5 and J6.

8.8.1.3 Defining the Cartesian target coordinates of the sPTP motion

With the Motion Control instruction "MC_MoveDirectAbsolute", you move a kinematics with a synchronous "point-to-point" motion (sPTP motion) to an absolute position. With the Motion Control instruction "MC_MoveDirectRelative", you move a kinematics with an sPTP motion relative to the position which was present at the start of the job processing.

You define the Cartesian target coordinates in the world coordinate system (WCS) or an object coordinate system (OCS). The single-axis motions are calculated from the start and target coordinates. The kinematics moves all single-axis motions synchronously. All kinematics axes move simultaneously and reach their target positions at the same time. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes.

Parameter inputs

Absolute Cartesian coordinates

You define the absolute Cartesian target coordinates of the sPTP motion with the following parameters of the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)":

- With the "CoordSystem" = 0, 1, 2 or 3 parameter, you define the WCS, OCS1, OCS2 or OCS3 as the reference coordinate system.
- With the "Position[1..4]" parameters, you define the absolute Cartesian target coordinates x, y, z and A.
- With the "LinkConstellation" parameter, you define the target joint position space.
- With up to 4 interpolating kinematics axes:
  - With the "PositionMode" parameter, you define for the kinematics types with orientation A whether the value of the parameter "Position[4]" is to be interpreted as absolute or relative for the axis A4. This is only possible if you have enabled Modulo functionality for the axis A4.
  - If "PositionMode" = 1, you define the direction of movement of the Cartesian orientation A with the "DirectionA" parameter. This is only possible if you have enabled Modulo functionality for the axis A4.
- With more than 4 interpolating kinematics axes:
  - With the "Position[5..6]" parameters, you define the absolute Cartesian target coordinates B and C.
  - With the parameter "TurnJoint[1..6]", you define the target joint position ranges of the joints J1 to J6.

Relative Cartesian coordinates

You define the relative Cartesian target coordinates of the sPTP motion with the following parameters of the Motion Control instruction "MC_MoveDirectRelative (Page 422)":

- With the "CoordSystem" = 0, 1, 2 or 3 parameter, you define the WCS, OCS1, OCS2 or OCS3 as the reference coordinate system.
- With the "Distance[1..4]" parameters, you define the relative Cartesian target coordinates x, y, z and A.

- With the "LinkConstellation" parameter, you define the target joint position space.
- With more than 4 interpolating kinematics axes:
  - With the "Distance[5..6]" parameters, you define the relative target coordinates B and C.
  - With the parameter "TurnJoint[1..6]", you define the target joint position ranges of the joints J1 to J6.

Joint position range

With more than 4 interpolating kinematics axes, you can define the target joint position ranges of the joints J1 to J6. You determine the joint position range of the joint J[i] at the target position with the "TurnJoint[i]" parameter. The parameter values are defined as follows:

Value	Description
m (m < 0)	-180° + m · 360° ≤ Position < 180° + m · 360°
-2	-900 ≤ position < -540
-1	-540 ≤ position < -180
0	Shortest distance
1	-180 ≤ position < 180
2	180 ≤ position < 540
3	540 ≤ position < 900
n (n > 0)	-180° + (n - 1) · 360° ≤ Position < 180° + (n - 1) · 360°

The parameterized values for the joint position ranges are absolute for the Motion Control instructions "MC_MoveDirectAbsolute" and "MC_MoveDirectRelative".

The current position setpoints of the joints J1 to J6 are indicated in the tags "<TO>.JointData.J[1..6].Position" of the technology object. You can derive the current joint position areas from the current position setpoints.

Example

The current position of a joint J[i] is 0°. The joint J[i] is therefore located in joint position range 1.

With the specification "Position[i]" = 90.0 and "TurnJoint[i]" = 2, the joint J[i] will not only rotate by 90°, but by 450° in order to reach the specified target joint position range 2.

With the specification "Position[i]" = 0.0 and "TurnJoint[i]" = 2, the joint J[i] will rotate by 360° in order to reach the center of the specified target joint position range 2.

8.8.2 Defining the dynamics factors of the sPTP motion

The dynamic response of the synchronous "point-to-point" motion (sPTP motion) is determined via dynamics factors. The factors relate to the configured maximum dynamic values of the kinematics axes. You configure the maximum dynamic values in "Technology objects > Configuration > Extended parameters > Limits > Dynamics limits" of the technology objects of the interconnected axes.

The single-axis motions, which move the kinematics axes synchronously, are calculated from the start and target positions. All kinematics axes move simultaneously and reach the corresponding target position at the same time. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes. For the motion profile calculation, the dynamic values of the individual kinematics axes are adapted to the kinematics axis with the longest movement time.

Parameter inputs

You define the dynamics of the sPTP motion with the following parameters of the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)" or "MC_MoveDirectRelative (Page 422)":

- With the "VelocityFactor" parameter, you define the velocity factor of the sPTP motion.
- With the "AccelerationFactor" parameter, you define the acceleration factor of the sPTP motion.
- With the "DecelerationFactor" parameter, you define the deceleration factor of the sPTP motion.
- With the "JerkFactor" parameter, you define the jerk factor of the sPTP motion.

Configure default settings

Proceed as follows to configure the defaults for the dynamics factors of the sPTP motion:

1. Open the "Technology object > Configuration > Extended parameters > Dynamics" configuration window of the kinematics technology object.
2. Select the entry "sPTP motion" in the "Settings for" drop-down list.
3. Enter the default for the velocity factor in the field "Velocity factor" (<TO>.DynamicDefaults.MoveDirect.VelocityFactor).
4. Enter the default for the acceleration factor in the field "Acceleration factor" (<TO>.DynamicDefaults.MoveDirect.AccelerationFactor).
5. Enter the default for the deceleration factor in the field "Deceleration factor" (<TO>.DynamicDefaults.MoveDirect.DecelerationFactor).
6. Enter the default for the jerk factor in the field "Jerk factor" (<TO>.DynamicDefaults.MoveDirect.JerkFactor).

8.8.3 Defining the transition of the sPTP motion

Multiple motions can be appended to one another, in which case the kinematics comes to a standstill between the individual motions. To achieve an uninterrupted Motion Control without standstill between the individual motion jobs, the individual motions can be blended with geometric transitions. You define the corresponding parameters at the new motion job (A2), into which the previous job (A1) is to be blended.

In the following examples, the various motion transitions are explained using an active linear motion (A1) and a subsequent sPTP motion (A2). The sPTP motion is shown as an example. The motion of the kinematics results from the joint position of the individual axes and the dynamics of the motion job.

Parameter inputs

You define the transition to the active motion with the following parameters of the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)" or "MC_MoveDirectRelative (Page 422)":

- With the "BufferMode" parameter, you define the mode of the motion transition.
- With the "TransitionParameter[1]" parameter, you define the rounding clearance.

Append motion

With the "BufferMode" = 1 parameter, the sPTP motion is appended to the active motion. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The sPTP motion (A2) is then executed.

In this case, the parameter "TransitionParameter[1]" is not relevant.

Blending motion

Blending between sPTP motions

With parameter "BufferMode" = 2, the active sPTP motion is blended with the subsequent sPTP motion. When blending two sPTP motions, the lower velocity of the two jobs is used.

With parameter "BufferMode" = 5, the active sPTP motion is blended with the subsequent sPTP motion. When blending two sPTP motions, the higher velocity of the two jobs is used.

To enable continuous blending between two sPTP motions, observe the following:

- Set a sufficiently large rounding clearance.
- Set the dynamic factors for the acceleration and jerk of the sPTP motion as high as possible.
- Set the dynamic response of the two sPTP motions similarly.

Blending between path motions and sPTP motions

When blending path motions and sPTP motions, the velocity of the blending segment is independent of the parameter value "BufferMode" = 2 or 5. The dynamic limits of the axes are not exceeded in the blending area.

To enable a continuous blending between path motions and sPTP motions, observe the following:

- Set a sufficiently large rounding clearance.
- Avoid small curvature radii in the resulting contour of the TCP.
- Set the dynamic response of the path motion and the sPTP motion similarly.
- Set the dynamic adaptation for the path motion.
- Set the dynamics factors of the sPTP motion to smaller than 1.0.
- Set the acceleration and the jerk of the path motion as high as possible.

Define blending distance

Rounding clearance d > 0.0

With the "TransitionParameter[1]" > 0.0 parameter, the active motion (A1) is blended with the sPTP motion (A2) as soon as the specified rounding clearance to the target position of the active motion is reached.

Rounding clearance d = 0.0

With the "TransitionParameter[1]" = 0.0 parameter, the sPTP motion is appended to the active motion as with "BufferMode" = 1. The active motion sequence (A1) is completed and the kinematics comes to a standstill. The sPTP motion (A2) is then executed.

Rounding clearance d < 0.0

With the "TransitionParameter[1]" < 0.0 parameter, the active motion (A1) is blended with the sPTP motion (A2) as soon as the maximum rounding clearance to the target position of the active motion is reached.

You configure the factor of the maximum rounding clearance under "Technology object > Configuration > Extended parameters > Job sequence" (<TO>.Transition.FactorBlendingLength). In the following example, the maximum rounding clearance is limited to 50% of the shorter distance.

Blending between orientation motions

The behavior is independent of whether the orientation motion is with or without a path motion.

8.8.4 Starting the sPTP motion job

After the start of the synchronous "point-to-point" job (sPTP motion) with "Execute" = TRUE, the job is added to the job sequence (Page 250). The processing status is indicated in the Motion Control instruction "MC_MoveDirectAbsolute (Page 414)" or. "MC_MoveDirectRelative (Page 422)" with the parameter "Busy" = TRUE. If the job is active, this is indicated with the parameter "Active" = TRUE and in the "<TO>.StatusWord.X11 (DirectCommand)" tag of the technology object.

The progress of execution is displayed using the "ExecutionTimeStatus" parameter. The parameter value starts at 0.0 and increases incrementally in the course of job execution.

As soon as the target position is reached or the sPTP motion is blended to the next motion, the job is completed. The status is indicated with the parameter "Done" = TRUE and "ExecutionTimeStatus" = 1.0 .

8.8.5 Tags: sPTP motion

The following technology object tags are relevant for motion control:

Tag	Description	
Status values		
<TO>.StatusWord	Status indicator for an active motion	
<TO>.StatusWord.X11 (DirectCommand)	The value "TRUE" is set if a job for sPTP motion is active ("MC_MoveDirectAbsolute", "MC_MoveDirectRelative").	
<TO>.Tcp	Target coordinates x, y, z, A, B, C of the kinematics motion in the world coordinate system	
<TO>.AxesData.A[1..6]	Current setpoints of the kinematics motion for the kinematics axes A1 to A6	
<TO>.JointData.J[1..6]	Current setpoints of the kinematics motion for the joints J1 to J6	
<TO>.StatusPath.CoordSystem	Coordinate system of the active motion job	
	0	World coordinate system
	1, 2, 3	Object coordinate system 1, 2, 3
	100	Machine coordinate system
	101	Joint coordinate system[1)]
<TO>.StatusMotionQueue.NumberOfCommands	Number of jobs in the job sequence	
Override		
<TO>.Override.Velocity	Velocity override	
Dynamic defaults		
<TO>.DynamicDefaults.MoveDirect.VelocityFactor	Factor for the velocity of the axis motions in relation to the respective maximum velocity of the axes with sPTP motion.	
<TO>.DynamicDefaults.MoveDirect.Acceleration-Factor	Factor for the acceleration of the axis motions in relation to the respective maximum acceleration of the axes with sPTP motion.	
<TO>.DynamicDefaults.MoveDirect.Deceleration-Factor	Factor for the deceleration of the axis motions in relation to the respective maximum deceleration of the axes with sPTP motion.	
<TO>.DynamicDefaults.MoveDirect.JerkFactor	Factor for the jerk of the axis motions in relation to the respective maximum jerk of the axes with sPTP motion.	
Rounding clearance		
<TO>.Transition.FactorBlendingLength	Factor of the maximum rounding distance in percent [%] The configuration takes place in "Technology object > Configuration > Extended parameters > Job sequence". Change the factor in the user program before sending the motion jobs to the job sequence so that the change is effective.	

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

Tag	Description	
<TO>.Transition.FactorBlendingLength	0.0	No blending possible
	50.0	Default value
	100.0	Blending possible with complete segment length or motion length

1) With up to 4 interpolating kinematics axes, the joint coordinate system is identical to the machine coordinate system.

8.9 Conveyor Tracking

With conveyor tracking, the kinematics can follow an object on a moving conveyor belt. The conveyor belt is represented by a leading-value-capable technology object. Leading-value-capable technology objects are:

- Positioning axis
- Synchronous axis
- External encoder
- Leading axis proxy

WARNING

Overrun of the dynamics in the vicinity of a singularity

In the vicinity of a singularity (Page 183) a path motion without dynamic adaptation mostly results in overruns of the dynamics. This means one or more kinematics axes can move at very high speed and accelerate or decelerate with excessive force.

This can cause the following damages:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damage, for example, through overload of the mechanical components

Activate the dynamic adaptation by setting the value for "DynamicAdaption" to "1" or "2" on the motion job. Also parameterize the dynamic reserve (<TO>.Conveyor.DynamicReserve[1..3]).

A typical motion sequence runs in 5 phases.

Phase 1: Detect the object position on the conveyor belt

Phase 2: Assign OCS to the object position

Phase 3: Synchronize TCP to tracked OCS

Phase 4: Move TCP within the tracked OCS

Phase 5: Desynchronize TCP from the OCS

The current status of conveyor tracking is displayed in the tag structure "<TO>.StatusConveyor[1..3].TrackingState". "StatusConveyor[1]" refers to OCS1.

8.9.1 Configuring and starting conveyor tracking

Configure and start the conveyor tracking function as follows:

- In the "Conveyor tracking" configuration window, interconnect the leading values and configure the type of coupling for conveyor tracking.
- Use the "MC_TrackConveyorBelt (Page 429)" Motion Control instruction to start the configured conveyor tracking.

Configure leading values for the conveyor tracking

Configure the coupling coefficients in the "Conveyor tracking" configuration window as follows:

1. In the table column "Possible technology objects", add all leading-value-capable technology objects that you need in the instruction as leading-value-capable values for conveyor tracking.

   An object coordinate system can only be coupled with a leading-value-capable technology object whose technology object is defined in this table.
2. In the "Type of coupling" column, select how the leading value of the leading value-capable technology object is to be coupled:
   - Via a setpoint
   - Via an actual value

     With external encoders, only the selection of the actual value is available.
   - Via a delayed setpoint/actual value

Assigning tracked OCS and defining reference position

You define the following parameters for conveyor tracking in the "MC_TrackConveyorBelt" Motion Control instruction:

- **Assigning a leading value-capable technology object**

  An OCS is assigned to a leading value-capable technology object representing the conveyor belt with the "ConveyorBelt" parameter.
- **Defining a frame for OCS reference position on the conveyor**

  The frame "ConveyorBeltOrigin" is used to define the original position of the conveyor belt in relation to the WCS.

  The x direction of the "ConveyorBeltOrigin" must be aligned in the direction of the conveyor belt.

  When defining frames, note the restrictions described in the "Define KCS/OCS frame (Page 204)" section.
- **Tracking position of the OCS**

  You define the tracking position of the OCS in relation to the OCS reference position in the "InitialObjectPosition" parameter.

  "InitialObjectPosition.x" contains the differential value to the belt position to determine the tracked position of the OCS in relation to the OCS reference position.

  The "InitialObjectPosition" is calculated as follows:

"InitialObjectPosition" = Detected position of the conveyor belt at the time of object detection - Distance of the measuring position from the "ConveyorBeltOrigin" in x direction

If the frame "ConveyorBeltOrigin" is exactly at the acquisition position of the object, then the "BeltPosition" corresponds to the "InitialObjectPosition".

- **Select tracked OCS**

  With the "CoordSystem" parameter, you define the number of the tracked OCS.

8.9.2 Phases of conveyor tracking

Phase 1: Detect the object position on the conveyor belt

The "ConveyorBeltOrigin" frame is defined in the example on the left side of the conveyor belt. However, the "ConveyorBeltOrigin" frame can be set so that it does not coincide with the zero point of the conveyor belt. The frame "ConveyorBeltOrigin" is assigned to the Motion Control instruction "MC_TrackConveyorBelt".

When an object reaches a defined position, the current position of the conveyor belt is recorded, e.g. using a measuring input function with a light barrier or with a camera. The "BeltPosition" tag shows the position of the leading-value-capable technology object. In the example, "BeltPosition" is 2000 mm at acquisition time t0. The distance between the measuring position and "ConveyorBeltOrigin" is 500 mm.

After the conveyor position has been acquired, you must enter the "InitialObjectPosition" at the Motion Control instruction "MC_TrackConveyorBelt".

The relative offset of the object to the ConveyorBeltOrigin in x direction is calculated from the difference between the "BeltPosition" and the "InitialObjectPosition".

At the time of acquisition, the "BeltPosition" is 2000 mm and the "InitialObjectPosition" is 1500 mm. This results in a relative offset of 500 mm. The offset of the tracked OCS in x direction to the reference position "ConveyorBeltOrigin" is displayed in the "ObjectPosition".

No OCS is yet coupled in this phase "TrackingState" is "0". The description of the tag and an overview of the behavior of the tag can be found in section "Behavior of the "TrackingState" tag (Page 295)".

Phase 2: OCS is assigned to the object position

With a Motion Control instruction "MC_TrackConveyorBelt", the OCS1 is assigned to the acquired object position ("ObjectPosition") at time t1. The OCS is then tracked with the object in x direction.

"TrackingState" changes from "0" to "1".

At time t1 the "BeltPosition" is 2400 mm. This calculates the "ObjectPosition" from the example as follows:

"ObjectPosition" = 2400 mm - 1500 mm = 900 mm.

When the conveyor belt moves, the "BeltPosition" and the "ObjectPosition" rise at the same time. The "InitialObjectPosition" is constant. The OCS is moved further in x direction.

At time t2, the conveyor belt has moved the object further in x direction of the OCS and the OCS1 continues to be tracked. The OCS frame moves with the leading value that the conveyor belt specifies.

At time t2 the "BeltPosition" is 2500 mm. This means that the "ObjectPosition" is 1000 mm.

Phase 3: Synchronize TCP to tracked OCS

With the first motion job in the tracked OCS, the TCP is synchronized to the motion of the OCS. Use the Motion Control instruction "MC_MoveLinearAbsolute" or "MC_MoveCircularAbsolute" for the first motion job. You specify the target position in absolute coordinates in the tracked OCS.

"TrackingState" changes with the start of the job from "1" to "2".

As soon as the target position is reached, "TrackingState" changes from "2" to "3" and the motion job is completed. The TCP now follows the object on the conveyor belt. If blended into the next motion job, the first motion job in the tracked OCS is already completed ("Done" = TRUE) before "TrackingState" changes to "3".

Phase 4: Move TCP within the OCS

In phase 4 you move the kinematics within the OCS, e.g. to grab or process the object. In phase 4, the TCP always follows the tracked OCS.

Select one of the following Motion Control instructions:

- "MC_MoveLinearAbsolute"
- "MC_MoveLinearRelative"
- "MC_MoveCircularAbsolute"
- "MC_MoveCircularRelative"

"TrackingState" remains at "3".

The figure shows three kinematics motions at different times.

- **t1:** The TCP is moved with the instruction "MC_MoveLinearAbsolute" in the tracked OCS1 downward in z direction toward the object.
- **t2:** The object is gripped. The TCP continues to move with the tracked OCS1.
- **t3:** The TCP is moved upwards in z direction with the instruction "MC_MoveLinearAbsolute" in the tracked OCS1, in order to lift the object from the conveyor belt. The TCP continues to be tracked with the OCS1.

Phase 5: Desynchronize TCP from the OCS

With a Motion Control instruction "MC_MoveLinearAbsolute" or "MC_MoveCircularAbsolute" in the WCS or a non-tracked OCS, the TCP is desynchronized from the OCS and no longer follows the motion of the conveyor belt.

"TrackingState" changes with the start of the job from "3" to "4".

"TrackingState" changes with the end of the job from "4" to "0". The OCS is not tracked with the object position anymore.

Define KCS/OCS frame (Page 204)

8.9.3 Behavior of the "TrackingState" tag

The tag "<TO>.StatusConveyor[1..3].TrackingState" indicates the status of conveyor tracking.

Tag	Description	
<TO>.StatusConveyor[1..3].TrackingState	Conveyor tracking status	
	0	OCS not assigned The OCS is not assigned to a leading-value-capable technology object.
	1	OCS assigned The Motion Control instruction "MC_TrackConveyorBelt" is finished and the OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS can be sent.
	2	TCP synchronizes to OCS The OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS is active.
	3	TCP follows OCS The OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS is completed. The kinematics has reached the position programmed in the path motion job. The kinematics follows the motion of the OCS.

Tag	Description	
<TO>.StatusConveyor[1-..3].TrackingState	4	TCP desynchronizes from OCS The motion of the kinematics in the tracked OCS is ended by a motion job in the WCS or a non-tracked OCS. When the motion job is completed, the "TrackingState" changes to 0 and the OCS is not tracked with the object position anymore.

The following overview shows how the value of "TrackingState" changes when a Motion Control instruction is issued:

Phase	Motion Control instruction	Status of the instruction	"TrackingState"
1	Position acquisition, for example "MC_MeasuringInput"		0
2	"MC_TrackConveyorBelt"	Done = False	0
		Done = False → True	0 → 1
3	• "MC_MoveLinearAbsolute" • "MC_MoveCircularAbsolute" Reference system: Currently tracked OCS	Active = False, Done = False	1
		Active = False → True, Done = False	1 → 2
		Active = True → False, Done = False → True	2 → 3
4	• "MC_MoveLinearAbsolute" • "MC_MoveLinearRelative" • "MC_MoveCircularAbsolute" • "MC_MoveCircularRelative" Reference system: Currently tracked OCS	Active = False, Done = False	3
		Active = False → True, Done = False	3
		Active = True → False, Done = False → True	3
5	• "MC_MoveLinearAbsolute" • "MC_MoveCircularAbsolute" Reference system: WCS or non-tracked OCS	Active = False, Done = False	3
		Active = False → True, Done = False	3 → 4
		Active = True → False, Done = False → True	4 → 0

Possible jobs to define the OCS depending on "TrackingState".

Motion Control instruction	"TrackingState"	Result with active job
"MC_SetOcsFrame"	0, 4	The OCS is redefined.
	1, 2, 3	• The OCS is not redefined. • The OCS is no longer tracked with the conveyor belt. • All kinematics motions are stopped. Please note the following information in this regard.
"MC_TrackConveyorBelt"	0, 1, 4	The OCS is tracked with the defined conveyor belt.
	2, 3	• The OCS is no longer tracked with the conveyor belt. • All kinematics motions are stopped. Please note the following information in this regard.

NOTICE

Product and machine damage

If the motion of the kinematics with an OCS is not yet finished and the OCS is stopped while the conveyor is running, this leads to an interruption of motion of the kinematics.

Close the coupled motion of the kinematics using the OCS or stop the conveyor belt.

8.9.4 Motion between two tracked OCS

For many tasks it is necessary to place motion jobs orders in two tracked OCS.

Example of a pick-and-place task

A product is to be picked up by conveyor belt 1 and placed in a packaging on conveyor belt 2. The object position on conveyor belt 1 is assigned to OCS1, the object position on conveyor belt 2 is assigned to OCS2. The motion between the conveyor belts takes place via an intermediate point in the WCS.

① Intermediate point in the WCS

NOTE

To approach the OCS2 more quickly, smooth the intermediate point in the WCS.

Initial situation: The "TrackingState" of OCS1 is "3". The product has already been gripped and the TCP of the kinematics follows the OCS1.

Program the following Motion Control instructions to move the kinematics from the tracked OCS1 into the tracked OCS2.

1. To assign the OCS2 to the acquired object position, transmit a "MC_TrackConveyorBelt" job.
2. Transmit a "MC_MoveLinearAbsolute" job to an intermediate point in the WCS.
3. Transmit a "MC_MoveLinearAbsolute" job in the tracked OCS2 above the position for the storage.

   The kinematics follows the OCS2.
4. To store the object, transmit a motion job in the OCS2.

8.9.5 Dynamics in the phases of the conveyor tracking

During synchronization or desynchronization, the dynamics of the kinematics results from the dynamics of the motion job and the dynamics required for synchronization or desynchronization. While traveling in the OCS, the dynamics results from the dynamics of the motion job and the dynamics of the conveyor belt.

The dynamics of the kinematics are additionally increased by a synchronization or desynchronization on conveyors with changing conveyor velocity. Execute the synchronization or desynchronization at a conveyor velocity that is as constant as possible.

The path length of the motion job for synchronization or desynchronization influences the dynamics of the kinematics. To reduce the dynamics of the kinematics during synchronization or desynchronization at a constant conveyor speed, increase the length of the path available for synchronization or desynchronization.

8.9.5.1 Dynamic adaptation during conveyor tracking

Use dynamic adaptation at any stage of conveyor tracking. Activate the dynamic adaptation on all motion jobs and parameterize a sufficient dynamic reserve to avoid exceeding the dynamic limits of the kinematics and the kinematics axes.

⚠ WARNING

Exceeding the dynamic limits despite active dynamic adaptation

The following factors can cause the dynamic limits to be exceeded despite activated dynamic adaptation:

- Changing conveyor velocity
- Synchronizing to the tracked OCS with short distance
- Change the range of kinematics motion during conveyor tracking

Exceeding the dynamic limits can cause the following damage:

- Personal injury, for example, caused by products or machine parts coming loose
- Machine damage, for example, through overload of the mechanical components

To avoid exceeding the dynamic limits, take the following measures:

- Parameterize a sufficient dynamic reserve.

  Note that despite parameterized dynamic reserve, the dynamic limits can be exceeded, e.g. by changing conveyor dynamics or short distances when synchronizing or desynchronizing.
- Execute the synchronization or desynchronization at the same conveyor velocity.
- Increase the length of the distance available for synchronization or desynchronization.

Mode of operation

The following overview shows which parameters influence the dynamics at the time of motion preparation and during motion execution in the tracked OCS.

The path motion of the kinematics is calculated in advance in the MC_LookAhead organization block. The following parameters are taken into account at the time of motion preparation ①:

- Dynamics specification on the motion job
- Velocity of the conveyor belt
- Dynamic limits of the Kinematics motion "<TO>.DynamicLimits.Path"
- Dynamic limits of the orientation motion "<TO>.DynamicLimits.Orientation"
- Dynamic limits of the kinematics axes "<TO>.DynamicLimits"

The dynamic limits take into account velocity, acceleration and deceleration. The maximum permissible jerk is not taken into account.

The following changes, which occur during motion in the tracked OCS ② and which were not taken into account at the time of motion preparation, affect the dynamics of the kinematics and the kinematics axes:

Changes	Effect
Changing conveyor dynamics	If the conveyor dynamics change after the motion preparation time, the dynamics of the kinematics motion in the x direction of the tracked OCS also changes.
Change in the range of kinematics motion	Due to the motion of the tracked OCS, the kinematics motion takes place in a different area than for motion preparation. Due to the changed area, the dynamics of individual kinematics axes can be higher than at the time of motion preparation.

Depending on the path length of the motion job and the conveyor dynamics, a dynamic is superimposed to or from the tracked OCS during synchronization or desynchronization.

Enable dynamic adaptation

Activate the Dynamic adaptation (Page 244) by setting the value for "DynamicAdaption" to "1" or "2" on the motion job. Alternatively, configure the default setting on the technology object by setting the "<TO>.DynamicDefaults.DynamicAdaption" variable to "1" or "2" and specifying the value "-1" on the motion job.

8.9.5.2 Dynamic reserve

To maintain the dynamic limits of the kinematics and the kinematics axes when changing the conveyor dynamic response and the working range, use the dynamic reserve "<TO>.Conveyor.DynamicReserve[1..3]". You can configure the dynamic reserve for the object coordinate systems 1 to 3.

NOTE

Dynamic reserve after switching between technology versions V8.0 and V9.0

Up to technology version V8.0 of the kinematics technology object, you can define a value for the dynamic reserve. After the upgrade to technology version V9.0, the default or configured dynamic reserve (<TO>.Conveyor.DynamicReserve[1..1]) is applied as dynamic reserve for the object coordinate systems 1 to 3 (<TO>.Conveyor.DynamicReserve[1..3]). If you are using conveyor tracking, check and configure a sufficient dynamic reserve for all object coordinate systems.

