  If the module receives a time-of-day frame from a non-synchronized NTP server with stratum ≥ 15, the time of day is not set according to the frame.

Reconnection delay

Note

If the partner cannot be reached, connection establishment via the mobile wireless network can take several minutes. This may depend on the particular network and current network load.

Depending on your contract, costs may result from each connection establishment attempt.

"Reconnection delay" parameter

The reconnection delay for connections in telecontrol communication is the waiting time between repeated attempts to establish the connection by the CP when the telecontrol server is not reachable or the connection has aborted. This waiting time avoids continuous connection establishment attempts at short intervals if there are connection problems.

A basic value is configured for the waiting time before the next connection establishment attempt. Starting at the basic value, the current waiting time is doubled after every 3 unsuccessful retries up to a maximum value of 900 s. Range of values for the basic value: 10 .. 300 s

Example: The basic value 20 results in the following intervals (waiting times) between the attempts to re-establish a connection.

- three times 20 s
- three times 40 s
- three times 80 s
- etc. up to max. 900 s

Note

Special characteristics with CP 1242-7 (6GK7242-7KX30-0XE0) together with TELECONTROL SERVER BASIC (V2)

If a second telecontrol server or a second router of the telecontrol server is configured, the CP attempts to connect to the second partner at the 4th attempt. If the second partner is also unreachable, the 7th time the CP attempts to connect to the first partner again.

Acknowledgment with IEC protocol

Acknowledgment mechanisms with telecontrol protocol IEC 60870-5-104

Reference: Configuration of the Ethernet interface of the CP > Parameter group "Advanced options" > Transfer settings"

With each sent data frame, the CP sends a continuous send sequence number. The data frame remains initially stored in the send buffer of the CP.

When it receives the data frame, the master sends the send sequence number from this or (if several frames are received) the last frame as an acknowledgment to the CP. The CP saves

the send sequence number returned by the master as a receive sequence number and uses it as an acknowledgment.

Frames whose send sequence number is equal to or lower than the current receive sequence number are evaluated as having been successfully transferred and are deleted from the send buffer of the CP.

Recommendations of the specification:

- w should not be higher than 2/3 of k.
- Recommended value for k: 12
- Recommended value for w: 8

Parameter:

- **k: Difference between send sequence number N(S) and receive sequence number N(R)**
  Maximum number of unacknowledged data frames (I-APDUs) as maximum difference between send sequence number N(S) and receive sequence number N(R).
  When k is reached and t_1 has not yet elapsed, the CP does not send any frames until all the frames sent have been acknowledged by the master.
  When k is reached and t_1 has elapsed, the TCP connection is terminated.
- **w: Max. number of unacknowledged data frames**
  Maximum number of received data frames (I-APDUs), after which the oldest frame received from the master must be acknowledged.

Parameters of the TIM for classic WAN

Interface operating mode

The operating mode of the interface specifies the mode of the data transfer. A maximum of one of two serial interfaces of a module may be operated in DMA mode. Range of values:

- Interrupt (block)
  This operating mode applies to the transmit and receive mode. The default mode Interrupt (block) is suitable for all connections. 4 characters are transferred per block. Following this, there is an interrupt. The received characters are checked only after a complete message has arrived.
- DMA
  This operating mode applies to the transmit and receive mode. The DMA mode should be used for connections with a high baud rate or a lot of message traffic, however not for GSM networks. A maximum of one of the two interfaces of a TIM module may be operated in DMA mode.
- Interrupt (individual characters)
  This operating mode is used only in the receive direction. In the transmit direction, the block mode continues to the used. This interrupt mode is suitable for extremely bad lines. An interrupt is triggered per transmitted character and each character is analyzed immediately after it is received allowing extremely good diagnostics of transmission errors. This mode is more reliable than the block mode but is slower.

Transmission criterion

The transmission criterion controls connection establishment for the transmission of conditional unsolicited messages from stations and node stations.

This reduces the number of connection retries. Range of values:

- Standard conditions
  No connection will be established due to the existence of conditionally spontaneous messages . The conditional spontaneous messages are sent only when a connection is established for sending unconditional spontaneous messages or a buffer overflow is threatening or the connection is established by the other end.
- Degree of filling
  The TIM only sends the conditionally spontaneous messages when the configured fill level of the send buffer for conditionally spontaneous messages is exceeded.
  In the input box, enter the fill level of the send buffer as a percentage at which when exceeded the TIM establishes a connection.
- Time
  The TIM sends the conditionally spontaneous messages at a configured time of day.
- Time scheme
  The TIM sends the conditionally spontaneous messages cyclically at a configurable interval.

Polling monitoring time

The TIM monitors the message traffic via WAN and sends a message to its local CPU indicating that the master station is disrupted if it is not called after a certain time has elapsed. The sequence is as follows:

- Polling monitoring time configured
  After the configured time elapses, the TIM sends a message to its local CPU.
- Polling monitoring time not configured
  If no monitoring time is configured, the TIM outputs a disruption message after the following internally calculated times.
  - At a transmission speed of 9,600 bps: After 4 seconds without message traffic
  - At a transmission speed of 1,200 bps: After 32 seconds without message traffic

Partner

Addressing a double / redundant TCSB system

Addressing of the duplicate or redundant telecontrol server

- **Addressing the main and substitute telecontrol server in TCSB V2**
  Only for CP 1242-7 (6GK7 242-7KX30-0XE0)
  With TCSB V2, two independent server PCs can be installed. The second IP address only needs to be configured when these are connected to the Internet via two routers.
- **Addressing the TCSB redundancy group in TCSB V3**
  In the LAN in the master to which the TCSB server PCs and the DSL router (e.g. SCALANCE M) are connected, the Network Load Balancing (NLB) of the computer operating system will assign a common virtual IP address to the two server PCs.
  This IP address is configured depending on the network setup:
  - If only CP 1243-1 modules without a DSL router are connected, the virtual address assigned by the NLB must be configured in the CPs as the IP address of the telecontrol server.
  - If a DSL router is used, only one IP address will be configured to address the redundant telecontrol server in the stations, the public address of the DSL router.
    Set the port forwarding on the DSL router so that the public IP address (external network) is led to the virtual IP address of the TCSB server PCs (internal network). Only the public IP address is reachable from the Internet. The station does not therefore receive any information telling it which of the two computers of the redundancy group it is connected to.

  If you configure a second IP address, you need to make sure that TCSB is reachable via the IP address of a second router.

Communication with the CPU

CPU scan cycle

Input data points are assigned to the read cycle of the CPU in the data point configuration in the "General > Read cycle" tab.

Structure of the CPU scan cycle

The cycle with which the transferring module (CP / TIM) scans the memory area of the CPU is made up of the following phases:

- **High-priority read jobs**
  (Fast cycle)
  For all data points with the assignment "Fast cycle" the PLC tags are read in every scan cycle.
  Normally it is adequate to assign only data to be acquired quickly such as alarms and contact changeover messages and command, setpoint and parameter objects for the 1oon check to the fast cycle.
- **Write jobs**
  In every cycle, the values of a certain number of unsolicited write jobs are written to the CPU.
  - Telecontrol CP / TIM 1500
    The number of tags written per cycle is specified for the transferring module in the "Communication with the CPU" parameter group with the "Max. number of write jobs" parameter. The tags whose number exceeds this value are then written in the next or one of the following cycles.
- **Low-priority read jobs - proportion**
  (Normal cycle)
  For data points with the assignment "Normal cycle", a proportion of the values of their PLC tags is read in every scan cycle.
  - Telecontrol CP / TIM 1500
    The number of tags read per cycle is specified for the transferring module in the "Communication with the CPU" parameter group with the "Max. number of read jobs" parameter. The tags that exceed this value and can therefore not be read in one cycle are then read in the next or one of the following cycles.
- **Cycle idle time**
  This waiting time between two scan cycles is used to reserve adequate time for other processes that access the CPU.

Duration of the CPU scan cycle

Since no fixed time can be configured for the cycle and since the individual phases cannot be assigned a fixed number of objects, the duration of the scan cycle is variable and can change dynamically.

Partner status and Path status of the TIM

You will find the parameters described below in the following parameter group of the TIM:

"Communication with the CPU" > "Partner status"

Partner

Here, you select the communications partner whose status and connection to the currently selected TIM will be monitored. The partner can be a CPU or an ST7cc.

In the table, the partner name can be selected from the possible partners.

Partner status

Here you select a PLC tag of the data type bool (DB, memory bit, output) to which the partner status will be written. Range of values:

- 0: Partner not reachable
- 1: Partner reachable

Path status

Here you select a PLC tag of the data type byte (DB, memory bit, output) to which the path status to a partner status will be written.

The PLC tag shows the status of the path to the partner from the perspective of the local TIM.

A maximum of 2 paths (main and substitute path) to a partner can be configured. Both paths must begin or end on a local TIM.

The PLC tag shows the following:

- The paths via which the partner can be reached.
- The path currently being used
- The TIM interface via which the main path was configured.
- The TIM interface via which the substitute path was configured.

The path of a connection is specified as a combination of the used interfaces of the TIM and the status of the path.

The path of a connection is specified as a combination of the used interfaces of the TIM and the status of the path.

- **Assignment of the byte of the PLC tag**
  The byte of the PLC tag is assigned as follows:
  - Two bits for the interface of the main path
  - Two bits for the interface of the substitute path
  - Two bits for the status of the main path
  - Two bits for the status of the substitute path

Bit 6 + 7	Bit 4 + 5	Bit 2 + 3	Bit 0 + 1
Configured interface		Path status	
No. for substitute path	No. for main path	Substitute path (2nd path)	Main path (1st path)

- **Configured interface**
  The TIM interfaces "Ethernet 1" (IE1), "Ethernet 2" (IE2), WAN1 and WAN2 are numbered through from 0 .. 3 (decimal):
  - 0 = "Ethernet 1" (IE1)
  - 1 = "Ethernet 2" (IE2)
  - 2 = WAN1
  - 3 = WAN2

Status of bit 5 (7)	Status of bit 4 (6)	Meaning
0	0	Coding for interface IE1 (decimal): No. 0)
0	1	Coding for interface IE2 (decimal: no. 1)
1	0	Coding for interface WAN1 (decimal: no. 2)
1	1	Coding for interface WAN2 (decimal: no. 3)

- **Path status**
  - Main path = 1. Path (bits 0 + 1)
  - Substitute path = 2nd path (bits 2 + 3)

Status of bit 1 (3)	Status of bit 0 (2)	Meaning bit 1	Meaning bit 0
0	0	Bit 1: Path not current	Bit 0: Subscriber not reachable
0	1	Bit 1: Path not current	Bit 0: Subscriber reachable
1	0	Bit 1: Path current	Bit 0: Subscriber not reachable
1	1	Bit 1: Path current	Bit 0: Subscriber reachable

Example of coding options

Same coding of the configured interface for the main and the substitute path means that there is no path redundancy (only 1 interface configured). The path status is output via the bits of the main path (1st path).

Table 10-83 Example of the coding for the PLC tag "Path status"

Configured interface		Path status	
No. for substitute path	No. for main path	Substitute path (2nd path)	Main path (1st path)
0 0	0 0 = coding for IE1	Irrelevant (not redundant)	Status IE1
0 0	0 1 = coding for IE2	Status IE1	Status IE2
0 0	1 0 = coding for WAN1	Status IE1	Status WAN1
0 0	1 1 = coding for WAN2	Status IE1	Status WAN2
0 1	0 0	Status IE2	Status IE1
0 1	0 1	Irrelevant (not redundant)	Status IE2
0 1	1 0	Status IE2	Status WAN1
0 1	1 1	Status IE2	Status WAN2

1 0	0 0	Status WAN1	Status IE1
1 0	0 1	Status WAN1	Status IE2
1 0	1 0	Irrelevant (not redundant)	Status WAN1
1 0	1 1	Status WAN1	Status WAN2
1 1	0 0	Status WAN2	Status IE1
1 1	0 1	Status WAN2	Status IE2
1 1	1 0	Status WAN2	Status WAN1
1 1	1 1	Irrelevant (not redundant)	Status WAN2

Operator input monitoring

Operator input monitoring

The Operator input monitoring is used to monitor operator input (buttons etc.) to protect against incorrect input.

For monitored operator input a minimum and maximum duration is specified. The monitoring status is saved in the "PLC tag for operator input monitoring" (byte).

The PLC tag can be used for entries via the following data point types:

- Command output (Cmd01B_S)
- Setpoint output (Set01W_S)
- Parameter entries (Par12D_S)

The Operator input monitoring is recommended particularly when commands are entered via digital inputs, for example using buttons connected to them. This also applies to the situation when setpoint and parameter entries are transmitted as the result of a trigger and this triggering is via a digital input, in other words for example once again via a button.

Monitoring incorrect input (input time)

Using Operator input monitoring reduces the risk of incorrect input when the entries are made via digital inputs. The following times and the code bits are relevant only for operator input over digital inputs.

- Min. input time
  For these entries, a minimum input time can be specified, in other words, the button must be pressed for the minimum time. The accidental activation of a button does not then lead to an unwanted transfer. When the minimum input time has elapsed and the button can be released, the "PLC tag for operator input monitoring" shows "entry OK" in bit 0 (see below).
  A time of at least 1 second is recommended.
  If you do not require the parameter, configure 0 (zero).
- Max. input time
  Apart from the minimum duration, a maximum input time can also be set for digital inputs. This allows a button that is sticking or defective digital inputs that supply a permanent 1 signal to be detected in good time. Such errors are written as "input error" to bit 1 of the PLC tag.
  Further hardware entries are not processed as long as the "input error" bit is set.
  If you do not require the parameter, configure 0 (zero).

Monitoring for 1 out of n errors.

Generally for all operator input via digital inputs. bit memory or data blocks the PLC tag returns the error status "1 out of n error" in bit 2. The error status is set when more than 1 bit is set at the same time.

The error is output in the following situations:

- 1-out-of-n error with "Cmd01B_S"
  More than 1 bit was set in the input byte of the command data point type "Cmd01B_S". To increase reliability of command input, only 1 bit may ever be set with this object. If two or more bits are set at the same time, the command input is rejected.
- 1-out-of-n errors with all command, setpoint and parameter entries in the fast read cycle
  If increased reliability is required for the input of commands, setpoints and parameters, all objects with which this data is sent should be assigned to the fast read cycle. All command, setpoint and parameter objects in the fast cycle are then subjected to a 1-out-of-n check. At the end of the fast cycle there is a check to make sure that there is a command, setpoint or parameter entry for only one of the acquired objects. Only then is the corresponding entry processed and transferred. If there is more than one entry, the entries are rejected. A new command, setpoint or parameter is processed only when previously no entry was acquired in at least one fast cycle.

Note

Resetting the command bit

If commands are entered over a memory or data byte, or a setpoint or parameter entry is enabled by a memory or data bit (trigger signal), the set command bit or trigger signal is automatically reset to zero.

If, however, a 1-out-of-n error is detected, the command bits are not automatically reset. They must then be reset by the user program.