On a change from technology version V9.0 to technology version V8.0, the settings for the dynamic reserve of OCS2 and OCS3 (<TO>.Conveyor.DynamicReserve[2, 3]) are lost. The default or configured dynamic reserve of OCS1 (<TO>.Conveyor.DynamicReserve[1]) is effective for all three object coordinate systems in technology version V8.0.

In order not to exceed the dynamic limits in case of dynamic changes, the motion preparation in x direction of the tracked OCS is calculated with reduced dynamic limits of the kinematics motion, the orientation motion and the kinematics axes. The dynamic limits are reduced by the dynamic reserve during motion preparation. This means that the dynamic reserve is available for dynamic changes during motion, e.g. when the speed of the conveyor is increased.

Parameterize the dynamic reserve according to the expected dynamics change. For strongly fluctuating conveyor dynamics, parameterize a higher dynamic reserve. At constant conveyor velocity, you can parameterize a low dynamic reserve.

① Reduced dynamic limit for motion preparation

② Dynamic reserve for dynamics changes

③ Dynamic limit

Example

The following example shows the dynamic behavior on a "TO_Kin_1" kinematics of the type "Cartesian Portal 3D" (without orientation) with different scenarios.

The kinematics axis A1 is aligned along the conveyor belt and thus travels in the x direction of the tracked OCS. In the example, the velocity of axis A1 and thus the path velocity in the x direction of the tracked OCS is limited by the dynamic adaptation. The dynamic reserve for OCS1 ("<TO>.Conveyor.DynamicReserve[1]") is parameterized with 30% (default setting).

The conveyor travels at a constant velocity of 20.0 mm/s. The OCS1 is tracked with the already recorded product with an "MC_TrackConveyorBelt" instruction.

Before the kinematics synchronizes to the first OCS, 3 linear motion jobs are transmitted.

- B1: Synchronization of the kinematics in x direction of the tracked OCS
- B2: Motion in z direction within the tracked OCS
- B3: Motion in the x direction within the tracked OCS to the next product.

The motions are not blended. A path velocity of 200 mm/s is specified on all 3 jobs.

The 3 motion jobs are processed together in the job sequence.

The dynamic limits of the kinematics axes A1, A2 and A3 are parameterized as follows:

- <A1...A3>.DynamicLimits.Velocity := 100.0
- <A1...A3>.DynamicsLimits.MaxVelocity := 100.0
- <A1...A3>.DynamicLimits.MaxAcceleration := 2000.0
- <A1...A3>.DynamicLimits.MaxDeceleration := 2000.0

The dynamic limits of the "TO_Kin_1" kinematics are parameterized as follows:

- <TO_Kin_1>.DynamicLimits.Path.Velocity := 100.0
- <TO_Kin_1>.DynamicLimits.Path.Acceleration := 1000.0
- <TO_Kin_1>.DynamicLimits.Path.Deceleration := 1000.0

Conveyor tracking with dynamic adaptation without segmentation of the path

A Scenario A

1. Due to the activated dynamic adaptation, the velocity limit of 100 mm/s and the dynamic reserve of 30 % are effective. The axis velocity of the A1 axis is limited to a maximum of 70 mm/s. The axis velocity is made up of the path velocity and the conveyor velocity (20 mm/s). Thus, the resulting path velocity of the motion job during motion preparation is 50 mm/s.
2. After the kinematics have been synchronized, the kinematics move downward at 100 mm/s in z direction. During motion preparation, the velocity is limited to 100 mm/s. The dynamic reserve is not effective because the kinematics motion is not executed in the x direction of the tracked OCS.
3. As the motion takes place while motion is coupled in the OCS, the path velocity within the tracked OCS is limited to 50 mm/s. The resulting axis velocity is 70 mm/s, as the conveyor velocity of 20 mm/s is superimposed on the path velocity. The dynamic reserve of 30 mm/s to the dynamic limit of 100 mm/s is therefore available.

B Scenario B

① The conveyor velocity increases to 40 mm/s during synchronization. The axis velocity of axis A1 during synchronization is thus higher, but remains within the dynamic limits.

② After the kinematics have been synchronized, the kinematics move downward at 100 mm/s in z direction. During motion preparation, the velocity is limited to 100 mm/s. The dynamic reserve is not effective because the kinematics motion is not executed in the x direction of the tracked OCS.

③ As in scenario A, a resulting axis velocity of 70 mm/s was calculated in the motion preparation. As the conveyor velocity increases by 20 mm/s after motion preparation, the axis velocity of axis A1 increases to approx. 90 mm/s.

Conveyor tracking without dynamic adaptation

A **Scenario A**

① The dynamic adaptation is not used and the axis velocity of axis A1 is not reduced to the velocity limit of 100 mm/s during synchronization.

② After the kinematics have been synchronized, the kinematics move downward at 100 mm/s in z direction. During motion preparation, the axis velocity is limited to 100 mm/s. As the kinematics motion only runs in the z direction of the tracked OCS, the kinematics travels with a path velocity of 100 mm/s within the tracked OCS.

③ Without dynamic adaptation, the axis velocity is not limited within the tracked OCS.

B Scenario B

① The conveyor velocity increases to 40 mm/s after motion preparation. The axis velocity exceeds the dynamic limits even more in this scenario when synchronizing.

② After the kinematics have been synchronized, the kinematics move downward at 100 mm/s in z direction. During motion preparation, the axis velocity is limited to 100 mm/s. As the kinematics motion only runs in the z direction of the tracked OCS, the kinematics travels with a path velocity of 100 mm/s within the tracked OCS.

③ The axis velocity exceeds the velocity limit higher than in scenario A, because the conveyor velocity has increased after motion preparation.

8.9.6 Stopping behavior with "MC_GroupStop" and "MC_GroupInterrupt"

"TrackingState" = "2" and "4"

An "MC_GroupStop" or "MC_GroupInterrupt" instruction completes the tracking of the OCS with "TrackingState" = "2" and "4". Alarm 811 is triggered and all kinematics motions are stopped.

"TrackingState" = "3"

The path motion within the coupled OCS is stopped with an "MC_GroupInterrupt" job or "MC_GroupStop" job. The status of the conveyor tracking "<TO>.StatusConveyor[1..3].TrackingState" = "3" is retained. The kinematics continues to follow the OCS.

An "MC_GroupContinue" job can be used to continue a motion that was interrupted with an "MC_GroupInterrupt" job.

The job sequence is emptied after an executed "MC_GroupStop" job. A new path motion is restarted with a new job in the tracked OCS.

To end all kinematics motions, follow these steps:

1. To stop the path motion within the tracked OCS, transmit an "MC_GroupStop" job.
2. If required, move the kinematics upward, e.g. with an "MC_MoveLinearRelative" job within the tracked OCS, to prevent mechanical collisions.
   If possible, you can alternatively stop the conveyor with a "MC_Halt" job.
3. To stop moving the TCP on the conveyor belt, move the kinematics, e.g. with an "MC_MoveLinearAbsolute" job to a position in WCS or in non-tracked OCS, e.g. to a waiting position.

8.9.7 Blending behavior

During conveyor tracking, blending between the following motions is possible:

"Tracking-State"	Description
1 → 2	In a motion job for moving into the first position in the tracked OCS
3 → 3	In a motion job for moving into the first position in the tracked OCS
4 → 0	From a motion job that desynchronizes the TCP from the tracked OCS, in the following motion job (see section "Motion between two tracked OCS")
As of technology version V8.0 in addition	
2 → 3	From a motion job that synchronizes the TCP with the tracked OCS to the subsequent motion job in the tracked OCS
3 → 4	In a motion job that desynchronizes the TCP from the tracked OCS

See also

Motion between two tracked OCS (Page 298)

8.10 Set kinematics to simulation mode

When disabling the kinematics axes or in case of single-axis motions, a kinematics motion is canceled, and the job sequence is cleared. By setting the kinematics to simulation mode, you will keep the motion processing at the kinematics technology object active. The jobs in the job sequence are retained.

With the "MC_KinematicsMotionSimulation" (Page 433) Motion Control instruction, you start or end the simulation mode for a kinematics technology object. In simulation mode, the setpoints of the kinematics are still being calculated. Setpoint changes through motion jobs at the kinematics technology object are no longer taken into consideration at the kinematics axes and are no longer being forwarded to the drives.

8.10.1 Starting simulation mode

With the "MC_KinematicsMotionSimulation (Page 433)" Motion Control instruction with "Execute" = TRUE and "Mode" = 1, you start simulation mode for a kinematics technology object. When the simulation is started, the position setpoints of the kinematics axes are kept constant. The velocity setpoint and the setpoint acceleration of the kinematics axes are immediately set to zero.

NOTE

Setpoint jump

When you activate the simulation during a kinematics motion, the kinematics axes will decelerate immediately with a jump of the velocity setpoint.

To stop the kinematics axes in a controlled manner, interrupt the kinematics motion with a "MC_GroupInterrupt" job before you activate the simulation. Once you have ended the simulation, you can continue the kinematics motion with a "MC_GroupContinue" job.

While the kinematics technology object is in simulation, you can move, disable and enable the kinematics axes again using single-axis jobs, without the motion processing being

canceled at the kinematics technology object. The same is true for technology alarms pending at the kinematics axes during the kinematics simulation.

Interrupting a kinematics motion and locking kinematics axes

1. Interrupt the kinematics motion with a "MC_GroupInterrupt" job.

   The kinematics axes are stopped.
2. Set the kinematics to simulation with a "MC_KinematicsMotionSimulation" job with "Execute" = TRUE and "Mode" = 1.
3. If necessary, move the individual kinematics axes using single-axis jobs.
4. Disable the individual kinematics axes with a "MC_Power" job.

   The jobs in the job sequence are retained.

8.10.2 Ending simulation mode

With the "MC_KinematicsMotionSimulation (Page 433)" Motion Control instruction with "Execute" = TRUE and "Mode" = 0, you end simulation mode for a kinematics technology object.

When simulation is exited with the "MC_KinematicsMotionSimulation" Motion Control instruction, the kinematics motion is continued. The setpoints take effect directly on the kinematics axes.

Releasing kinematics axes and resuming kinematics motion

1. Enable the individual kinematics axes again with a "MC_Power" job.
2. Move the individual kinematics axes using single-axis jobs to positions "<TO>.AxesData.A[1..6].Position". These position values match the position values after stopping the kinematics motion. With a modulo axis, additionally ensure that the axis is in the same modulo cycle as at the start time of the simulation.
3. Exit the kinematics simulation with a "MC_KinematicsMotionSimulation" job with "Execute" = TRUE and "Mode" = 0.
4. Continue the kinematics motion with a "MC_GroupContinue" job.

8.10.3 Tags: Kinematics to simulation

The following tags of the technology object are relevant for simulation:

Status indicators		
Tag	**Description**	
<TO>.StatusWord.X19 (InSimulation)	Kinematics simulation	
	FALSE	Not simulated
	TRUE	Simulated

Status indicators	
Tag	**Description**
<TO>.AxesData.A[1..6].Position	Position setpoints of the kinematics motion for the kinematics axes 1 to 6
<TO>.AxesData.A[1..6].Velocity	Velocity setpoints of the kinematics motion for the kinematics axes 1 to 6
<TO>.AxesData.A[1..6].Acceleration	Acceleration setpoints of the kinematics motion for the kinematics axes 1 to 6

8.11 Setting a tool to active

If you use kinematics with multiple tools, you can set the tool that is configured and mounted on the real kinematics to active in the following way:

- You select the active tool in the kinematics control panel during commissioning (Page 322).
- With the "MC_SetTool" Motion Control instruction, you set a tool to active in the user program.

Tool 1 is active by default.

NOTE

Zone monitoring

Before changing the tool, make sure that the dimensioning of the activated tool zone (Page 212) is suitable for the new tool and the tool is enveloped by the zone.

Otherwise, create a suitable zone for the tool and activate it. In addition, deactivate the tool zone of the unused tool.

Setting a tool to active with a Motion Control instruction

Specify the tool number in the "ToolNumber" parameter in an "MC_SetTool" Motion Control instruction.

The "<TO>.StatusTool.ActiveTool" tag of the technology object data block contains the tool number of the currently active tool.

Define tool frames (Page 206)

3D visualization

9

The 3D visualization supports you visually in the configuration, commissioning and diagnostics of the kinematics technology object with the following components:

- 3D display (Page 310)
- Diagnostics window (Page 339)
- Toolbar (Page 311)
- Directional pad (Page 314)
- Kinematics control panel (Page 317)

Online view

In the online view, the kinematics, zones and coordinate systems are updated based on the online values. The refresh rate depends on multiple factors, for example, on the performance of the programming device and the CPU, the communication times, etc. The 3D visualization, therefore, does not show the behavior of the real machine. Note the behavior of the real machine when using calibration, diagnostics and the kinematics trace.

9.1 Structure of the 3D visualization

The 3D visualization has a function-oriented structure. Different functions are available in the 3D visualization depending on the configuration window.

The following table gives you an overview of the configuration windows with a 3D visualization and the available functions:

Configuration window	Structure				
	3D display	Toolbar	Visualization of the positions	Directional pad	Kinematics control panel with "Control panel status" diagnostics window.
Zones configuration window	✓	✓	–	–	–
Diagnostics	✓	✓	✓	–	–
Kinematics trace	✓	✓	✓	–	–
Calibration	✓	✓	✓	✓	✓
Commissioning	✓	✓	✓	✓	✓

3D display

The following values and information are visualized in the 3D display:

Configuration window	Graphically displayed values and information
Zones	• Zones • Position KCS in WCS
Diagnostics	• Kinematics and tool center point (TCP) • Zones
Kinematics trace	• Kinematics and tool center point (TCP) • Traces – Tool center point (TCP) – Kinematics – OCS frames
Calibration	• Kinematics and tool center point (TCP) • Zones – Calibrated workspace zones – Configured kinematics zones • Calibrated object coordinate systems • Values for the calibration – Configured points and angles – Guide lines – Offset of the OCS from the origin – Current position of the TCP – Graphically highlighted active calibration point
Commissioning	• Kinematics and tool center point (TCP) • Zones

NOTE

You set the dimensions for the representation of the kinematics in the 3D display under "Technology object > Configuration > Geometry".

9.2 Working with the 3D display

A description is provided below of how to adapt the view of the coordinate system with mapped kinematics in the 3D view using the toolbar or the mouse.

Customizing the appearance of the 3D display

You can adapt the display in the 3D view as follows:

1. To hide or show the coordinate system in the display, click the # symbol in the toolbar.
2. To adjust the brightness of the 3D display, select a preset brightness level via the 100 selection box.

   Alternatively, change the brightness using the (darker) button or the (brighter) button.

Customizing the display of the kinematics and the coordinate system

1. In the WCS selection box, select a coordinate system that is displayed in the 3D display.

   In addition, the selected coordinate system is displayed in the "Positions" window. If you select the kinematics coordinate system (KCS), the WCS is displayed in the "Positions" window.

   See also Monitoring and comparing position values (Page 315).

   You can select the FCS or TCS in the configuration of the kinematics zones.

2. To change the display of the kinematics, click the button. If you click on the arrow, the other display options of the kinematics are shown and you can directly select the desired display:

Button	Description
	Shows the kinematics.
	Shows a simplified view of the kinematics.
	Hides the view of the kinematics.

3. To change the tool, select an already configured tool in the Tool 1 selection box.

   This selection box is available in the configuration of the kinematics zones and in the calibration.

4. To display the TCS, click the button. With more clicks on the button, or if you click the arrow, the following buttons are displayed and you can display or hide the TCS or the TCP:

Button	Description
	Shows the TCS
	Shows the TCP
	Hides the TCS selected via the button or the TCP selected via the button.

   During calibration, the TCS is already shown in the online view and you can change the display using the button.

5. To switch the focus of the view to the TCS or TCP, click the button.

   During the path motion of the kinematics, the focus is always on the TCS or the TCP. In standstill, the view can be moved or rotated using the mouse.

Change screen section

1. To switch the view between 2D or 3D display, use the following buttons:
   – To use the 2D display, click the button.
   – To use the 3D display, click the button.
2. To change the plane view of the selected coordinate system, use the following buttons:

Button/mouse	Description
	Show xz plane
	Show the xz plane rotated around the z axis
	Show yz plane
	Show the yz plane rotated around the z axis
	Show xy plane
	Show the xy plane rotated around the x axis

3. To rotate the view as desired, hold down the left mouse button and move the mouse in the desired direction.
4. To center the view and display the entire kinematics, click the icon in the toolbar.
5. Use the mouse wheel to zoom in and out of the display of the kinematics continuously.
6. To move the kinematics in the view, hold down the right mouse button and move the mouse in the desired direction.

9.3 Operating the zone display

You show or hide all active and inactive zones with the button.

In addition, with the active icon , you can show and hide all active and inactive workspace zones individually with the icon in the following areas:

- Diagnostics > "Status zones" window
- Calibration > Object coordinate systems / Workspace zones > "Zone display" window

Zone display in calibration

When you click on the icon, values of the workspace zones and the kinematics zones at the current point in time are read back from the CPU. When you click the icon in the "Number" column, 2 additional rows are displayed. The additional rows contain the following values:

- Start values of the CPU
- Start values in project

  You can edit these values. If you want to apply the change, load the changes from the project into the device.

If you have performed an offline recalibration of a workspace zone calibrated online, both zones are displayed in the graphic view. Load the changes from the project to the device. The display is updated and the result of the last calibration is displayed.

9.4 Operating the directional pad

The directional pad offers the following functions:

- In offline mode: Move the tool center point (TCP) in the 3D view
- In online mode: Specify target position in "Jog to target position" mode in the WCS or OCS

Moving the tool center point (TCP)

During calibration, you can move the tool center point (TCP) in the 3D view in offline mode using the directional pad.

NOTE

Singularity

When you move the kinematics into a singularity (Page 183), a message is output in the graphic display and you can no longer move the kinematics using the directional pad. To be able to move the kinematics once again, click on "Reset kinematics" in the message.

---

1. To move the TCP to a position, click on the positive or negative x, y or z direction on the directional pad.

In the 3D view, you can see the motion of the kinematics model and the TCP.

The coordinates of the TCP are displayed in the Positions window.

2. To change the orientation of the TCP, click "ROT" or the intersection of the axes.

Instead of the directional pad, arrows for the orientation motion are displayed.

3. Click the arrow to rotate in a positive or negative direction.

The Cartesian coordinates and the Cartesian orientations in space are displayed in the "Positions" window.

If you have shown a kinematics zone, you will see the rotation of the kinematics zone in the 3D view.

4. To move the TCP again, click "LIN".

   The directional pad is displayed.

Specify target position

In online mode, you can use the directional pad to specify the target position in the WCS or OCS in "Jog to target position" mode. This function is available during commissioning and calibration.

The target position in the selected coordinate system is applied and you can jog the kinematics to the target position with the kinematics control panel.

The operation of the kinematics control panel in "Jog to target position" mode is described in the section "Jogging the kinematics (Page 333)".

9.5 Monitoring and comparing position values

You monitor and compare position information with the following 3D visualization functions:

- "Positions" diagnostics window
- Position values in the graphically displayed trace

Operating the "Positions" diagnostics window

The "Positions" window provides the following functions:

- Monitor position values, e.g. during diagnostics
- Check approached points of the kinematics during calibration with the current position
- Compare position values in two different coordinate systems, e.g. during calibration

The values in the "Positions" window are displayed as follows:

- During commissioning, in the diagnostics and in the kinematics trace, the positions are displayed in online mode.
- The positions in offline and online mode are displayed in the calibration.

Selecting a reference coordinate system for recording in the kinematics trace

The selection of the coordinate systems in the toolbar and in the "Positions" window depends on the signals you have activated under "Technology object > Kinematics trace > Configuration > Traces". The following table shows the available coordinate systems depending on the active signals:

Active signals	Coordinate system 1	Coordinate system 2
TCP and kinematics	World coordinate system (WCS), kinematics coordinate system (KCS)	Machine coordinate system (MCS), WCS, JCS
TCP	WCS, KCS,	WCS

Active signals	Coordinate system 1	Coordinate system 2
TCP, OCS1	WCS, KCS, OCS1	WCS
TCP, OCS1, OCS2	WCS, KCS, OCS1, OCS2	WCS
TCP, OCS1, OCS2, OCS3	WCS, KCS, OCS1, OCS2, OCS3	WCS

If you activate another signal or the "Monitoring on/off" function, the available coordinate systems are updated.

Comparing position values

1. Select a coordinate system in the toolbar. The selected coordinate system is displayed in the left field of the "Positions" window.

   When you select the kinematics coordinate system (KCS) in the toolbar, the WCS is displayed in the "Positions" window.
2. Select another coordinate system in the "Positions" window in the right drop-down list.
3. The actual position of the active tool in the selected reference coordinate system is displayed.

The meaning of the position information is described in the table in the section "Positions (Page 345)".

Position values in the graphic display

If you position the mouse cursor on one of the traces in the 3D visualization in the kinematics trace, the position values are displayed directly on the trace.

The following values are displayed:

- Measuring point number
- Coordinates x, y, z and A, B, C

The values displayed show the position and rotation in the set coordinate system.

Commissioning 10

You can find the kinematics control panel under "Technology object > Commissioning". The kinematics control panel enables you to assume master control for a kinematics technology object and control the motions of the kinematics, the individual axes or the individual joints. You can therefore move the kinematics without affecting the user program.

You can find the dynamics settings (Page 331) for commissioning in the Inspector window under "Properties".

3D visualization (Page 310) provides visual support for commissioning the kinematics technology object. The status LEDs in the "Control panel status (Page 317)" diagnostics window show you whether all kinematics axes are switched on and homed and whether errors are pending at the kinematics or the kinematics axes. You can also show additional diagnostics windows (Page 339) via the toolbar.

You can also find the kinematics control panel in the project tree under "Technology object > Calibrate (Page 355)". In calibration, you move the real kinematics online via the kinematics control panel in the "Jog" or "Jog to target position" operating modes.

10.1 Control panel status

You use the "Control panel status" diagnostics window in "Technology object > Commissioning" in the TIA Portal to monitor the status and error messages of the kinematics and the kinematics axes during commissioning.

The diagnostics function is available in online operation. The "Control panel status" diagnostics window is shown in the graphical display during commissioning. You can show the diagnostics window via the symbol of the toolbar and move the window to a desired position within the graphic display.

Kinematics status

The following table shows the possible statuses of the kinematics:

Status	Description
Valid	The transformation values are valid. (<TO>.StatusKinematics.Valid)
Error	An error occurred at the technology object. Error messages are displayed in the Inspector window under "Diagnostics > Alarm display".

Axis status

The following table shows the possible states of the kinematics axes:

Status	Description
Enabled	The technology object has been enabled. The axis can be moved with motion jobs.
Error	An error occurred at the technology object. Error messages are displayed in the Inspector window under "Diagnostics > Alarm display".
Homed	The technology object is homed.

10.2 Taking over master control and enabling kinematics

WARNING

Unexpected axis motions

During operation with the kinematics control panel, the kinematics can execute unexpected motions (for example, due to incorrect configuration of the drive or technology object). In addition, when a leading axis is moved with the kinematics control panel, any synchronized following axis is also moved.

Therefore, take the following protective measures before operation with the kinematics control panel:

- Ensure that the EMERGENCY OFF switch is within the reach of the operator.
- Enable the hardware limit switches.
- Enable the software limit switches.
- Use blocked zones to prevent mechanical collisions.
- Ensure that following error monitoring is enabled.
- Make sure that no following axis is coupled to the axis to be moved.
- Make sure that the dynamic settings in the kinematics control panel do not violate the dynamic limits of the kinematics axes or process.
- Ensure that the kinematics control panel is configured correctly.

WARNING

Overrun of the dynamics through singularities

Overruns of the dynamics in the vicinity of singularities can result in the following damages:

- Machine damage through overload of the mechanical components
- Personal injury caused by products or machine parts coming loose

To prevent dynamic overruns in the vicinity of singularities, take the following measures:

- Move the kinematics in the MCS or the JCS.
- In the WCS or OCS, avoid the "Jog" mode. The dynamic adaptation in "Jog" mode in the WCS or OCS is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.
- Up to technology version V5: In the WCS or OCS, avoid using the "Jog to target position" mode. The dynamic adaptation in "Jog to target position" mode in the WCS or OCS is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.
- As of technology version V6: Move the kinematics to the "Jog to target position" mode in the WCS or OCS using the kinematics control panel. "Dynamic adaptation without segmentation of the path" is permanently active in the "Jog to target position" mode, and the dynamic limits of the kinematics axes are taken into account.

WARNING

Moving leading axes with active synchronous operation

Any synchronized following axis is moved as well when a leading axis is moved with the kinematics control panel.

Requirements

- The kinematics and the kinematics axes are locked in the user program.
- No axis control panel or drive control panel is active for any kinematics axis.
- The kinematics technology object is configured.
- The travel directions of the kinematics axes match the joint travel directions of the kinematics used.

  Use the axis control panel to check whether the travel directions of the kinematics axes match the joint travel directions of the kinematics used. The joint travel direction can be found in the Manufacturer descriptions. Invert the drive and encoder directions in the kinematics axis if the directions are inverse.
- The joint travel directions of the kinematics used correspond to the travel directions defined by Siemens from the kinematics type.

  Check whether the joint travel directions of the kinematics used match the travel directions defined by Siemens from the Kinematics type (Page 58). If the directions are inverse, then invert the joint direction at the associated joint in the Kinematics technology object.

- The kinematics axes are homed.

  The joint zero position corresponds to the position 0.0 of the kinematics axis. For mechanical axis couplings, first home the coupling axes.
- Possible joint offsets are defined.

  Check whether the joint zero position of the kinematics deviates from the joint zero position of the kinematics type defined by Siemens. In this case, you must define a joint offset. If the offset cannot be determined from data sheets, then you can determine it practically. To do this, jog the joint in the zero position defined by Siemens and then accept the position of the joint as offset.
- All kinematics axes are ready to start.
- The CPU must be in the RUN mode.
- No alarm is active on the kinematics technology object.

Procedure

1. Click the "Activate" button.
2. Read the warning.
3. Set the sign-of-life monitoring time to a value between 1000 and 60 000 ms.

Setting the sign-of-life monitoring time

The kinematics control panel requires a direct connection from its TIA Portal to the controller, which is monitored cyclically. If there is no sign-of-life from the PG/PC within the monitoring time, master control is handed over for safety reasons.

Monitoring time	Effect
Too low	Master control is often handed over because the monitoring time is exceeded. The kinematics stops with maximum deceleration because the communication time between TIA Portal and CPU is longer than the configured monitoring time.
Appropriate	The monitoring time is not exceeded. The kinematics is stopped in time if the online connection is lost or the sign-of-life monitoring is exceeded. Recommendation: 1000 ms to 2000 ms
Too high	The kinematics continues to move with the last setpoints of the kinematics control panel, although the connection between the TIA Portal and the CPU has been interrupted or the communication time between the TIA Portal and the CPU is too long. The kinematics is not stopped on time because the monitoring time is still running.

Result

- An online connection to the CPU is established and the kinematics control panel takes master control of the technology object.
- The kinematics can now only be moved with this kinematics control panel. The user program has no influence on the functions of the technology object. Motion Control jobs from the user program to the technology object are rejected with error ("ErrorID" = 16#8012: Kinematics control panel enabled).
- Access to the kinematics and the kinematics axes is blocked by another instance of the TIA Portal.

Enabling the kinematics

1. Click the "Enable" button to enable interconnected axes of the selected kinematics technology object.
   Result: The kinematics or the kinematics axes can now be moved or actively homed with the kinematics control panel.
2. Use the status LEDs in the "Control panel status" diagnostics window to check whether all kinematics axes are switched on and homed and whether errors are pending. Use the alarm display (Inspector window > "Diagnostics > Alarm display") in the TIA Portal to display pending causes of the error.

Behavior during operation of the kinematics control panel

In the following situation, the kinematics control panel retains master control and the kinematics remain in motion:

- The kinematics control panel is embedded in the TIA Portal, and you switch to another window, for example, to the kinematics trace. Use the "Split editor area" option to use the kinematics control panel and the kinematics trace at the same time.

In the following situation, the kinematics control panel retains master control but stops the kinematics with maximum deceleration and revokes the enabling of the technology objects:

- The kinematics control panel is detached in the TIA Portal, and you switch to another window within the TIA Portal, for example, to the kinematics trace.
- You switch to a window outside the TIA Portal.

In the following situations, the kinematics is stopped or the axes are stopped with maximum deceleration and the kinematics control panel returns the master control to the user program:

- The communication time between TIA Portal and CPU is longer than the configured monitoring time. In the banner above the toolbar, the message is displayed that the master control has been handed over because the monitoring time has been exceeded. Adapt the time for the sign-of-life monitoring in the warning.
- The online connection to the CPU is impaired by a communication load that is too high. The following message is entered in the alarm display log: "Commissioning error. Sign-of-life failure between controller and TIA Portal". Adapt the time for the sign-of-life monitoring in the warning.
- A dialog (e.g. "Save as") or another window within the TIA Portal covers the kinematics control panel.

10.3 Selecting an active tool

If you use kinematics with multiple tools, you can select the different tools in the kinematics control panel. This allows you to define the position of the TCP in the flange coordinate system (FCS) in relation to this tool. In the real kinematics, the tool is not changed by the changed selection.

Requirement

Kinematics is enabled in the kinematics control panel.

Procedure

1. In the "Active tool" drop-down list, select the tool that is mounted on the real kinematics.
2. If you want to use zone monitoring (Page 208), activate the tool zone associated with the active tool. If necessary, deactivate the tool zone that is not required (e.g. after a tool change). See section "Activating zone monitoring" (Page 219).

NOTE

Before you return master control to the user program, the tool that the user program expects must be installed and set. The active tool is not set automatically to the active tool at the time of takeover of master control.

In the user program, you can change the tool with the "MC_SetTool" Motion Control instruction after handing over master control.

10.4 Operator controls for jogging and homing

You can use the slider to execute the following functions of the kinematics control panel:

- Jog axes, joints, or the kinematics Cartesian in a direction or to the set target position. (Page 333)
- Start active homing of a kinematics axis (Page 330)

Different sliders and buttons are displayed in the "Control" area in the kinematics control panel depending on the selected coordinate system, the kinematics type and the operating mode.

NOTICE
Deviating jog velocity due to velocity override with technology versions <V10.0 If the velocity override is changed by the user program while the kinematics control panel is active, undesired deviations in the jog velocity can occur. With active master control, both settings on velocity override take effect in jog mode of the kinematics. The value set under "Adapt" with the "Velocity" slider as well as the value configured in the "<TO>.Override.Velocity" tag have a multiplicative effect on the final velocity in jog mode. For example, the following settings result in a final velocity of 25 mm/s: • Jog velocity = 100 mm/s • "<TO>.Override.Velocity" is set cyclically to 50% in OB1. • The "Velocity" slider is set to 50%. The resulting final velocity is calculated as follows: 100 mm/s × 0.5 × 0.5 = 25 mm/s. To avoid undesired deviations in the resulting final velocity, make sure that both parameters are set correctly and the velocity override with active master control is not changed by the user program. With a query of the kinematics control panel status (<TO>.StatusWord.X4 (ControlPanelActive)) when the "<TO>.Override.Velocity" tag is written, you can prevent writing of the tag with an active kinematics control panel.

Jogging and homing velocity

The preset jogging and homing velocity is calculated as follows:

Jogging/homing velocity = configured velocity * slider position * "Velocity" factor under "Adjust"

The following shows the operation of the slider using kinematics axis A1. Operation is identical for jogging of joints and the kinematics in the Cartesian space.

Jogging with the keyboard

WARNING

Using keyboard control

When keyboard control is activated, keyboard entries cause immediate kinematics motions.

Deactivate the keyboard control immediately after the last operation to avoid unintended kinematic motions.

You can operate the slider for jogging the axes, joints or kinematics with the mouse or with the keyboard.

You use keys of the number pad for keyboard control.

Follow these steps to control the slider with the keyboard:

1. Activate keyboard control with the "Activate" button.

   The buttons that can be controlled via the keyboard show the respective key for the controller.
2. To choose an axis or joint with the numbers 1 to 6, enable the number pad on your keyboard using the Num-Lock key.
3. To use the number pad for the cursor control, disable the number pad on your keyboard using the Num-Lock key.
4. You can now control the slider using the four direction keys, the two scroll keys and the "Home" and "End" keys of the number pad.
5. To end keyboard control, click "Deactivate".

NOTE

Ending keyboard control with other operator actions

Other operator actions, e.g. clicking with the mouse in the "Control" area, deactivate keyboard control.

Selecting the axes for jogging/jogging to target position in the MCS

To jog the axes in the MCS, first select the respective axis.

For example, the selection of interconnected axes with the Cartesian portal 3D with orientation kinematics type looks like this:

① All interconnected kinematics axes

② Selected axis

When keyboard control is enabled, the number keys are shown with which you can select the axes.

Selecting the joints for jogging/jogging to target position in the JCS

To jog the joints in the MCS, first select the respective joint.

① All joints of the kinematics type

② Selected joint

When keyboard control is enabled, the number keys are shown with which you can select the joints.

Jogging/jogging to target position in the MCS/JCS

Jogging

① Jog backward

② Jog forward

Select one of the following operating options to jog an axis/joint:

- Slider

  ①: Click the slider and drag the slider to the left.

  ②: Click the slider and drag the slider to the right.

  The further you drag the slider away from the central position, the faster the axis/joint moves in the respective direction.

- Button

  ①: To jog backward at the maximum preset jogging velocity, click the ◀◀ symbol.

  ②: To jog forward at the maximum preset jogging velocity, click the ▶▶ symbol.

- Keyboard control

  ①: When keyboard control is enabled, you jog backward with the direction keys ←.

  ②: When keyboard control is enabled, you jog forward with the direction key →.

  As soon as you press the number key, the axis/joint moves backward/forward at the maximum preset velocity.

Jogging to target position

Select one of the following operating options to jog an axis/joint to target position:

- Slider

  Click the slider and drag the slider to the right. The further you move the slider to the right, the faster the axis/joint moves at the maximum preset velocity.

- Button

  To jog to the target position at the maximum preset jog velocity, click the icon ▶▶.

- Keyboard control

  When keyboard control is enabled, you jog with the direction key → to the target position. As soon as you press the number key, the axis/joint moves to the target position at the maximum preset velocity.

Stop jogging

If you release the pressed mouse button/key when jogging using the slider/keyboard control, the slider automatically jumps to zero and the axis/joint is stopped with the specified deceleration.

Jogging in the WCS/OCS

To jog the kinematics in the WCS/OCS, you can choose between the following modes for kinematics types with orientation:

- Cartesian

  In "Cartesian" mode, you jog the kinematics in the x, y and z direction.

- Orientation

  In "Orientation" mode, you can rotate the TCS and move the TCP.

You activate the respective mode using the button of the same name.

You can only jog kinematics types without orientation in Cartesian mode.

Jogging in "Cartesian" mode

① Jogging kinematics in positive/negative x direction
② Jogging kinematics in positive/negative y direction
③ Jogging kinematics in positive/negative z direction

Select one of the following operating options to jog the kinematics:

- Slider

  Click the slider and drag the slider to the left/right/up/down. The further you drag the slider away from the central position, the faster the kinematics moves in the respective direction.

- Button

  To jog at the maximum preset jogging velocity, click the respective icon / / / .

- Keyboard control

  When keyboard control is enabled, you jog with the four direction keys and the two scroll keys. As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

Jogging 2D and 3D kinematics types with orientation in "Orientation" mode

To change the position of the TCS, rotate the TCS around the z axis or move the TCP along the z axis.

① Rotate TCS around the z axis

② Move TCP along the z axis

To rotate the TCS around the z axis, select one of the following operating options for the slider ①:

- Slider

  Click the slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCS is rotated.

- Button

  To jog at the maximum preset velocity, click the icon / .

- Keyboard control
  - To rotate in the negative direction, tap the "Up" scroll key.
  - To rotate in the positive direction, tap the "Down" scroll key.

  As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

Use one of the following operating options to move the TCP along the z axis:

- Slider

  Click the slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCP is moved.

- Button

  To jog in the negative direction at the maximum preset velocity, click the icon ◀◀ / ▶▶.

- Keyboard control

  – To jog in the negative direction, tap the "End" scroll key.

  – To jog in the positive direction, tap the "Home" scroll key.

  As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

Jog kinematic types with more than four interpolating kinematics axes in "Orientation" mode

① Turn TCS in the west/east direction

② Turn TCS in the north/south direction

③ Rotate TCS around the x axis (only for kinematics types "6-axis articulated arm with central wrist" and "6-axis articulated arm with offset wrist")

④ Move TCP along the x axis

In the graphical display, a sphere is represented on which you can jog the orientation in four directions. The center of the sphere is the TCP. The x axis of the TCS is shown extended and intersects the surface of the sphere. With the sliders in the controller, you move this intersection point along the sphere surface in the four directions. You thus change the orientation of the TCS. The position of the TCP remains the same.

To change the orientation of the TCS, use one of the following operating options of the sliders ① and ②:

- Slider

  Click the slider and drag the slider to the left/right/up/down. The further you drag the slider away from the central position, the faster the TCS is rotated.

- Button

  To jog at the maximum preset jogging velocity, click the respective icon ◀◀ / ▶▶ / ▲ / ▼.

- Keyboard control

  When keyboard control is enabled, you jog with the four direction keys. As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

With the "6-axis articulated arm with central wrist" and "6-axis articulated arm with offset wrist" kinematics type, you can rotate the TCS around the x axis with the slider ③.

To rotate the TCS around the x axis, select one of the following operating options for the slider:

- Slider

  Click the slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCS is rotated.

- Button

  To jog at the maximum preset velocity, click the icon ◀◀ / ▶▶.

- Keyboard control
  - To rotate in the negative direction, tap the ↑ scroll key.
  - To rotate in the positive direction, tap the ↓ scroll key.

  As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

You move the TCP along the x axis using the slider ④.

Use one of the following operating options to move the TCP along the x axis:

- Slider

  Click the slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCP is moved.

- Button

  To jog in the negative direction at the maximum preset velocity, click the icon ◀◀ / ▶▶.

- Keyboard control
  - To jog in the negative direction, tap the "End" key.
  - To jog in the positive direction, tap the "Home" key.

  As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.

Stop jogging

Release the pressed mouse button. The slider automatically jumps to zero and the axis/joint/kinematics is stopped with the specified deceleration.

Set home position

To set the reference position for a kinematics axis, click the "Set" button.

Active homing

Click the slider and drag the slider to the right. Homing is executed at the maximum preset velocity. The homing stops automatically with the set dynamics.

To home at the maximum preset velocity, click the ▶▶ symbol.

See also

Specifying dynamics in the kinematics control panel (Page 331)

10.5 Setting the home position of a kinematics axis

This function corresponds to direct homing (absolute) or setting the actual position or "Mode" = 0 at the "MC_Home" Motion Control instruction. The current position of the technology object is set to the value of parameter "Position".

Requirements

Kinematics is enabled in the kinematics control panel.

Procedure

1. In the drop-down list, select "Single axes: Set home position".
2. Enter the home position of the respective kinematics axis in the text box.
3. Click the "Set" button of the axis with the actual position you want to set.

   Result: The specified actual position is set. The kinematics axis is homed.
4. In the "Status and errors bits" diagnostics window, check whether the axis was homed.

10.6 Active homing of the kinematics axis

This function corresponds to active homing with "Mode" = 3. The positioning axis/synchronous axis technology object performs a homing movement according to the configuration of the active homing.

⚠ WARNING
Avoiding collisions Make sure that no unwanted positions are approached and that no collisions occur during the automatic homing movement.

Requirements

- Kinematics is enabled in the kinematics control panel.
- The kinematics are in a position from which the homing movement of the kinematics axes is possible.

Procedure

1. In the drop-down list, select "Single axes: Homing".
2. Enter the home position of the respective kinematics axis in the text box.
3. To start active homing, click the slider and drag the slider to the right.
4. To cancel homing, release the pressed mouse button.
   Result: The axis executes the homing movement configured under "Active homing". The other kinematics axes are not moved. The entered position of the kinematics control panel is used as home position.

NOTE

Up to technology version V7: Absolute encoder calibration is not possible in the kinematics control panel. The technology object is not homed when this mode is used with an absolute encoder.

As technology version V7: Absolute encoder adjustment can be performed in the kinematics control panel.

10.7 Specifying dynamics in the kinematics control panel

In the "Jog" and "Jog to target position" modes, you can specify the dynamics for the next step of the commissioning. The dynamics settings can be found in the Inspector window under "Properties".

Default setting of dynamic values

The default settings of the dynamic values are as follows when the kinematics control panel is called:

Dynamic value	Default value MCS/JCS coordinate systems	Default value WCS/OCS coordinate system
Acceleration	10% of the maximum acceleration of the kinematics axis	10% of the maximum acceleration of the kinematics motion
Deceleration	100% of the maximum deceleration of the kinematics axis	100% of the maximum deceleration of the kinematics motion
Jerk	100% of the maximum jerk of the kinematics axis	100% of the maximum jerk of the kinematics motion

Specifying dynamic values

In the WCS or OCS, these values apply to the motion in x, y and z direction and for the orientation.

To change these defaults temporarily, select the "User-defined dynamics" check box and enter the dynamic values.

If you have changed the values in the configuration of the technology object during operation with the kinematics control panel, these changes have no effect on the operation of the kinematics control panel. Changed values in the configuration only take effect after they have been loaded into the CPU and the control panel has been reopened.

Resetting dynamic values to default values

As soon as the check box "User-defined dynamics" is cleared or the commissioning is completed, the original default values are valid again. The specified dynamics values are replaced by the predefined default values in the following cases. If necessary, transfer the values to your configuration.

Transferring dynamic values from the kinematics control panel to the technology object

If you want to retain your specified dynamic values as default values or as dynamic limits after jogging in the WCS or OCS, transfer the dynamic values of the kinematics control panel to the configuration of the technology objects.

1. Make a note of the dynamic values of the kinematics control panel.
2. Click the "Deactivate" button.
3. Apply the noted dynamics values as the default setting of the dynamics or dynamics limit in the "Dynamics" configuration window of the kinematics.
4. Load the changed configuration into the CPU.

   The changed parameters are now effective in the user program.

Adjusting the velocity

To adjust the velocity for traversing with the kinematics control panel, define a velocity override under "Adjust".

Under "Adjust", you correct the configured velocity using a percentage.

Example:

- Configured velocity in the kinematics control panel: 100 mm/s
- Adjust velocity: 50%
- Resulting velocity specification: 50 mm/s

You can set a value with the slider or enter a value between 1% and 200% directly in the text box below. With the two buttons to the left and right of the slider, you can increase or decrease the velocity in 10% increments.

The velocity override set in the kinematics control panel is not adopted in the configuration of the kinematics technology object ("<TO>.Override.Velocity" tag). When you close the kinematics control panel, the changed values under "Adjust" are reset.

NOTICE

Deviating jog velocity due to velocity override with technology versions <V10.0

If the velocity override is changed by the user program while the kinematics control panel is active, undesired deviations in the jog velocity can occur.

With active master control, both settings on velocity override take effect in jog mode of the kinematics. The value set under "Adapt" with the "Velocity" slider as well as the value configured in the "<TO>.Override.Velocity" tag have a multiplicative effect on the final velocity in jog mode.

For example, the following settings result in a final velocity of 25 mm/s:

- Jog velocity = 100 mm/s
- "<TO>.Override.Velocity" is set cyclically to 50% in OB1.
- The "Velocity" slider is set to 50%.

The resulting final velocity is calculated as follows: 100 mm/s × 0.5 × 0.5 = 25 mm/s.

To avoid undesired deviations in the resulting final velocity, make sure that both parameters are set correctly and the velocity override (<TO>.Override.Velocity) with active master control is not changed by the user program. With a query of the kinematics control panel status (<TO>.StatusWord.X4 (ControlPanelActive)) when the "<TO>.Override.Velocity" tag is written, you can prevent writing of the tag with an active kinematics control panel.

NOTE

Adapting the velocity as a percentage in the "Individual axis: Homing" mode

For kinematics as of technology version V8.0, you can adapt the velocity as a percentage in the kinematics control panel, also in "Individual axis: Homing" mode.

For kinematics up to technology version V7.0, the "Adjust" area is in the "Single axis: Homing" mode.

10.8 Jogging the kinematics

In "Jog" mode, the following values are preset with 10% of the default value:

- Velocity of kinematics axes
- Velocity of the joints or joint angle
- Velocity in x, y and z direction
- Velocity for the orientations A, B and C

You can define the velocity override under "Adjust" (Page 331).

Requirement

Kinematics is enabled in the kinematics control panel.

10.8.1 Jogging the kinematics axes in the MCS

In the MCS, you can jog each kinematics axis individually forwards, backwards or to a predefined target position or target angle. With mechanical couplings of the axes, select the "JCS" coordinate system to jog the joints of the kinematics (Page 335).

WARNING

Limits of the joint traversing range are not taken into consideration in the MCS in the technology version < V9.0

When you move the kinematics axes in the kinematics control panel in the MCS, the limits that have been set for the joint traversing ranges (Page 56) are not taken into account for the joints.

In the case of kinematics without mechanically coupled axes, you can limit the joint position to the operating range by using software limit switches. The software limit switches have to be correctly set and existing offsets or the inverted traversing direction of the joints must be taken into consideration.

In the case of kinematics with mechanically coupled axes, you cannot completely limit the joint position to the operating range using the software limit switches. Therefore, you must yourself take into consideration the configured limits for the joint traversing ranges. Make sure that no unwanted positions are approached and that no collisions occur.

Procedure for jogging forwards or backwards

1. Select the "Jog" operating mode in the drop-down list.
2. Select the "MCS" coordinate system in the drop-down list.
3. Select the axis that you want to move using the button "A1 ... A6".
4. Enter the velocity for the axis.
5. Move the axis by dragging the slider forward or backward.
6. To stop the axis, release the pressed mouse button. The slider automatically jumps to the center position and the axis is stopped with the specified dynamics.

Procedure for jogging to a target position

1. Select the "Jog to target position" operating mode in the drop-down list.
2. Select the "MCS" coordinate system in the drop-down list.
3. Select the axis that you want to move using the button "A1 ... A6".
4. Enter the target position for the kinematics axis.
5. Enter the velocity for the axis.
6. To specify the velocity, drag the slider to the right. The further you drag the slider to the right, the higher the velocity of the axis movement.
7. To stop the axis before the target position is reached, release the pressed mouse button. The slider automatically jumps to zero to the left and the axis stops with the set dynamics.
8. The axis stops automatically with the specified dynamics when the target position has been approached.

10.8.2 Jogging joints in the JCS

In the JCS, you can jog each kinematics joint individually forwards, backwards or to a set target position. In contrast to jogging in the MCS where only the axis coordinates are taken into account, the mechanical axis coupling is taken into account when jogging in the JCS.

For kinematics types with up to 4 interpolating axes, the jogging of the joints in the JCS corresponds to the jogging of the axes in the MCS.

NOTE

Jogging joints in the JCS

For coupled axes with coupling factor ≠ 1, the jogging of joints in the JCS can result in an unwanted position change of the coupled axes.

Jog forward or backward

To move a joint forward or backward in jog mode, proceed as follows:

1. In the "Operating mode" drop-down list, select the "Jog" entry.
2. In the "Coordinate system" drop-down list, select the "JCS" entry.
3. Select the joint that you want to move using the button "J1 ... J6".
4. Enter the velocity for the joint.
5. To move a joint in the positive direction, drag the slider to the right.

   The joint moves in the positive direction as long as you keep the slider pressed and to the right of the zero position.
6. To move a joint in the negative direction, drag the slider to the left.

   The joint moves in the negative direction as long as you keep the slider pressed and hold it to the left of the zero position.
7. To stop the joint moving, release the pressed mouse button.

   The slider automatically jumps to the center position and the joint is stopped with the specified dynamics.

Jogging to a target position

To move a joint to a target position in jog mode, proceed as follows:

1. In the "Operating mode" drop-down list, select the "Jog to target position" entry.
2. In the "Coordinate system" drop-down list, select the "JCS" entry.
3. Select the joint that you want to move using the button "J1 ... J6".
4. Enter the velocity for the joint.
5. Enter the target position for the joint.
6. To move the joint to the target position, move the slider to the right. The further you move the slider to the right, the higher the velocity of the joint movement.

   The kinematics stops as soon as you release the pressed mouse button or the target position is reached.

10.8.3 Cartesian kinematics jogging in WCS/OCS

In WCS or OCS, you can move each kinematic in jog mode in x, y and z direction or rotate the tool center point around the x, y and z-axis (rotation A, B, C).

When jogging to a target position, you move the kinematics to the position specified under "Target position" with a linear motion. The direction of movement of the Cartesian orientation is not limited to the positive direction here. For kinematics with up to 4 interpolating axes, the A4 kinematics axis is moved using the "Shortest path" mode.

WARNING

Overrun of the dynamics through singular positions

Overruns of the dynamics in the vicinity of singular positions can result in the following damage:

- Machine damage through overload of the mechanical components
- Personal injury caused by products or machine parts coming loose

To prevent dynamic overruns in the vicinity of singular positions, take the following measures:

- Move the kinematics in the MCS or the JCS.
- In the WCS or OCS, avoid the "Jog" mode. The dynamic adaptation in "Jog" mode in the WCS or OCS is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.
- Up to technology version V5: In the WCS or OCS, avoid using the "Jog to target position" mode. The dynamic adaptation in "Jog to target position" mode in the WCS or OCS is not active in the kinematics control panel. The dynamic limits of the kinematics axes are not taken into account during a kinematics motion with the kinematics control panel.
- As of technology version V6: Move the kinematics to the "Jog to target position" mode in the WCS or OCS using the kinematics control panel. "Dynamic adaptation without segmentation of the path" is permanently active in the "Jog to target position" mode, and the dynamic limits of the kinematics axes are taken into account.

Jog

To jog the kinematics in the WCS/OCS, you can choose between the following modes for kinematics types with orientation:

- Cartesian

  In "Cartesian" mode, you jog the kinematics in the x, y and z direction.
- Orientation

  In "Orientation" mode, you can rotate the TCS and move the TCP.

You activate the respective mode using the button of the same name.

You can only jog kinematics types without orientation in Cartesian mode.

To move the kinematics axes in jog mode, follow these steps:

1. In the "Operating mode" drop-down list, select the "Jog" entry.
2. In the "Coordinate system" drop-down list, select the "WCS" or "OCS" entry.
3. Choose whether you want to jog the kinematics in "Cartesian" or "Orientation" mode.

Jogging kinematics in "Cartesian" mode

1. Enter the velocity for the x, y and z directions.
2. To move a kinematics axis in the positive or negative direction, click the slider and drag the slider in the respective direction.

   The kinematics moves in the respective direction as long as you keep the slider pressed and not in the zero position. As soon as you release the pressed mouse button, the slider automatically jumps to zero and the kinematics is stopped with the specified dynamics. Depending on the kinematics type, several axes can be moved.

Jogging 2D and 3D kinematics types with orientation in "Orientation" mode

1. Enter the velocity for the rotation of the TCS and the offset of the TCP.
2. To rotate the TCS around the z axis, click the "R" slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCS is rotated.

   As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.
3. To move the TCP along the z axis of the TCS, click the "v" slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCP is moved.

Jogging 3D kinematics types with 2 orientations, "6-axis articulated arm with central wrist" and "6-axis articulated arm with offset wrist" in "Orientation" mode

1. Enter the velocity for the orientation, the rotation of the TCS and the offset of the TCP.
2. To change the orientation of the TCS, click the slider and drag the slider to the left/right/up/down. The further you drag the slider away from the central position, the faster the TCS is rotated.
3. To rotate the TCS around the x axis for the "6-axis articulated arm with central wrist" and "6-axis articulated arm with offset wrist" kinematics type, click the "R" slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCS is rotated.

   As soon as you press one of the keys, the kinematics travels with the maximum preset velocity.
4. To move the TCP along the x axis of the TCS, click the "v" slider and drag the slider to the left or right. The further you drag the slider away from the central position, the faster the TCP is moved.

Jogging to a Cartesian target position

To move the kinematics to a target position in jog mode, proceed as follows:

1. In the "Operating mode" drop-down list, select the "Jog to target position" entry.
2. In the "Coordinate system" drop-down list, select the "WCS" or "OCS" entry.

   The target position is shown in the 3D display.
3. Enter the velocity for the path and the orientation motion.
4. Enter the Cartesian target position (Page 226) in the selected coordinate system.

   With a 3D kinematics with 2 orientations, you can select the value 0° or -180° for the rotation C.

   Alternatively, you can specify the target position with the directional pad (Page 314).
5. To move the kinematics to the target position, click the "Start" slider, hold down the mouse button and move the slider to the right.

   The kinematics moves to the specified target position. Movements of the kinematics axis are possible in both the positive and the negative direction. For kinematics with up to 4 interpolating axes, the A4 kinematics axis is moved using the "Shortest path" mode.

   The kinematics stops as soon as you release the pressed mouse button or the target position is reached.

10.9 Disabling kinematics and handing over master control

Procedure

To return the master control to the user program, perform the following steps:

1. Jog the kinematics to a basic position from which the kinematics can be moved with the user program.
2. Set the currently mounted tool in the kinematics control panel and activate the tool zone associated with the active tool. If necessary, deactivate the tool zone that is no longer required (e.g. after a tool change).
3. Click the "Disable" button.

   The kinematics axes are disabled.
4. Click "Deactivate".

   The master control is returned from the kinematics control panel to the user program.

Result

You can move the kinematics via an automatic program or an HMI.

Diagnostics 11

The description of Motion Control diagnostics is limited to the diagnostics view of the technology objects in TIA Portal, the technology alarms and the error IDs on Motion Control instructions.

"Debug" program mode is available for testing the execution of your Interpreter program.

The following descriptions can be found in the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation:

- Diagnostics concept
- Technology alarms
- Error IDs in Motion Control instructions

A comprehensive description of the system diagnostics of the S7-1500 CPU can be found in the "Diagnostics" function manual (https://support.industry.siemens.com/cs/ww/en/view/59192926).

11.1 Kinematics technology object

11.1.1 Structure of the diagnostics

The diagnostics of the kinematics in "Technology object > Diagnostics" is divided into the following areas:

- Graphic display
- Diagnostics window

Diagnostics window

The following diagnostics windows are available in the graphic display:

- Status and error bits (Page 340)
- Zones status (Page 342)
- Motion and Tools (Page 343)
- Positions (Page 345)

With the following buttons, you can show or hide the associated diagnostics windows:

Button	Function
	Status and error bits
	Zones status
	Motion and tools
	Positions

You can also move the diagnostics window to a desired position within the graphic display.

11.1.2 Status and error bits

With the diagnostics window "Status and error bits" in "Technology object > Diagnostics" you monitor the status and error messages of the technology object in the TIA Portal. The diagnostics function is available in online operation.

The diagnostics window "Status and error bits" is shown in the graphic display of the diagnostics. You can show the diagnostics window via the symbol of the toolbar and move the window to a desired position within the graphic display.

The meaning of the status and error messages is described in the following tables. The associated technology object tag is given in parentheses.