Assignment of the status byte of "PLC tag for operator input monitoring"

Table 10-84 Bit assignment of the status byte

Bit:	.7 *	.6 *	.5 *	.4 *	.3 *	.2	.1	.0
Status:	-	-	-	-	-	1-out-of-n error	Input error	Input OK
For value:	0	0	0	0	0	1	1	1
* Unused bits are set to 0								

Data point editor

Configuring data points and messages

Data point-related communication with the CPU

No program blocks need to be programmed for the telecontrol modules with data point configuration to transfer user data between the station and communications partner. The data areas in the memory of the CPU intended for communication with the communications partner are configured data point-related on the module. Each data point is linked to a PLC tag or a or the tags of a data block.

Requirement: Created PLC tags

PLC tags or DBs must first be created in the CPU program to allow configuration of the data points.

The PLC tags for data point configuration can be created in the standard tag table or in a user-defined tag table. All PLC tags intended to be used for data point configuration must have the attribute "Visible in HMI".

Address areas of the PLC tags are input, output or bit memory areas on the CPU.

The formats and S7 data types of the PLC tags that are compatible with the protocol-specific data point types of the CP can be found in the section Datapoint types (Page 1177).

Access to the memory areas of the CPU

The values of the PLC tags or DBs referenced by the data points are read and transferred to the communications partner by the CP.

Data received from the communications partner is written by the CP to the CPU via the PLC tags or DBs.

Configuring the data points and messages in STEP 7

You configure the data points in STEP 7 in the data point and message editor. You can find this using the project tree:

Project > directory of the relevant station > Local modules > CP 1200 / TIM 3vxx/4Rxx

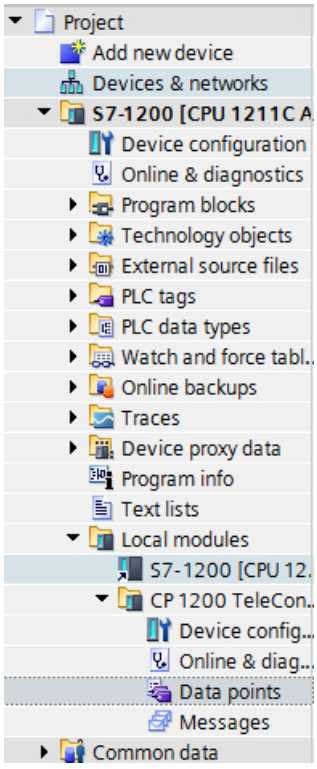

Figure 10-8 Configuring data points and messages

By double-clicking on the entry, the data point or message editor.

Using the two entries to the right above the table, you can switch over between the data point and message editor.

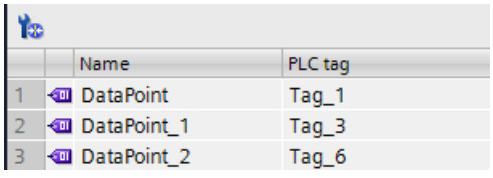

Figure 10-9 Switching over between the two editors

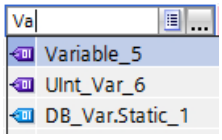
Creating obects

With the data point or message editor open, create a new object (data point / message) by double clicking "<Add object>" in the first table row with the grayed out entry.

A preset name is written in the cell. You can change the name to suit your purposes but it must be unique within the CP.

	Name	PLC tag
1	DataPoint	Tag_1
2	DataPoint_1	Tag_3
3	DataPoint_2	Tag_6

Figure 10-10 Data point table



You configure the remaining properties of every object using the drop-down lists of the other table columns and using the parameter boxes shown at the bottom of the screen.

Assigning data points to their data source

After creating it, you assign a new data point to its data source. Depending on the data type of the data point a PLC tag can serve as the data source.

For the assignment you have the following options:

- Click on the table symbol in the cell of the "PLC tag" column.
  All configured PLC tags and the tags of the created data blocks are displayed. Select the required data source with the mouse or keyboard.
- Click the symbol ....
  A selection list of the configured PLC Tags and the blocks is displayed. From the relevant table, select the required data source.
- In the name box of the PLC tag, enter part of the name of the required data source.
  All configured PLC tags and tags of the data blocks whose names contain the letters you have entered are displayed.

Select the required data source.

Note

Assignment of parameter values to PLC tags

The mechanisms described here also apply when you need to assign the value of a parameter to a PLC tag. The input boxes fro the PLC tag (e.g.: PLC tag for partner status support the functions described here for selecting the PLC tag.

Arranging and copying objects

As with many other programs in the data point or message editor you can also arrange the columns, sort the table according to your requirements and copy and insert objects.

- Arrange columns
  If you click on a column header with the left mouse button pressed, you can move the column.
- Sorting objects
  If you click briefly with the left mouse button on a column header, you can sort the objects of the table in ascending or descending order according to the entries in this column. The sorting is indicated by an arrow in the column header.
  After sorting in descending order of a column the sorting can be turned off by clicking on the column header again.

- Adapting the column width
  You call this function using the shortcut menu that opens when you click on a column header with the right mouse key.
- Showing / hiding columns
  You call this function using the shortcut menu that opens when you click on a column header with the right mouse key.
- Copying, pasting, cutting and deleting objects
  If you click in a parameter box of an object in the table with the right mouse key, you can use the functions named with the shortcut menu (copy, paste, cut, delete).
  You can paste cut or copied objects within the table or in the first free row below the table.

Exporting and importing data points

To simplify the engineering of larger plants, you can export the data points of a configured module and import them into other modules in the project. This is an advantage particularly in projects with many identical or similar stations or modules.

The export / import function is available when you select the module for example in the network or device view and select the relevant shortcut menu.

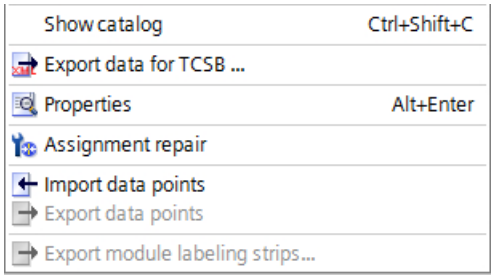


Figure 10-11 Shortcut menu of the CP

When it is exported the data point information of a CP is stored in one CSV file.

Export

When you call the export function, the export dialog opens. Here, you select the CPs or modules of the project whose data point information needs to be exported. When necessary, you can export the data points of all modules of the project at one time.

In the export dialog, you can select the storage location in the file directory. When you export the data of a module you can also change the preset file name.

When you export from several modules, the files are formed with preset names made up of the station name and module name.

The file itself contains the following information in addition to the data point information:

- Module name
- Module type
- CPU name
- CPU type

Editing the data point information

You can edit the data point information in an exported CSV file. This allows you to use this file as a configuration template for many other stations.

If you have a project with many stations of the same type, you can copy the CSV file with the data points of a fully configured module for other as yet unconfigured stations and adapt individual parameters to the particular station. This saves you having to configure the data points for every module in STEP 7. Instead, you simply import the copied and adapted CSV file to the other modules of the same type. When you import this file into another module, the changed parameter values of the CSV file are adopted in the data point configuration of this module.

The lines of the CSV file have the following content:

- Line 1: ,Name,Type,
  This line must not be changed.
- Line 2: PLC,<CPU name>, <CPU type>,
  Meaning: PLC (designation of the station class), CPU name, CPU type
  Only the elements <CPU name> and <CPU type> may be changed.
  The CPU type must correspond exactly to the name of the CPU in the catalog.
- Line 3: Module,<module name>,<module type>,
  Meaning: Module (Designation of the module class), module type, module name
  Only the elements <module name> and <module type> may be changed.
  Be careful when changing the module names if you want to import data points into several modules (see below).
  The module type must correspond exactly to the name of the module in the catalog.
- Line 4: Parameter names (English) of the data points
  This line must not be changed.
- Lines 5..n: Values of the parameters according to line 4 of the individual data points
  You can change the parameter values for the particular station.

Importing into a module

Before importing the data points make sure that the PLC tags required for the data points have been created.

Note that when you import a CSV file all the data points existing on the module will be deleted and replaced by the imported data points.

Select a CP and select the import function from the shortcut menu of the module. The import dialog opens in which you select the required CSV file in the file directory.

If the information on the assignment of the individual data points to the relevant PLC tags matches the assignment in the original module, the data points will be assigned to the corresponding PLC tags.

When you import data points into a CP, but some required PLC tags have not yet been created in the CPU, the corresponding data point information cannot be assigned. In this case, you can subsequently create missing PLC tags and them assign them the imported data point information. The "Assignment repair" function is available for this (see below).

If the names of the PLC tags in the module into which the import is made have different names than in the module that exported, the corresponding data points cannot be assigned to your PLC tags.

Importing into several modules

You can import the data points from several modules into the modules of a different project. To do this in the import dialog select all the required CSV files with the control key.

Before importing the data points, make sure that the respective stations have been created with CPUs of the same name, modules of the same name and PLC tags of the same name.

When you import the corresponding stations of the project are searched for based on the module names in the CSV files. If a target station does not exist in the project or the module has a different name, the import of the particular CSV file will be ignored.

Restrictions for the import of data points

In the following situations the import of data points will be aborted:

- The telecontrol protocol used by the modules differs from the original module.
  The following CPs with the "TeleControl Basic" protocol are compatible with each other:
  - CP 1242-7 GPRS V2
  - CP 1243-1
  - CP 1243-7 LTE

  This means, for example, that data points can be imported from a CP 1243-1 into a CP 1243-7 LTE or from a CP 1242-7 GPRS V2 to a CP 1243-1.
- An attribute required by the module is missing in the CSV file to be imported.
  Example: If a data point to be imported uses a time trigger, the import will be aborted if no time-of-day synchronization was configured for the module.

Only when importing into several modules:

- The import is aborted when a module or CPU name is different from the data in the CSV file.

Assignment repair

If you have named the PLC tags in a station into which you want to import differently from the station from which the CSV file was exported, the assignment between data point and PLC tag is lost when you import.

You then have the option to either rename the existing PLC tags appropriately or add missing PLC tags. You can then repair the assignment between unassigned data points and PLC tags. This function is available either via the shortcut menu of the CP (see above) or with the following icon to the upper left in the data point editor: 

If a PLC tag with a matching name is found for a data point by the repair function, the assignment is restored. However the data type of the tag is not checked.

After the assignment repair make sure that you check whether the newly assigned PLC tags are correct.

Datapoint types

During the configuration of the user data to be transferred by the module, each data point is assigned a protocol-specific data point type. The data point types supported by the module along with the compatible S7 data types are listed below. They are grouped according to format (memory requirements).

The direction relates to the direction of transfer (monitoring direction = "in", control direction = "out").

Note

Effect of the change of arrays for data points

If an array is modified later, the data point must be recreated.

CP 1243-1, CP 1242-7 GPRS V2, CP 1243-7 LTE: Supported data point types of the protocol "TeleControl Basic"

Table 10-85 Supported data point types and compatible S7 data types

Format (memory requirements)	Data point type	S7 data types	Operand area
Bit	Digital input	Bool	I, Q, M, DB
	Digital output	Bool	Q, M, DB
Byte	Digital input	Byte, Char, USInt	I, Q, M, DB
	Digital output	Byte, Char, USInt	Q, M, DB
Integer with sign (16 bits)	Analog input	Int	I, Q, M, DB
	Analog output	Int	Q, M, DB
Counter (16 bits)	Counter input	Word, UInt	I, Q, M, DB
Integer with sign (32 bits)	Analog input	DInt	Q, M, DB
	Analog output	DInt	Q, M, DB
Counter (32 bits)	Counter input	UDInt, DWord	I, Q, M, DB
Floating-point number with sign (32 bits)	Analog input	Real	Q, M, DB
	Analog output	Real	Q, M, DB
Floating-point number with sign (64 bits)	Analog input	LReal	Q, M, DB
	Analog output	LReal	Q, M, DB
Data block (1 .. 64 bytes)	Data	ARRAY [1)]	DB
	Data	ARRAY [1)]	DB

[1)] For the possible formats of the ARRAY data type, refer to the following section.

For the data types of the DNP3 and IEC protocols of the CP 1243-1 see below.

Data block (ARRAY)

With the ARRAY data type, contiguous memory areas up to a size of 64 bytes can be transferred. The following S7 data types are compatible components of ARRAY:

- Byte, USInt (total of up to 64 per data block)
- Char (total of up to 64 per data block) - CP as of firmware version 2.1.77

- Int, UInt, Word (total of up to 32 per data block)
- DInt, UDInt, DWord (total of up to 16 per data block)

If the array is modified later, the data point must be recreated.

Time stamp in UTC format

Time stamps are transferred in UTC format (48 bits) and contain the time difference in milliseconds since 01.01.1970.

ST7-TIM, CP 1243-8 IRC (ST7): Supported data point types

Table 10-86 Supported data point types and compatible S7 data types

Format (memory requirements)	Data point type	S7 data types STEP 7 Basic	Operand area	Number of data points per SINAUT object	SINAUT object
Bit	Digital input (Status Input)	Bool	I, Q, M, DB	8	Bin08X_S
	Digital output (Status Output)	Bool	Q, M, DB	8	Bin08X_R
Byte	Digital input (Binary Input)	Byte, USInt	I, Q, M, DB	4	Bin04B_S
	Digital output (Binary Output)	Byte, USInt	Q, M, DB	4	Bin04B_R

[1] See below, section "1: Mirroring back"

[2] See below, section "2: Data block"

1: Mirroring

The mirroring back function using the "Value monitoring" parameter can be configured for the following data point types:

- Setpoint Output
- Parameter Output

The local values of the data points of this type can be monitored for change and the changes transferred to the master with the Value monitoring function.

Changing a local value can, for example, be caused by manual operator input on site.

To allow the value resulting from local events or interventions to be transferred to the master, the Value monitoring function generates a mirroring back channel for the relevant data point via which the locally changed value is mirrored back.

Remember that to use the mirror back function, you need to interconnect the local values in the controller with the relevant PLC tag of the data point.

2: Data block

With the ARRAY data type, blocks of data from contiguous memory areas up to a size of 4 .. 48 bytes can be transferred.

Compatible components of ARRAY are DInt, UDint, DWord or Real. The components within an array must be of the same type.

CP 1243-1 (DNP3), CP 1243-8 IRC (DNP3), DNP3 TIM: Supported data point types

Table 10-87 Supported data point types, DNP3 object groups, variants and compatible S7 data types

[1] This object group can be configured in the Data point editor of STEP 7 using the substitute object group 12.

[2] This object group can be configured in the Data point editor of STEP 7 using the substitute object group 20.

[3] This object group can be configured in the Data point editor of STEP 7 using the substitute object group 22.

[4] This object group can be configured in the Data point editor of STEP 7 using the substitute object group 41.

[5] With these data point types, contiguous memory areas up to a size of 64 bytes can be transferred. All S7 data types with a size between 1 and 64 bytes are compatible.