"Kinematics status"

The following table shows the possible statuses of the kinematics:

Status	Description
Error	An error occurred at the technology object. Detailed information about the error is available in the "Error" area and in the "<TO>.ErrorDetail.Number" and "<TO>.ErrorDetail.Reaction" tags of the technology object. (<TO>.StatusWord.X1 (Error))
Restart active	The technology object is being reinitialized. (<TO>.StatusWord.X2 (RestartActive))
Kinematics control panel active	The kinematics control panel is activated. The kinematics control panel has master control over the technology object. The kinematics cannot be controlled from the user program. (<TO>.StatusWord.X4 (ControlPanelActive))
Restart required	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object. (<TO>.StatusWord.X3 (OnlineStartValuesChanged))
Valid	The transformation values are valid. (<TO>.StatusKinematics.Valid)
Simulation active	The kinematics technology object is in simulation. (<TO>.StatusWord.X19 (InSimulation))
JCS enabled	The kinematics technology object uses the JCS. (<TO>.StatusWord.X21 (EnabledJCS))

"Error"

The following table shows the possible errors:

Error	Description
System	A system-internal error has occurred. (<TO>.ErrorWord.X0 (SystemFault))
Configuration	A configuration error has occurred. One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data was incorrectly modified during runtime of the user program. (<TO>.ErrorWord.X1 (ConfigFault))

Error	Description
Transformation	A transformation error has occurred. (<TO>.ErrorWord.X4 (TransformationFault))
User program	An error has occurred in the user program at a Motion Control instruction or its use (e.g. by the kinematics control panel). (<TO>.ErrorWord.X2 (UserFault))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because necessary requirements have not been met (e.g. technology object not homed). (<TO>.ErrorWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.ErrorWord.X6 (DynamicError))

"Warnings"

The following table shows the possible warnings:

Warning	Description
Configuration	One or more configuration parameters are temporarily adjusted internally. (<TO>.WarningWord.X1 (ConfigWarning))
Job rejected	A job cannot be executed. A Motion Control instruction cannot be executed because the necessary conditions have not been met. (<TO>.WarningWord.X3 (CommandNotAccepted))
Dynamic limitation	The dynamic values are limited to the dynamic limits. (<TO>.WarningWord.X6 (DynamicWarning))

"Motion status"

The following table shows the possible statuses of the kinematics motion:

Status	Description
Done (no job running)	There is no active motion job at the technology object. (<TO>.StatusWord.X6 (Done))
Linear motion active	There is a linear motion job active at the technology object. (<TO>.StatusWord.X8 (LinearCommand))
Circular motion active	There is a circular motion job active at the technology object. (<TO>.StatusWord.X9 (CircularCommand))
sPTP motion active	There is a synchronous "point-to-point" motion job active at the technology object. (<TO>.StatusWord.X11 (DirectCommand))
Constant velocity	The kinematics is moved with constant velocity or is stationary. (<TO>.StatusWord.X12 (ConstantVelocity))
Accelerating	The kinematics is being accelerated. (<TO>.StatusWord.X13 (Accelerating))

Status	Description
Decelerating	The kinematics is being decelerated. (<TO>.StatusWord.X14 (Decelerating))
Motion interrupted	The active kinematics motion is interrupted by an "MC_GroupInterrupt" job. (<TO>.StatusWord.X17 (Interrupted))
Orientation movement active	There is an orientation motion active at the technology object. (<TO>.StatusWord.X15 (OrientationMotion))

"StatusWord" tag (kinematics) (Page 501)
"ErrorWord" tag (kinematics) (Page 502)
"WarningWord" tag (kinematics) (Page 504)

11.1.3 Zones status

Using the diagnostics windows "Status Zones" in "Technology object > Diagnostics", you monitor the status of the workspace zones and the kinematics zones of the technology object in the TIA portal. The diagnostics function is available in online operation.

The diagnostics window "Zones Status" is displayed in the graphic display of the diagnostics. You can show the diagnostics window via the symbol of the toolbar and move the window to a desired position within the graphic display.

"Zones status"

The "Workspace zones" and "Kinematics zones" tables show the status of the individual zones. The following symbols are displayed for this purpose:

Symbol	Description
	The zone is not defined.
	The zone is inactive.
	The zone is active.
	The zone was violated.

You can use the toolbar icon in the graphic display of the diagnostics to show and hide all zones. In addition, when the icon is active, you can display and hide the zones using the symbol .

See also

Structure of the diagnostics (Page 339)

11.1.4 Motion and tools

You monitor the path motions and the tools of the technology object in the TIA Portal using the diagnostics window "Motion and Tools" in "Technology object > Diagnostics". The diagnostics function is available in online operation.

The diagnostics window "Motion and Tools" is shown in the graphic display of the diagnostics. You can show the diagnostics window via the symbol of the toolbar and move the window to a desired position within the graphic display.

"Motion and Tools"

The following table describes the meaning of the parameters of the motion and tools:

Status	Description
Path dynamics values	
Limit path dynamics to axis dynamics	Dynamic adaptation (<TO>.StatusPath.DynamicAdaption)
Velocity	Current path velocity (setpoint reference) (<TO>.StatusPath.Velocity)
Acceleration	Current path acceleration (setpoint reference) (<TO>.StatusPath.Acceleration)
Orientation velocity	Resulting orientation velocity (<TO>.StatusPath.OrientationVelocity)
Override	Percentage correction of the velocity specification The setpoint velocity set in Motion Control instructions or from the kinematics control panel is superimposed with an override signal and corrected as a percentage. The following values are permitted as velocity correction: • Path motion: from 0.0% to 200.0% • sPTP motion: from 0.0% to 100.0% (<TO>.Override.Velocity)
Job sequence	
Existing jobs	Current number of jobs for the kinematics technology object in the job sequence. (<TO>.StatusMotionQueue.NumberOfCommands)
Prepared jobs	Number of prepared jobs for the kinematics technology object in the job sequence. (<TO>.StatusMotionQueue.NumberOfPreparedCommands)
Prepared jobs (distance)	
Total path length	Total path length of linear and circular path motions (<TO>.StatusPath.TotalPathLength) Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job • Remaining distance of the motion job • Calculated distance of all jobs in the job sequence
Accumulated path length	Accumulated path length of linear and circular path motions (<TO>.StatusPath.AccumulatedPathLength) Sum of: • Distance of all completed motion jobs • Distance travelled of the active motion job
Active tool	

Status	Description
Active tool	Currently selected tool (<TO>.StatusTool.ActiveTool)
Tool center point in the FCS	
x position	x coordinate of the current tool frame in the flange coordinate system (FCS) (<TO>.StatusTool.Frame[1..3].x)
y position	y coordinate of the current tool frame in the FCS (<TO>.StatusTool.Frame[1..3].y)
z position	z coordinate of the current tool frame in the FCS (<TO>.StatusTool.Frame[1..3].z)
Rotation A	A-coordinate of the current tool frame in the FCS (<TO>.StatusTool.Frame[1..3].a)
Rotation B	B-coordinate of the current tool frame in the FCS (<TO>.StatusTool.Frame[1..3].b)
Rotation C	C-coordinate of the current tool frame in the FCS (<TO>.StatusTool.Frame[1..3].c)
Joints	
J1 ... J6 velocity setpoint	Current velocity setpoint of the respective joint J1 to J6 (<TO>.JointData.J[1..6].Velocity)
J1 ... J6 acceleration setpoint	Current acceleration setpoint of joint J1 to J6 (<TO>.JointData.J[1..6].Acceleration)
Conveyor tracking	
OCS1 ... 3	Active coupled OCS 1, 2 or 3
Coupled technology object	Technology object for active conveyor tracking Leading-value-capable technology objects are: • Positioning axis • Synchronous axis • External encoder • Leading axis proxy (<TO>.StatusConveyor[1..3].ConveyorBelt)
Conveyor position	Conveyor position of the technology object (<TO>.StatusConveyor[1..3].BeltPosition)
Position of the OCS in x direction	Position of the OCS in x direction on the conveyor (<TO>.StatusConveyor[1..3].ObjectPosition)
Conveyor tracking status	Conveyor tracking status (<TO>.StatusConveyor[1..3].TrackingState)
	OCS not assigned: The OCS is not assigned to a leading-value-capable technology object. (<TO>.StatusConveyor[1..3].TrackingState = 0)
	OCS assigned: The Motion Control instruction "MC_TrackConveyorBelt" is finished and the OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS can be sent. (<TO>.StatusConveyor[1..3].TrackingState = 1)

Status			Description	
		Conveyor tracking status	TCP synchronizes to OCS	The OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS is active. (<TO>.StatusConveyor[1..3].TrackingState = 2)
			TCP follows OCS	The OSC is assigned to a leading-value-capable technology object. The position of the OCS is reached. The kinematics is moved with the position of the OCS. (<TO>.StatusConveyor[1..3].TrackingState = 3)
			TCP desynchronizes from OCS	The motion of the kinematics in the tracked OCS is ended by a motion job in the WCS or a non-tracked OCS. When the motion job is completed, the "TrackingState" changes to 0 and the OCS is not tracked with the product position anymore. (<TO>.StatusConveyor[1..3].TrackingState = 4)

See also

Structure of the diagnostics (Page 339)

11.1.5 Positions

You monitor the position values of the technology object in the TIA Portal using the diagnostics window "Positions" in "Technology object > Diagnostics". The diagnostics function is available in online operation.

The diagnostics window "Positions" is shown in the graphical display of the diagnostics. You can show the diagnostics window via the symbol of the toolbar and move the window to a desired position within the graphic display.

The available functions are described in the section "Monitoring and comparing position values (Page 315)".

"Positions"

The following table describes the meaning of the position information:

Status		Description
Coordinate system 1		Reference coordinate system • In "Diagnostics", in "Calibration" and in "Kinematics trace", this field shows the coordinate system that you have selected in the toolbar. • In "Commissioning", this field shows the coordinate system that you have selected in the kinematics control panel. • When you select the kinematics coordinate system (KCS) in the toolbar, the WCS is displayed in the "Positions" window in "Diagnostics" and in "Kinematics trace".
	x position	x coordinate of the active tool in the set coordinate system (<TO>.Tcp.x; <TO>.TcpInOcs[1..3].x.Position)
	y position	y coordinate of the active tool in the set coordinate system (<TO>.Tcp.y; <TO>.TcpInOcs[1..3].y.Position)
	z position	z coordinate of the active tool in the set coordinate system (<TO>.Tcp.z; <TO>.TcpInOcs[1..3].z.Position)

Status	Description
Rotation A	A coordinate of the active tool in the set coordinate system (<TO>.Tcp.a; <TO>.TcpInOcs[1..3].a.Position)
Rotation B	B coordinate of the active tool in the set coordinate system (<TO>.Tcp.b; <TO>.TcpInOcs[1..3].b.Position)
Rotation C	C coordinate of the active tool in the set coordinate system (<TO>.Tcp.c; <TO>.TcpInOcs[1..3].c.Position)
Coordinate system 2	Reference coordinate system In the drop-down list, you can select an additional coordinate system in order to display the actual position of the active tool in this coordinate system.
WCS, OCS1, OCS2, OCS3	
x position	x coordinate of the active tool in the set coordinate system (<TO>.Tcp.x; <TO>.TcpInOcs[1..3].x.Position)
y position	y coordinate of the active tool in the set coordinate system (<TO>.Tcp.y; <TO>.TcpInOcs[1..3].y.Position)
z position	z coordinate of the active tool in the set coordinate system (<TO>.Tcp.z; <TO>.TcpInOcs[1..3].z.Position)
Rotation A	A coordinate of the active tool in the set coordinate system (<TO>.Tcp.a; <TO>.TcpInOcs[1..3].a.Position)
Rotation B	B coordinate of the active tool in the set coordinate system (<TO>.Tcp.b; <TO>.TcpInOcs[1..3].b.Position)
Rotation C	C coordinate of the active tool in the set coordinate system (<TO>.Tcp.c; <TO>.TcpInOcs[1..3].c.Position)
MCS	
A[1..6]	Current position setpoint of axis A[1..6] (<TO>.Position)
JCS	
J[1..6]	Current position setpoint of joint JJ[1..6] (<TO>.JointData.J[1..6].Position)

Structure of the diagnostics (Page 339)

Kinematics trace 12

The kinematics trace offers the following functions:

- 3D visualization of the current motion of the tool center point (TCP) and the object coordinate systems (OCS)
- Recording, playing and saving kinematic motions
- Exporting and importing the recordings

You can find the kinematics trace of the kinematics technology object in the project tree under "Technology object > Kinematics trace".

12.1 Defining parameter values for recording

You specify the parameter values for the recording under "Technology object > Kinematics trace > Configuration"

Setting the sampling

Configure the duration of a recording as follows:

1. In the "Time of recording" drop-down list, select the desired recording time between the following OBs:
   - MC_Servo
   - MC_Interpolator
2. In the "Record all" drop-down list, select the desired value for the recording interval:
   - Specification in cycles
   - Specification in seconds
3. The calculated value of the maximum recording duration is displayed in the "Max. recording duration" field.

   If you change the recording interval in the field "Record all", the maximum recording time changes.
4. To set the recording duration to the maximum possible, select the "Use maximum recording duration" check box.
5. In the "Recording duration (a)" drop-down list, select the desired type of recording duration display for the recording:
   - In seconds
   - Number of samples

Setting triggers

Configure the start of a recording as follows:

1. In the "Trigger mode" drop-down list, select the desired trigger mode for your recording:
   - Record now
     The recording starts immediately after the configuration is loaded.
   - Trigger on tag
     The system waits for a trigger event that triggers the recording.
2. In the "Trigger tag" field, select a tag of the data type "BOOL".
3. In the "Event" drop-down list, select the desired event to be used as trigger event:
   - Positive edge
   - Falling edge
4. In the "Pretrigger (b)" drop-down list, select a suitable pretrigger for your recording:
   - In seconds
   - Number of samples

   The "pretrigger" is used to record measuring points in advance of the start of the trigger event. As soon as the trigger event occurs, the recording is displayed in the graphic view.

Selecting the traces to be recorded

Select the traces for the recording as follows.

1. Select whether the setpoint positions of the kinematics axes should be recorded with the coordinates of the tool center point (TCP). You have the following options:
   - Tool center point (TCP) and kinematics

     If you activate this option, the coordinates of the TCP and the set positions of the kinematics axis are recorded. The motions of the TCP and the motions of the kinematic axes are displayed when a recording is played.
   - Tool center point (TCP)

     If you activate this option, only the coordinates of the TCP will be recorded. The motions of the TCP are displayed when a recording is played, the motions of the kinematic axes are not displayed.
2. Select the object coordinate systems (OCS) to be recorded.
   - OCS 1 frame
   - OCS 2 frame
   - OCS 3 frame

Maximum number of signals per kinematics trace

You can record a maximum of 64 signals in a kinematics trace. The following table shows how many signals are required for the traces.

Kinematics type	Trace	Required signals
2D	Tool center point (TCP) and kinematics	4
	Tool center point (TCP)	2
	per OCS	3
2D with orientation	Tool center point (TCP) and kinematics	6
	Tool center point (TCP)	3
	per OCS	2
3D	Tool center point (TCP) and kinematics	6
	Tool center point (TCP)	3
	per OCS	6
3D with orientation	Tool center point (TCP) and kinematics	8
	Tool center point (TCP)	4
	per OCS	4
3D with 2 orientations A, B	Tool center point (TCP) and kinematics	10
	Tool center point (TCP)	5
	per OCS	4
3D with 3 orientations	Tool center point (TCP) and kinematics	12
	Tool center point (TCP)	6
	per OCS	6
6-axis articulated arm with central wrist, 6-axis articulated arm with offset wrist	Tool center point (TCP) and kinematics	12
	Tool center point (TCP)	6
	per OCS	6

The more traces you record, the lower the maximum recording duration and the number of samples per trace.

12.2 List of recordings

The list of recordings is displayed below the graphic display as tabular editor. The list contains the following recordings:

- The current recording
- All saved recordings for the selected technology object

The recordings are displayed line by line.

Functions

The following functions are available in the list of recordings:

- Saving and deleting recordings (Page 352)
- Showing traces of a recording

  You can also show all traces of a recording by expanding the line of a recording.
- Showing and hiding traces in the graphic display

  The button for showing and hiding a trace has the following functions depending on the status:

Button	Status and function
	The recording or the trace is hidden. Shows the hidden recording or trace.
	The traces of the recording are partially shown and hidden.
	The recording or the trace is shown. Hides the recording or trace

12.3 Recording and playing kinematics motions

For the recording, use the values set under "Technology object > Kinematics trace > Configuration".

Switch to live display

You can show the current motion or position of the kinematics with the icon in online mode. The button for the live display is active when a saved recording is selected or while a recording is played. In offline mode and when no recording is available, the live display button is inactive.

Requirement

- The kinematics trace was configured under "Technology object > Kinematics trace > Configuration".

Record kinematics motion

To record a kinematics motion, proceed as follows:

1. Click the icon in the toolbar to establish an online connection to the device.

   The kinematics trace establishes an online connection to the device. If the online and offline trace configurations differ, the trace configuration is loaded into the device.
2. To start a recording, click on the symbol in the toolbar.

   If you start a recording directly without previously establishing the online connection (step 1), an online connection is established automatically.
3. Move the kinematics.
4. To end the recording, click on the symbol on the toolbar.

   The current recording and the configuration are kept until the "kinematics trace" has been closed. When you start a new recording, the current recording is overwritten.

Play kinematics motion

To play a kinematics motion, proceed as follows:

1. If the live display is activated, switch off the live display by clicking the symbol .
2. In the list of recordings, select the recording you want to play.
3. To show the trace in the graphic display, click on the symbol in the line of the selected recording.

   The complete trace of the selected recording is displayed graphically in the display.
4. To play the recording, click on the symbol at the bottom of the graphic display.

   The recording that is selected as a line in the list is played.
5. To adjust the playback speed, change the position of the speed slider in the toolbar for playing a recording.

   .
6. Use the following buttons to control the playback of a recording:

Button	Function
	Jumps back to the start of the selected recording.
	Jumps back step-by-step in the selected recording.
	Jumps forward step-by-step in the selected recording.
	Jumps to the end of the selected recording.

7. To pause a recording, click on the symbol in the toolbar for playing a recording.
8. To stop a recording, click on the symbol in the toolbar for playing a recording.

Show TCP orientation

Use the button to show or hide the TCP orientation as a trace in the kinematics trace.

Displaying and comparing position values

In the kinematics trace, you can monitor position values of the technology object or compare the position values in two different reference coordinate systems with the "Positions" window.

In addition, you can view position values directly on the trace.

The available functions are described in the section "Monitoring and comparing position values (Page 315)".

12.4 Saving and deleting recordings

Saving a recording

You can save a current recording. A saved recording contains the following data:

- Kinematics type
- Coordinates of:
  - Kinematics
  - Tool center point (TCP)
  - Object coordinate systems (OCS)
- Valid online geometry at the time of the recording

To adjust and save a recording, proceed as follows:

1. In the "Current recording" area, enter the name of the recording in the "Name" column.
2. In the "Color" column, select the desired colors for the traces.
3. If necessary, enter comments in the "Comment" column.
4. To save the current recording, click on the symbol in the "Current recording" area.

   The recording is inserted in the "Saved recordings" area in the tabular editor.

NOTE

Up to 20 recordings which can be saved

The tabular editor can save a maximum of 20 recordings.

To save additional recordings, delete the recording you no longer need.

Deleting saved recordings

To delete a recording, follow these steps:

1. To delete a recording, click on the symbol ✕ in the corresponding line in the "Saved recordings" area.

   The record is deleted.

NOTE

Traces cannot be deleted individually

You cannot delete traces individually. When you delete a recording, all included traces are deleted.

12.5 Importing and exporting recordings

You have the option to export a recording as measurement, as *.ltr or *.csv file. The exported file contains the TCP position values, the OCS position values and the configuration of the kinematics technology object. Optionally, the following values can be exported:

- Up to technology version V6.0: Axis position values
- As of technology version V7.0: Joint position values

You can re-import an exported *.ltr file into the kinematics trace. The recordings saved under measurements cannot be imported into the kinematics trace again.

Export record as file

To export a record, proceed as follows:

1. From the list of recordings, select the record to be exported.
2. Click on the symbol in the toolbar.

   The "Export recording" dialog opens.
3. Select "*.csv" or "*.ltr" as file format.
4. Select the storage location.
5. Click "Save".

   The file is exported and saved.

Import recording as file

To import a recording, proceed as follows:

1. Click on the symbol in the toolbar.

   The "Import recording" dialog opens.
2. In the corresponding folder, select the file of the "*.ltr" file format to be imported.
3. Click the "Open" button.

   The file is imported. The recording is displayed in the tabular editor under saved recordings.

Save recording as measurement

With the trace you have extended evaluation options to analyze kinematics motion in detail.

To save the recording as a measurement, proceed as follows:

1. Select the current recording or a saved recording.
2. Click on the symbol in the toolbar.

   The recording is saved under "Traces > Measurements".
3. Open the recording stored under "Traces > Measurements" in the trace.

   The recorded parameters are displayed in the trace.

Calibration 13

During calibration, you move a kinematics to relevant points and use the position values to determine the exact position of an object coordinate system (OCS) in the world coordinate system (WCS), to check a predefined OCS in the WCS or to define a workspace zone.

Open calibration under "Technology object > Calibration".

Alternatively, you can open the calibration to the following type:

- To calibrate an object coordinate system, select an object coordinate system in the selection box under "Technology object > Configuration > Extended parameters > Object coordinate systems" and click the symbol.
- To calibrate a workspace zone, go to "Technology object > Configuration > Extended parameters > Zones > Workspace zones" and click the symbol in the line for the respective workspace zone.

Requirement

The kinematics technology object is correctly configured and connected.

Structure

Calibration is divided into two views:

- Object coordinate systems
- Workspace zones

Each view is divided into the following areas:

- Configuration section (Page 355)
- 3D visualization (Page 355) and control pad (Page 314)
- Kinematics control panel (Page 317)

13.1 Using 3D display for the calibration

The 3D display provides you with visual support during calibration. The following values are displayed graphically depending on the configured calibration method:

- Configured points and angles
- Guide lines
- Offset of the OCS from the origin
- Current position of the TCP
- Graphically highlighted active calibration point
- Active and inactive workspace zones

In addition, you can also use the following functions of the 3D visualization for the calibration:

- Operating the zone display (Page 313)
- Selecting values for the calibration (Page 311)
- Monitoring and comparing position values (Page 315)

In the configuration area, select a calibration method and set all the required parameters for the calibration.

The configuration area is structured differently for the calibration of object coordinate systems, the calibration of workspace zones and depending on the selected calibration method.

- Configuring calibration of an object coordinate system (Page 359)
- Configuring calibration of a workspace zone (Page 378)

13.2 Moving the kinematics for calibration

For the calibration, you can move the kinematics as follows:

- **Offline, move the tool center point in the 3D view using the control pad**

  See also section "Operating the directional pad (Page 314)".

- **Moving real kinematics online**

  You move the real kinematics online via the control panel in the "Jog" or "Jog to target position" mode. In the 3D view, you can see the motion of the kinematics model.

  To specify the target position in the "Jog to target position" mode, you can determine the coordinates with the control pad or enter them directly on the control panel.

  The functionality of the kinematics control panel is described in section "Commissioning (Page 317)".

13.3 Display progress and status

The progress and notes on the input of the values are displayed in the configuration area of the calibration method.

The entered values of the calibration are checked for the "Three-point" and "Two-point" methods. The distances between the points in the OCS are compared with the distances between the points in the WCS. Comparison of the points is not required with the "One-point" method.

If the entries are still incomplete, the status indicator is displayed in red. Depending on your inputs, the status indicator shows the following:

- In the case of the "Three-point" (Page 361) calibration method
  - Angle of triangles in the WCS and the OCS, less than 20°
  - Deviation of the points in WCS and OCS to each other greater than 5%
- In the case of the "Two-point" (Page 360) calibration method
  - Deviation of the points in WCS and OCS to each other greater than 5%

Each correctly set point is shown in green in the progress display.

If your entries are complete and correct, the status indicator "Finished" appears green. You can accept the values in the configuration.

13.4 Setting points

To set points, use the following input options:

- Enter the position manually
- Apply TCP position
- Couple coordinates to TCP position

Each of the values displayed in the fields is a position value in the following coordinate system:

- Calibrate object coordinate system: WCS or selected object coordinate system (marking in adjustment range of the individual points)
- Calibrate workspace zone: Coordinate system of the workspace zone (selection in the zone properties)

Enter the position manually

1. Enter the position of the workspace zone in the x, y and z directions in the respective field.

Apply TCP position

To adopt the current position value of the TCP, proceed as follows:

1. Move the kinematics to a position.

   You can monitor the current position values in the "Positions" window.

2. To adopt the current position value of the TCP, click the symbol.
   - To apply all coordinates of a position, click the uppermost and higher-level symbol in the area for a point.
   - To apply the coordinates individually or an angle of a position, click the symbol next to the field for the coordinates or the angle.

   The position value of the TCP is displayed in the selected fields. An angle for a rotation defined by the position value is displayed in the graphical view.

Couple coordinates to TCP position

1. To link the coordinates to the TCP, click the symbol.
   - To couple all coordinates of a position, click the uppermost and higher-level symbol in the area for a point.
   - To couple a single coordinate or angle, click the symbol next to the respective field for the coordinate or angle.

   The symbol changes to and the position value is coupled to the TCP. The corresponding fields of the coordinates are inactive.

2. Move the kinematics to a position.

   In the corresponding fields of the coupled coordinates, the current value of the TCP is displayed while moving the kinematics. An angle for a rotation defined by the position value is displayed in the graphical view.

3. To decouple the coordinates from the TCP, click the symbol .
   - To decouple all coordinates of a position, click the uppermost and higher-level symbol in the area for a point.
   - To uncouple a single coordinate or angle, click the symbol next to the respective field for the coordinate or angle.

   The corresponding fields of the coordinates can be edited again.

4. To adopt the current position value or the angle of the TCP, click the symbol.

   The position value of the TCP is displayed in the selected fields. An applied angle is shown in the graphic view .

See also

Apply or reset values (Page 359)

13.5 Apply or reset values

Apply values

If you have entered new values for the calibration and the "status indicator" is green, you can click on the button "Apply values". The values from the calibration are applied to the configuration. If you calibrate an already defined zone and adopt the calibrated values, the previously defined values are overwritten.

The "Apply values" button becomes inactive as soon as the values from the calibration have been successfully applied in the configuration.

Reset values

With the "Reset values" button, you reset the entered values of the calibration.

13.6 Calibrate object coordinate systems

13.6.1 Configuring calibration of an object coordinate system

Requirement

The kinematics technology object is correctly configured and connected.

Selecting the object coordinate system

1. Select an OCS from the drop-down list.

Selecting the calibration method

Select a calibration method In the drop-down list.

Depending on the type of kinematics, you can use the calibration methods as follows:

Kinematics type	Definition OCS / Checking the OCS position	Calibration methods
2D	Move OCS	Two-point (Page 360)
	Move OCS and rotate around the y axis	Move and rotate around y (Page 361)
2D with orientation	Move OCS	One-point (Page 361)
3D, 3D with 3 orienta-	Move OCS	Three-point (Page 361)

Kinematics type	Definition OCS / Checking the OCS position	Calibration methods
tions, 6-axis articulated arm with central wrist and 6-axis articulated arm with offset wrist	Move OCS and rotate around an axis	• Three-point (Page 361) • Move and rotate (Page 361)
	Move OCS and rotate around two axes	• Three-point (Page 361) • Plane (Page 361)
3D with orientation and 3D with 2 orientations A, B	Move OCS	Two-point (Page 360)
	Move OCS and rotate around the z axis	Move and rotate around z (Page 363)

13.6.2 Move OCS with the "Two-point" calibration method

To move the origin of the object coordinate system (OCS) and define the location of the OCS, use the "Two-point" calibration method.

"Two-point" calibration method

Using this method, you can move the OCS origin or check the position of an already defined OCS in the WCS.

The calibration method assumes that the defined points for the tool center point (TCP) of the kinematics can be reached.

With this method, you calibrate the OCS based on 2 points. You define the OCS origin using the first item in the menu "1. Set point 1" .

You define the second point in the "2. Set point 2" menu as follows:

- With 2D kinematics: Define a point on the xz plane
- With 3D kinematics with orientation or with 2 orientations: Define a point on the xy plane. The z coordinate is automatically applied from the first point and cannot be changed for the second point.

The points entered in the WCS and in the OCS each form a route. The method compares the length and location of the two distances in the WCS and the OCS. If the deviation between the two distances is greater than 5%, this is shown in red in the status display. If the entries are incomplete, this is also shown in red in the status display.

To compare the actual position of an OCS in the WCS with your configured OCS frames, move the kinematics to the corresponding points.

13.6.3 Move OCS and rotate around the y axis

To move the origin of the object coordinate system (OCS) and define the position of the OCS, use the "Move and rotate around y" calibration method.

"Move and rotate around y" calibration method

With this method, you can move the OCS origin to a point and rotate the OCS with an angle of rotation around the y axis.

In the menu "1. Move origin of OCS", you define the new position of the OCS origin.

In the second step, you define the rotation of the OCS in the menu "2. Rotate OCS around one coordinate axis". First select the x axis or z axis from the "Rotate around" drop-down list. This determines which axis should be rotated around the y axis. Then move the kinematics to a point through which the selected coordinate axis should run after rotation. In the "Angle" field, you accept the value of the TCP and thus define the angle of rotation for the selected coordinate axis and the OCS.

13.6.4 Move OCS with the "One-point" calibration method

To move the origin of the object coordinate system (OCS) and define the position of the OCS, use the "One-point" calibration method.