Explanation of the table footnotes [1], [2], [3], [4]: Configuring data points using substitute object groups

The initial data point types of the following object groups can be configured using the substitute object groups listed above:

- 10 [2]
- 11 [1, 2]
- 21 [1, 2, 5, 6]
- 23 [1, 2, 5, 6]
- 40 [1, 2, 3]
- 42 [1, 2, 4, 5, 6, 7, 8]

To configure the DNP3 CP, use the specified substitute object group.

Assign each data point on the master using the configurable data point index in STEP 7. The data point of the DNP3 CP is then assigned to the corresponding data point on the master.

Example of configuring the data point Binary Output (10 [2])
The data point is configured as follows:
On the DNP3 CP as Binary Command (12 [1])
On the master as Binary Output (10 [2])

With the data point types Binary Output Event (11) and Analog Output Event (42), you also need to enable mirroring; refer to the next section.

Configuration of the mirroring for output events (object groups 11 and 42)

You first create the data point types Binary Output Event (object group 11) and Analog Output Event (object group 42) as described above as data points of the object groups 12 or 41.

The local values of these two object groups can be monitored for change and the changes transferred to the master (). Changing a local value can, for example, be caused by manual operator input on site.

To allow the value resulting from local events or interventions to be transferred to the master, the data point in question requires a channel for mirroring back. You configure this mirroring back function is configured using the "Value monitoring" option in data point configuration, General tab.

Remember that to use the mirror back function, you need to interconnect the local values in the controller with the relevant PLC tag of the data point.

Time stamp for DNP3-CP in UTC format

Time stamps are transferred in UTC format (48 bits) and contain milliseconds since 01.01.1970.

CP 1243-1 (IEC), CP 1243-8 IRC (IEC): Supported data point types

Table 10-88 Supported data point types, IEC types and compatible S7 data types

Format (memory requirements)	Data point type	IEC type	Direction	S7 data types	Operand area

	Bitstring of 32 bits with time tag CP56Time2a [1] [3]	<64>	out	[3]	DB

[1] For the format of the time stamp, see the following section.

[2] For these data point types, create a data block with an array of precisely 2 bool.

[3] With these data point types, contiguous memory areas up to a size of 32 bits can be transferred. Only the S7 Bool data type is compatible.

Time stamp with the IEC CP

IEC CP time stamps are transferred according to the IEC specification in the "CP56Time2a" format. Note that in the frames only the first 3 bytes for milliseconds and minutes are transferred.

CP 1243-1 PCC: Supported data point types

Table 10-89 Supported data point types and compatible S7 data types

Format (memory requirements)	Data point type	S7 data types	Operand area
Bit	Digital input	Bool	I, Q, M, DB
Byte	Digital input	Byte, USInt	I, Q, M, DB
Integer with sign (16 bits)	Analog input	Int	I, Q, M, DB
Counter (16 bits)	Counter input	Word, UInt	I, Q, M, DB
Integer with sign (32 bits)	Analog value	DInt	Q, M, DB
Counter (32 bits)	Counter	UDInt, DWord	I, Q, M, DB
Floating-point number with sign (32 bits)	Analog value	Real	Q, M, DB
Floating-point number with sign (64 bits)	Analog value	LReal	Q, M, DB
Data block (1 .. 64 bytes)	Data	ARRAY [1]	DB
	Data	ARRAY [1]	DB

[1] For the possible formats of the ARRAY data type, refer to the following section.

Data block (ARRAY)

With the ARRAY data type, contiguous memory areas up to a size of 64 bytes can be transferred.

The following equivalent S7 data types are compatible components of ARRAY:

- Bool (total of up to 512 per data block)
- Byte, USInt (total of up to 64 per data block)
- Int, UInt, Word (total of up to 32 per data block)
- DInt, UDInt, Real, DWord (total of up to 16 per data block)
- LReal (total of up to 8 per data block)

Note

No processing of arrays in the operation center

The array data type cannot be processed in the operation center.

Time stamp in UTC format

Time stamps are transferred in UTC format (48 bits) and contain the time difference in milliseconds since 01.01.1970.

Process image, type of transmission, event classes, triggers

Introduction

Some of the functions described below differ depending on the protocol used by the module in question:

- TeleControl Basic CPs:
  - CP 1242-7 GPRS V2
  - CP 1243-1
  - CP 1243-7 LTE
- CP 1243-8 IRC / TIM 3V-IE / TIM 4R-IE
- CP 1243-1 DNP3 / TIM 3V-IE DNP3 / TIM 4R-IE DNP3
- CP 1243-1 IEC

Storage of values

As a rulethe values of all data points are stored in the image memory of the module. Values in the image memory are transferred only after being called by master station (ST7 TIM, TeleControl Basic CPs) or the master (DNP 3 TIM, CP 1243-1 DNP3 / IEC).

Events are also stored in the send buffer and can be transferred unsolicited.

The image memory, the process image of the module

The image memory is the process image of the CP. All the current values of the configured data points are stored in the image memory. New values of a data point overwrite the last stored value in the image memory.

The values are sent only after a query by the communications partner - see below "Transfer after call" in the "Types of transmission" section - or along with a message from the send buffer that needs to be transferred immediately.

The send buffer

The send buffer of the CP is the memory for the individual values of data points that are configured as an event. You will find the size of the send buffer in the manual of the relevant module.

The capacity of the send buffer is divided up equally for all enabled partners.

If the connection to a communications partner is interrupted, the individual values of the events are retained in the buffer. When the connection returns, the buffered values are sent. The frame memory operates chronologically; in other words, the oldest frames are sent first (FIFO principle).

If a frame was transferred to the communications partner, the transferred value is deleted from the send buffer.

If frames cannot be transferred for a longer period of time and the send buffer is threatening to overflow, the response is as follows:

- Telecontrol Basic-CPs, ST7 TIM, ST7 CP (CP 1243-8 IRC)
  The forced image mode
  If the send buffer reaches a fill level of 80%, the CP changes to the forced image mode. New values from data points configured as an event are no longer added to the send buffer but rather they overwrite older existing values in the image memory.
  When the connection to the communications partner returns, the CP changes back to the send buffer mode if the fill level of the send buffer has fallen below 50%.
- CP 1243-1 DNP3 / CP 1243-1 IEC
  If a send buffer fill level of 100% is reached, the oldest values are overwritten.

Saving the data point values

As a rule, the values of data points are stored in the image memory of the moodule and transferred only when queried by the communications partner.

Events are also stored in the send buffer and can be transferred unsolicited.

Data points are configured as a static value or as an event using the "Type of transmission" parameter (see below):

- **Static value (no event)**
  Static values are entered in the image memory (process image of the CP).
  Static values correspond to the following classes:
  - DNP3: Class 0
  - IEC: Class 2
- **Event**
  The values of data points configured as an event are also entered in the image memory of the CP. The value of the event is sent unsolicited to the communications partner if this function is enabled by the master.
  The values of events are also entered in the send buffer of the CP.
  Events correspond to the following classes:
  - DNP3: Class 1 / 2 / 3
  - IEC: Class 1

Types of transmission

The following types of transmission are possible:

- **Transfer after call (class 0)**
  The current value of the data point is entered in the image memory of the CP. New values of a data point overwrite the last stored value in the image memory.
  After being called by the communications partner, the current value at this time is transferred.
- **Triggered (events)**
  The values of data points configured as an event are entered in the image memory and also in the send buffer of the CP.
  The values of events are saved in the following situations:
  - The configured trigger conditions are fulfilled (data point configuration > "Trigger" tab, see below)
  - The value of a status bit of the status identifiers of the data point changes; see sectionStatus IDs of the data points (Page 1189).
    Example:
    When the value of a data point configured as an event is updated during startup of the station by reading the CPU data for the first time, the status "RESTART" of this data point changes (bit status change 1 → 0). This leads to generation of an event.

  The configurable event classes of the various CP types are described in the following sections.

Event classes with the "Triggered" type of transmission

Depending on the protocol used, the following event classes are available:

- **TeleControl Basic / ST7**
  - **Every value triggered**
    Each value change is entered in the send buffer in chronological order.
  - **Current value triggered**
    Only the last, current value is entered in the send buffer. It overwrites the value stored there previously.
- **DNP3**
  The evaluation of the following classification must be handled by the master.
  - **Event class 1**
    Class according to DNP3 protocol: Class 1
    Each value change is entered in the send buffer in chronological order.
  - **Event class 2**
    Class according to DNP3 protocol: Class 2
    Each value change is entered in the send buffer in chronological order.
  - **Event class 3**
    Class according to DNP3 protocol: Class 3
    Only the current value at the time the trigger condition was met is entered in the send buffer and overwrites the last value stored there.
- **IEC**
  Both of the following event classes correspond to the user data class 1 of the IEC protocol
  - **Every value triggered**
    Each value change is entered in the send buffer in chronological order.
  - **Current value triggered**
    Only the current value at the time the trigger condition was met is entered in the send buffer and overwrites the last value stored there.

Trigger

Various trigger types are available for starting event-driven transfer:

- **Threshold value trigger**
  The value of the data point is transferred when this reaches a certain threshold. The threshold is calculated as the difference compared with the last stored value, refer to the section Threshold value trigger (Page 1196).
- **Time trigger**
  The value of the data point is transferred at configurable intervals or at a specific time of day.
- **Event trigger**
  The value of the data point is transferred when a configurable trigger signal is fired. For the trigger signal, the edge change (0 → 1) of a trigger tag is evaluated that is set by the user program. When necessary, a separate trigger tag can be configured for each data point.
  Resetting the trigger tag in the bit memory area / DB:
  If the memory area of the trigger tag is in the bit memory or in a data block, the trigger tag is reset to zero when the data point value is transferred.

Whether the value of a data point is transferred to the communications partner immediately after the trigger or after a delay depends on the protocol used and the settings.

- DNP3 / IEC
  The spontaneous transmission in these protocols depends on whether spontaneous sending or asymmetric communication is possible in the network.
- TeleControl Basic
  Here you set the time of transmission with the "Transmission mode" parameter; see below.

Transmission mode

Only when using the "TeleControl Basic" or "ST7" protocol.

The transmission mode of a frame is set in the "Trigger" tab of the data point. With the two options, you specify whether frames of events are sent immediately or following a delay:

- Spontaneous
  The value is transferred immediately.
- Conditional spontaneous
  The value is transferred only when one of the following conditions is fulfilled:
  - The communications partner queries the station.
  - The value of another event with the transmission mode "Unsolicited" is transferred.
  - The fill level of the transmission buffer has reached 80% of its maximum capacity.

Status IDs of the data points

Status identifiers

The status identifiers of the data points listed in the following tables are transferred along with the value in each frame to the communications partner. They can be evaluated by the communications partner.

The entries in the table row "Significance" relate to the entry in the table row "Bit status".

CP 1243-1, CP 1242-7 GPRS V2, CP 1243-7 LTE, CP 1542SP-1 IRC (TeleControl Basic)

The status bits are converted to the OPC quality code as follows by TCSB.

- Quality = BAD, if:
  NON_EXISTENT or OVER_RANGE = 1
- Quality = UNCERTAIN, if:
  RESTART or CARRY or SB = 1
- Quality = GOOD, if:
  Bits 1, 2, 3, 5 and 6 = 0

Table 10-90 Bit assignment of status byte 0

Bit	7	6	5	4	3	2	1	0
Flag name	-	NON_ EXISTENT	Substituted	LOCAL_ FORCED	CARRY	OVER_ RANGE	RESTART	ONLINE
Meaning	-	Data point does not exist or S7 address unreachable	Substitute value	Local operator control	Counted value overflow before reading the value	Limit value of the analog preprocessing overshot / undershot	Value not yet updated after start	Value is valid
Bit status	*(always 0)*	1	1	1	1	1	1	1

CP 1243-1 DNP3, CP 1542SP-1 IRC (DNP3)

The status IDs correspond to the following elements of the specification:

OBJECT FLAGS - DNP3 Specification, Volume 6, Data Object Library - Part 1

Table 10-91 Bit assignment of the status byte

Bit	7	6	5	4	3	2	1	0
Flag name	-	-	-	LOCAL_ FORCED	DISCONTI NUITY	OVER_ RANGE	RESTART	ONLINE
Meaning	-	-	-	Local operator control	Counted value overflow before reading the value	Limit value of the analog preprocessing overshot / undershot	Value not yet updated after start	Value is valid
Bit status	*(always 0)*	*(always 0)*	*(always 0)*	1	1	1	1	1

CP 1243-1 IEC, CP 1542SP-1 IRC (IEC)

The status IDs correspond to the following elements of the specification:

Quality descriptor - IEC 60870 Part 5-101

Table 10-92 Bit assignment of the status byte

Bit	7	6	5	4	3	2	1	0
Flag name	-	-	SB substituted	-	CY carry	OV overflow	NT not topical	IV invalid
Meaning	-	-	Substitute value	-	Counted value overflow before reading the value	Value range exceeded, analog value	Value not updated	Value is valid
Bit status	*(always 0)*	*(always 0)*	1	*(always 0)*	1	1	1	0

CP 1243-1 PCC

Table 10-93 Bit assignment of status byte 0

Bit	7	6	5	4	3	2	1	0
Flag name	-	NON_ EXISTENT	Substituted	LOCAL_ FORCED	CARRY	OVER_ RANGE	RESTART	ONLINE
Meaning	-	Data point does not exist or S7 address unreachable	Substitute value	Local operator control	Counted value overflow before reading the value	Limit value of the analog preprocessing overshot / undershot	Value not yet updated after start	Value is valid
Bit status	*(always 0)*	1	1	1	1	1	1	1

CP 1243-8 IRC

The CP 1243-8 IRC does not supply any status identifiers.

Rules for configuring the data point index:

Configuration of the data point index

Below you will find the rules for configuring the data point index for the individual CP types.

CPs using the TeleControl Basic protocol

Within a CP, the indexes of the data point classes must comply with the following rules:

- Input
  The index of a data point of the type input must be unique throughout all data point types (digital inputs, analog inputs etc.).
- Output
  - A data point of the type output can have the same index as a data point of the type input.
  - Several data points of the type output can have the same index.

Note

Data points for the inter-station communication with a CP in another S7 station

Note that for inter-station communication, the indexes of the two corresponding data points (data point pair) must be identical for the sending and receiving CP.

CPs using the DNP3 protocol

On a CP, data point indexes must be unique within each of the following object groups:

- Binary Input / Binary Input Event
- Binary Output / Binary Command
- Counter / Counter Event
- Analog Input / Analog Input Event
- Analog Output
- Octet String / Octet String Event

Indexes of two data points in different object groups can be identical.

CPs using the IEC protocol

The data point indexes must be unique in a CP.

Data point indexes assigned twice are indicated as errors in the consistency check and prevent the project being saved.

CP 1243-8 IRC

The data point indexes must be unique in a CP.

Data point indexes assigned twice are indicated as errors in the consistency check and prevent the project being saved.

CP 1243-1 PCC

The data point indexes must be unique in a CP.

Data point indexes assigned twice are indicated as errors in the consistency check and prevent the project being saved.

"Local setpoint input" (TIM)

Functions of the data point types for setpoint transfer

For transferring setpoints, for local setpoint entries and for feedback of the local values, the two data point types described below are available. For the functions the relevant input and output data points must be created for the communications partners.

The parameters for local setpoint entries and for the feedback are optional. If you do not require this, leave it disabled.

- **Setpoint input (Set01W_S)**
  Functions:
  - Sending a setpoint to the communications partner
    The setpoint is stored in the PLC tag (Word) in the "General" (Data source) tab.
  - Reception of the remote setpoint input mode "local" from the partner object
    The value is transferred to the PLC tag "Setpoint input mode "local"" (Bool).
  - Reception of the return value from the partner
    The value is transferred to the PLC tag "Return value" (Word, Int).
- **Setpoint output (Set01W_R)**
  Functions:
  - Reception of a setpoint from the communications partner
    The setpoint is transferred to the PLC tag (Word) in the "General" (Data source) tab.
  - Sending the local setpoint input status to the partner object
    The information as to whether the locally assigned setpoint or the remote setpoint is valid is read from the PLC tag "Setpoint status" (Bool).
  - Sending a locally entered setpoint to the partner
    The setpoint is read from the PLC tag "Local setpoint" (Word, Int).

Local setpoint input - Reception

The **Setpoint input (Set01W_S)**is used to send a setpoint to the communications partner.

In addition, the following parameters for local setpoints are available in the "Local setpoint input" tab of data point configuration:

- **Setpoint input mode of the partner**
  If the option is enabled, the setpoint input mode "local" received from the remote partner data point is saved in a PLC tag (Bool).
  - 0 = remote data point of the partner in the 'setpoint receipt' mode
  - 1 = remote data point of the partner in the setpoint input mode 'local'

  Via the parameter the feedback that the remote data point is set to local operator input (Setpoint status = 1) is received.
  The parameter is used only for signaling. With this parameter and with the corresponding parameter of the partner data point, there is no interlocking of the remote with the local setpoint assignment. An interlock of the remote and local setpoint assignment must be implemented in the user program.
  After startup of the CPU or partner CPU, or after the return of the connection, a general request ensures that the current, valid status of the partner is displayed at the parameter.
- **Return value**
  The partner data point that receives the setpoint feeds back the currently valid setpoint if the parameter "Setpoint status" is enabled there. This mirrored back setpoint is displayed here.
  If the partner object is set to 'local' and if new input is made there, the setpoint changed there is displayed here if the Local setpoint parameter is enabled for the partner object.
  After startup of the CPU or partner CPU, or after the return of the connection, a general request ensures that the current, valid setpoint of the partner is displayed at the parameter.

Local setpoint input - Sending

The **Setpoint output (Set01W_R)** is used to receive a setpoint from the communications partner.

In addition, the following parameters for local setpoints are available in the "Local setpoint input" tab of data point configuration:

- **Setpoint status**
  If the option is activated, the information as to whether the locally entered setpoint or the remote setpoint is valid is read from the PLC tag "Setpoint status" (Bool) and sent to the remote partner object.
  - 0 = remote setpoint of the partner
  - 1 = locally entered setpoint

  The information as to whether the locally set setpoint or the remote setpoint is valid can be signaled via this input. The current status of the Local input and a copy of the current local setpoint is returned (mirrored) to the partner. A setpoint sent by the remote partner (for example, master station) can also be accepted by the object if "Setpoint status" is set.
  The parameter is used only for information. An interlock with the remote setpoint assignment must be implemented in the user program.
- **Local setpoint**
  Via the parameter, the locally active setpoint is read from the PLC tag (Word, Int) and mirrored back to the send data point of the communications partner.

"Trigger“ tab

Trigger

Data points are configured as a static value or as an event using the "Type of transmission" parameter:

Saving the value of a data point configured as an event

Saving the value of a data point configured as an event in the send buffer (message memory) can be triggered by various trigger types:

- **Threshold value trigger**
  The value of the data point is saved when this reaches a certain threshold. The threshold is calculated as the difference compared with the last stored value, refer to the section Threshold value trigger (Page 1196).
- **Time trigger**
  The value of the data point is saved at configurable intervals or at a specific time of day.
- **Event trigger (Trigger tag)**
  The value of the data point is saved when a configurable trigger signal is fired. For the trigger signal, the edge change (0 → 1) of a trigger tag is evaluated that is set by the user program. When necessary, a separate trigger tag can be configured for each data point.
  Resetting the trigger tag in the bit memory area / DB:
  If the memory area of a trigger tag is in the bit memory or in a data block, the CP resets the trigger variable itself to 0 (zero) as soon as the value of the data point has been transferred. This can take up to 500 milliseconds.

Note

Fast setting of triggers

Triggers must not be set faster than a minimum interval of 500 milliseconds. This also applies to hardware triggers (input area).

Note

Hardware trigger

You need to reset hardware triggers via the user program

Transferring the value of a data point configured as an event

You specify whether the value of a data point is transferred to the communications partner immediately after the trigger fires or after a delay in the "Transmission mode" parameter.

Transmission mode

The transmission mode of a frame is set in the "Trigger" tab of the data point. With the option, you specify whether messages of events are sent immediately or following a delay:

- Immediate transfer - Spontaneous
  The value is transferred immediately.
- Buffered transfer - Conditionally spontaneous
  The value is transferred only when one of the following conditions is fulfilled:
  - The communications partner queries the station.
  - The value of another event with the transmission mode “Spontaneous" is transferred.

Threshold value trigger

Note

Threshold value trigger: Calculation only after "Analog value preprocessing"

Note that the analog value preprocessing is performed before the check for a configured threshold value and before calculating the threshold value.

This affects the value that is configured for the threshold value trigger.

Note

No Threshold value trigger if Mean value generation is configured

If mean value generation is configured, no threshold value trigger can be configured for the analog value event involved.

For the time sequence of the analog value preprocessing refer to the section Analog value preprocessing (Page 1198).

Threshold value trigger

Function

If the process value deviates by the amount of the threshold value, the process value is saved.

Two methods are used to calculate the threshold value deviation:

- **Absolute method**
  With binary and counter values as well as with analog values with configured mean value generation, the absolute method is used to calculate the threshold value deviation.
- **Integrative method**
  With analog values without configured mean value generation, the integrating method is used to calculate the threshold value deviation.
  In the integration threshold value calculation, it is not the absolute value of the deviation of the process value from the last stored value that is evaluated but rather the integrated deviation.

Absolute method

For each binary value a check is made to determine whether the current (possibly smoothed) value is outside the threshold value band. The current threshold value band results from the last saved value and the amount of the configured threshold value:

- Upper limit of the threshold value band: Last saved value + threshold value
- Lower limit of the threshold value band: Last saved value - threshold value

As soon as the process value reaches the upper or lower limit of the threshold value band, the value is saved. The newly saved value serves as the basis for calculating the new threshold value band.

Integrative method

The integration threshold value calculation works with a cyclic comparison of the integrated current value with the last stored value. The calculation cycle in which the two values are compared is 500 milliseconds.
(Note: The calculation cycle must not be confused with the scan cycle of the CPU memory areas).

The deviations of the current process value are totaled in each calculation cycle. The trigger is set only when the totaled value reaches the configured value of the threshold value trigger and a new process value is entered in the send buffer.

The method is explained based on the following example in which a threshold value of 2.0 is configured.

Table 10-94 Example of the integration calculation of a threshold value configured with 2.0

Time [s] (calculation cycle)	Process value stored in the send buffer	Current process value	Absolute deviation from the stored value	Integrated deviation
0	**20.0**	**20.0**	0	0
0.5		20.3	+0.3	0.3
1.0		19.8	-0.2	0.1
1.5		20.2	+0.2	0.3
2.0		20.5	+0.5	0.8
2.5		20.3	+0.3	1.1
3.0		20.4	+0.4	1.5
3.5	**20.5**	**20.5**	+0.5	**2.0**
4.0		20.4	-0.1	-0.1
4.5		20.1	-0.4	-0.5
5.0		19.9	-0.6	-1.1
5.5		20.1	-0.4	-1.5
6.0	**19.9**	**19.9**	-0.6	**-2.1**

With the changes in the process value shown in the example, the threshold value trigger configured with 2.0 fires twice:

- At the time 3.5 s: The value of the integrated deviation is at 2.0. The new process value stored in the send buffer is 20.5.
- At the time 6.0 s: The value of the integrated deviation is at 2.1. The new process value stored in the send buffer is 19.9.

In this example, if a deviation of the process value of approximately 0.5 should fire the trigger, then with the behavior of the process value shown here a threshold value of approximately 1.5 ... 2.5 would need to be configured.

Analog value preprocessing

CPs with data point configuration support analog value preprocessing. For analog value data points, some or all of the functions described below can be configured.

Requirements and restrictions

You will find the requirements for the configuration of the preprocessing options and restrictions in the section relating to the particular function.

Note

Restrictions due to configured triggers

The analog value preprocessing options "Fault suppression time", "Limit value calculation" and "smoothing" are not performed if no threshold value trigger is configured for the relevant data point.. In these cases, the read process value of the data point is entered in the image memory of the CP before the preprocessing cycle of the threshold value calculation (500 ms) elapses.

Sequence of the analog value preprocessing options

The values of analog inputs configured as an event are processed on the CPU according to the following scheme:

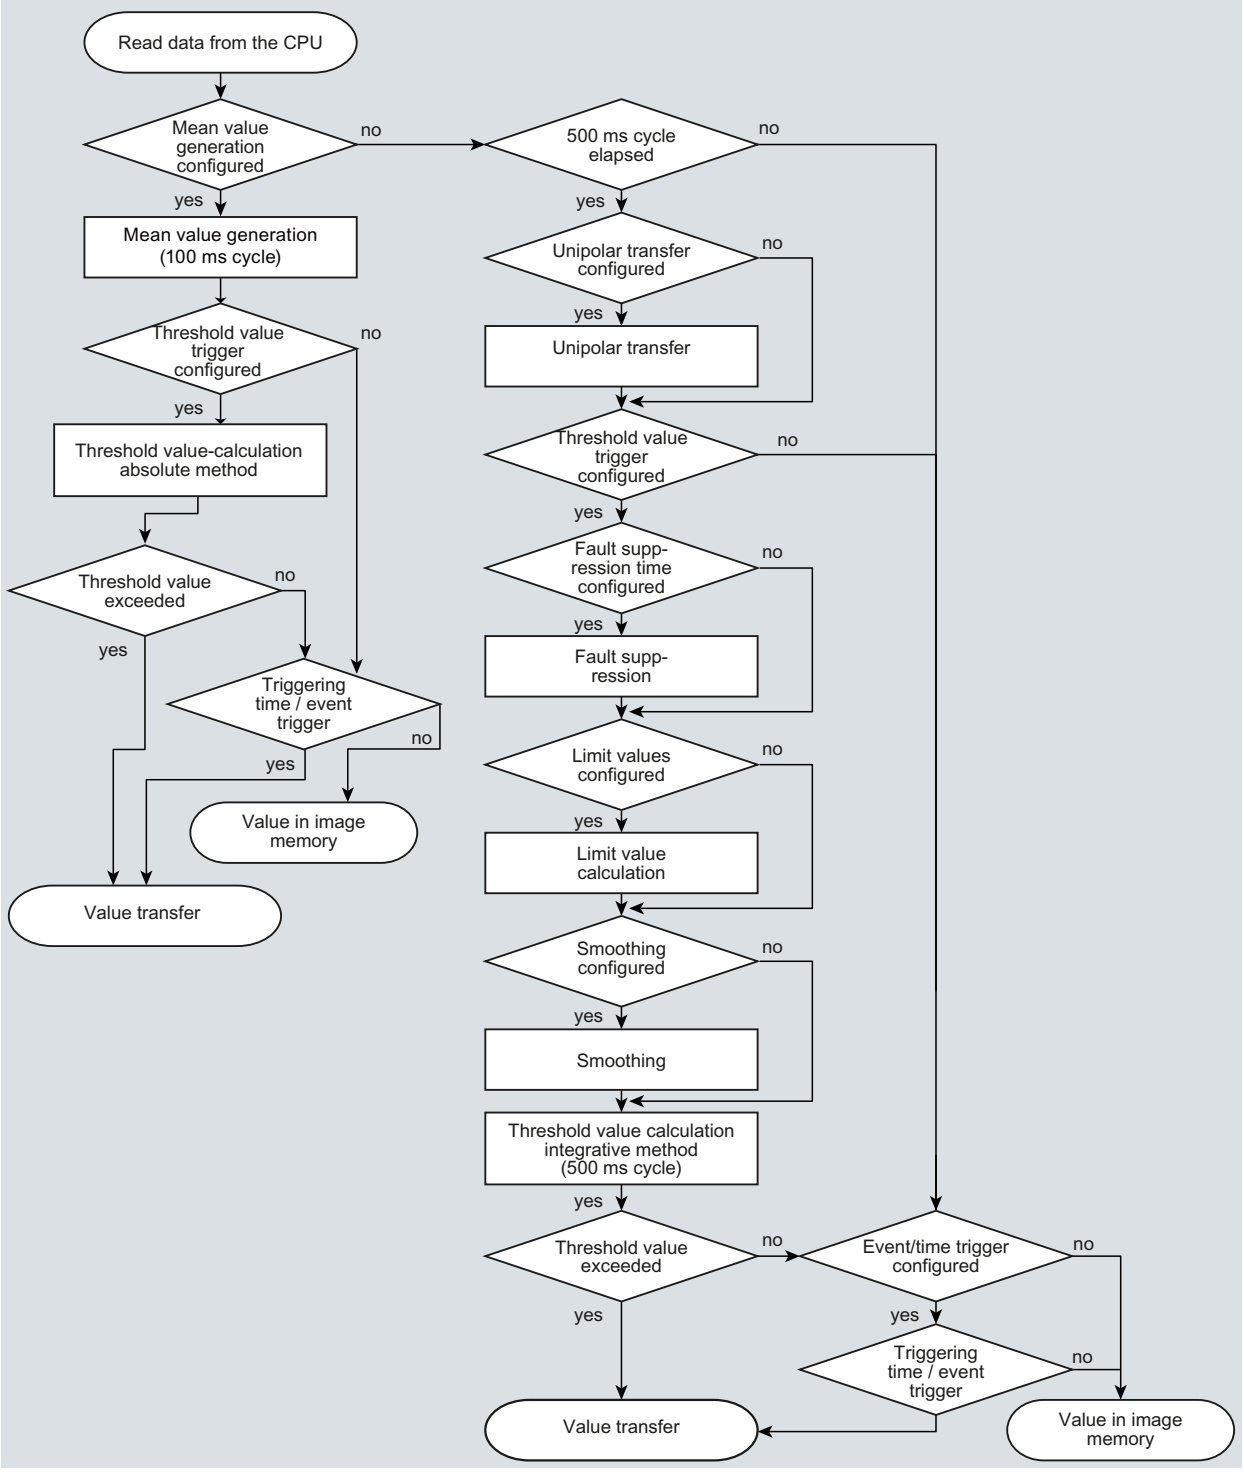

Figure 10-12 Sequence of the analog value preprocessing

The 500 millisecond cycle is started by the integrative threshold value calculation. In this cycle, the values are saved even when the following preprocessing options are enabled:

- Unipolar transfer
- Fault suppression time
- Limit value calculation
- Smoothing

Mean value generation

Note

Restricted preprocessing options if mean value generation is configured

If you configure mean value generation for an analog value event, the following preprocessing options are not available:

- Unipolar transfer
- Fault suppression time
- Smoothing

Function

With this parameter, acquired analog values are transferred as mean values.