"One-point" calibration method

Using this method, you can move the OCS origin or check the position of an already defined OCS in the WCS.

The calibration method assumes that the defined points for the tool center point (TCP) of the kinematics can be reached.

With this method, you calibrate the OCS based on one point. In the menu "1. Set point 1" you define the x and z coordinates of the point in the WCS. Then enter the corresponding coordinates in the OCS.

The method checks whether all coordinates for the point have been entered. If the entries are still incomplete, the status indicator is displayed in red.

To compare the actual position of an OCS in the WCS with your configured OCS frames, move the kinematics to the corresponding point.

13.6.5 Move OCS and rotate around one axis or two axes

Use one of the following calibration methods to move the origin of the object coordinate system (OCS) and define the position of the OCS:

- Move and rotate
- Three-point
- Plane

With the "Move and rotate" calibration method, you can rotate the OCS around 1 axis. If you want to rotate the OCS around a second axis, use the "Three-point" or "Plane" calibration method.

"Three-point" calibration method

With this method, you can:

- Move the OCS origin and rotate the OCS around 2 axes
- Check the position of an already defined OCS in the WCS

The calibration method assumes that the defined points for the tool center point (TCP) of the kinematics can be reached.

With this method, you calibrate the OCS based on 3 points. You define the coordinates of the points in the WCS. Then enter the corresponding coordinates in the OCS.

The points entered in the WCS and the OCS each form a triangle. The method compares the angles and side lengths of the two triangles.

The status of the check gives you feedback on the accuracy of your information. Depending on your inputs, the status indicator shows the following:

- Angle of triangles in the WCS and the OCS, less than 20°
- Deviation of the points in WCS and OCS to each other greater than 5%
- Conformity error of the side lengths of the triangle greater than 5%

If the entries are incomplete, this is also shown in red in the status display.

If the two triangles are within the tolerances, the position of the OCS is defined via the 3 points.

To compare the actual position of an OCS in the WCS with your configured OCS frames, move the kinematics to the corresponding points.

"Move and rotate" calibration method

With this method, you can move the OCS origin to a point and rotate the OCS with an angle of rotation around one of the three coordinate axes.

In the menu "1. Move origin of OCS", you define the new position of the OCS origin.

In the second step, you define the rotation of the OCS in the menu "2. Rotate OCS around one coordinate axis". First, select a coordinate axis (x, y or zaxis) in the drop-down list "Rotate around" around which the OCS is to be rotated. Then select a coordinate axis in the "Axis to rotate" drop-down list that is to be rotated around the previously selected coordinate axis. To conclude, move the kinematics to a point through which the coordinate axis selected in the second step should pass after the rotation. In the "Angle" field, you accept the value of the TCP and thus define the angle of rotation for the selected coordinate axis and the OCS.

"Plane" calibration method

With this method, you can move the OCS origin to a point and rotate the OCS with 2 angles of rotation around 2 coordinate axes.

In the menu "1. Move origin of OCS", you define the new position of the OCS origin.

In the second step, you define the first rotation of the OCS in the menu "2. Rotate coordinate axis to TCP". In the "Axis" drop-down list, first select the coordinate axis (x, y or z-axis) to be rotated to the TCP. Then move the kinematics to a point through which the selected

coordinate axis should run after rotation. Adopt the value of the TCP to define the angle of rotation for the selected coordinate axis and the OCS.

In the last step, you define the second rotation of the OCS in the menu "Span plane over two coordinate axes". First select a plane from the "Plane" drop-down list, which is spanned between the previously rotated and a second coordinate axis. Then move the kinematics to a point through which the spanned plane should run. Adopt the value of the TCP to define the angle of rotation for the selected coordinate axes and the OCS.

13.6.6 Move OCS and rotate around the z axis

To move the origin of the object coordinate system (OCS) and define the position of the OCS, use the "Move and rotate around z" calibration method.

"Move and rotate around z" calibration method

With this method, you can move the OCS origin to a point and rotate the OCS with an angle of rotation around the z axis.

In the menu "1. Move origin of OCS", you define the new position of the OCS origin.

In the second step, you define the rotation of the OCS in the menu "2. Rotate OCS around one coordinate axis". First select the x or y axis in the "Rotate around" drop-down list. This determines which axis should be rotated around the z axis. Then move the kinematics to a point through which the selected coordinate axis should run after rotation. In the "Angle" field, you accept the value of the TCP and thus define the angle of rotation for the selected coordinate axis and the OCS.

13.6.7 Examples

13.6.7.1 Introduction

The following examples show you how to calibrate an object coordinate system using the different calibration methods.

The example looks at the following application. A kinematics stacks products on pallets. The products have 4 different shapes, for which the pallet is repositioned in each case depending on the surrounding area. The position of the pallet is described by the OCS 1 frame. Based on a few details relating to position, the calibration determines the position of the OCS 1 frame after a change of position.

To illustrate all calibration methods, the following examples are carried out with the different types of Cartesian Portal kinematics.

Kinematics	New position of the pallet	Calibration method used	Example
Cartesian portal 2D	Position 1	Two-point	Move OCS 1 (Page 368)
Cartesian portal 2D with orientation		One-point	
Cartesian portal 2D	Position 2	Move and rotate around y	Move OCS 1 and rotate around the y axis (Page 370)
Cartesian portal 3D		Move and rotate	

Kinematics	New position of the pallet	Calibration method used	Example
Cartesian portal 3D	Position 3	Move and rotate	Move OCS 1 and rotate around z axis (Page 372)
Cartesian portal 3D with orientation		Move and rotate around z	
Cartesian portal 3D	Position 4	• Three-point • Plane	Move OCS 1 and rotate it around the z axis and y axis (Page 374)

Pallet

The pallet has the following dimensions:

- Width: 800.0 mm
- Height: 144.0 mm
- Depth: 1200.0 mm

The origin of the pallet is the same for all four positions and has the following position in the WCS:

	Position in the WCS (mm)	
	2D	3D
x	600.0	600.0
y	0.0	600.0
z	0.0	0.0

The pallet is rotated differently in each position. The following angles are used for the new positioning:

- **Position 1**

  2D kinematics

① Origin of the pallet

3D kinematics

① Origin of the pallet

- **Position 2**

  2D kinematics

① Origin of the pallet

② Rotation with angle B

3D kinematics

① Origin of the pallet

② Rotation with angle B

- **Position 3**

① Origin of the pallet

② Rotation with angle A

- **Position 4**

① Origin of the pallet
② First rotation with angle A
③ Second rotation with angle B

Position	Angle		
	A	B	C
1	0°	0°	0°
2	0°	-45°	0°
3	45°	0°	0°
4	45°	30°	0°

Kinematics

Execute the examples for each of the kinematics types mentioned in the overview and enter the following values for the geometry:

Parameters	2D kinematics / 2D kinematics with orientation	3D kinematics / 3D kinematics with orientation
Length L1	500.0 mm	
Length L2	500.0 mm	
Length L3	-	500.0 mm
Flange length FL	100.0 mm	
x minimum	-500.0 mm	
x maximum	2500.0 mm	
y minimum	-	0.0 mm

Parameters	2D kinematics / 2D kinematics with orientation	3D kinematics / 3D kinematics with orientation
y maximum	-	2000.0 mm
z minimum	0.0 mm	
z maximum	1000.0 mm	

If you want to use a different kinematics, consider the position and dimensions of the pallet when defining the geometric parameters of the kinematics. Make sure that all points are accessible for the kinematics.

13.6.7.2 Move OCS 1

Introduction

The pallet was moved in the direction of the x axis in the WCS. Two corner points at the pallet edge are used to determine the new position of the OCS 1 frame.

The position of the first pallet corner defines the origin of the OCS 1. Using the position of the second pallet corner, an additional point for the OCS 1 in the WCS can be determined using the "Two-point" calibration method.

The following methods are used for calibration:

- 2D kinematics: "Two-point" calibration method
- 2D kinematics with orientation: "One-point" calibration method

Coordinates of the points used in the example

		Position in the WCS (mm)		Position in the OCS (mm)	
		x	z	x	z
1	Point P1 on pallet corner	600.0	144.0	0.0	0.0
2	Point P2 on pallet corner	1800.0	144.0	1200.0	0.0

2D kinematics: "Two-point" calibration method

Two corner points at the pallet edge are used to determine the new position of the OCS 1 frame.

The position of the first pallet corner defines the origin of the OCS 1. The position of the second pallet corner can be used to determine the position in the WCS for another point.

1. Select the object coordinate system "OCS 1".
2. Select the "Two-point" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol next to the field "Position in WCS".
3. Enter the values for the position in OCS for the point P1 ①.

   You have defined the origin of OCS 1.

Define the point P2 ② as follows:

1. Move the kinematics to the point P2 ② on the pallet.
2. Define the coordinates for point P2 ② in the WCS by adopting the current position values of the TCP. Click the symbol next to the "Position in WCS" field.
3. For the point P2 ②, enter the values for the position in the OCS.

The position of the OCS is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

2D kinematics with orientation: "One-point" calibration method

A corner point of the pallet is used to determine the new position of the OCS 1 frame.

The position of the pallet corner defines the origin of the OCS 1.

1. Select the object coordinate system "OCS 1".
2. Select the "One-point" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol next to the field "Position in WCS".
3. Enter the values for the position in OCS for the point P1 ①.

   You have defined the origin of OCS 1.

The position of the OCS is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

13.6.7.3 Move OCS 1 and rotate around the y axis

Introduction

The pallet has been tilted. Two points at the pallet edge are used to determine the new position of the OCS 1 frame.

The position of the pallet corner defines the origin of the OCS 1. The angle of rotation for the OCS 1 is determined via a point on the pallet edge.

The following methods are used for calibration:

- 3D kinematics: "Move and rotate" calibration method
- 2D kinematics: "Move and rotate around y" calibration method

Coordinates of the points used in the example

① Point P1 pallet corner

② Point at pallet edge
The rotated x axis now runs through this point

③ Angle of rotation OCS 1

		Position in the WCS (mm)				
		3D kinematics			2D kinematics	
		x	y	z	x	z
①	Point pallet corner	498.5	600.0	102.0	498.5	102.0
②	Point at pallet edge	900.0	600.0	504.0	900.0	504.0

3D kinematics: "Move and rotate" calibration method

1. Select the object coordinate system "OCS 1".
2. Select the "Move and rotate" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking the button next to the field "Position in WCS".

   You have defined the origin of the OCS 1 with point P1 ①.

Define the angle of rotation ③ for the OCS 1 as follows:

1. Select the y axis as the coordinate axis around which the OCS 1 is rotated.
2. Select the x axis as the coordinate axis that is rotated around the y axis to the TCP or point ②.
3. Move the kinematics to the point ② at the pallet edge.
4. Rotate OCS 1 by clicking on the symbol next to the field for the angle.

   The set angle of rotation ③ is shown in the field and in the graphic display . The rotated x axis now runs through the point ②.

The position of the OCS 1 is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

2D kinematics: "Move and rotate around y" calibration method

1. Select the object coordinate system "OCS 1".
2. Select the "Move and rotate around y" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol next to the field "Position in WCS".

   You have defined the origin of the OCS 1 with point P1 ①.

Define the angle of rotation ③ for the OCS 1 as follows:

1. Select the rotation of the x axis around the y axis.

   In this way, you specify that the x axis is rotated around the y axis to the TCP or point ②.
2. Move the kinematics to the point ② at the pallet edge.
3. Rotate OCS 1 by clicking on the symbol next to the field for the angle.

   The set angle of rotation ③ is shown in the field and in the graphic display . The rotated x axis now runs through the point ②.

The position of the OCS 1 is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

13.6.7.4 Move OCS 1 and rotate around z axis

Introduction

The pallet was rotated horizontally. Two points at the pallet edge are used to determine the new position of the OCS 1 frame.

The position of the pallet corner defines the origin of the OCS 1. The angle of rotation for the OCS 1 is determined via a point on the pallet edge.

The following methods are used for calibration:

- 3D kinematics: "Move and rotate" calibration method
- 3D kinematics with orientation: "Move and rotate around z" calibration method

Coordinates of the points used in the example

① Point P1 on pallet corner

② Point at pallet edge
The rotated x axis now runs through this point

③ Angle of rotation OCS 1

		Position in the WCS (mm)		
		x	y	z
①	Point P1 on pallet corner	600.0	600.0	144.0
②	Point at pallet edge	1000.0	1000.0	144.0

3D kinematics: "Move and rotate" calibration method

1. Select the object coordinate system "OCS 1".
2. Select the "Move and rotate" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol ←1 next to the field "Position in WCS".

   You have defined the origin of the OCS 1 with point P1.

Define the angle of rotation ③ for the OCS 1 as follows:

1. Select the z axis as the coordinate axis around which the OCS 1 is rotated.
2. Select the x axis as the coordinate axis that is rotated around the z axis to the TCP or point ②.
3. Move the kinematics to the point ② at the pallet edge.
4. Rotate OCS 1 by clicking on the symbol ←1 next to the field for the angle.

   The set angle of rotation ③ is shown in the field and in the graphic display . The rotated x axis now runs through the point ②.

The position of the OCS 1 is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

3D kinematics with orientation: "Move and rotate around z" calibration method

1. Select the object coordinate system "OCS 1".
2. Select the "Move and rotate around z" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the point P1 ① on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol ←1 next to the field "Position in WCS".

   You have defined the origin of the OCS 1 with point P1 ①.

Define the angle of rotation ③ for the OCS 1 as follows:

1. Select the rotation of the x axis around the z axis.

   In this way, you specify that the x axis is rotated around the z axis to the TCP or point ②.
2. Move the kinematics to the point ② at the pallet edge.
3. Rotate OCS 1 by clicking on the symbol ←1 next to the field for the angle.

   The set angle of rotation ③ is shown in the field and in the graphic display . The rotated x axis now runs through the point ②.

The position of the OCS 1 is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

13.6.7.5 Move OCS 1 and rotate it around the z axis and y axis

Introduction

The pallet was tilted and also rotated horizontally.

3D kinematics: "Plane" calibration method

Three points on the pallet surface are used to determine the new position of the OCS 1 frame.

The origin of the OCS 1 is determined via the position of a pallet corner. The positions of the other two points are used to determine the angles of rotation for the OCS 1.

The "Plane" calibration method is used for calibration with 3D kinematics.

Coordinates of the points used in the example

① Point pallet corner as origin of the OCS 1

② Point at pallet edge
The set point through which the rotated x axis passes defines the angle of rotation for the x axis.

③ Angle of rotation for the x axis

④ Point on pallet surface
The set point, together with the first two points, defines the selected xy plane.

⑤ xy plane which passes through the three set points

		Position in the WCS (mm)		
		x	y	z
①	Point pallet corner	549.1	549.1	124.7
②	Point pallet edge	916.5	916.5	424.7
④	Point pallet surface	633.7	1199.3	424.7

1. Select the object coordinate system "OCS 1".
2. Select the "Plane" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to point P1 on the pallet.
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol ↵1 next to the field "Position in WCS".

   You have defined the origin for OCS 1.

Define the angle of rotation for the OCS 1 as follows:

1. Select the x axis as the coordinate axis to be rotated to the TCP or point ②.
2. Move the kinematics to the point ② at the pallet edge.
3. Rotate OCS 1 by clicking on the symbol next to the field for the coordinate axis.
   The set angles of rotation are shown in the graphic display.
4. Select the xy plane to be spanned between the three set points.
5. Move the kinematics to the point ④ on the pallet surface.
6. To align the OCS 1, click the symbol next to the field for the plane.
   The spanned plane is shown in the graphic display.

The position of the OCS 1 is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

3D kinematics: "Three-point" calibration method

Three corner points of the pallet are used to determine the new position of the OCS 1 frame.

The positions of the corner points in OCS 1 can be derived from the dimensions of the pallet. The position of the corner points in the WCS is determined using the "three-point" method.

The origin of the OCS 1 is determined via the position of a pallet corner. The positions of the other two corner points are used to determine the angles of rotation for OCS 1.

Coordinates of the points used in the example

	Position in the WCS (mm)			Position in the OCS (mm)		
	x	y	z	x	y	z
Point P1 pallet corner	549.1	549.1	124.7	0.0	0.0	0.0
Point P2 pallet corner	1283.9	1283.9	724.7	1200.0	0.0	0.0
Point P3 pallet corner	-16.6	1114.8	124.7	0.0	800.0	0.0

1. Select the object coordinate system "OCS 1".
2. Select the "Plane" calibration method in the drop-down list.

Define the origin for the OCS 1 as follows:

1. Move the kinematics to the pallet corner (point P1).
2. Accept the position coordinates of the TCP in WCS by clicking on the symbol next to the field "Position in WCS".
3. For the point P1, enter the values for the position in OCS 1.

   You have defined the origin of OCS 1.

Define the angle of rotation for the OCS 1 as follows:

1. Move the kinematics to the second pallet corner (point P2).
2. Define the coordinates for point P2 in the WCS by adopting the current position values of TCP. Click the symbol next to the "Position in WCS" box.
3. For the point P2, enter the values for the position in the OCS.
4. Move the kinematics to point P3 on the pallet.
5. Define the coordinates for point P3 in the WCS by adopting the current position values of the TCP. Click the symbol next to the "Position in WCS" box.
6. For the point P3, enter the values for the position in the OCS.

The position of the OCS is thus unambiguously determined and the "Apply values" button is active.

1. Accept the values from the calibration into the configuration.

13.7 Calibrate workspace zones

13.7.1 Configuring calibration of a workspace zone

Requirement

The kinematics technology object is correctly configured and connected.

Configuring zone properties

1. In the "Workspace zone" drop-down list, select the zone you want to calibrate.

   If you have opened the calibration for a zone via the symbol in the configuration window "Configuration > Extended parameters > Zones", the corresponding zone is already preselected. If you open the calibration via the project tree, workspace zone 1 is preselected.
2. In the "Status" drop-down list, select the activation status "Active" or "Inactive".

   If you select status "Not defined", all other settings in the configuration mask for the calibration are deactivated.
3. In the "Zone type" drop-down list, select the Blocked zone or Signal zone work zone type.
4. In the "Geometry" drop-down list, select the shape Cuboid, Cylinder or Sphere.
5. In the "Coordinate system" drop-down list, select the "WCS" or an "OCS".

You can find more information on the zone parameters in the section "Defining zones (Page 211)".

Selecting the suitable calibration method

The selectable calibration methods are dependent on the selected geometry of the zone. The calibration methods "circular plane" and "radius" are not suitable for calibrating zones containing obstacles as the zones are traversed during calibration. As a result, these two calibration methods for calibrating blocked and signal zones which usually contain obstacles are not suitable.

The following table shows an overview of the calibration methods that are suitable for the selected type of zone:

Selected zone type	Suitable calibration methods		
	Cuboid	Cylinder	Sphere
Work zone	Corner points (Page 379)	Circular plane (Page 381)	Radius (Page 383)
Signal zones		Surface line (Page 380)	Diameter (Page 382)
Blocked zones			

The individual points are fixed for each calibration method. However, you can calibrate the individual points in any order.

13.7.2 Calibrate cuboid zone with corner points

You calibrate a cuboid workspace zone using the "Corner points" calibration method.

Definition

With this calibration method, the cuboid zone is defined by the position values of three or four corner points.

A cuboid workspace zone for 2D kinematics is defined by three points.

Requirements

- The kinematics technology object is correctly configured and connected.
- You have selected a cuboid workspace zone for the calibration.

Procedure

1. Enter the origin of the cuboid as point P1.
2. Starting from the origin, use the other points to determine the edge lengths in x, y and z direction.

13.7.3 Calibrate cylindrical zone with surface line

A cylindrical signal or blocked zone is calibrated using the "Surface line" calibration method.

Definition

With this calibration method, the cylindrical zone is defined by the points of the surface line and the diameter.

Requirements

- The kinematics technology object is correctly configured and connected.
- You have selected a cylindrical signal or blocked zone for the calibration.

Procedure

1. Set the point P1 as the start of the surface line.
2. Set point P2 as the end of the surface line.

   With the points P1 and P2 you have defined the surface line of the cylinder. The surface line defines the height and orientation of the cylinder.
3. To define the diameter of the cylinder, set point P3 diametrically to the surface line P1 ↔ P2.

   The surface opposite the P1 ↔ P2 surface line runs through the point P3. As the height of the cylinder is defined by surface line P1 ↔ P2, you can also set point P3 outside the cylinder height.

13.7.4 Calibrate cylindrical zone with circular plane

You calibrate a cylindrical workspace zone using the "Circular plane" calibration method.

Definition

With this calibration method, the cylindrical zone is defined by the points of the circular plane and the height.

Requirements

- The kinematics technology object is correctly configured and connected.
- You have selected a cylindrical work zone for the calibration.

Procedure

1. Set the point P1 on the circumference of the cylinder.
2. Set point P2 diametrically to point P1 and on the circumference of the cylinder.

   With points P1 and P2, you have defined the diameter and orientation of the cylinder.
3. To define the height of the cylinder, set point P3 at distance h from the circular plane.

   Since point P3 only determines the height of the cylinder, you can also set point P3 outside the previously set cylinder width.

13.7.5 Calibrate spherical zone with diameter

You calibrate a spherical signal or blocked zone using the "Diameter" calibration method.

Definition

With this calibration method, the spherical zone is defined by two points for the diameter.

Requirements

- The kinematics technology object is correctly configured and connected.
- You have selected a spherical signal or blocked zone for the calibration.

Procedure

1. Enter the first point on the surface of the sphere as point P1.
2. To form the diameter, enter the point P2 on the surface of the sphere and diametrical to the point P1.

13.7.6 Calibrate spherical zone with radius

You calibrate a spherical workspace zone using the "Radius" calibration method.

Definition

With this calibration method, the spherical zone is defined by two points for the radius.

Requirements

- The kinematics technology object is correctly configured and connected.
- You have selected a spherical work zone for the calibration.

Procedure

1. Enter the origin of the sphere as point P1.
2. To determine the radius, set the second point P2 on the surface.

Instructions 14

14.1 Kinematics motions

14.1.1 MC_GroupInterrupt V10

14.1.1.1 MC_GroupInterrupt: Interrupt motion execution V10

Description

With the Motion Control instruction "MC_GroupInterrupt", you interrupt the execution of the motion on a kinematics technology object.

The Motion Control instruction offers you the following:

- Interrupting motion control at the kinematics technology object (Page 234)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- The interconnected axes are enabled.

Override response

The override response for "MC_GroupInterrupt" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GroupInterrupt":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge

Parameter	Declaration	Data type	Default value	Description	
Mode	INPUT	DINT	0	Mode for dynamic behavior (Page 234)	
				0	Stop with the dynamics of the motion job to be interrupted When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.
				1	Stop with maximum dynamics of kinematics motion When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.1.2 MC_GroupContinue V10

14.1.2.1 MC_GroupContinue: Continue motion execution V10

Description

With the Motion Control instruction "MC_GroupContinue", you continue a kinematics motion that was previously interrupted with a "MC_GroupInterrupt" job.

The Motion Control instruction offers you the following:

- Resuming interrupted motion control at the kinematics technology object (Page 234)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- The interconnected axes are enabled.

Override response

- An "MC_GroupContinue" job is not aborted by any other Motion Control job.
- A new "MC_GroupContinue" job aborts a current "MC_GroupInterrupt" job.
- The override response for "MC_GroupContinue" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GroupContinue":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.1.2.2 MC_GroupContinue: Function chart V10

Function chart: Continue motion execution

The kinematics is moved with an "MC_MoveLinearAbsolute" job (A1).

At time ①, the "MC_MoveLinearAbsolute" job is interrupted by an "MC_GroupInterrupt" job (A2). The kinematics is in "Interrupted" state. With "Mode" = 0 the motion is stopped with the dynamics of the "MC_MoveLinearAbsolute" job. The completion of the "MC_GroupInterrupt" job is reported via "Done_2".

At time ②, the "MC_MoveLinearAbsolute" job is continued by an "MC_GroupContinue" job (A3).

14.1.3 MC_GroupStop V10

14.1.3.1 MC_GroupStop: Stop motion V10

Description

With the Motion Control instruction "MC_GroupStop", you stop and abort an active motion on the kinematics technology object.

The Motion Control instruction offers you the following:

- Stopping active motion at the kinematics technology object (Page 234)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- The interconnected axes are enabled.

Override response

The override response for "MC_GroupStop" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_GroupStop":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	0	Mode for dynamic behavior (Page 234)	
				0	Stop with the dynamics of the motion job to be interrupted When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.

Parameter	Declaration	Data type	Default value	Description	
Mode	INPUT	DINT	0	1	Stop with maximum dynamics of kinematics motion When dynamic adaptation is activated, the dynamics of the motion can also be reduced so that the dynamic limits of the axes are not exceeded.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.1.3.2 MC_GroupStop: Function chart V10

Function chart: Stop motion

The kinematics is moved with an "MC_MoveLinearAbsolute" job (A1).

At time ①, the "MC_MoveLinearAbsolute" job is aborted by an "MC_GroupStop" job (A2). The job abort is signaled via "Abort_1". With "Mode" = 0 the motion is stopped with the dynamics of the "MC_MoveLinearAbsolute" job. The completion of the "MC_GroupStop" job is reported via "Done_2".

14.1.4 MC_MoveLinearAbsolute V10

14.1.4.1 MC_MoveLinearAbsolute: Position kinematics with linear path motion V10

Description

With the Motion Control instruction "MC_MoveLinearAbsolute", you move a kinematics with a linear motion (Page 258) to an absolute position. Cartesian orientation is also used absolute.

The Motion Control instruction offers you the following:

- Define absolute target position (Page 258)
- Define dynamics (Page 259)
- Define motion transition (Page 261)
- Start job (Page 263)
- Show motion status and remaining distance (Page 230)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveLinearAbsolute" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveLinearAbsolute":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Position	INPUT	ARRAY [1..6] OF LREAL	-	Absolute target coordinates in the specified reference coordinate system (Page 258)	
Position[1]	INPUT	LREAL	0.0	x coordinate	
Position[2]	INPUT	LREAL	0.0	y coordinate	
Position[3]	INPUT	LREAL	0.0	z coordinate	
Position[4]	INPUT	LREAL	0.0	A coordinate	
Position[5]	INPUT	LREAL	0.0	B coordinate[1)]	
Position[6]	INPUT	LREAL	0.0	C coordinate[1)]	
Velocity	INPUT	LREAL	-1.0	Velocity (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Jerk)
DirectionA	INPUT	DINT	3	Direction of movement of the Cartesian orientation A (Page 258)	
				1	Positive direction
				2	Negative direction
				3	Shortest distance
				With more than 4 interpolating kinematics axes: Not relevant	
CoordSystem	INPUT	DINT	0	Reference coordinate system (Page 258)	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
BufferMode	INPUT	DINT	1	Motion transition (Page 261)	
				1	Append motion
				2	Smooth with the lower velocity
				5	Smooth with the higher velocity
TransitionParameter	INPUT	ARRAY [1..5] OF LREAL		Transition parameter	
TransitionParameter[1]	INPUT	LREAL	-1.0	Rounding clearance (Page 261)	
				≥ 0.0	The specified value is used.
				< 0.0	The maximum possible rounding clearance is used.
TransitionParameter[2..5]	INPUT	LREAL	-	Reserved	
DynamicAdaption	INPUT	DINT	-1	Dynamic adaptation (Page 259)	
				< 0	The configured setting in "Technology object > Configuration > Extended parameters > Dynamic" is used. (<TO>.DynamicDefaults.DynamicAdaption)
				0	Without dynamic adaptation
				1	Dynamic adaptation with segmentation of the path
				2	Dynamic adaptation without segmentation of the path
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Active	OUTPUT	BOOL	FALSE	FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
RemainingDistance	OUTPUT	LREAL	-1.0	Remaining distance of the current job (Page 230)	

1) Only relevant with more than 4 interpolating kinematics axes.

14.1.4.2 MC_MoveLinearAbsolute: Function chart V10

Function chart: Position kinematics with linear path motion

The kinematics is moved with an "MC_MoveLinearAbsolute" job (A1).

At time ① an additional "MC_MoveLinearAbsolute" job (A2) is initiated. As the "MC_MoveLinearAbsolute" jobs have no override effect on one another, the job A2 is arranged in the job sequence.