If mean value generation is active, it makes sense to configure a time trigger..

The current values of an analog data point are read in a 100 millisecond cycle and totaled. The number of read values per time unit depends on the read cycle of the CPU and the CPU scan cycle of the CP.

The mean value is calculated from the accumulated values as soon as the transfer is triggered by a trigger. Following this, the accumulation starts again so that the next mean value can be calculated.

The mean value can also be calculated if the transmission of the analog value message is triggered by a request from the communications partner. The duration of the mean value calculation period is then the time from the last transmission (for example triggered by the trigger) to the time of the request. Once again, the accumulation restarts so that the next mean value can be calculated.

Input modules: Overflow range / underflow range

As soon as a value is acquired in the overflow or underflow range, mean value generation is stopped. The value 32767 / $7FFF_h$ or -32768 / 8000_h is saved as an invalid mean value for the current mean value calculation period and sent with the next message.

The calculation of a new mean value is then started. If the analog value remains in the overflow or underflow range, one of the two values named is again saved as an invalid mean value and sent when the next message is triggered.

Note

Fault suppression time > 0 configured

If you have configured an error suppression time and then enable mean value generation, the value of the error suppression time is grayed out but no longer used. If mean value generation is enabled, the error suppression time is set to 0 (zero) internally.

Unipolar transfer

Restrictions

Unipolar transfer cannot be configured at the same time as mean value generation. Enabling unipolar transfer has no effect when mean value generation is activated.

Function

With unipolar transfer, negative values are corrected to zero. This can be desirable if values from the underrange should not be transferred as real measured values.

Exception: With process data from input modules, the value -32768 / 8000_h for wire break of a live zero input is transferred.

With a software input, on the other hand, all values lower than zero are corrected to zero.

Fault suppression time

Requirements for the function

Configuration of the threshold trigger for this data point

Restrictions

The fault suppression time cannot be configured at the same time as mean value generation. A configured value has no effect when mean value generation is activated.

Function

A typical use case for this parameter is the suppression of peak current values when starting up powerful motors that would otherwise be signaled to the control center as a disruption.

The transmission of an analog value in the overflow ($7FFF_h$) or underflow range (8000_h) is suppressed for the specified time. The value $7FFF_H$ or 8000_H is only sent after the fault suppression time has elapsed, if it is still pending.

If the value returns to the measuring range before the fault suppression time elapses, the current value is transferred.

Input modules

The suppression is adjusted to analog values that are acquired directly by the S7 analog input modules as raw values. These modules return the specified values for the overflow or underflow range for all input ranges (also for live zero inputs).

An analog value in the overflow range (32767 / $7FFF_h$) or underflow range (-32768 / 8000_h) is not transferred for the duration of the fault suppression time. This also applies to live zero inputs. The value in the overflow/underflow range is only sent after the fault suppression time has elapsed, if it is still pending.

Recommendation for finished values that were preprocessed by the CPU:

If the CPU makes preprocessed finished values available in bit memory or in a data block, suppression is only possible or useful if these finished values also adopt the values listed above 32767 / $7FFF_h$ or -32768 / 8000_h in the overflow or underflow range. If this is not the case, the parameter should not be configured for preprocessed values.

For finished values preprocess in the CPU, the limits for the overflow and underflow can be freely assigned.

Smoothing factor

Requirements for the function

Configuration of the threshold trigger for this data point

Restrictions

The smoothing factor cannot be configured at the same time as mean value generation. A configured value has no effect when mean value generation is activated.

Function

Analog values that fluctuate quickly can be evened out using the smoothing function.

The smoothing factors are calculated according to the following formula as with S7 analog input modules.

$$y_n = \frac{x_n + (k-1)y_{n-1}}{k}$$

where
y_n = smoothed value in the current cycle
x_n = value acquired in the current cycle n
k = smoothing factor

The following values can be configured for the module as the smoothing factor.

- 1 = No smoothing
- 4 = Weak smoothing
- 32 = Medium smoothing
- 64 = Strong smoothing

Set limit value 'low' / Set limit value 'high'

Requirements for the function

- Configuration of the threshold trigger for this data point
- PLC tag in the bit memory operand area or data area
  The analog value data point must be linked to a PLC tag in the bit memory or data area (data block). For PLC tags of hardware modules (input operand area) limit value configuration is not possible.

The configuration of limit values is pointless for measured values that have already been preprocessed on the CPU.

Function

In these two input boxes, you can set a limit value in the direction of the start of the measuring range or in the direction of the end of the measuring range. You can also evaluate the limit values, for example as the start or end of the measuring range.

Status identifier "OVER_RANGE"

With CPs that support status identifiers (not the CP 1243-8 IRC), if the limit value is overshot or undershot, the status identifier "OVER_RANGE" of the data point is set. This status identifiers are described in the section Status IDs of the data points (Page 1189).

The "OVER_RANGE" bit of the status identifier of the data point is set as follows when the relevant analog value is transferred:

- Limit value 'high':
  - If the limit value is exceeded: OVER_RANGE = 1
  - If the value falls below the limit value: OVER_RANGE = 0
- Limit value 'low':
  - If the value falls below the limit value : OVER_RANGE = 1
  - If the value then exceeds the limit value: OVER_RANGE = 0

Configuration of the limit value

The limit value is configured as a whole decimal number. The range of values is based on the range of values of the raw value of analog input modules.

Range	Raw value (16 bits) of the PLC tag		Module output [mA]			Measuring range [%]
	Decimal	Hexadecimal	0 .. 20 (unipolar)	-20 .. +20 (bipolar)	4 .. 20 (life zero)	
Overflow	32767	7FFF	> 23.515	> 23.515	> 22.810	> 117.593
Overrange	32511 ... 27649	7EFF ... 6C01	23.515 ... 20.001	23.515 ... 20.001	22.810 ... 20.001	117.593 ... 100.004
Nominal range (unipolar / life zero)	27648 ... 0	6C00 ... 0000	20 ... 0		20 ... 4	100 ... 0

Range	Raw value (16 bits) of the PLC tag		Module output [mA]			Measuring range [%]
	Decimal	Hexadecimal	0 .. 20 (unipolar)	-20 .. +20 (bipolar)	4 .. 20 (life zero)	
Nominal range (bipolar)	27648 ... 0 ... -27648	6C00 ... 0000 9400		20 ... 0 ... -20		100 ... 0 ... -100
Underrange (unipolar / life zero)	-1 ... -4864	FFFF ... ED00	-0.001 ... -3.518		3.999 ... 1.185	-0.004 ... -17.59
Underrange (bipolar)	-27649 ... -32512	93FF ... 8100		-20.001 ... -23.516		-100.004 ... -117.593
Undershoot / wire break	-32768	8000	< -3.518		< 1.185	< -17.593

Note

Evaluation of the value even when the option is disabled

If you enable one or both options and configure a value and then disable the option later, the grayed out value is nevertheless evaluated.

To disable the two options, delete the previously configured values limit values from the input boxes and then disable the relevant option.

Recommendation for quickly fluctuating analog values:

If the analog value fluctuates quickly, it may be useful to smooth the analog value first if limit values are configured.

Masks

Masking of individual bits in the byte of binary inputs (Bin04B_S)

The "Masks" parameter group provides three options for transmitting binary value messages. The corresponding bits are masked in hexadecimal format.

By entering hexadecimal values you can specify bit-by-bit whether certain bits do not trigger message transmission or which bits are transferred in a different transmission mode.

- **Alarm mask**
  Changes in masked bits cause an unconditional spontaneous message transmission. Changes from 0 to 1 and from 1 to 0 are evaluated.
  The "alarm mask" is only practical when the data point is transmitted over a dialup network and the option "Conditional spontaneous" was activated.
- **Send buffer principle mask**
  Changes in masked bits cause a message transmission according to the send buffer principle. Changes from 0 to 1 and from 1 to 0 are evaluated.
  The send buffer mask is only practical with data points that have the "Image memory" option enabled.
- **Disable mask**
  Masked bits are ignored when changes are checked. This means that changes to the masked bits for this data point do not trigger message transmission. A masked bit always has the value 0 in the message.

Example of byte assignment

The following table shows the masking of the bits according to the hexadecimal value "A3" entered in the input box od the parameters.

Table 10-95 Byte assignment

Bit:	.7	.6	.5	.4	.3	.2	.1	.0
Masked	1	0	1	0	0	0	1	1
Hex mask	A				3			

The bits with the value 1 are masked; in other words bits no. 0, 1, 5 and 7 cause the relevant function in the described masks.

DNP3 parameters

The following parameters apply only to the CP when using the DNP3 protocol

Parameters for the data point type Binary Command Output (12)

The data point type allows receipt of a DNP3 command with the following control information (control code):

- **LATCH_ON / LATCH_OFF**
  or
- **PULSE_ON**
  When the byte "Control Code" is received with the function "PULSE_ON" information sent with it by the master "Count", "On-time" and "Off-time" is evaluated and compared to the object parameters "Max. pulse duration", "Pulse duration replacement time" and "Max. number of pulses" (see below).

The following control codes sent by the master are evaluated.

Table 10-96 Functions of the data object

Receipt of:			Reaction of the object depends on the configuration	
Control Code	**TCC ***	**Op Type ****	**Output mode = Pulse on**	**Output mode = Latch on/off**
0x01	NUL	PULSE_ON	The output is set to 1 for the duration of “On-time“.	The command is rejected.
0x03	NUL	LATCH_ON	The command is rejected.	The output is set permanently to 1.
0x04	NUL	LATCH_OFF	The command is rejected.	The output is set permanently to 0.
0x41	CLOSE	PULSE_ON	The output is set permanently to 1 (as with LATCH_ON).	The command is rejected.
0x81	TRIP	PULSE_ON	The output is set permanently to 0 (as with LATCH_OFF).	The command is rejected.

***** Trip-Close Code field

****** Operation Type field

Parameter

Name: **Max. number of pulses**

Range of values: 0 ... 255

Default: 0

Explanation: Monitors the number of pulses sent by the master (Count). If the number of pulses received from the master exceeds the value configured here, the command is rejected.

If you enter 0 (zero), the monitoring is disabled.

Name: **Max. pulse duration**

Range of values: 0 ... 2147483647

Default: 0

Explanation: Monitors the pulse duration sent by the master (On-time). If the pulse duration received from the master exceeds the value configured here, the command is rejected.

If you enter 0 (zero), the monitoring is disabled.

Name: **Pulse duration equivalent time**

Range of values: 0 ... 2147483647

Default: 0

Explanation: Replacement value for the pulse duration If the pulse duration received from the master exceeds the value configured in “Max pulse duration“. The parameter is only used when “Max. pulse duration“ is configured.

If the value is 0 (zero), no replacement value is used.

Message editor

Processing status of messages (e-mails / SMS messages)

Enable status identifier / External status

If the option is enabled, the CP writes a processing status about the sent e-mail / SMS to a PLC tag.

The meaning of the statuses is as follows:

Table 10-97 SMS: Meaning of the status ID output in hexadecimal format

Status	Meaning
0000	Transfer completed free of errors
0001	Error in the transfer, possible causes: • SIM card invalid. • No network • Wrong destination phone number (number not reachable)

Table 10-98 E-mails: Meaning of the processing status output in hexadecimal format

Status	Meaning
0000	Transfer completed free of errors
82xx	Other error message from the e-mail server Apart from the leading "8", the status corresponds to the three-digit error number of the SMTP protocol.
8401	No channel available Possible cause: There is already an e-mail connection via the CP. A second connection cannot be set up at the same time.
8403	No TCP/IP connection could be established to the SMTP server.
8405	The SMTP server has denied the login request.
8406	An internal SSL error or a problem with the structure of the certificate was detected by the SMTP client.
8407	Request to use SSL was denied.
8408	The client could not obtain a socket for creating a TCP/IP connection to the mail server.
8409	It is not possible to write via the connection. Possible cause: The communications partner reset the connection or the connection aborted.

Status	Meaning
8410	It is not possible to read via the connection. Possible cause: The communications partner terminated the connection or the connection was aborted.
8411	Sending the e-mail failed. Cause: There was not enough memory space for sending.
8412	The configured DNS server could not resolve specified domain name.
8413	Due to an internal error in the DNS subsystem, the domain name could not be resolved.
8414	An empty character string was specified as the domain name.
8415	An internal error occurred in the cURL module. Execution was aborted.
8416	An internal error occurred in the SMTP module. Execution was aborted.
8417	Requests to SMTP on a channel already being used or invalid channel ID. Execution was aborted.
8418	Sending the e-mail was aborted. Possible cause: Execution time exceeded.
8419	The channel was interrupted and cannot be used before the connection is terminated.
8420	Certificate chain from the server could not be verified with the root certificate of the CP.
8421	Internal error occurred. Execution was stopped.
8450	Action not executed: Mailbox not available / unreachable. Try again later.
84xx	Other error message from the e-mail server Apart from the leading "8", the status corresponds to the three-digit error number of the SMTP protocol.
8500	Syntax error: Command unknown. This also includes the error of having a command chain that is too long. The cause may be that the e-mail server does not support the LOGIN authentication method. Try sending e-mails without authentication (no user name).
8501	Syntax error. Check the following configuration data: Message configuration > Message parameters: • Recipient address ("To" or "Cc").
8502	Syntax error. Check the following configuration data: Message configuration > Message parameters: • Email address (sender)
8535	SMTP authentication incomplete. Check the "User name" and "Password" parameters in the CP configuration.
8550	SMTP server cannot be reached. You have no access rights. Check the following configuration data: • CP configuration > E-mail configuration: – User name – Password – Email address (sender) • Message configuration > Message parameters: – Recipient address ("To" or "Cc").
8554	Transfer failed
85xx	Other error message from the e-mail server Apart from the leading "8", the status corresponds to the three-digit error number of the SMTP protocol.

Activation of the serial interface interface of the CP 1243-8 IRC (V3) for the ST7 protocol

Serial interface of the CP 1243-8 IRC

When you insert the CP from the catalog in the project, the serial interface of the CP is not visible in the network view of STEP 7.

When using the types of communication "DNP3" and "IEC" the serial interface cannot be used.

After activating thde type of communication "ST7", the serial interface is visible but cannot be configured. To use the serial interface of the CP, a TS module is required.

Follow the steps below to insert the TS module and to activate the serial interface for ST7 communication.

1. From the network view, open the device view of the CP (double-click on the module).
   The device view opens.
   At the same time the catalog view changes. Among other things the Communications modules" directory appears.
2. Expand the "Communications modules" directory:
   > Industrial Remote Communication > TS Modules
3. Expand the subdirectory of the required TS module.
4. Select the TS module.
   A vertical blue line appears on the symbol of the CP.
5. Now drag the TS module onto the blue line of the CP in the device view.
6. The TS moduell with the serial interface is inserted in the station.
   At the same time a new WAN interface is inserted in the network view.

You can configure the serial interface directly in the device view with the TS adapter or in the WAN interface of the CP in the network view.

Configuring telecontrol connections for the TIM

To be able to use ST7 communication of the TIM via classic WAN networks (dedicated line, dialup network) you need to create telecontrol connections in the "Network data" editor.

Opening the "Network data" editor with the "Telecontrol" tab

To open the editor, follow the steps below:

1. Open the network view of the project.
   On the right you will find the initially hidden "Network data" editor.
2. Open the "Network data" editor using the arrow symbol.
   The "Network data" editor is displayed with several tabs. The first tab on the left is the network overview.
3. Expand the "Network data" editor until the "Telecontrol" tab appears on the right.
   In this tab you configure the telecontrol connections.

Creating telecontrol connections for the the ST7 communication of the TIM

For ST7 communication between two stations with a TIM module via classic WAN networks (dedicated line, dialup network) you require at least one telecontrol connection. Follow the steps outlined below:

1. In the "Starting point" box, click on a free line in the "Telecontrol" tab of the "Network data" editor.
   The drop-down list that opens displays the configured stations (CPUs or applications) that use the ST7 protocol.
2. Select a station by double-clicking.
   The connection will then be included in the list of telecontrol connections.
   The name of the connection is preset, but you can change it.
3. Now in the "Endpoint" box select the connection partner from the displayed drop-down list.

Boxes with a missing or bad configuration are shown on a red background.

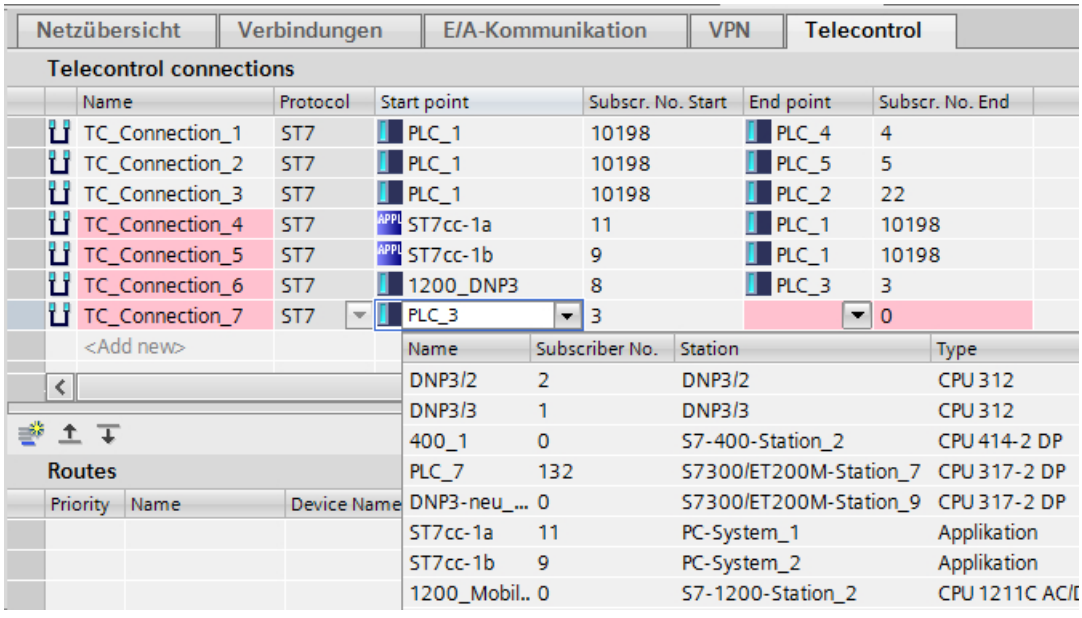

Figure 10-13 "Network data" editor, "Telecontrol" tab

Specification of the connection sequence

Then specify the connection sequence of the created telecontrol connection.

1. Above the second table "Configured connections" click the paths symbol  .
   The dialog "Add connection paths" opens and the possible connections re searched for.
2. if one or more connections are displayed in the upper table, select the required connection in the upper table.
   The connection details with the connection sequence are shown in the second table.
3. Close the dialog with the "Close" button if no connection is found.
   In this case, there is no suitable network between the two stations and you will need to complete the configuration.
4. Click on "Add" if you want to choose the selected connection as the configured connection.

5. The reaction whether the connection was added or whether there is an error in the configuration is displayed at the bottom of the dialog in "Information".
6. Close the dialog with the "Close" button if the configured connection corresponds to the demands of the project.

The connection details of every possible and selected connection are displayed in the lower table "Connection details".

- The "Position" column shows a station symbol with symbol for the connection point (starting point, node, endpoint)
  Based on the color of the symbols for the connection endpoint you can recognize connections that are not permitted.
  - Blue symbols for the connection point: Valid connections
  - Red symbols for the connection point: Invalid connections

Delete invalid or redundant connections

If you have configured several connections between two stations and the connections are shown on a red background in the table, the connection configuration is invalid. When checking the possible connections. the table "Connection details" supports you.

If you have non-permitted redundant connections you need to delete a connection. Follow the steps outlined below:

1. To delete a connection in the table "Configured connections", select the connection you do not need.
2. Delete the connection using the shortcut menu "Delete".

Rules for connection configuration

Note the following rules for connection configuration:

- For a redundant ST7cc control center, i STEP 7 create two PC stations each with an ST7cc application.
  Only in this way can you configure a connection from a subscriber to every ST7cc.
- An MSC connection can only run via the first Ethernet interface [X1] of a TIM.
- A connection via an inconsistent network is invalid. Examples:
  - Subscriber with incompatible modems
  - Incompatible settings of two modems in a connection
  - Incompatible settings between modem and network parameters
  - Connections via nodes that are not configured s node stations
- Two connections to one partner (endpoint) via the same interface of a TIM (start point) are not permitted.
- A connection via a network in which two MD3 modems communicate with each other and that are configured with 1200 bps / half duplex / AT mode is invalid.

Configuration of further connection properties

If you select a connection in the table "Telecontrol connections" at the top in the "network data" editor, three parameter groups are displayed in the "Properties" tab of the Inspector window in which you can check, complete or correct the configuration of the connections.

- **General**
  Here, you will find the basic properties of a telecontrol connection.
- **Reduntant ST7cc**
  If you use a redundant ST7cc control center in your project, you must first create the two PC stations and the two connections as described above.
  Afterwards you create a redundancy group for each individual connection to the ST7cc here in the parameter group "Redundant ST7cc".
  - To do this, activate the option "Add redundant ST7cc/ST7cc partner" for every connection of a station to the ST7cc.
  - Select the required application from the "Redundant application" drop-down list.
- **Destination subscriber properties**
  - General request supervision time
    This is the maximum time required by a destination subscriber to respond fully to a general request (GR).
    If the GR response has not arrived completely at the requesting TIM when the supervision time has expired, a message is entered in the diagnostics buffer of this TIM.
    The time should be selected generously. In particular with dial-up connections, it should be remembered that the time for connection establishment is included in the supervision time. In addition to this, with dial-up stations the messages stored in the send buffer further delay processing of the GR because the queried messages are entered in the send buffer behind all other messages.
  - Frames to destination subscriber with time stamp
    The parameter relates to the destination subscriber that was configured as the endpoint of the connection.
    If the option is enabled all messages are sent to this destination subscriber with a time stamp.
    If the option is disabled all messages are sent to this destination subscriber without a time stamp.

Mobile wireless CPs

CP 1242-7 (6GK7 242-7KX30-0XE0)

Operating modes of CP 1242-7

Modes of the CP

CP 1242-7 (6GK7 242-7KX30-0XE0) allows an S7-1200 to communicate as a GPRS station with a master or other remote networks via the GSM network. For communication using GPRS, the CP is set to one of the following operating modes:

- **Telecontrol**
  This operating mode of the CP allows the GPRS station to exchange data with the following partners:
  - Communication with the Telecontrol server
    This CP mode allows the GPRS station to exchange data with a telecontrol server. The Telecontrol server is a PC connected to the Internet with the "TCSB" application. It is generally located in the master and serves to monitor and control the remote GPRS stations. Data can be exchanged with the OPC client of a central control system via the integrated OPC interface.
    The Telecontrol server PC is not configured in STEP 7. The "TCSB" application has its own configuration user interface.
  - Communication with another remote GPRS station
    The message frames are transmitted via the Telecontrol server.
  - Communication with an engineering station (for TeleService)

  Communication with the Telecontrol server is performed via the GSM network and the Internet.
  This operating mode requires a SIM card with GPRS service enabled and a Telecontrol server that can be reached by the CP.
- **GPRS direct**
  This operating mode of the CP is used for direct communication between remote stations via the GSM network. No Telecontrol server is required.
  To allow network nodes in public wireless networks to be directly accessible, these need to be addressed using a fixed address. Here, SIM cards with a fixed IP address are used that allow the stations to address each other directly.
  The possible communications services and security functions (for example VPN) depend on what is offered by the network provider.
  Possible communications partners of the station with a CP 1242-7 in "GPRS direct" mode are:
  - A node that can be reached by the CP via an IP address (S7 station with CP 1242-7)
  - An engineering station (for TeleService)

See also

Connection establishment with a CP 1242-7 (Page 1214)

Connection establishment with a CP 1242-7

Connection modes of CP 1242-7 (6GK7 242-7KX30-0XE0)

- "GPRS direct" mode
  There are no different connection modes in the "GPRS direct" mode.
- "Telecontrol" mode
  The CP can be configured for the following connection modes.
  - "Permanent" connection mode
    There is a permanent TCP connection to the telecontrol server. Following connection establishment, there is a permanent TCP connection to the telecontrol server even if data is not transferred permanently.
  - "Temporary" connection mode
    A connection is only established to the telecontrol server when required.

If a TCP connection is established, process data is sent as soon as the telecontrol instructions are called on the CPU.

A connection is always established by the CP. If a connection established by the CP is interrupted, the CP automatically attempts to re-establish the connection.

Triggering connection establishment for permanent stations ("Telecontrol" mode)

In the "Telecontrol" mode, the permanent connection to the telecontrol server is established when the station starts up. If there is an interruption on the connection, the establishment of the connection can be triggered by a wake-up SMS (see below).

Triggering connection establishment for temporary stations ("Telecontrol" mode)

With "temporary" stations, connection establishment can be triggered by the following events:

- Event on the local CPU that needs to be evaluated by the program.
  In terms of the program, two situations need to be distinguished:
  - Events that lead to a single connection establishment (for example alarms or commands from the operator).
  - Expiry of an interval that leads to cyclic connection establishment (for example once daily for data transmission)
- Request by a communications partner (OPC client or S7 station)
  The request from the communications partner leads to the connection being established.
- Request for TeleService by an engineering station
  The request switched by the telecontrol server or TeleService gateway does not need to be evaluated in the program.
- Wake-up SMS of the telecontrol server
  The wake-up SMS can be triggered spontaneously on the telecontrol server. It is also possible to configure cyclic sending on the telecontrol server.

- Telephone wake-up call
  The wake-up call can be sent from a telephone that has a phone number authorized in the STEP 7 project. The telephone must support the CLIP function (transfer of its own call number).
  The connection establishment with the (main) telecontrol server is triggered.
- Telephone wake-up SMS
  The wake-up SMS can be sent from a telephone that has a phone number authorized in the STEP 7 project. The telephone must support the CLIP function (transmission of its own number) and sending of SMS.
  The connection establishment with the telecontrol server specified in the SMS is triggered.

When a temporary station is woken up, all the data is transferred if this has changed since the last data transfer.

Wake-up call / wake-up SMS in the "Telecontrol" operating mode

For wake-up call or wake-up SMS, see section Wake-up of cellular CPs (Page 1215).

Triggering connection establishment in "GPRS direct" mode

In "GPRS direct" mode, a connection establishment is triggered by the following events:

- Event on the local CPU that is evaluated by the program.
- Request by a communications partner (not an engineering station)
  The request in the frame received from the communications partner is evaluated in the program by calling the telecontrol instructions.
- Request for TeleService by an engineering station
  The request switched by the telecontrol server or TeleService gateway does not need to be evaluated in the program.

Wake-up of cellular CPs

Right to wake-up by "Authorized phone numbers"

The CP only accepts a wake-up SMS or a wake-up call if the sending communication partner is authorized based on its phone number. These numbers are in configured for the CP in STEP 7 in the "authorized phone numbers" list.

Note

"Authorized phone numbers" in the STEP 7 project

- A phone number entered here gives the sender who transfers this phone number the right to trigger connection establishment.
- If an asterisk (*) is entered in the list, the CP accepts SMS messages from all senders.
- If the list is empty, the CP cannot be woken up for connection establishment.

Wake-up SMS

Depending on the connection type and the triggering server or intermediary TeleService server, the following text must be transferred in the wake-up SMS:

- For telecontrol connections:
  - Text for the wake-up SMS message for establishing a connection to the telecontrol server:
    `TELECONTROL`
  - Text for the wake-up SMS message for establishing a connection to the main telecontrol server:
    `TELECONTROL MAIN`
  - Text for the wake-up SMS message for establishing a connection to the substitute telecontrol server:
    `TELECONTROL BACKUP`

  The configuration of the telecontrol server for the GPRS CP is set in STEP 7 in "Telecontrol interface > Operating mode > main or substitute telecontrol server".

  Note

  Wake-up with a mobile phone

  - One of the texts listed above can be used in a wake-up SMS message.
  - With a wake-up call, the station always connects to the main telecontrol server.

- For TeleService connections:
  - Text for the wake-up SMS message for establishing a connection to the first configured TeleService server:
    `TELESERVICE`
    or
    `TELESERVICE 1`
  - Text for the wake-up SMS message for establishing a connection to the second configured TeleService server:
    `TELESERVICE 2`

  The configuration of the TeleService server for the GPRS CP is set in STEP 7 in "Telecontrol interface > TeleService authorization > 1st or 2nd TeleService server".

Preferred mobile wireless networks

Selection of the preferred mobile wireless networks

The following options are available to select the networks that the mobile wireless CP should preferably dial up:

- Automatic
  The CP dials with highest priority into the mobile wireless network of the contracted network provider set on the SIM card. If a dialing up the contract network fails, the CP dials up other mobile wireless networks with which the network provider has roaming contracts and whose access data is stored on the SIM card.
- Contract network only
  The CP only dials up the mobile wireless network of the contract network provider whose SIM card is plugged into the CP. No roaming.
- Contract network and preferred networks
  The CP dials up the contracted network with the highest priority. If dialing up the contract network is unsuccessful, the CP dials up alternative mobile wireless networks, in decreasing priority, as entered in the list of preferred network providers.
  The alternative networks are entered in the list as "Public Land Mobile Network" (PLMN). PLMN is a construct of Mobile Country Code (MCC) and Mobile Network Code (MNC).
  Example: 26276
  This is the PLMN for the test network of Siemens AG with MCC = 262 and MNC = 76.