At the point in time ②, completion of the A1 job is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 2 is set for job A2, the motion transition is blended with the lower velocity of the two jobs. As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.5 MC_MoveLinearRelative V10

14.1.5.1 MC_MoveLinearRelative: Relative positioning of kinematics with linear path motion V10

Description

With the Motion Control instruction "MC_MoveLinearRelative", you move a kinematics with a linear motion (Page 258) relative to the position which was present at the start of the job processing. Cartesian orientation is also used relative.

The Motion Control instruction offers you the following:

- Define relative target position (Page 258)
- Define dynamics (Page 259)
- Define motion transition (Page 261)
- Start job (Page 263)
- Show motion status and remaining distance (Page 230)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveLinearRelative" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveLinearRelative":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Distance	INPUT	ARRAY [1..6] OF LREAL	-	Relative target coordinates in the specified reference coordinate system (Page 258)	
Distance[1]	INPUT	LREAL	0.0	x coordinate	
Distance[2]	INPUT	LREAL	0.0	y coordinate	
Distance[3]	INPUT	LREAL	0.0	z coordinate	
Distance[4]	INPUT	LREAL	0.0	A coordinate	
Distance[5]	INPUT	LREAL	0.0	B coordinate[1)]	
Distance[6]	INPUT	LREAL	0.0	C coordinate[1)]	
Velocity	INPUT	LREAL	-1.0	Velocity (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 259)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Jerk	INPUT	LREAL	-1.0	< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Jerk)
CoordSystem	INPUT	DINT	0	Reference coordinate system (Page 258)	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
BufferMode	INPUT	DINT	1	Motion transition (Page 261)	
				1	Append motion
				2	Smooth with the lower velocity
				5	Smooth with the higher velocity
TransitionParameter	INPUT	ARRAY [1..5] OF LREAL	-	Transition parameter	
TransitionParameter[1]	INPUT	LREAL	-1.0	Rounding clearance (Page 261)	
				≥ 0.0	The specified value is used.
				< 0.0	The maximum possible rounding clearance is used.
TransitionParameter[2..-5]	INPUT	LREAL	-	Reserved	
DynamicAdaption	INPUT	DINT	-1	Dynamic adaptation (Page 259)	
				< 0	The configured setting in "Technology object > Configuration > Extended parameters > Dynamic" is used. (<TO>.DynamicDefaults.DynamicAdaption)
				0	Without dynamic adaptation
				1	Dynamic adaptation with segmentation of the path
				2	Dynamic adaptation without segmentation of the path
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
RemainingDistance	OUTPUT	LREAL	-1.0	Remaining distance of the current job (Page 230)	

1) Only relevant with more than 4 interpolating kinematics axes.

14.1.5.2 MC_MoveLinearRelative: Function chart V10

Function chart: Relative positioning of kinematics with linear path motion

The kinematics is moved with an "MC_MoveLinearRelative" job (A1).

At time ① an additional "MC_MoveLinearRelative" job (A2) is initiated. As the "MC_MoveLinearRelative" jobs have no override effect on one another, the job A2 is arranged in the job sequence.

At the point in time ②, completion of the A1 job is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 5 is set for job A2, the motion transition is blended with the higher velocity of the two jobs. As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.6 MC_MoveCircularAbsolute V10

14.1.6.1 MC_MoveCircularAbsolute: Position kinematics with circular path motion V10

Description

With the Motion Control instruction "MC_MoveCircularAbsolute", you move a kinematics with a circular motion (Page 265) to an absolute position. Cartesian orientation is also used absolute.

The Motion Control instruction offers you the following:

- Define circular path:
  - Define circular path via intermediate point and target position (Page 265)
  - Define circular path via center point and angle (Page 267)
  - Define circular path via radius and target position (Page 269)
- Define dynamics (Page 272)
- Define motion transition (Page 273)
- Start job (Page 276)
- Show motion status and remaining distance (Page 230)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveCircularAbsolute" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveCircularAbsolute":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
CircMode	INPUT	DINT	0	Definition of circular path	
				0	Define circular path via intermediate point and target position (Page 265)
				1	Define circular path via center point and angle (Page 267)
				2	Define circular path via radius and target position (Page 269)
AuxPoint	INPUT	ARRAY [1..3] OF LREAL	-	When "CircMode" = 0: Intermediate point on the circular path (Page 265)	
				When "CircMode" = 1: Center point of the circular path (Page 267)	
				When "CircMode" = 2: Not relevant	
AuxPoint[1]	INPUT	LREAL	0.0	x coordinate	
AuxPoint[2]	INPUT	LREAL	0.0	y coordinate	
AuxPoint[3]	INPUT	LREAL	0.0	z coordinate	
EndPoint	INPUT	ARRAY [1..6] OF LREAL	-	Target position in the specified reference coordinate system	
				When "CircMode" = 1: "EndPoint[1..3]" not relevant	
EndPoint[1]	INPUT	LREAL	0.0	x coordinate	
EndPoint[2]	INPUT	LREAL	0.0	y coordinate	
EndPoint[3]	INPUT	LREAL	0.0	z coordinate	
EndPoint[4]	INPUT	LREAL	0.0	A coordinate	
EndPoint[5]	INPUT	LREAL	0.0	B coordinate[1)]	
EndPoint[6]	INPUT	LREAL	0.0	C coordinate[1)]	
PathChoice	INPUT	DINT	0	When "CircMode" = 1: Orientation of the circular path (Page 267)	
				0	Positive direction of rotation
				1	Negative direction of rotation
				When "CircMode" = 2: Orientation of the circular path (Page 269)	
				0	Shorter positive circle segment
				1	Shorter negative circle segment
				2	Longer positive circle segment

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
PathChoice	INPUT	DINT	0	3	Longer negative circle segment
				When "CircMode" = 0: Not relevant	
CirclePlane	INPUT	DINT	0	When "CircMode" = 1 and 2: Main plane of the circular path	
				0	xz plane
				1	yz plane
				2	xy plane
				When "CircMode" = 0: Not relevant	
Radius	INPUT	LREAL	0.0	When "CircMode" = 2: Radius of the circular movement (Page 269)	
				When "CircMode" = 0 and 1: Not relevant	
Arc	INPUT	LREAL	0.0	When "CircMode" = 1: Angle of the circular movement (Page 267) The absolute value of the specified value is used.	
				When "CircMode" = 0 and 2: Not relevant	
Velocity	INPUT	LREAL	-1.0	Velocity (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Acceleration)
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation
				< 0.0	The value configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Jerk)
DirectionA	INPUT	DINT	3	Direction of movement of the Cartesian orientation A	
				1	Positive direction
				2	Negative direction
				3	Shortest distance
				With more than 4 interpolating kinematics axes: Not relevant	
CoordSystem	INPUT	DINT	0	Reference coordinate system	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
BufferMode	INPUT	DINT	1	Motion transition (Page 273)	
				1	Append motion
				2	Smooth with the lower velocity
				5	Smooth with the higher velocity
TransitionParameter	INPUT	ARRAY [1..5] OF LREAL		Transition parameter	
TransitionParameter[1]	INPUT	LREAL	-1.0	Rounding clearance (Page 273)	
				≥ 0.0	The specified value is used.
				< 0.0	The maximum possible rounding clearance is used.
TransitionParameter[2..5]	INPUT	LREAL	-	Reserved	
DynamicAdaption	INPUT	DINT	-1	Dynamic adaptation (Page 272)	
				< 0	The configured setting in "Technology object > Configuration > Extended parameters > Dynamic" is used. (<TO>.DynamicDefaults.DynamicAdaption)

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
DynamicAdaption	INPUT	DINT	-1	0	Without dynamic adaptation
				1	Dynamic adaptation with segmentation of the path
				2	Dynamic adaptation without segmentation of the path
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
RemainingDistance	OUTPUT	LREAL	-1.0	Remaining distance of the current job (Page 230)	

1) Only relevant with more than 4 interpolating kinematics axes.

14.1.6.2 MC_MoveCircularAbsolute: Function chart V10

Function chart: Position kinematics with circular path motion

In the function chart, sections A1 and A2 of the following kinematics motion are viewed:

The kinematics is moved with an "MC_MoveLinearAbsolute" job (A1).

At time ① an "MC_MoveCircularAbsolute" job (A2) is initiated. As the "MC_MoveCircularAbsolute" job has no overdrive effect, the job A2 is arranged in the job sequence.

At the point in time ②, completion of the A1 job is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 2 is set for job A2, the motion transition is smoothed with the lower velocity of both jobs and the rounding clearance d_1. The circular motion is determined with "CircMode" = 1 via the center of the circle ($x_2|y_2|z_2$) and the angle α. As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.7 MC_MoveCircularRelative V10

14.1.7.1 MC_MoveCircularRelative: Relative positioning of kinematics with circular path motion V10

Description

With the Motion Control instruction "MC_MoveCircularRelative", you move a kinematics with a circular motion (Page 265) to a relative position. Cartesian orientation is also used relative.

The Motion Control instruction offers you the following:

- Define circular path:
  - Define circular path via intermediate point and target position (Page 265)
  - Define circular path via center point and angle (Page 267)
  - Define circular path via radius and target position (Page 269)
- Define dynamic response (Page 272)
- Define motion transition (Page 273)
- Start job (Page 276)
- Show motion status and remaining distance (Page 230)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveCircularRelative" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveCircularRelative":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
CircMode	INPUT	DINT	0	Definition of circular path	
				0	Define circular path via intermediate point and target position (Page 265)
				1	Define circular path via center point and angle (Page 267)
				2	Define circular path via radius and target position (Page 269)
AuxPoint	INPUT	ARRAY [1..3] OF LREAL	-	When "CircMode" = 0: Intermediate point on the circular path relative to the start position (Page 265)	
				When "CircMode" = 1: Center point of the circular path relative to the start position (Page 267)	
				When "CircMode" = 2: Not relevant	
AuxPoint[1]	INPUT	LREAL	0.0	x coordinate	
AuxPoint[2]	INPUT	LREAL	0.0	y coordinate	
AuxPoint[3]	INPUT	LREAL	0.0	z coordinate	
EndPoint	INPUT	ARRAY [1..6] OF LREAL	-	Target position relative to the start position in the specified reference coordinate system	
				When "CircMode" = 1: "EndPoint[1..3]" not relevant	
EndPoint[1]	INPUT	LREAL	0.0	x coordinate	
EndPoint[2]	INPUT	LREAL	0.0	y coordinate	
EndPoint[3]	INPUT	LREAL	0.0	z coordinate	
EndPoint[4]	INPUT	LREAL	0.0	A coordinate	
EndPoint[5]	INPUT	LREAL	0.0	B coordinates[1)]	
EndPoint[6]	INPUT	LREAL	0.0	C coordinates[1)]	
PathChoice	INPUT	DINT	0	When "CircMode" = 1: Orientation of the circular path (Page 267)	

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
PathChoice	INPUT	DINT	0	0	Positive direction of rotation
				1	Negative direction of rotation
				When "CircMode" = 2: Orientation of the circular path (Page 269)	
				0	Shorter positive circular path
				1	Shorter negative circular path
				2	Longer positive circular path
				3	Longer negative circular path
				When "CircMode" = 0: Not relevant	
CirclePlane	INPUT	DINT	0	When "CircMode" = 1 and 2: Main plane of the circular path	
				0	xz plane
				1	yz plane
				2	xy plane
				When "CircMode" = 0: Not relevant	
Radius	INPUT	LREAL	0.0	When "CircMode" = 2: Radius of the circular movement (Page 269)	
				When "CircMode" = 0 and 1: Not relevant	
Arc	INPUT	LREAL	0.0	When "CircMode" = 1: Angle of the circular movement (Page 267) The absolute value of the specified value is used.	
				When "CircMode" = 0 and 2: Not relevant	
Velocity	INPUT	LREAL	-1.0	Velocity (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Velocity)
Acceleration	INPUT	LREAL	-1.0	Acceleration (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Acceleration)

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
Deceleration	INPUT	LREAL	-1.0	Deceleration (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	Not permitted
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Deceleration)
Jerk	INPUT	LREAL	-1.0	Jerk (Page 272)	
				> 0.0	The specified value is used.
				= 0.0	No jerk limitation
				< 0.0	The velocity configured in "Technology object > Configuration > Extended parameters > Dynamic default values" is used. (<TO>.DynamicDefaults.Path.Jerk)
CoordSystem	INPUT	DINT	0	Reference coordinate system	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
BufferMode	INPUT	DINT	1	Motion transition (Page 273)	
				1	Append motion
				2	Smooth with the lower velocity
				5	Smooth with the higher velocity
TransitionParameter	INPUT	ARRAY [1..5] OF LREAL		Transition parameter	
TransitionParameter[1]	INPUT	LREAL	-1.0	Rounding clearance (Page 273)	
				≥ 0.0	The specified value is used.
				< 0.0	The maximum possible rounding clearance is used.
TransitionParameter[2..5]	INPUT	LREAL	-	Reserved	
DynamicAdaption	INPUT	DINT	-1	Dynamic adaptation (Page 272)	
				< 0	The configured setting in "Technology object > Configuration > Extended parameters > Dynamic" is used. (<TO>.DynamicDefaults.DynamicAdaption)
				0	Without dynamic adaptation
				1	Dynamic adaptation with segmentation of the path

1) Only relevant with more than 4 interpolating kinematics axes.

Parameter	Declaration	Data type	Default value	Description	
DynamicAdaption	INPUT	DINT	-1	2	Dynamic adaptation without segmentation of the path
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
RemainingDistance	OUTPUT	LREAL	-1.0	Remaining distance of the current job (Page 230)	

1) Only relevant with more than 4 interpolating kinematics axes.

14.1.7.2 MC_MoveCircularRelative: Function chart V10

Function chart: Relative positioning of kinematics with circular path motion

In the function chart, sections A1 and A2 of the following kinematics motion are viewed:

The kinematics is moved with an "MC_MoveLinearRelative" job (A1).

At time ① an "MC_MoveCircularRelative" job (A2) is initiated. As the "MC_MoveCircularRelative" job has no overdrive effect, the job A2 is arranged in the job sequence.

At the point in time ②, completion of the A1 job is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 2 is set for job A2, the motion transition is smoothed with the lower velocity of both jobs and the rounding clearance d_1. The circular motion is determined with "CircMode" = 2 via the radius r and the end point (x_2|y_2|z_2). As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.8 MC_MoveDirectAbsolute V10

14.1.8.1 MC_MoveDirectAbsolute: Absolute movement of kinematics with synchronous "point-to-point" motion V10

Description

With the Motion Control instruction "MC_MoveDirectAbsolute", you can move the kinematics with a synchronous "point-to-point" motion (sPTP motion) (Page 278) to absolute positions. All kinematics axes are moved at the same time. The axes start the movement at the same time and reach the target position at the same time.

The movement path of the tool center point (TCP) results from the dynamic values of the axes. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes. The position of the TCP results from the positions of the kinematics axes.

The Motion Control instruction offers you the following:

- Define target position:
  - Define absolute axis target positions (Page 279)
  - Define absolute joint target positions (Page 280)
  - Defining absolute Cartesian target coordinates (Page 281)
- Define dynamic factors (Page 283)
- Define motion transition (Page 284)
- Start job and show execution progress (Page 286)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveDirectAbsolute" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveDirectAbsolute":

Parameter	Declaration	Data type	Default value	Description
AxesGroup	INPUT	TO_Kinematics	-	Technology object
Execute	INPUT	BOOL	FALSE	TRUE: Start job with a positive edge
Position	INPUT	ARRAY [1..6] OF LREAL	-	When "CoordSystem" = 100: Absolute axis positions (Page 279)
				When "CoordSystem" = 101[1) 2)]: Absolute joint positions (Page 280)
				When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 1: Absolute Cartesian target coordinates in the specified reference coordinate system (Page 281)
				When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 2: Absolute Cartesian position and relative Cartesian orientation (Page 281)
Position[1]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Position of axis A1
				When "CoordSystem" = 101[1) 2)]: Position of joint J1
				When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 1 or 2: x coordinate
Position[2]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Position of axis A2
				When "CoordSystem" = 101[1) 2)]: Position of joint J2
				When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 1 or 2: y coordinate
Position[3]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Position of axis A3
				When "CoordSystem" = 101[1) 2)]: Position of joint J3

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

Parameter	Declaration	Data type	Default value	Description
Position[3]	INPUT	LREAL	0.0	When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 1 or 2: z coordinate
Position[4]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Position of axis A4
				When "CoordSystem" = 101[1) 2)]: Position of joint J4
				When "CoordSystem" = 0, 1, 2 or 3 and "PositionMode" = 1 or 2: A coordinate
Position[5]	INPUT	LREAL	0.0	When "CoordSystem" = 100[1)]: Position of axis A5
				When "CoordSystem" = 101[1)]: Position of joint J5
				When "CoordSystem" = 0, 1, 2 or 3[1)]: B coordinate
				With up to 4 interpolating kinematics axes: Not relevant
Position[6]	INPUT	LREAL	0.0	When "CoordSystem" = 100[1)]: Position of axis A6
				When "CoordSystem" = 101[1)]: Position of joint J6
				When "CoordSystem" = 0, 1, 2 or 3[1)]: C coordinate
				With up to 4 interpolating kinematics axes: Not relevant
VelocityFactor	INPUT	LREAL	-1.0	Factor for the velocity (Page 283) of axis motions in relation to the respective maximum velocity of the axes (<TO>.DynamicLimits.MaxVelocity) Permitted range of values: Factor < 0.0 and 0.01 ≤ Factor ≤ 1.0
				< 0.0 — The velocity factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.VelocityFactor)
				≥ 0.01 — The specified factor is used.
				1.0 — The maximum velocity of the axes is used.
AccelerationFactor	INPUT	LREAL	-1.0	Factor for the acceleration (Page 283) of axis motions in relation to the respective maximum acceleration of the axis (<TO>.DynamicLimits.MaxAcceleration) Permitted range of values: Factor ≤ 1.0

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

Parameter	Declaration	Data type	Default value	Description	
AccelerationFactor	INPUT	LREAL	-1.0	< 0.0	The acceleration factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.AccelerationFactor)
				0.0	Not permitted
				> 0.0	The specified factor is used.
				1.0	The maximum acceleration of the axes is used.
DecelerationFactor	INPUT	LREAL	-1.0	Factor for the deceleration (Page 283) of axis motions in relation to the respective maximum deceleration of the axis (<TO>.DynamicLimits.MaxDeceleration) Permitted range of values: Factor ≤ 1.0	
				< 0.0	The deceleration factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.DecelerationFactor)
				0.0	Not permitted
				> 0.0	The specified factor is used.
				1.0	The maximum deceleration of the axes is used.
JerkFactor	INPUT	LREAL	-1.0	Factor for the jerk (Page 283) of axis motions in relation to the respective maximum jerk of the axis (<TO>.DynamicLimits.MaxJerk) Permitted range of values: Factor < 0.0 and 0.1 < Factor ≤ 0.9	
				< 0.0	The jerk factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.JerkFactor)
				0.0	No jerk limitation
				≥ 0.1	The specified factor is used.
LinkConstellation	INPUT	DWORD	16#FFFF FFFF	When "CoordSystem" = 0, 1, 2 or 3: Target joint position space (Page 281) The joint position space is specified depending on the respective kinematics type (Page 58).	
				#FFFF FFFF	Keep current joint position space

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

14.1.8.2 MC_MoveDirectAbsolute: Function chart V10

Function chart: Absolute movement of kinematics with synchronous "point-to-point" motion

The kinematics is moved with an "MC_MoveDirectAbsolute" job (A1).

At time ①, an additional "MC_MoveDirectAbsolute" job (A2) is initiated. As the "MC_MoveDirectAbsolute" jobs have no override effect on one another, the job A2 is arranged in the job sequence.

At time ②, completion of the job A1 is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 2 is set for job A2, the motion transition is blended with the lower velocity of the two jobs. As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.9 MC_MoveDirectRelative V10

14.1.9.1 MC_MoveDirectRelative: Relative movement of kinematics with synchronous "point-to-point" motion V10

Description

With the Motion Control instruction "MC_MoveDirectRelative", you can move the kinematics with a synchronous "point-to-point" motion (sPTP motion) (Page 278) to relative positions. All kinematics axes are moved at the same time. The axes start the movement at the same time and reach the target position at the same time.

The movement path of the tool center point (TCP) results from the dynamic values of the axes. The kinematics axis with the longest travel time determines the travel time of the sPTP motion and therefore the travel time of all other kinematics axes. The position of the TCP results from the positions of the kinematics axes.

The Motion Control instruction offers you the following:

- Define target position:
  - Define relative axis target positions (Page 279)
  - Define relative joint target positions (Page 280)
  - Define relative Cartesian target coordinates (Page 281)
- Define dynamic factors (Page 283)
- Define motion transition (Page 284)
- Start job and show execution progress (Page 286)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

With the "TransitionParameter[1]" parameter, you determine the distance from the target point of the previous motion job at which the new motion job is superimposed.

The override response for "MC_MoveDirectRelative" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_MoveDirectRelative":

Parameter	Declaration	Data type	Default value	Description
AxesGroup	INPUT	TO_Kinematics	-	Technology object
Execute	INPUT	BOOL	FALSE	TRUE: Start job with a positive edge
Distance	INPUT	ARRAY [1..6] OF LREAL	-	When "CoordSystem" = 100: Relative axis positions (Page 279)
				When "CoordSystem" = 101[1) 2)]: Relative joint positions (Page 280)
				When "CoordSystem" = 0, 1, 2 or 3: Relative target coordinates in the specified reference coordinate system (Page 281)
Distance[1]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Relative position of the axis A1
				When "CoordSystem" = 101[1) 2)]: Relative position of joint J1
				When "CoordSystem" = 0, 1, 2 or 3: x coordinate
Distance[2]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Relative position of the axis A2
				When "CoordSystem" = 101[1) 2)]: Relative position of joint J2
				When "CoordSystem" = 0, 1, 2 or 3: y coordinate
Distance[3]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Relative position of the axis A3
				When "CoordSystem" = 101[1) 2)]: Relative position of joint J3
				When "CoordSystem" = 0, 1, 2 or 3: z coordinate
Distance[4]	INPUT	LREAL	0.0	When "CoordSystem" = 100: Relative position of the axis A4
				When "CoordSystem" = 101[1) 2)]: Relative position of joint J4
				When "CoordSystem" = 0, 1, 2 or 3: A coordinate
Distance[5]	INPUT	LREAL	0.0	When "CoordSystem" = 100[1)]: Relative position of axis A5
				When "CoordSystem" = 101[1)]: Relative position of joint J5
				When "CoordSystem" = 0, 1, 2 or 3[1)]: B coordinate

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

Parameter	Declaration	Data type	Default value	Description
Distance[5]	INPUT	LREAL	0.0	With up to 4 interpolating kinematics axes: Not relevant
Distance[6]	INPUT	LREAL	0.0	When "CoordSystem" = 100[1]: Relative position of axis A6
				When "CoordSystem" = 101[1]: Relative position of joint J6
				When "CoordSystem" = 0, 1, 2 or 3[1]: C coordinate
				With up to 4 interpolating kinematics axes: Not relevant
VelocityFactor	INPUT	LREAL	-1.0	Factor for the velocity (Page 283) of axis motions in relation to the respective maximum velocity of the axes (<TO>.DynamicLimits.MaxVelocity) Permitted range of values: Factor < 0.0 and 0.01 ≤ Factor ≤ 1.0
				< 0.0: The velocity factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.VelocityFactor)
				≥ 0.01: The specified factor is used.
				1.0: The maximum velocity of the axes is used.
AccelerationFactor	INPUT	LREAL	-1.0	Factor for the acceleration (Page 283) of axis motions in relation to the respective maximum acceleration of the axis (<TO>.DynamicLimits.MaxAcceleration) Permitted range of values: Factor ≤ 1.0
				< 0.0: The acceleration factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.AccelerationFactor)
				0.0: Not permitted
				> 0.0: The specified factor is used.
				1.0: The maximum acceleration of the axes is used.
DecelerationFactor	INPUT	LREAL	-1.0	Factor for the deceleration (Page 283) of axis motions in relation to the respective maximum deceleration of the axis (<TO>.DynamicLimits.MaxDeceleration) Permitted range of values: Factor ≤ 1.0

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

Parameter	Declaration	Data type	Default value	Description	
DecelerationFactor	INPUT	LREAL	-1.0	< 0.0	The deceleration factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.DecelerationFactor)
				0.0	Not permitted
				> 0.0	The specified factor is used.
				1.0	The maximum deceleration of the axes is used.
JerkFactor	INPUT	LREAL	-1.0	Factor for the jerk (Page 283) of axis motions in relation to the respective maximum jerk of the axis (<TO>.DynamicLimits.MaxJerk) Permitted range of values: Factor < 0.0 and 0.1 < Factor ≤ 0.9	
				< 0.0	The jerk factor configured under "Technology object > Configuration > Extended parameters > Dynamics > Settings for sPTP motion" is used. (<TO>.DynamicDefaults.MoveDirect.JerkFactor)
				0.0	No jerk limitation
				≥ 0.1	The specified factor is used.
LinkConstellation	INPUT	DWORD	16#FFFF FFFF	When "CoordSystem" = 0, 1, 2 or 3: Target joint position space (Page 281) The joint position space is specified depending on the respective kinematics type (Page 58).	
				#FFFF FFFF	Keep current joint position space
				When "CoordSystem" = 100 or 101: Not relevant	
CoordSystem	INPUT	DINT	0	Reference coordinate system	
				0	World coordinate system (WCS)

				3	540 ≤ position < 900
				n (n > 0)	-180° + (n - 1) · 360° ≤ Position < 180° + (n - 1) · 360°
ExecutionTimeStatus	OUTPUT	LREAL	0.0	Display of execution progress (Page 286) Value range: 0.0 ... 1.0 The job is completed with "ExecutionTimeStatus" = 1.0.	
				0.0	The job has not yet been executed.
				> 0.0	The job is being executed.
				1.0	The job was executed.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Active	OUTPUT	BOOL	FALSE	TRUE	The setpoints are calculated.
				FALSE	When "Busy" = TRUE: Job is waiting. (Typical: A preceding job is still active.)

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint target position in the JCS corresponds to the axis target position in the MCS.

14.1.9.2 MC_MoveDirectRelative: Function chart V10

Function chart: Relative movement of kinematics with synchronous "point-to-point" motion

The kinematics is moved with an "MC_MoveDirectRelative" job (A1).

At time ①, an additional "MC_MoveDirectRelative" job (A2) is initiated. As the "MC_MoveDirectRelative" jobs have no override effect on one another, the job A2 is arranged in the job sequence.

At time ②, completion of the job A1 is signaled via "Done_1" and the job A2 is started. As "BufferMode" = 5 is set for job A2, the motion transition is blended with the higher velocity of the two jobs. As soon as the target position is reached, the completion of the A2 job is signaled via "Done_2".

14.1.10 MC_TrackConveyorBelt V10

14.1.10.1 MC_TrackConveyorBelt: Start conveyor tracking V10

Description

With the "MC_TrackConveyorBelt" Motion Control instruction, an OCS is assigned to a leading value-capable technology object which represents the conveyor belt.

The Motion Control instruction offers you the following:

- Assigning tracked OCS and defining reference position (Page 290)

Applies to

- Kinematics

Requirement

- The technology objects have been configured correctly.
- You have selected a kinematics type that can execute path motion jobs.
- There is no active single axis job (e.g. "MC_MoveVelocity") on the interconnected axes.

Override response

- A "MC_SetOcsFrame" job cancels the tracking of the OCS with a leading value-capable technology object.
- A technology alarm on the kinematics, with the alarm response of terminating the motion, cancels the tracking of the OCS on the conveyor.
- The override response for "MC_TrackConveyorBelt" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_TrackConveyorBelt":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Kinematics technology object	
ConveyorBelt	INPUT	TO_PositioningAxis TO_SynchronousAxis TO_ExternalEncoder TO_LeadingAxisProxy	-	Leading value-capable technology object to which the OCS is coupled. Leading-value-capable technology objects are: • Positioning axis • Synchronous axis • External encoder • Leading axis proxy	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ConveyorBeltOrigin	INPUT	TO_Struct_Kinematics_Frame	-	Frame for the OCS reference position on the conveyor	
InitialObjectPosition	INPUT	TO_Struct_Kinematics_Frame	0.0	"InitialObjectPosition.x" contains the differential value on the belt position to determine the tracked position of the OCS in relation to the OCS reference position Permitted values: • "InitialObjectPosition.x" <=> 0.0 • "InitialObjectPosition.y" = 0.0 • "InitialObjectPosition.z" = 0.0 • "InitialObjectPosition.a" = 0.0 • "InitialObjectPosition.b" = 0.0 • "InitialObjectPosition.c" = 0.0	
CoordSystem	INPUT	DINT	1	Number of the tracked OCS	
				1	OCS1
				2	OCS2
				3	OCS3
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.1.10.2 MC_TrackConveyorBelt: Function chart V10

Function chart: Start conveyor tracking

Section A

The position of an object at time ① is recorded via a "MC_MeasuringInput" job (A1). The recorded position "MV" is reported via "Done_1" and written into the variable "CONV_POS.x".

With a "MC_TrackConveyorBelt" job (A2), an OCS is assigned at the time ② via the parameter "ConveyorBelt" to a leading-value capable technology object, which represents the conveyor belt. The OCS is assigned to a known conveyor position to this purpose. The OCS is assigned with the OCS frame and the object position to an object on the conveyor.

The "ObjectPosition" is calculated from the conveyor position minus the "InitialObjectPosition". In the present case the "InitialObjectPosition" is the position of the conveyor ("MV") at the time ①.

The status of conveyor tracking ("TrackingState") changes from 0 to 1.

Via a "MC_MoveLinearAbsolute" job at the time ③ the kinematics is moved to the position specified in the OCS. When the kinematics moves to the object position, the status of conveyor tracking changes from 1 to 2. When the kinematics follows the object position, the status of conveyor tracking changes from 2 to 3.

Section B

To complete the process of the kinematics with the tracked OCS, a "MC_MoveLinearAbsolute" job is started in the WCS at the time ④. When the kinematics moves to the position in WCS, the status of conveyor tracking changes from 3 to 4.

The completed conveyor tracking is reported via "Done_4" and the "TrackingState" changes to 0. The OCS is not tracked with the conveyor position anymore.

14.1.11 MC_KinematicsMotionSimulation V10

14.1.11.1 MC_KinematicsMotionSimulation: Start/end simulation of kinematics V10

Description

With the "MC_KinematicsMotionSimulation" Motion Control instruction, you start or end the simulation mode (Page 307) for a kinematics technology object.

The Motion Control instruction offers you the following:

- Interrupting a kinematics motion and locking kinematics axes (Page 307)
- Releasing kinematics axes and resuming kinematics motion (Page 308)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- The interconnected axes are enabled.
- When switching on and off, a single-axis job (e.g. "MC_MoveAbsolute") is not active on any of the interconnected axes.
- To exit the simulation with "Execute" = TRUE and "Mode" = 0, the kinematics axes must be at position "<TO>.AxesData.A[1..6].Position". A modulo axis must also be in the same modulo cycle as at the start time of the simulation.

Override response

An "MC_KinematicsMotionSimulation" job is not aborted by any other Motion Control job. You can add more motion jobs to the job sequence or cancel the kinematics motion with an "MC_GroupStop" job without exiting the simulation. The simulation remains active even when the kinematics axes is disabled with "MC_Power.Enable" = FALSE or "MC_Stop".

When a single-axis job is active on a kinematics axis when you exit the simulation, execution of the "MC_KinematicsMotionSimulation" job is rejected with an error.

A restart of the kinematics technology object or one of the kinematics axes terminates the kinematics motion and the simulation.

A new "MC_KinematicsMotionSimulation" job does not abort any other Motion Control jobs.

A new "MC_KinematicsMotionSimulation" job is aborted without errors in the following cases and has no effect:

- The kinematics are not in simulation mode when the job is started with "Execute" = TRUE and "Mode" = 0 .
- The kinematics are already in simulation mode when the job is started with "Execute" = TRUE and "Mode" = 1 .

Parameter

The following table shows the parameters of the Motion Control instruction "MC_KinematicsMotionSimulation":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Kinematics technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Mode	INPUT	DINT	FALSE	0	Exit simulation mode of the kinematics
				1	Set kinematics to simulation mode or leave in simulation
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	0	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.2 Zones

14.2.1 MC_DefineWorkspaceZone V10

14.2.1.1 MC_DefineWorkspaceZone: Define workspace zone V10

Description

With the Motion Control instruction "MC_DefineWorkspaceZone", you define a workspace zone in relation to the world coordinates system or an object coordinates system. The zones (<TO>.WorkspaceZone[1..10]) defined under "Technology object > Configuration > Extended parameters > Zones" are not hereby changed are available again after a restart of the technology object. The "<TO>.StatusWorkspaceZone" tag of the technology object data block contains the currently effective workspace zones.

The "MC_DefineWorkspaceZone" job interjects itself in the job sequence on the Kinematics technology object and therefore effective for the following motion jobs.

The Motion Control instruction offers you the following:

- Defining workspace zones (Page 211)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

- The override response for "MC_DefineWorkspaceZone" jobs is described in section "Override response V10: Kinematics motion commands".

Parameter

The following table shows the parameters of the Motion Control instruction "MC_DefineWorkspaceZone":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	The job is accepted in the job sequence.

Parameter	Declaration	Data type	Default value	Description	
ZoneType	INPUT	DINT	0	Zone type (Page 214)	
				0	Blocked zone
				1	Work zone
				2	Signal zone
ZoneNumber	INPUT	DINT	1	Zone number (Page 214)	
				1 to 10	Zone 1 ... 10
ReferenceSystem	INPUT	DINT	0	Reference coordinate system (Page 215)	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
Frame	INPUT	TO_Struct_Kinematics_-Frame	-	Offset of the zone zero point in relation to the reference system (Page 219)	
GeometryType	INPUT	DINT	0	Zone geometry type (Page 216)	
				0	Cuboid
				1	Sphere
				2	Cylinder
GeometryParameter	INPUT	ARRAY [1..3] OF LREAL	-	Geometric parameters (Page 216)	
GeometryParameter[1]	INPUT	LREAL	0.0	Length x	
				When "GeometryType" = 1 or 2: Radius	
GeometryParameter[2]	INPUT	LREAL	0.0	Length y	
				When "GeometryType" = 2: Height	
GeometryParameter[3]	INPUT	LREAL	0.0	Length z	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.2.2 MC_DefineKinematicsZone V10

14.2.2.1 MC_DefineKinematicsZone: Define kinematics zone V10

Description

With the Motion Control instruction "MC_DefineKinematicsZone", you define a kinematics zone in relation to the tool and flange coordinate system. The zones (<TO>.KinematicsZone[2..10]) defined under "Technology object > Configuration > Extended parameters > Zones" are not hereby changed are available again after a restart of the technology object. The "<TO>.StatusKinematicsZone" tag of the technology object data block contains the currently effective kinematics zones.

The "MC_DefineKinematicsZone" job is added to the queue of the job sequence and is therefore effective for subsequent motion jobs.

The Motion Control instruction offers you the following:

- Defining kinematics zones (Page 212)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

- The override response for "MC_DefineKinematicsZone" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_DefineKinematicsZone":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	The job is accepted in the job sequence.
ZoneNumber	INPUT	DINT	2	Zone number (Page 214)	
				2 ... 10	Zone 2 ... 10

Parameter	Declaration	Data type	Default value	Description	
ReferenceSystem	INPUT	DINT	0	Reference coordinate system (Page 215)	
				0	Flange coordinate system (FCS)
				1	Tool coordinate system (TCS)
Frame	INPUT	TO_Struct_Kinematics_-Frame	-	Offset of the zone zero point in relation to the reference system (Page 219)	
GeometryType	INPUT	DINT	0	Zone geometry type (Page 216)	
				0	Cuboid
				1	Sphere
				2	Cylinder
GeometryParameter	INPUT	ARRAY [1..3] OF LREAL	-	Geometric parameters (Page 216)	
GeometryParameter[1]	INPUT	LREAL	0.0	Length x	
				When "GeometryType" = 1 or 2: Radius	
GeometryParameter[2]	INPUT	LREAL	0.0	Length y	
				When "GeometryType" = 2: Height	
GeometryParameter[3]	INPUT	LREAL	0.0	Length z	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.2.3 MC_SetWorkspaceZoneActive V10

14.2.3.1 MC_SetWorkspaceZoneActive: Activate workspace zone V10

Description

You use the "MC_SetWorkspaceZoneActive" Motion Control instruction to set a defined workspace zone to active

The Motion Control instruction offers you the following:

- Activating zone monitoring (Page 219)

The "MC_SetWorkspaceZoneActive" job is added to the queue of the job sequence and is therefore effective for subsequent motion jobs. When an "MC_SetWorkspaceZoneActive" job becomes part of the job sequence, the zone specified at the "ZoneNumber" parameter must already be defined. Otherwise, the job is rejected with "ErrorID" = 16#80C7. You can ensure this as follows:

- Do not submit the "MC_SetWorkspaceZoneActive" job until the "MC_DefineWorkspaceZone" job is completed ("Done" = TRUE).
- Check whether the tag "StatusWorkspaceZone[1..10].Valid" = TRUE before you submit the "MC_SetWorkspaceZoneActive" job.

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.
- The zone to be activated is defined.

Override response

- The override response for "MC_SetWorkspaceZoneActive" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetWorkspaceZoneActive":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ZoneNumber	INPUT	DINT	1	Zone number	
				1 to 10	Zone 1 ... 10
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

14.2.4 MC_SetWorkspaceZoneInactive V10

14.2.4.1 MC_SetWorkspaceZoneInactive: Deactivate workspace zone V10

Description

You use the "MC_SetWorkspaceZoneInactive" Motion Control instruction to set one or more active workspace zones to inactive.

The Motion Control instruction offers you the following:

- Deactivating zone monitoring (Page 220)

The "MC_SetWorkspaceZoneInactive" job is added to the queue of the job sequence and is therefore effective for subsequent motion jobs.

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.
- The zone to be deactivated is defined.

Override response

- The override response for "MC_SetWorkspaceZoneInactive" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetWorkspaceZoneInactive":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ZoneNumber	INPUT	DINT	1	Zone number	
				1 to 10	Zone 1 ... 10
Mode	INPUT	DINT	0	Set zones of a zone type to inactive	
				0	Set a specific zone to inactive
				1	Set all workspace zones to inactive
				2	Set all blocked zones to inactive
				3	Set all signal zones to inactive
				4	Set workspace to inactive.
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

14.3 Tools

14.3.1 MC_DefineTool V10

14.3.1.1 MC_DefineTool: Redefine tool V10

Description

You redefine the tool frame for Tool 1 with the "MC_DefineTool" Motion Control instruction. The configured start values are not overwritten. Tool 1 is active by default.

The "MC_DefineTool" job is not added to the queue of the job sequence of the kinematics technology object and therefore takes effect immediately.

The Motion Control instruction offers you the following:

- Defining a tool frame for Tool 1 (Page 206)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.
- The kinematics is at a standstill.
- The kinematics is not in "Interrupted" state.
- No kinematics motion is active.

Override response

- An "MC_DefineTool" job cannot be aborted by any other Motion Control job.
- A new "MC_DefineTool" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_DefineTool":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
Frame	INPUT	TO_Struct_Kinematics_KinematicsFrame	-	Coordinates in relation to the FCS (Page 206)	
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.3.2 MC_SetTool V10

14.3.2.1 MC_SetTool: Change active tool V10

Description

With the "MC_SetTool" Motion Control instruction, you activate a tool.

The Motion Control instruction offers you the following:

- Setting a tool to active (Page 309)

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.
- The kinematics is at a standstill.
- The kinematics is not in "Interrupted" state.
- No kinematics motion is active.

Override response

- An "MC_SetTool" job cannot be aborted by any other Motion Control job.
- A new "MC_SetTool" job does not abort any active Motion Control job.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetTool":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	Start job with a positive edge
ToolNumber	INPUT	DINT	1	Number of the tool to be activated (Page 309)	
				1 to 3	Tool 1 to 3
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.4 Coordinate systems

14.4.1 MC_SetOcsFrame V10

14.4.1.1 MC_SetOcsFrame: Redefine object coordinate systems V10

Description

With the "MC_SetOcsFrame" Motion Control instruction, you define the position of an object coordinate system (OCS) in relation to the world coordinate system (WCS). The initial values stored in the technology object data block are not overwritten in the process.

The "MC_SetOcsFrame" job is added to the queue of the job sequence and is therefore effective only for subsequent motion jobs.

The Motion Control instruction offers you the following:

- Defining an OCS frame (Page 204)

Applies to

- Kinematics

Requirement

- The technology object has been configured correctly.
- A single axis job (e.g. "MC_MoveVelocity") is not active on any of the interconnected axes.

Override response

The override response for "MC_SetOcsFrame" jobs is described in section "Override response V10: Kinematics motion commands".

Parameters

The following table shows the parameters of the Motion Control instruction "MC_SetOcsFrame":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Execute	INPUT	BOOL	FALSE	TRUE	The job is accepted in the job sequence.
Frame	INPUT	TO_Struct_Kinematics_Frame	-	Coordinates in relation to the WCS (Page 204)	
OcsNumber	INPUT	DINT	1	Object coordinate system (Page 204)	

Parameter	Declaration	Data type	Default value	Description	
OcsNumber	INPUT	DINT	1	1 to 3	OCS1 to OCS3
Done	OUTPUT	BOOL	FALSE	TRUE	Job is completed. The new values are active for the display and the motion.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The job was aborted by another job during execution.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	

14.4.2 MC_KinematicsTransformation V10

14.4.2.1 MC_KinematicsTransformation: Convert axis coordinates to Cartesian coordinates V10

Description

With the Motion Control instruction "MC_KinematicsTransformation", you convert the setpoints of positions, velocity and acceleration of the kinematics axes or joints to Cartesian coordinates, velocity and acceleration of the tool center point (TCP). The active tool is hereby taken into consideration.

With the instruction, you can determine the Cartesian position, orientation, velocity and acceleration of the axis values or joints.

The instruction is for information purposes only - the kinematics is not moved.

Use the Motion Control instruction "MC_KinematicsTransformation" in the following organization blocks, depending on the kinematics type and the transformation of the values:

Transformation of values	Predefined kinematics	User-defined kinematics
Synchronous to the MC_Servo or MC_Interpolator cycle	MC_PreServo MC_PostServo MC_PreInterpolator	MC_PreInterpolator **Note** The call in MC_PreServo and MC_PostServo triggers technology alarm 803.
In the Main cycle	Main	Main

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.

Override response

- An "MC_KinematicsTransformation" job cannot be aborted by any other Motion Control job.
- A new "MC_KinematicsTransformation" job does not abort any active Motion Control jobs.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_KinematicsTransformation":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The calculation is carried out in the cycle of the calling organization block.
AxesPosition	INPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Positions of the kinematics axes	
				When "AxesCoordSystem" = 101[1]: Positions of the joints	
AxesPosition[1..6]	INPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Position of the axis A[1..6]	
				When "AxesCoordSystem" = 101[1]: Position of the joint J[1..6]	
AxesVelocity	INPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Velocity of kinematics axes	
				When "AxesCoordSystem" = 101[1]: Velocity of the joints	
AxesVelocity[1..6]	INPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Velocity of axis A[1..6]	
				When "AxesCoordSystem" = 101[1]: Velocity of the joint J[1..6]	
AxesAcceleration	INPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Acceleration of the kinematics axes	
				When "AxesCoordSystem" = 101[1]: Acceleration of the joints	
AxesAcceleration[1..6]	INPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Acceleration of the axis A[1..6]	
				When "AxesCoordSystem" = 101[1]: Acceleration of the joint J[1..6]	

[1] Only relevant with more than 4 interpolating kinematics axes.

[2] With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

Parameter	Declaration	Data type	Default value	Description	
CoordSystem	INPUT	DINT	0	Reference coordinate system of the output parameters	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
AxesCoordSystem	INPUT	DINT	100	Reference coordinate system of the input parameters	
				100	Machine coordinate system (MCS)
				101	Joint coordinate system (JCS)[1) 2)]
Valid	OUTPUT	BOOL	FALSE	TRUE	The output parameters are valid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
Position	OUTPUT	ARRAY[1..6] OF LREAL	-	Cartesian position of the TCP in the reference coordinate system	
Position[1]	OUTPUT	LREAL	0.0	x coordinate	
Position[2]	OUTPUT	LREAL	0.0	y-coordinate	
Position[3]	OUTPUT	LREAL	0.0	z coordinate	
Position[4]	OUTPUT	LREAL	0.0	A coordinate	
Position[5]	OUTPUT	LREAL	0.0	B coordinate[1)]	
Position[6]	OUTPUT	LREAL	0.0	C coordinate[1)]	
Velocity	OUTPUT	ARRAY[1..6] OF LREAL	-	Cartesian velocity of the TCP	
Velocity[1]	OUTPUT	LREAL	0.0	Velocity in x direction	
Velocity[2]	OUTPUT	LREAL	0.0	Velocity in y direction	
Velocity[3]	OUTPUT	LREAL	0.0	Velocity in z direction	
Velocity[4]	OUTPUT	LREAL	0.0	Velocity of rotation A	
Velocity[5]	OUTPUT	LREAL	0.0	Velocity of rotation B[1)]	
Velocity[6]	OUTPUT	LREAL	0.0	Velocity of rotation C[1)]	
Acceleration	OUTPUT	ARRAY[1..6] OF LREAL	-	Cartesian acceleration of the TCP	
Acceleration[1]	OUTPUT	LREAL	0.0	Acceleration in x direction	
Acceleration[2]	OUTPUT	LREAL	0.0	Acceleration in y direction	
Acceleration[3]	OUTPUT	LREAL	0.0	Acceleration in z direction	

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

Parameter	Declaration	Data type	Default value	Description
Acceleration[4]	OUTPUT	LREAL	0.0	Acceleration of rotation A
Acceleration[5]	OUTPUT	LREAL	0.0	Acceleration of rotation B[1)]
Acceleration[6]	OUTPUT	LREAL	0.0	Acceleration of rotation C[1)]
LinkConstellation	OUTPUT	DINT	0	Joint position information The joint position space is specified depending on the respective kinematics type (Page 58). The parameter is to be interpreted bit by bit.

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

14.4.3 MC_InverseKinematicsTransformation V10

14.4.3.1 MC_InverseKinematicsTransformation: Convert Cartesian coordinates to axis coordinates V10

Description

With the Motion Control instruction "MC_InverseKinematicsTransformation", you convert Cartesian coordinates, velocity and acceleration of the tool center point (TCP) to the setpoints of positions, velocity and acceleration of the kinematics axes or joints. The active tool is hereby taken into consideration.

You can use the instruction to test, for example, whether specific Cartesian positions can be reached with the kinematics or whether software limit switches of the axes or joint traversing ranges are violated with kinematics movements.

The instruction is for information purposes only - the kinematics is not moved.

Use the Motion Control instruction "MC_InverseKinematicsTransformation" in the following organization blocks, depending on the kinematics type and the transformation of the values:

Transformation of values	Predefined kinematics	User-defined kinematics
Synchronous to the MC_Servo or MC_Interpolator cycle	MC_PreServo MC_PostServo MC_PreInterpolator	MC_PreInterpolator **Note** The call in MC_PreServo and MC_PostServo triggers technology alarm 803.
In the Main cycle	Main	Main

Applies to

- Kinematics

Requirements

- The technology object has been configured correctly.

Override response

- An "MC_InverseKinematicsTransformation" job cannot be aborted by any other Motion Control job.
- A new "MC_InverseKinematicsTransformation" job does not abort any active Motion Control jobs.

Parameters

The following table shows the parameters of the Motion Control instruction "MC_InverseKinematicsTransformation":

Parameter	Declaration	Data type	Default value	Description	
AxesGroup	INPUT	TO_Kinematics	-	Technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The calculation is carried out in the cycle of the calling organization block.
Position	INPUT	ARRAY[1..6] OF LREAL	-	Cartesian position of the TCP in the reference coordinate system	
Position[1]	INPUT	LREAL	0.0	x coordinate	
Position[2]	INPUT	LREAL	0.0	y coordinate	
Position[3]	INPUT	LREAL	0.0	z coordinate	
Position[4]	INPUT	LREAL	0.0	A-coordinate	
Position[5]	INPUT	LREAL	0.0	B coordinate[1)]	
Position[6]	INPUT	LREAL	0.0	C coordinate[1)]	
Velocity	INPUT	ARRAY[1..6] OF LREAL	-	Cartesian velocity of the TCP	
Velocity[1]	INPUT	LREAL	0.0	Velocity in x direction	
Velocity[2]	INPUT	LREAL	0.0	Velocity in y direction	
Velocity[3]	INPUT	LREAL	0.0	Velocity in z direction	
Velocity[4]	INPUT	LREAL	0.0	Velocity of rotation A	
Velocity[5]	INPUT	LREAL	0.0	Velocity of rotation B[1)]	
Velocity[6]	INPUT	LREAL	0.0	Velocity of rotation C[1)]	
Acceleration	INPUT	ARRAY[1..6] OF LREAL	-	Cartesian acceleration of the TCP	
Acceleration[1]	INPUT	LREAL	0.0	Acceleration in x direction	
Acceleration[2]	INPUT	LREAL	0.0	Acceleration in y direction	
Acceleration[3]	INPUT	LREAL	0.0	Acceleration in z direction	
Acceleration[4]	INPUT	LREAL	0.0	Acceleration of rotation A	

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

Parameter	Declaration	Data type	Default value	Description	
Acceleration[5]	INPUT	LREAL	0.0	Acceleration of rotation B[1]	
Acceleration[6]	INPUT	LREAL	0.0	Acceleration of rotation C[1]	
CoordSystem	INPUT	DINT	0	Reference coordinate system of the input parameters	
				0	World coordinate system (WCS)
				1	Object coordinate system 1 (OCS1)
				2	Object coordinate system 2 (OCS2)
				3	Object coordinate system 3 (OCS3)
LinkConstellation	INPUT	DINT	0	Joint position information The joint position space is specified depending on the respective kinematics type (Page 58). The parameter is to be interpreted bit by bit.	
AxesCoordSystem	INPUT	DINT	100	Reference coordinate system of the output parameters	
				100	Machine coordinate system (MCS)
				101	Joint coordinate system (JCS)[1] [2]
TurnJoint	INPUT	ARRAY [1..6] OF DINT	-	Target joint position range of the joint J[1..6][1]	
TurnJoint[1..6]	INPUT	DINT	0	m (m < 0)	-180° + m · 360° ≤ Position < 180° + m · 360°
				-2	-900 ≤ position < -540
				-1	-540 ≤ position < -180
				0	Basic joint position area: -180 ≤ position < 180
				1	-180 ≤ position < 180
				2	180 ≤ position < 540
				3	540 ≤ position < 900
				n (n > 0)	-180° + (n - 1) · 360° ≤ Position < 180° + (n - 1) · 360°
Valid	OUTPUT	BOOL	FALSE	TRUE	The output parameters are valid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The job is being processed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred while processing the job. The job is rejected. The cause of the error can be found in the "ErrorID" parameter.
ErrorID	OUTPUT	WORD	16#0000	Error ID for parameter "ErrorID" You can find more detailed information in the "Error IDs" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.	
AxesPosition	OUTPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Positions of the kinematics axes	

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

Parameter	Declaration	Data type	Default value	Description
AxesPosition	OUTPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 101[1]: Positions of the joints
AxesPosition[1..6]	OUTPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Position of the axis A[1..6]
				When "AxesCoordSystem" = 101[1]: Position of the joint J[1..6]
AxesVelocity	OUTPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Velocity of kinematics axes
				When "AxesCoordSystem" = 101[1]: Velocity of the joints
AxesVelocity[1..6]	OUTPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Velocity of axis A[1..6]
				When "AxesCoordSystem" = 101[1]: Velocity of the joint J[1..6]
AxesAcceleration	OUTPUT	ARRAY[1..6] OF LREAL	-	When "AxesCoordSystem" = 100: Acceleration of the kinematics axes
				When "AxesCoordSystem" = 101[1]: Acceleration of the joints
AxesAcceleration[1..6]	OUTPUT	LREAL	0.0	When "AxesCoordSystem" = 100: Acceleration of the axis A[1..6]
				When "AxesCoordSystem" = 101[1]: Acceleration of the joint J[1..6]

1) Only relevant with more than 4 interpolating kinematics axes.

2) With up to 4 interpolating kinematics axes, the joint position in the JCS corresponds to the axis position in the MCS.

14.5 Override response of Motion Control jobs V10

14.5.1 Override response V10: Homing and motion jobs

The following table shows how a new Motion Control job affects active homing and motion jobs:

⇒ **Active job** ⇓ **New job**	**MC_Home "Mode" = 2-, 8, 10**	**MC_Home "Mode" = 3, 5**	**MC_Halt "Mode" = 1 MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 0, 1 active MC_Move-Velocity MC_MoveJog**	**MC_Move-Absolute/ MC_Move-Relative/ MC_Position-Profile "Buffer-Mode" = 1 waiting**	**MC_Halt "Mode" = 0**	**MC_Stop**	**MC_Move-Super-imposed MC_Motion-InSuper-imposed MC_Motion-InSuper-imposed-Axes MC_Halt-Super-imposed**	**MC_Motion-InVelocity MC_Motion-InPosition**
MC_Home[1)] "Mode" = 3, 5	A	A	A	A	A	N	A	A
MC_Home "Mode" = 9	A	-	-	-	-	N	-	-
MC_Halt "Mode" = 1	-	A	A	A	-	N	-	A
MC_Halt "Mode" = 0 **MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity MC_MoveJog**	-	A	A	A	A	N	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

⇒ Active job ⇓ New job	MC_Home "Mode" = 2-, 8, 10	MC_Home "Mode" = 3, 5	MC_Halt "Mode" = 1 MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 0, 1 active MC_MoveVelocity MC_MoveJog	MC_MoveAbsolute/ MC_MoveRelative/ MC_PositionProfile "BufferMode" = 1 waiting	MC_Halt "Mode" = 0	MC_Stop	MC_MoveSuperimposed MC_MotionInSuperimposed MC_MotionInSuperimposedAxes MC_HaltSuperimposed	MC_MotionInVelocity MC_MotionInPosition

MC_GearOut MC_CamOut waiting[4)]	N	N	N	N	N	N	-	N
MC_GearOut MC_CamOut active[5)]	N	N	N	N	N	N	A	N

A The running job is aborted with "CommandAborted" = TRUE.

B An "MC_Stop" job is aborted by another "MC_Stop" job with a stop response that is the same or higher.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) The status "Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE corresponds to a waiting synchronous operation.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) The status "Busy" = TRUE, "StartSyncOut" = FALSE corresponds to a pending desynchronization job.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) An "MC_CamIn" job with "SyncProfileReference" = 5 does not abort an "MC_[...]Superimposed" job. Running job continues to be executed.

NOTE

Override response with active fixed stop

With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

14.5.2 Override response V10: Synchronous operation jobs

The following table shows how a new Motion Control job affects the motion of the axis on active synchronous operation jobs:

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_Home[1] "Mode" = 3, 5	A	A	-	N	-	-	-	-	A
MC_Halt "Mode" = 0, 1 **MC_MoveAbsolute/ MC_MoveRelative** "BufferMode" = 0 Active **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog**	A	A	-	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]
MC_MoveAbsolute/-MC_MoveRelative "BufferMode" = 1 active, waiting **MC_PositionProfile** "BufferMode" = 1 active, waiting	N	N	-	N	N	N	-	N	N

MC_Stop	A	A	A	A	A	A	-	A	A

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

⇒ Active job ⇓ New job	MC_GearIn	MC_GearInVelocity	MC_GearInPos MC_CamIn waiting[2]	MC_GearInPos MC_CamIn active[3]	MC_PhasingAbsolute MC_PhasingRelative	MC_OffsetAbsolute MC_OffsetRelative	MC_LeadingValueAdditive	MC_GearOut MC_CamOut waiting[4]	MC_GearOut MC_CamOut active[5]

MC_GearOut MC_CamOut waiting[4]	-	N	A[7] [8]	-	-	-	-	A[7]	N
MC_GearOut MC_CamOut active[5]	A[7]	N	A[7] [8]	A[7]	A	A	-	A[7]	N

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) In the case of a virtual or simulated axis, the running job is not aborted.

2) A waiting synchronous operation job ("Busy" = TRUE, "StartSync" = FALSE, "InSync" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

3) The status "Busy" = TRUE, "StartSync" or "InSync" = TRUE corresponds to an active synchronous operation.

4) A pending desynchronization job ("Busy" = TRUE, "StartSyncOut" = FALSE) does not abort any active jobs. Abort with an "MC_Power" job is possible.