TeleService via mobile wireless

Download using TeleService

The following behavior applies to all mobile wireless CPs:

- CP 1242-7 (6GK7 242-7KX30-0XE0)
- CP 1242-7 GPRS V2 (6GK7 242-7KX31-0XE0)
- CP 1243-7 LTE-EU (6GK7 243-7KX30-0XE0)
- CP 1243-7 LTE-US (6GK7 243-7SX30-0XE0)

Connection resources for TeleService

The TeleService function occupies a connection resource on the engineering station.

The function download to device or upload from device during a TeleService session occupies a second connection resource on the engineering station.

Download to device

Only use the "Download to device" function with the mobile wireless CP via a TeleService connection as follows:

1. Select the CP in STEP 7.
2. Select the "Online" > "Download to device" menu.
3. In the "Extended download" dialog that appears, select the TeleService interface.
4. Download the project data from the "Extended download" dialog.

Download from device

The "Download from device" function via a TeleService connection is supported by the mobile wireless CPs with the following TeleService server applications:

- TeleControl Server Basic as of version V3
- TeleService Gateway as of version V3

TeleService via telecontrol

Communication path for TeleService via telecontrol

With TeleService via telecontrol, the connection between the engineering station and a remote S7 station always runs through a TeleService server as an intermediary.

The request for connection establishment is triggered by the engineering station and forwarded by the TeleService server. Depending on the available communication paths to the station, the TeleService server forwards the request to the next station via LAN or by a wake-up SMS. The telecontrol CP in the S7-1200 station establishes a connection to the engineering station via the TeleService server.

An alternative intermediary (TeleService server) is:

- A telecontrol server
  The telecontrol server can be a separate PC or installed on the engineering station in the form of the "TCSB" application.
- A TeleService gateway
  A TeleService gateway is used when no telecontrol server is available.

The TeleService server can be connected to the engineering station via LAN or Internet and the TeleService function can be called from there.

Requirements for TeleService via telecontrol

- A TeleService server
- The STEP 7 project with the required stations

Note on project engineering

The TeleService server is not configured in STEP 7.

Establish remote connection via telecontrol

Requirements for TeleService via telecontrol

For the requirements and mechanisms, see section TeleService via telecontrol (Page 1218).

Start a TeleService session via telecontrol

Start TeleService via telecontrol as follows:

1. In the project on the authorized engineering station, select the remote S7 station with which you want to establish a TeleService connection via WAN.
2. Alternatively, open the "Connect online" dialog box as follows:
   - "Connect online" button
   - "Connect online" shortcut menu (right mouse button)
   - "Online" > "Connect online" menu

   The "Connect online" dialog box opens.
3. Select the interface type "TeleService via Telecontrol" in the "Type of PG/PC interface" drop-down list.
4. In the "PG/PC interface" drop-down list, select the "TeleService board" option if it is not automatically displayed.
5. Click on the "Connect" icon next to the "PG/PC interface" drop-down list.
   The "Establish remote connection via telecontrol" dialog box opens.
6. Make the necessary settings in this dialog.
   Details of this are contained in the tooltip cascade of STEP 7.

The following details are required to successfully establish a connection:

Details required to establish a connection with the S7 station

The following information is necessary in the Establish remote connection" dialog:

- IP address or DNS name of the telecontrol server
- TCP port number of the telecontrol server or the DSL router via which the connection between the engineering station and the remote S7 station is running.
- Server password of the ES to authenticate the engineering station at the telecontrol server
  Only required if a group-specific password has been configured in the "TCSB" application.
- TeleService user name
  See CP configuration in STEP 7.
- TeleService password
  See CP configuration in STEP 7.
- Access ID of the CP
  Only required when there are several telecontrol CPs in the station. See CP configuration in STEP 7.

Status

Connection states with TeleService via telecontrol

The connection states described below can be displayed in the "Establish remote connection via telecontrol" dialog box.

When opening the dialog

- Not connected
  There is no connection to the remote S7 station. Connection establishment has not yet started.

When establishing a connection

If connection establishment was started by clicking the "Connect" button, the following states are displayed one after the other after the connection has been established:

- Connect to telecontrol server
  The engineering station connects to the telecontrol server.
- Wait for S7 station
  The wake-up SMS has been sent to the remote station. Wait for reply from station.
- Authentication at S7 station
  The S7 station has established an IP connection with the engineering station via GPRS and Internet and is checking the received logon and authentication data.
- Connected
  The station has successfully established the connection to the engineering station.

If connection establishment is unsuccessful

The following states may be displayed if the connection cannot be successfully established:

- Telecontrol server not accessible
  Possible causes:
  - The connection between the engineering station and the telecontrol server has been interrupted.
  - The telecontrol server is switched off.
- Wrong server password
  Cause: The wrong server password for logging on and authentication was entered at the telecontrol server.
- S7 station not responding
  Possible causes:
  - The communication between the telecontrol server and the station is disrupted.
  - There is a disrupted connection between the mobile wireless network and the Internet.
  - Faulty Internet connection.
  - The telecontrol server could not send a wake-up SMS.
  - The CP has not received a wake-up SMS.
  - The sender of the SMS was not configured in the list of authorized wake-up call numbers.

- Wrong TeleService user name or TeleService password
  Possible causes:
  - An incorrect TeleService user name or incorrect TeleService password was entered in the authentication dialog for the CP.
  - The TeleService user name or TeleService password was not configured in STEP 7.
- All TeleService access points are in use.
- The CP is not known to the telecontrol server.
  Cause: The CP originates from a STEP 7 project that does not match the project of the telecontrol server.
- No resources available for TeleService on the CP: Please contact the hotline.
- Protocol error
  Cause: Wrong frame or frame from wrong subscriber. Please contact the hotline.

CP 1243-8 IRC (V2.1)

Ethernet interface

"Station address" (CP 1243-8 IRC V2.1) parameter group

"Station address": Adoption of the subscriber numbers from STEP 7 V5

The subscriber numbers are only displayed after you have imported the configuration data of the station from the STEP 7 V5 project.

The subscriber numbers cannot be edited.

As a default, all CPUs and CP 1243-8 have the subscriber number 0.

The displayed parameters are shown alongside the corresponding parameters in STEP 7 V5.

In the text file of the configuration data you will find the parameters in the SDB "Subscriber data".

Table 10-99 "Station address" parameter group

Parameter in STEP 7 Basic / Professional	Parameter in STEP 7 V5	Configuration in STEP 7 V5	Remarks
Node number of the CPU	Node number of the CPU	SINAUT configuration tool > Subscriber administration	
Node number of the TIM	Node number of the TIM	SINAUT configuration tool > Subscriber administration	

Time-of-day synchronization

Time synchronization: Adoption of parameters from STEP 7 V5

The parameter group "Time synchronization" is only displayed after you have imported the configuration data from the STEP 7-V5 project.

The displayed parameters are shown alongside the corresponding parameters in STEP 7 V5.

In the text file of the configuration data you will find the parameters in the SDB "WAN data".

Table 10-100 "Time synchronization" parameter group

Parameter in STEP 7 Basic / Professional	Parameter in STEP 7 V5	Configuration in STEP 7 V5	Remarks
Synchronization cycle	Synchronization cycle	Properties dialog TIM > "Time Service" tab	
• Seconds intervals • Minute intervals • Hourly intervals • Time • No synchronization	• Seconds intervals • Minute intervals • Hourly intervals • Time • No synchronization	Properties dialog TIM > "Time Service" tab	
Hourly intervals / Minute intervals / Seconds intervals	Hourly intervals / Minute intervals / Seconds intervals	Properties dialog TIM > "Time Service" tab	Displays the configured value
Time master	Synchronization master	Properties dialog TIM > "Time Service" tab	

Advanced options > TCP connection monitoring

Ethernet interface (X1) > Advanced options > TCP connection monitoring

The setting applies to all TCP connections of the CP.

Exception: The settings made here do not apply to connections programmed for Open User Communication with the program blocks.)

- **TCP connection monitoring time**
  If there is no data traffic within the connection monitoring time, the CP sends a keepalive to the communications partner.
- **TCP keepalive monitoring time**
  After sending a keepalive frame, the CP expects a reply from the communications partner within the keepalive monitoring time. If the CP does not receive a reply within the configured time, the keepalive frame is repeated twice. After the monitoring time elapses three times without a reply, the CP terminates and re-establishes the connection.

"MSC station parameters" (CP 1243-8 IRC V2.1) parameter group

"Advanced options" > "MSC station parameters": Adoption of the data from STEP 7 V5

The following parameters are only displayed after you have imported the configuration data of the station from the STEP 7 V5 project.

The displayed parameters are shown alongside the corresponding parameters in STEP 7 V5.

Table 10-101 "MSC master" parameter group

Parameter in STEP 7 Basic / Professional	Parameter in STEP 7 V5	Configuration in STEP 7 V5	Remarks
Port number MSC master	MSC port of the TIM	SINAUT configuration tool > "MSC Master Properties"	MSC port of the master
MSCsec	Security protocol active	SINAUT configuration tool > "MSC Station Properties"	MSCsec protocol is used when option is enabled
Key exchange interval	Rekeying interval [hours]	SINAUT configuration tool > "MSC Station Properties"

Partner stations

"Partner stations (CP 1243-8 IRC V2.1)" parameter group

Import partner configuration

With the "Import partner configuration" button, you import the text data with the STEP 7 V5 configuration data of the proxy from the file system of the engineering station.

You will find a description of the parameters in the following sections.

Reset partner configuration

With the "Reset partner configuration" button, you delete all the configuration data of the CP that you previously imported from a text file with the "Import partner configuration" button. With this function you reset the partner configuration data to the status of an unconfigured module.

Imported configuration data file

This output box shows the name of the text file whose configuration data you last loaded on this CP.

Last import

This output box shows the time at which you imported the configuration data file.

Partner configuration data

Adoption of parameters from STEP 7 V5

After importing the configuration data of the station from the STEP 7 V5 project, the partner configuration data is displayed.

For the individual partner stations, only the two following parameters can be configured:

- Report partner status (connection to partner)
- PLC tag for partner status

The remaining parameters are only displayed. In the text file of the configuration data you will find the parameters in the SDBs "Subscriber data" and "Ethernet data".

Table 10-105 "Partner stations" parameter group

Parameter in STEP 7 Basic / Professional	Parameter in STEP 7 V5	Configuration in STEP 7 V5	Remarks
Subscriber x			
Subscriber ID			Identifier for the subscriber type: 0 = CPU 1 = TIM
Subscriber number	Subscriber number	SINAUT configuration tool > Subscriber administration	
Subscriber additional identifier			Automatically assigned identifier
Subscriber type			Module type of the STEP 7 V5 configuration
Report partner status (connection to partner)	- -		If the option is enabled, the CP signals the status of the connection to the remote communications partner to the CPU.
PLC tag for partner status	- -		PLC tag for the partner status
Connection to partner			
Interface identifier			Automatically assigned identifier
Subnet of the partner			Automatically assigned identifier

Parameter in STEP 7 Basic / Professional	Parameter in STEP 7 V5	Configuration in STEP 7 V5	Remarks
CFB reference			Automatically assigned identifier
Connection type			Automatically assigned identifier

Download from device

Restrictions when downloading from a CP 1243-8 IRC

When you download the configuration data from a CP 1243-8 IRC using the online functions, the following data will not be fully downloaded:

- Partner station data
- Configuration and partner data of the data points
- References to PLC tags related to communication partners

In order to use the STEP 7 project after a complete download from the devices, you need to download the original export files from STEP 7 V5 with the configuration data of proxies into each CP 1243-8 IRC (Import partner configuration).

10.1.4.5 SCALANCE X, W and M

Configuring SCALANCE X / W / M

Legal notice

Qualified personnel

The product/system belonging to this documentation may only be handled by qualified personnel for the intended purpose taking into account the documentation relating to the intended purpose and, in particular, the safety and warning notices it contains. Due to training and experience, **qualified personnel** is capable of recognizing risks and avoiding possible dangers when handling these products/systems.

Configuring a SCALANCE device as an IO device

With a SCALANCE device configured as a PROFINET IO device and assigned to an IO controller, the functions "Compile" and "Download to device" only download the data to the SCALNCE device that can also be configured in Web Based Management (WBM) (System, Layer 2, Layer 3, Security).

If you want to use the "Compile" or "Download to device" functions for the PROFINET IO device data of the device, first select the assigned IO controller.

Configuring SCALANCE X

System functions

Availability of the system functions

The following table shows the availability of the system functions on the IE switches. Note that all functions are described in the online help. Depending on your IE switch, some functions are not available.

We reserve the right to make technical changes.

	Rules for VLAN ACL IP	-	-	-	128

[1] With the SCALANCE XB-200, the number of DHCP pools and manageable IPv4 addresses depends on the number of ports. The number of ports corresponds to the maximum number of DHCP pools and manageable IPv4 addresses.

[2] This is an IP interface.

Useful information

IP addresses

IPv4 / IPv6

What are the essential differences?