5) The status "Busy" = TRUE, "StartSyncOut" = TRUE corresponds to an active desynchronization job.

6) When the following axis is in position-controlled mode, execution of the running job is continued. When the following axis is not in position-controlled mode, the new job is rejected.

7) An "MC_GearOut" job only terminates an "MC_Gear[...]" job. Correspondingly, an "MC_CamOut" job only cancels a "MC_Cam[...]" job.

8) A job with "SyncProfileReference" = 5 aborts a pending synchronous operation. Canceling a pending synchronous operation has no influence on an active synchronous operation.

NOTE
Override response with active fixed stop
With an active force and torque limiting with "MC_TorqueLimiting", running jobs are aborted if the drive is held at the fixed stop with "InClamping" = TRUE.

14.5.3 Override response V10: Measuring input jobs

The following table shows which new Motion Control jobs will override active measuring input jobs:

⇒ **Active job** ⇓ **New job**	**MC_MeasuringInput**	**MC_MeasuringInputCyclic**
MC_Home "Mode" = 2, 3, 5, 8, 9, 10	B	B
MC_Home "Mode" = 0, 1, 6, 7, 11, 12	-	-
MC_MeasuringInput **MC_MeasuringInputCyclic** **MC_AbortMeasuringInput**	A	A

A The running job is aborted with "CommandAborted" = TRUE.

B The running job is aborted with "ErrorID" = 16#80A3.

- No effect. Running job continues to be executed.

14.5.4 Override response V10: Kinematics motion commands

Single axis jobs are not overridden by kinematics jobs.

The following table shows how a new Motion Control job affects active kinematics motion jobs:

⇒ **Active job** ⇓ **New job**	**MC_MoveLinearAbsolute** **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt** **MC_DefineWorkspaceZone** **MC_DefineKinematicsZone** **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive** **MC_SetOcsFrame**	**MC_GroupInterrupt**	**MC_GroupStop**
MC_Home **MC_MoveSuperimposed** **MC_GearOut** **MC_CamOut**	N	N	N
MC_Halt **MC_MoveAbsolute/** **MC_MoveRelative/** **MC_PositionProfile** "BufferMode" = 0 Active **MC_MoveVelocity** **MC_MoveJog** **MC_Stop** **MC_GearIn** **MC_GearInPos** **MC_GearInVelocity** **MC_CamIn** **MC_MotionInVelocity** **MC_MotionInPosition**	A	A	A
MC_GroupStop	A	A	N
MC_GroupInterrupt **MC_GroupContinue**	B	A	N
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative** **MC_TrackConveyorBelt**	-	-	N

⇒ Active job ⇓ New job	MC_MoveLinearAbsolute MC_MoveLinearRelative MC_MoveCircularAbsolute MC_MoveCircularRelative MC_MoveDirectAbsolute MC_MoveDirectRelative MC_TrackConveyorBelt MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive MC_SetOcsFrame	MC_GroupInterrupt	MC_GroupStop
MC_DefineWorkspaceZone MC_DefineKinematicsZone MC_SetWorkspaceZoneActive MC_SetWorkspaceZoneInactive MC_SetKinematicsZoneActive MC_SetKinematicsZoneInactive			
MC_SetOcsFrame	C, -	-	N

A The running job is aborted with "CommandAborted" = TRUE.

B Running job is interrupted or resumed.

C Synchronization of the OCS with the conveyor belt is aborted with "MC_SetOcsFrame" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed. A new kinematics job is added to the job sequence.

14.5.5 Override response V10: Interpreter jobs

The following table shows how a new Motion Control job affects running Interpreter jobs:

⇒ Active job ⇓ New job	MC_LoadProgram	MC_RunProgram	MC_StopProgram
MC_LoadProgram	N	N	N
MC_RunProgram	-[1]	N	N
MC_StopProgram	A	A	A[2]
MC_Reset	-/N[3]	-/N[3]	-/N[3]

A The running job is aborted with "CommandAborted" = TRUE.

N Not permitted. Running job continues to be executed. The new job is rejected.

- No effect. Running job continues to be executed.

1) The new job is also executed.

2) A new "MC_StopProgram" job with "Mode" = 0 cancels a running "MC_StopProgram" job with "Mode" = 1 or 2. A new "MC_StopProgram" job with "Mode" = 1 aborts a current "MC_StopProgram" job with "Mode" = 2.

3) An "MC_Reset" job with "Restart" = TRUE is rejected. Running job continues to be executed.

Override response for technology objects controlled by the Interpreter

The following table shows how a new Motion Control job acts in relation to a technology object controlled by the Interpreter during the execution of an Interpreter program ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)):

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_Power disable/enable with technology object	✓	✓
MC_Reset with "Restart" = TRUE	✓	✓
MC_Reset with "Restart" = FALSE	✓	-
MC_Home **MC_Halt** **MC_Stop**	✓	✓
MC_MoveAbsolute **MC_MoveRelative** **MC_MoveVelocity** **MC_MoveJog**	✓	✓
MC_SetAxisSTW **MC_WriteParameter**	✓	-
MC_MoveSuperimposed **MC_MotionInSuperimposed** **MC_MotionInSuperimposedAxes** **MC_HaltSuperimposed**	-	-
MC_MotionInVelocity **MC_MotionInPosition**	✓	✓
MC_GearIn **MC_GearInPos** **MC_GearInVelocity** **MC_GearOut** **MC_CamIn** **MC_CamOut**	✓	✓[1)]
MC_PhasingRelative **MC_PhasingAbsolute**	-	-
MC_LeadingValueAdditive	✓	-
MC_OffsetRelative **MC_OffsetAbsolute**	-	-
MC_TorqueAdditive **MC_TorqueRange**	✓	-
MC_TorqueLimiting	✓	-/✓[2)]
MC_SynchronizedMotionSimulation	✓	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

⇓ New job	The new job will be executed.	The new job aborts the execution of the Interpreter program.
MC_MoveLinearAbsolute **MC_MoveLinearRelative** **MC_MoveCircularAbsolute** **MC_MoveCircularRelative** **MC_MoveDirectAbsolute** **MC_MoveDirectRelative**	-	-
MC_GroupInterrupt **MC_GroupContinue**	-	-
MC_GroupStop	✓	✓
MC_KinematicsMotionSimulation	✓	-
MC_TrackConveyorBelt	-	-
MC_DefineTool **MC_SetTool** **MC_SetOcsFrame**	-	-
MC_KinematicsTransformation **MC_InverseKinematicsTransformation**	✓	-
MC_DefineWorkspaceZone **MC_SetWorkspaceZoneActive** **MC_SetWorkspaceZoneInactive** **MC_DefineKinematicsZone** **MC_SetKinematicsZoneActive** **MC_SetKinematicsZoneInactive**	-	-

1) When the synchronization/desynchronization starts, the execution of the Interpreter program is cancelled.

2) If a technology alarm is issued due to a fixed stop, the execution of the Interpreter program is cancelled.

NOTE

MC_Power

Note that a "MC_Power" request with "Enable" = FALSE always locks the specified technology object, even if the technology object was enabled via an Interpreter program with "powerOn()".

Mixed operation of MC_Power (SCL) and powerOn() (MCL) is not permitted.

NOTE

MC_Stop

Note that when starting a motion controlled by the Interpreter no "MC_Stop" job may be active, otherwise the motion job will be aborted.

NOTE

MC_GroupStop

Note that when starting a kinematics motion controlled by the Interpreter, no "MC_GroupStop" job may be active, otherwise the motion job will be aborted.

A "MC_GroupStop" job only affects active kinematics motions or if the kinematics technology object is controlled by the Interpreter ("<TO>.StatusInterpreterMotion.StatusWord.X0" = TRUE (ControlledByInterpreter)).

Tags of the technology object data blocks 15

15.1 Legend

Tag	Name of the tag	
Data type	Data type of the tag	
Values	Value range of the tag - minimum value to maximum value (L - linear specification R - rotary specification) If no specific value is shown, the value range limits of the relevant data type apply or the information under "Description".	
W	Effectiveness of changes in the technology data block	
	DIR	Direct: Values are changed via direct assignment and take effect at the start of the next MC_Servo.
	CAL	At call of Motion Control instruction: Values are changed directly and take effect at the start of the next MC_Servo after the call of the corresponding Motion Control instruction in the user program.
	RES	Restart: Changes to the start value in the load memory are made using the extended instruction "WRIT_DBL" (write to DB in load memory). Changes will not take effect until after restart of the technology object.
	RON	Read only: The tag cannot and must not be changed during runtime of the user program.
Description	Description of the tag	

Access to the tags is with "<TO>.<tag name>". The placeholder <TO> represents the name of the technology object.

15.2 Tags of the kinematics technology object

15.2.1 "Tcp" tag (kinematics)

The tag structure "<TO>.Tcp.<Tag name>" contains the position of the tool center point (TCP), the TCP frame in the World Coordinate System (WCS).

15.2.6 "DynamicDefaults" tag (kinematics)

The tag structure "<TO>.DynamicDefaults.<Tag name>" contains the configuration of the dynamic presets. These settings will be used when you specify a dynamic value less than 0.0 for a Motion Control instruction. Changes to the default dynamics will be applied at the next positive edge at the "Execute" parameter of a Motion Control instruction.

Tags

Legend

15.2.7 "DynamicLimits" tag (kinematics)

The tag structure "<TO>.DynamicLimits.<Tag name>" contains the configuration of the dynamic limits. During Motion Control, no dynamic values greater than the dynamic limits are permitted. If you specify greater values in a Motion Control instruction, then motion is performed using the dynamic limits, and a warning is indicated (alarm 501 to 503 - Dynamic values are limited).

15.2.25 "StatusConveyor[1..3]" tag (kinematics)

The tag structure "<TO>.StatusConveyor[1..3].<Tag name>" contains the conveyor tracking status.

Tags

Legend

Tag	Data type	Values	W	Description
StatusConveyor[1..3].	ARRAY [1..3] OF TO_Struct_Kinematics_StatusConveyor			
ConveyorBelt	DB_ANY	-	RON	Active leading-value-capable technology object to which the object coordinate system (OCS) is coupled: Leading-value-capable technology objects are: • Positioning axis • Synchronous axis • External encoder • Leading axis proxy
BeltPosition	LREAL	-	RON	Position of the leading-value-capable technology object.
ObjectPosition	TO_Struct_Kinematics_Status_Frame	-	RON	Object position Relative offset of the OCS in x direction to the reference position "ConveyorBeltOrigin" "ObjectPosition.x" = "BeltPosition" - "InitialObjectPosition.x"
x	LREAL	-1.0E12 ... 1.0E12	RON	x coordinate
y	LREAL	-1.0E12 ... 1.0E12	RON	y coordinate
z	LREAL	-1.0E12 ... 1.0E12	RON	z coordinate
a	LREAL	-180.0 to 179.999	RON	A coordinate
b	LREAL	-180.0 to 179.999	RON	B coordinate
c	LREAL	-180.0 to 179.999	RON	C coordinate
TrackingState	DINT	0 to 4	RON	Conveyor tracking status
				0 — OCS not assigned The OCS is not assigned to a leading-value-capable technology object.
				1 — OCS assigned The Motion Control instruction "MC_TrackConveyorBelt" is finished and the OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS can be sent.

Tag	Data type	Values	W	Description	
TrackingState	DINT	0 to 4	RON	2	TCP synchronizes to OCS The OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS is active.
				3	TCP follows OCS The OCS is assigned to a leading-value-capable technology object. The first path motion job in the tracked OCS is completed. The kinematics has reached the position programmed in the path motion job. The kinematics follows the motion of the OCS.
				4	TCP desynchronizes from OCS The motion of the kinematics in the tracked OCS is ended by a motion job in the WCS or a non-tracked OCS. When the motion job is completed, the "TrackingState" changes to 0 and the OCS is not tracked with the object position anymore.

15.2.26 "StatusWorkspaceZone[1..10]" tag (kinematics)

The tag structure "<TO>.StatusWorkspaceZone[1..10].<Tag name>" contains the status of the workspace zones.

Tags

Legend

15.2.32 "StatusInterpreterMotion" tag (kinematics)

The tag structure "<TO>.StatusInterpreterMotion.<tag name>" contains status information on motion jobs controlled by a technology object Interpreter.

Tags

Legend

Tag	Data type	Values	W	Description
StatusInterpreterMotion.	TO_Struct_Kinematics_StatusInterpreterMotion			
StatusWord.	DWORD	-	RON	Status information
Bit 0	-	-	-	"ControlledByInterpreter" An MCL job is processed or active or the bit is set via the MCL instruction "setControlledByInterpreter()".
Bit 1	-	-	-	"MotionByInterpreter" An MCL motion job is in effect.
Bit 2 ... Bit 31	-	-	-	Reserved

15.2.33 "StatusWord" tag (kinematics)

The "<TO>.StatusWord" tag contains the status information of the technology object.

Information on the evaluation of the individual bits (e.g. bit 2 "RestartActive") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

Legend

Tag		Data type	Values	W	Description
StatusWord		DWORD	-	RON	Status information of the technology object
	Bit 0	-	-	-	Reserved
	Bit 1	-	-	-	"Error" An error is present.
	Bit 2	-	-	-	"RestartActive" A restart is active. The technology object is being reinitialized.
	Bit 3	-	-	-	"OnlineStartValuesChanged" The restart tags have been changed. For the changes to be applied, the technology object must be reinitialized.
	Bit 4	-	-	-	"ControlPanelActive" The kinematics control panel is activated.
	Bit 5	-	-	-	Reserved
	Bit 6	-	-	-	"Done" No motion job is in progress and the kinematics control panel is deactivated.
	Bit 7	-	-	-	Reserved
	Bit 8	-	-	-	"LinearCommand" A linear motion is active.
	Bit 9	-	-	-	"CircularCommand" A circular motion is active.
	Bit 10	-	-	-	Reserved
	Bit 11	-	-	-	"DirectCommand" A synchronous point-to-point motion is active.
	Bit 12	-	-	-	"ConstantVelocity" The velocity setpoint is reached. The path motion of the kinematics is moving at this constant velocity or is at a standstill.
	Bit 13	-	-	-	"Accelerating" An acceleration operation of a path motion is active.
	Bit 14	-	-	-	"Decelerating" A deceleration operation of a path motion is active.
	Bit 15	-	-	-	"OrientationMotion" An orientation motion is active.
	Bit 16	-	-	-	"Stopping" An "MC_GroupStop" job is running. The motion of the kinematics technology object is aborted

Tag	Data type	Values	W	Description
Bit 17	-	-	-	"Interrupted" The motion of the kinematics technology object is interrupted with an "MC_GroupInterrupt" job. The motion can be continued with a "MC_GroupContinue" job.
Bit 18	-	-	-	"Blending" A blending segment is active.
Bit 19	-	-	-	"InSimulation" The technology object is in simulation.
Bit 20	-	-	-	Reserved
Bit 21	-	-	-	"EnabledJCS" The kinematics technology object uses the JCS.
Bit 22	-	-	-	Reserved
Bit 23	-	-	-	Reserved
Bit 24	-	-	-	"StandardOrientationMode5D" A linear or circular motion of a 3D kinematics with 2 orientations is active.
Bit 25	-	-	-	"StandardOrientationMode6D" A linear or circular motion of a 3D kinematics with 3 orientations is active.
Bit 26 ... Bit 31	-	-	-	Reserved

15.2.34 "ErrorWord" tag (kinematics)

The "<TO>.ErrorWord" tag indicates technology object errors (technology alarms).

Information on the evaluation of the individual bits (e.g. bit 3 "CommandNotAccepted") can be found in the "Evaluating StatusWord, ErrorWord and WarningWord" section of the "S7-1500/S7-1500T Motion Control Overview" documentation.

ErrorWord	DWORD	-	RON	
Bit 0	-	-	-	"SystemFault" A system-internal error has occurred.
Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters are inconsistent or invalid.
Bit 2	-	-	-	"UserFault" Error in the user program at a Motion Control instruction or its use (e.g. by the kinematics control panel).
Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.

Tag		Data type	Values	W	Description
	Bit 4	-	-	-	"TransformationFault" Error in the kinematics transformation
	Bit 5	-	-	-	Reserved
	Bit 6	-	-	-	"DynamicError" Specified dynamic values are limited to permissible values.
	Bit 7	-	-	-	"ConveyorFault" Error in the conveyor tracking
	Bit 8	-	-	-	"JointLimit" Joint traversing range limit approached or overtraveled.
	Bit 9 ... Bit 31	-	-	-	Reserved

15.2.35 "ErrorDetail" tag (kinematics)

The tag structure "<TO>.ErrorDetail.<Tag name>" contains the alarm number and the effective local alarm response for the technology alarm that is currently pending on the technology object.

You can find a list of the technology alarms and alarm responses in the "Overview of the technology alarms" section of the "S7-1500/S7-1500T Motion Control alarms and error IDs" documentation.

Tags

	Bit 1	-	-	-	"ConfigFault" Configuration error One or more configuration parameters will be adjusted internally.
	Bit 2	-	-	-	"UserFault" Error in user program at a Motion Control instruction or its use
	Bit 3	-	-	-	"CommandNotAccepted" Job cannot be executed A Motion Control instruction cannot be executed because the necessary conditions have not been met.
	Bit 4	-	-	-	Reserved
	Bit 5	-	-	-	Reserved
	Bit 6	-	-	-	"DynamicWarning" Specified dynamic values are limited to permissible values.
	Bit 7 ... Bit 31	-	-	-	Reserved

15.2.37 "ControlPanel" tag (kinematics)

The tag structure "<TO>.ControlPanel.<tag name>" contains no relevant data for you. This tag structure is internally used.

15.2.38 "InternalToTrace" tag (kinematics)

The tag structure "<TO>.InternalToTrace.<tag name>" contains no relevant data for you. This tag structure is internally used.

6.5 Error IDs 16#8040 - 16#804F 95

6.6 Error IDs 16#8050 - 16#805F 96

6.7 Error IDs 16#8060 - 16#806F 97

6.8 Error IDs 16#8070 - 16#807F 97

6.9 Error IDs 16#8080 - 16#808F 98

6.10 Error IDs 16#80A0 - 16#80AF 99
6.11 Error IDs 16#80B0 - 16#80BF 100
6.12 Error IDs 16#80C0 - 16#80CF 101
6.13 Error IDs 16#80D0 - 16#80DF 102
6.14 Error IDs 16#80E0 - 16#80EF 103
6.15 Error IDs 16#80F0 - 16#80FE 105
6.16 Error IDs 16#8110 - 16#8121 106
6.17 Error detection 16#8130 - 16#813F 107
6.18 Error IDs 16#8200 - 16#82FF 107
6.19 Error IDs 16#8FF0 - 16#8FFF 108

Introduction 1

Purpose of the documentation

This documentation provides important information that you need to configure and commission the integrated Motion Control functionality of the S7-1500 Automation systems.

Required basic knowledge

In order to understand this documentation, the following knowledge is required:

- General knowledge in the field of automation
- General knowledge in the field of drive engineering and motion control

Validity of the documentation

This documentation is valid for the S7-1500 product range.

Conventions

- The path specifications in the project tree assume that the "Technology objects" folder is open in the subtree of the CPU. The "Technology object" placeholder represents the name of the technology object.

  Example: "Technology object > Configuration > Basic parameters".
- The <TO> placeholder represents the name set in tags for the respective technology object.

  Example: <TO>.Actor.Type
- This documentation contains pictures of the devices described. The pictures may differ in minor details from the devices supplied.

You should also observe the notes that are marked as follows:

NOTE

A note contains important information about the product described in the documentation, about the handling of the product, and about sections in this documentation demanding your particular attention.

Industry Mall

The Industry Mall is the catalog and ordering system of Siemens Aktiengesellschaft for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

1.1 S7-1500 Motion Control Documentation Guide

Product information

Please also note the supplementary information on the Motion Control documentation:

- Product information on the S7-1500/1500T Motion Control documentation
  https://support.industry.siemens.com/cs/ww/en/view/109794046
  (https://support.industry.siemens.com/cs/ww/en/view/109794046)

Documentation

The documentation of the Motion Control functions is divided into the following documents:

- S7-1500/S7-1500T Motion Control Overview
  https://support.industry.siemens.com/cs/en/view/109990070
  (https://support.industry.siemens.com/cs/ww/en/view/109990070)

  This document describes the innovations in the technology versions, how to upgrade the technology version, functions that are used for all technology objects, and the operational sequence of Motion Control applications.
- S7-1500/S7-1500T Motion Control alarms and error IDs
  https://support.industry.siemens.com/cs/ww/en/view/109990076
  (https://support.industry.siemens.com/cs/ww/en/view/109990076)

  This document describes the technology alarms of the technology objects and the error identifications of the Motion Control instructions.
- S7-1500/S7-1500T Axis functions
  https://support.industry.siemens.com/cs/en/view/109990072
  (https://support.industry.siemens.com/cs/ww/en/view/109990072)

  This document describes the drive and encoder connection and functions for single-axis movements.
- S7-1500/S7-1500T Synchronous operation functions
  https://support.industry.siemens.com/cs/ww/en/view/109990074
  (https://support.industry.siemens.com/cs/ww/en/view/109990074)

  This document describes gearing, velocity synchronous operation and camming as well as cross-PLC synchronous operation.

- S7-1500/S7-1500T Measuring input and output cam functions
  https://support.industry.siemens.com/cs/ww/en/view/109990075
  (https://support.industry.siemens.com/cs/ww/en/view/109990075)
  This document describes the detection of the actual position via a measuring input and the output of switching signals via output cam or cam track.
- S7-1500T kinematics functions
  https://support.industry.siemens.com/cs/ww/en/view/109990073
  (https://support.industry.siemens.com/cs/ww/en/view/109990073)
  This document describes the control of kinematics with up to 6 interpolating axes.
- S7-1500T Interpreter functions
  https://support.industry.siemens.com/cs/ww/en/view/109990077
  (https://support.industry.siemens.com/cs/ww/en/view/109990077)
  This documentation describes the control of technology objects via an Interpreter program.

1.2 Function Manuals documentation guide

1.2.1 Information classes Function Manuals

The documentation for the SIMATIC S7-1500 automation system, for the 1513/1516pro-2 PN, SIMATIC Drive Controller CPUs based on SIMATIC S7-1500 and the SIMATIC ET 200MP, ET 200SP, ET 200AL and ET 200eco PN distributed I/O systems is arranged into three areas.

This arrangement enables you to access the specific content you require.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742705).

Basic information

The system manuals and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, SIMATIC Drive Controller, ET 200MP, ET 200SP, ET 200AL and ET 200eco PN systems. Use the corresponding operating instructions for 1513/1516pro-2 PN CPUs.

The STEP 7 online help supports you in the configuration and programming.

Examples:

- Getting Started S7-1500
- System manuals
- Operating instructions ET 200pro and 1516pro-2 PN CPU
- Online help TIA Portal

Device information

Equipment manuals contain a compact description of the module-specific information, such as properties, wiring diagrams, characteristics and technical specifications.

Examples:

- Equipment manuals for CPUs
- Equipment manuals for interface modules
- Equipment manuals for digital modules
- Equipment manuals for analog modules
- Equipment manuals for communication modules
- Equipment manuals for technology modules
- Equipment manuals for power supply modules
- Equipment manuals for BaseUnits

General information

The function manuals contain detailed descriptions on general topics relating to the SIMATIC Drive Controller and the S7-1500 automation system.

Examples:

- Function Manual Diagnostics
- Function Manual Communication
- Function Manuals Motion Control
- Function Manual Web Server
- Function Manual Cycle and Response Times
- PROFINET Function Manual
- PROFIBUS Function Manual

Product Information

Changes and supplements to the manuals are documented in a Product Information. The Product Information takes precedence over the device and system manuals.

You will find the latest Product Information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/de/en/view/68052815)
- SIMATIC Drive Controller (https://support.industry.siemens.com/cs/de/en/view/109772684/en)
- Motion Control (https://support.industry.siemens.com/cs/de/en/view/109794046/en)
- ET 200SP (https://support.industry.siemens.com/cs/de/en/view/73021864)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109765611)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP/SIMATIC Drive Controller (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)
- ET 200eco PN (https://support.industry.siemens.com/cs/ww/en/view/109781058)

1.2.2 Basic tools

Tools

The tools described below support you in all steps: from planning, over commissioning, all the way to analysis of your system.

TIA Selection Tool

The TIA Selection Tool tool supports you in the selection, configuration, and ordering of devices for Totally Integrated Automation (TIA).

As successor of the SIMATIC Selection Tools , the TIA Selection Tool assembles the already known configurators for automation technology into a single tool.

With the TIA Selection Tool , you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/109767888)

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to perform commissioning and maintenance activities on various SIMATIC S7 stations as bulk operations independent of TIA Portal.

The SIMATIC Automation Tool offers a wide range of functions:

- Scanning of a PROFINET/Ethernet system network and identification of all connected CPUs
- Assignment of addresses (IP, subnet, Gateway) and device name (PROFINET device) to a CPU
- Transfer of the date and the programming device/PC time converted to UTC time to the module
- Program download to CPU
- RUN/STOP mode switchover
- CPU localization through LED flashing
- Reading out of CPU error information
- Reading the CPU diagnostic buffer
- Reset to factory settings
- Firmware update of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet.
(https://support.industry.siemens.com/cs/ww/en/view/98161300)

PRONETA

SIEMENS PRONETA (PROFINET network analysis) is a commissioning and diagnostic tool for PROFINET networks. PRONETA Basic has two core functions:

- In the network analysis, you get an overview of the PROFINET topology. Compare a real configuration with a reference installation or make simple parameter changes, e.g. to the names and IP addresses of the devices.
- The "IO test" is a simple and rapid test of the wiring and the module configuration of a plant, including documentation of the test results.

You can find SIEMENS PRONETA Basic on the Internet:
(https://support.industry.siemens.com/cs/ww/en/view/67460624)

SIEMENS PRONETA Professional is a licensed product that offers you additional functions. It offers you simple asset management in PROFINET networks and supports operators of automation systems in automatic data collection/acquisition of the components used through various functions:

- The user interface (API) offers an access point to the automation cell to automate the scan functions using MQTT or a command line.
- With PROFIenergy diagnostics, you can quickly detect the current pause mode or the readiness for operation of devices that support PROFIenergy and change these as needed.
- The data record wizard supports PROFINET developers in reading and writing acyclic PROFINET data records quickly and easily without PLC and engineering.

You can find SIEMENS PRONETA Professional on the Internet.
(https://www.siemens.com/proneta-professional)

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and the optimal use of resources

You can find SINETPLAN on the Internet (https://new.siemens.com/global/en/products/automation/industrial-communication/profinet/sinetplan.html).

1.2.3 SIMATIC Technical Documentation

Additional SIMATIC documents will complete your information. You can find these documents and their use at the following links and QR codes.

The Industry Online Support gives you the option to get information on all topics. Application examples support you in solving your automation tasks.

Overview of the SIMATIC Technical Documentation

Here you will find an overview of the SIMATIC documentation available in Siemens Industry Online Support:

Industry Online Support International (https://support.industry.siemens.com/cs/ww/en/view/109742705)

Watch this short video to find out where you can find the overview directly in Siemens Industry Online Support and how to use Siemens Industry Online Support on your mobile device:

Quick introduction to the technical documentation of automation products per video (https://support.industry.siemens.com/cs/us/en/view/109780491)

YouTube video: Siemens Automation Products - Technical Documentation at a Glance (https://youtu.be/TwLSxxRQQsA)

Retention of the documentation

Retain the documentation for later use.

For documentation provided in digital form:

1. Download the associated documentation after receiving your product and before initial installation/commissioning. Use the following download options:
   - Industry Online Support International: (https://support.industry.siemens.com)

     The article number is used to assign the documentation to the product. The article number is specified on the product and on the packaging label. Products with new, non-compatible functions are provided with a new article number and documentation.
   - ID link:

     Your product may have an ID link. The ID link is a QR code with a frame and a black frame corner at the bottom right. The ID link takes you to the digital nameplate of your product. Scan the QR code on the product or on the packaging label with a smartphone camera, barcode scanner, or reader app. Call up the ID link.
2. Retain this version of the documentation.

Updating the documentation

The documentation of the product is updated in digital form. In particular in the case of function extensions, the new performance features are provided in an updated version.

1. Download the current version as described above via the Industry Online Support or the ID link.
2. Also retain this version of the documentation.

mySupport

With "mySupport" you can get the most out of your Industry Online Support.