	IPv4	IPv6
IP configuration	• DHCP server • Manual	• Stateless Address Autoconfiguration (SLAAC): Stateless autoconfiguration using NDP (Neighbor Discovery Protocol) – Creates a link local address for every interface that does not require a router on the link. – Checks the uniqueness of the address on the link that requires no router on the link. – Specifies whether the global addresses are obtained via a status-free mechanism, a mechanism with status or via both mechanisms. (Requires a router on the link.) • Manual • DHCPv6 (status dependent)
Available IP addresses	32-bit: 4, 29 * 10^9 addresses	128-bit: 3, 4 * 10^{38} addresses
Address format	Decimal: 192.168.1.1 with port: 192.168.1.1:20	Hexadecimal: 2a00:ad80::0123 with port: [2a00:ad80::0123]:20
Loopback	127.0.0.1	::1
IP addresses of the interface	4 IP addresses	Multiple IP addresses • LLA: A link local address (formed automatically) fe80::/128 per interface • ULA: Several unique local unicast addresses per interface • GUA: Several global unicast addresses per interface
Header	• Checksum • Variable length • Fragmentation in the header • No security	• Checking at a higher layer • Fixed size • Fragmentation in the extension header
Fragmentation	Host and router	Only endpoint of the communication

	IPv4	IPv6
Quality of service	Type of Service (ToS) for prioritization	The prioritization is specified in the header field "Traffic Class".
Types of frame	Broadcast, multicast, unicast	Multicast, unicast, anycast
Identification of DHCP clients/ server	Client ID: MAC address	DUID + IAID(s) = exactly one interface of the host DUID = DHCP unique identifier Identifies server and clients uniquely and should not change, not even when replacing network components! IAID = Identity Association Identifier At least one per interface is generated by the client and remains unchanged when the DHCP client restarts Three methods of obtaining the DUID • DUID-LLT • DUID-EN • DUID-LL
DHCP	via UDP with broadcast	via UDP with unicast RFC 3315, RFC 3363 **Stateful DHCPv6** Status-dependent configuration in which the IPv6 address and the configuration settings are transferred. Four DHVPv6 messages are exchanged between client and server: 1. SOLICIT: Sent by the DHCPv6 client to localize DHCPv6 servers. 2. ADVERTISE The available DHCPv6 servers reply to this. 3. REQUEST The DHCPv6 client requests an IPv6 address and the configuration settings from the DHCPv6 server. 4. REPLY The DHCPv6 server sends the IPv6 address and the configuration settings. If the client and server support the function "Rapid commit" the procedure is shortened to two DHCPv6 messages SOLICIT and REPLY . **Stateless autoconfiguration** In stateless DHCPv6, only the configuration settings are transferred. **Prefix delegation** The DHCPv6 server delegates the distribution of IPv6 prefixes to the DHCPv6 client. The DHCPv6 client is also known as PD router.
Resolution of IP addresses in hardware addresses	ARP (Address Resolution Protocol)	NDP (Neighbor Discovery Protocol)

IPv4 address

Structure of an IPv4 address

Address classes

IP address range	Max. number of networks	Max. number of hosts/network	Class	CIDR
1.x.x.x through 126.x.x.x	126	16777214	A	/8
128.0.x.x through 191.255.x.x	16383	65534	B	/16
192.0.0.x through 223.255.255.x	2097151	254	C	/24
224.0.0.0 - 239.255.255.255	Multicast applications		D	
240.0.0.0 - 255.255.255.255	Reserved for future applications		E	

An IP address consists of 4 bytes. Each byte is represented in decimal, with a dot separating it from the previous one. This results in the following structure, where XXX stands for a number between 0 and 255:

XXX.XXX.XXX.XXX

The IP address is made up of two parts, the network ID and the host ID. This allows different subnets to be created. Depending on the bytes of the IP address used as the network ID and those used for the host ID, the IP address can be assigned to a specific address class.

Subnet mask

The bits of the host ID can be used to create subnets. The leading bits represent the address of the subnet and the remaining bits the address of the host in the subnet.

A subnet is defined by the subnet mask. The structure of the subnet mask corresponds to that of an IP address. If a "1" is used at a bit position in the subnet mask, the bit belongs to the corresponding position in the IP address of the subnet address, otherwise to the address of the computer.

Example of a class B network:

The standard subnet address for class B networks is 255.255.0.0; in other words, the last two bytes are available for defining a subnet. If 16 subnets must be defined, the third byte of the subnet address must be set to 11110000 (binary notation). In this case, this results in the subnet mask 255.255.240.0.

To find out whether two IP addresses belong to the same subnet, the two IP addresses and the subnet mask are ANDed bit by bit. If both logic operations have the save result, both IP addresses belong to the same subnet, for example, 141.120.246.210 and 141.120.252.108.

Outside the local area network, the distinction between network ID and host ID is of no significance, in this case packets are delivered based on the entire IP address.

Note

In the bit representation of the subnet mask, the "ones" must be set left-justified; in other words, there must be no "zeros" between the "ones".

IPv6 addresses

IPv6 terms

Network node

A network node is a device that is connected to one or more networks via one or more interfaces.

Router

A network node that forwards IPv6 packets.

Host

A network node that represents an end point for IPv6 communication relations.

Link

A link is, according to IPv6 terminology, a direct layer 3 connection within an IPv6 network.

Neighbor

A network node located on the same link as the network node.

IPv6 interface

Physical or logical interface on which IPv6 is activated.

Path MTU

Maximum permitted packet size on a path from a sender to a recipient.

Path MTU discovery

Mechanism for determining the maximum permitted packet size along the entire path from a sender to a recipient.

LLA

Link local address FE80::/10

As soon as IPv6 is activated on the interface, a link local address is formed automatically. Can only be reached by accounts located on the same link.

ULA

Unique Local Address

Defined in RFC 4193. Via this address, the IPv6 interface can be reached in the LAN.

GUA

Global Unicast Address Via this address, the IPv6 interface can be reached, e.g. via the Internet.

Interface ID

The interface ID is formed with the EUI-64 method or manually.

EUI-64

Extended Unique Identifier (RFC 4291); method for forming the interface ID. In Ethernet, the interface ID is formed from the MAC address of the interface. Divides the MAC address into

the manufacturer-specific part (OUI) and the network-specific part (NIC) and inserts FFFE between the two parts.

Example:

MAC address = AA:BB:CC:DD:EE:FF

OUI = AA:BB:CC

NIC = DD:EE:FF

EUI-64 = OUI + **FFFE** + NIC = AA:BB:CC:**FF:FE**:DD:EE:FF

Scope

Defines the range of the IPv6 address.

Structure of an IPv6 address

IPv6 address format - notation

IPv6 addresses consist of 8 fields each with four-character hexadecimal numbers (128 bits in total). The fields are separated by a colon.

Example:

fd00:0000:0000:ffff:02d1:7d01:0000:8f21

Rules / simplifications:

- If one or more fields have the value 0, a shortened notation is possible.
  The address fd00:**0000:0000**:ffff:02d1:7d01:0000:8f21 can also be shortened and written as follows:
  fd00**::**ffff:02d1:7d01:0000:8f21
  To ensure uniqueness, this shortened form can only be used once within the entire address.
- Leading zeros within a field can be omitted.
  The address fd00:0000:0000:ffff:**02d1**:7d01:0000:8f21 can also be shortened and written as follows:
  fd00**::**ffff:**2d1**:7d01:0000:8f21
- Decimal notation with periods
  The last 2 fields or 4 bytes can be written in the normal decimal notation with periods.
  Example: The IPv6 address fd00::ffff.125.1.0.1 is equivalent to fd00::ffff:7d01:1

Structure of the IPv6 address

The IPv6 protocol distinguishes three types of address: Unicast , anycast and multicast. The following section describes the structure of the global unicast addresses.

IPv6 prefix		Suffix
Global prefix: n bits	Subnet ID m bits	Interface ID 128 - n - m bits
Assigned address range	Description of the location, also subnet prefix or subnet	Unique assignment of the host in the network. The ID is generated from the MAC address.

The prefix for the link local address is always fe80:0000:0000:0000. The prefix is shortened and noted as follows: fe80::

IPv6 prefix

Specified in: RFC 4291

The IPv6 prefix represents the subnet identifier.

Prefixes and IPv6 addresses are specified in the same way as with the CIDR notation (Classless Inter-Domain Routing) for IPv4.

Design

IPv6 address / prefix length

Example

IPv6 address: 2001:0db8:1234::1111/48

Prefix: 2001:0db8:1234::/48

Interface ID: ::1111

Entry and appearance

The entry of IPv6 addresses is possible in the notations described above. IPv6 addresses are always shown in the hexadecimal notation.

PROFINET

PROFINET

PROFINET is an open standard (IEC 61158/61784) for industrial automation based on Industrial Ethernet. PROFINET uses existing IT standards and allows end-to-end communication from the field level to the management level as well as plant-wide engineering. PROFINET also has the following features:

- Use of TCP/IP
- Automation of applications with real-time requirements
  - Real-Time (RT) communication
  - Isochronous Real-Time (IRT) communication
- Seamless integration of fieldbus systems

You configure PROFINET in "System > PROFINET (Page 1374)".

PROFINET IO

Within the framework of PROFINET, PROFINET IO is a communications concept for implementing modular, distributed applications. PROFINET IO is implemented by the PROFINET standard for programmable controllers (IEC 61158-x-10).

EtherNet/IP

EtherNet/IP

EtherNet/IP (Ethernet/Industrial Protocol) is an open industry standard for industrial real-time Ethernet based on TCP/IP and UDP/IP. With EtherNet/IP, Ethernet is expanded by the Common Industrial Protocol (CIP) at the application layer. In EtherNet/IP, the lower layers of the OSI reference model are adopted by Ethernet with the physical, network and transport functions.

You configure EtherNet/IP in "System > EtherNet/IP (Page 1375)".

Common Industrial Protocol

The Common Industrial Protocol (CIP) is an application protocol for automation that supports transition of the field buses in Industrial Ethernet and in IP networks. This industry protocol is used by field buses/industrial networks such as DeviceNet, ControlNet and EtherNet/IP at the application layer as an interface between the deterministic fieldbus world and the automation application (controller, I/O, HMI, OPC, ...). The CIP is located above the transport layer and expands the pure transport services with communications services for automation engineering. These include services for cyclic, time-critical and event-controlled data traffic. CIP distinguishes between time-critical I/O messages (implicit messages) and individual query/response frames for configuration and data acquisition (explicit messages). CIP is object-oriented; all data "visible" from the outside is accessible in the form of objects. CIP has a common configuration basis: EDS (Electronic Data Sheet).

Electronic Data Sheet

Electronic Data Sheet (EDS) is an electronic datasheet for describing devices.

The EDS required for EtherNet/IP operation can be found in "System > Load&Save".

VLAN

VLAN

Network definition regardless of the spatial location of the nodes

VLAN (Virtual Local Area Network) divides a physical network into several logical networks that are shielded from each other. Here, devices are grouped together to form logical groups. Only nodes of the same VLAN can address each other. Since multicast and broadcast frames are only forwarded within the particular VLAN, they are also known as broadcast domains.

The particular advantage of VLANs is the reduced network load for the nodes and network segments of other VLANs.

To identify which packet belongs to which VLAN, the frame is expanded by 4 bytes. This expansion includes not only the VLAN ID but also priority information.

Options for the VLAN assignment

There are various options for the assignment to VLANs:

- Port-based VLAN
  Each port of a device is assigned a VLAN ID. You configure port-based VLAN in "Layer 2 > VLAN > Port-based VLAN".
- Protocol-based VLAN
  Each port of a device is assigned a protocol group. You configure protocol-based VLAN in "Layer 2 > VLAN > Protocol-based VLAN port".
- IPv4 Subnet-based VLAN
  The IPv4 address of the device is assigned a VLAN ID. You configure subnet-based VLAN in "Layer 2 > VLAN > IPv4 subnet-based VLAN".

processing the VLAN assignment

If more than one VLAN assignment is created on the device, the assignments are processed in the following order:

1. IPv4 subnet-based VLAN
2. Protocol-based VLAN
3. Port-based VLAN

The frame is first examined for the IPv4 address. If a rule on the "IPv4 subnet-based VLAN" tab applies, the frame is sent to the corresponding VLAN. If no rule applies, the protocol type of the frame is examined. If a rule on the "Protocol-based VLAN port" tab applies, the frame

is sent to the corresponding VLAN. If no rule applies, the frame is sent via the port-based VLAN. The rules for the port-based VLAN are specified on the "Port-based VLAN" tab.

General (Page 1394)

GVRP (Page 1397)

Port-based VLAN (Page 1398)

Protocol-based VLAN group (Page 1399)

Protocol-based VLAN port (Page 1400)

IPv4 subnet-based VLAN (Page 1400)

VLAN tagging

Expansion of the Ethernet frames by four bytes

For CoS (Class of Service, frame priority) and VLAN (virtual network), the IEEE 802.1Q standard defined the expansion of Ethernet frames by adding the VLAN tag.

Note

The VLAN tag increases the permitted total length of the frame from 1518 to 1522 bytes. The end nodes on the networks must be checked to find out whether they can process this length / this frame type. If this is not the case, only frames of the standard length may be sent to these nodes.

The additional 4 bytes are located in the header of the Ethernet frame between the source address and the Ethernet type / length field:

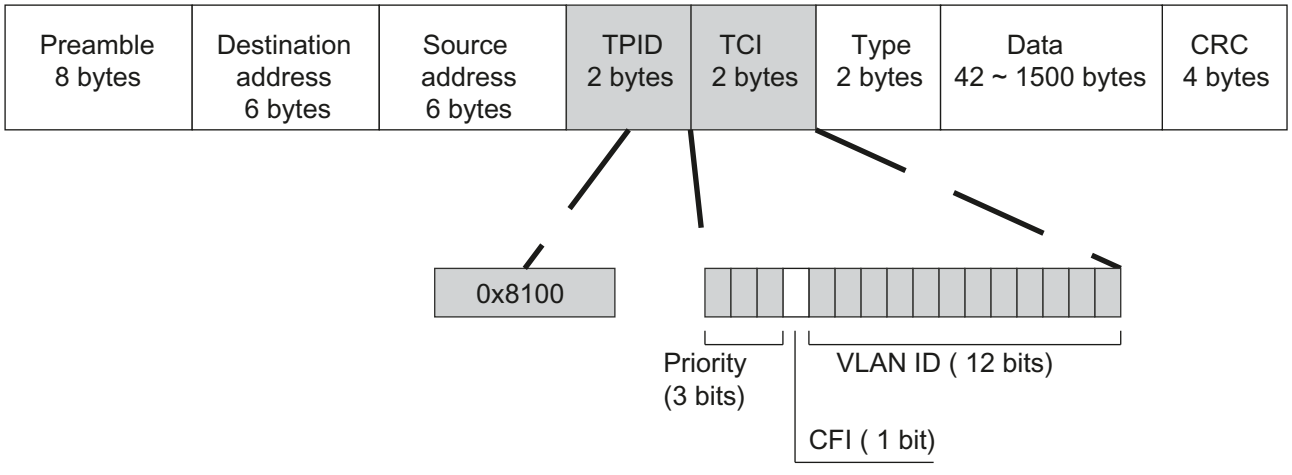

Figure 10-14 Structure of the expanded Ethernet frame

The additional bytes contain the tag protocol identifier (TPID) and the tag control information (TCI).

Tag protocol identifier (TPID)

The first 2 bytes form the Tag Protocol Identifier (TPID) and always have the value 0x8100. This value specifies that the data packet contains VLAN information or priority information.

Tag Control Information (TCI)

The 2 bytes of the Tag Control Information (TCI) contain the following information:

QoS Trust

The tagged frame has 3 bits for the priority that is also known as Class of Service (CoS), see also IEEE 802.1Q.

CoS bits	Priority	Type of the data traffic
000	0 (lowest)	Background
001	1	Best Effort
010	2	Excellent Effort
011	3	Critical Applications
100	4	Video, < 100 ms delay (latency and jitter)
101	5	Voice (language), < 10 ms delay (latency and jitter)
110	6	Internetwork Control
111	7 (highest)	Network Control

The prioritization of the data packets is possible only if there is a queue in the components in which they can buffer data packets with lower priority.

The device has multiple parallel queues in which the frames with different priorities can be processed. As default, first, the frames with the highest priority are processed. This method ensures that the frames with the highest priority are sent even if there is heavy data traffic.

Canonical Format Identifier (CFI)

The CFI is required for compatibility between Ethernet and the token Ring.
The values have the following meaning:

Value	Meaning
0	The format of the MAC address is canonical. In the canonical representation of the MAC address, the least significant bit is transferred first. Standard-setting for Ethernet switches.
1	The format of the MAC address is not canonical.

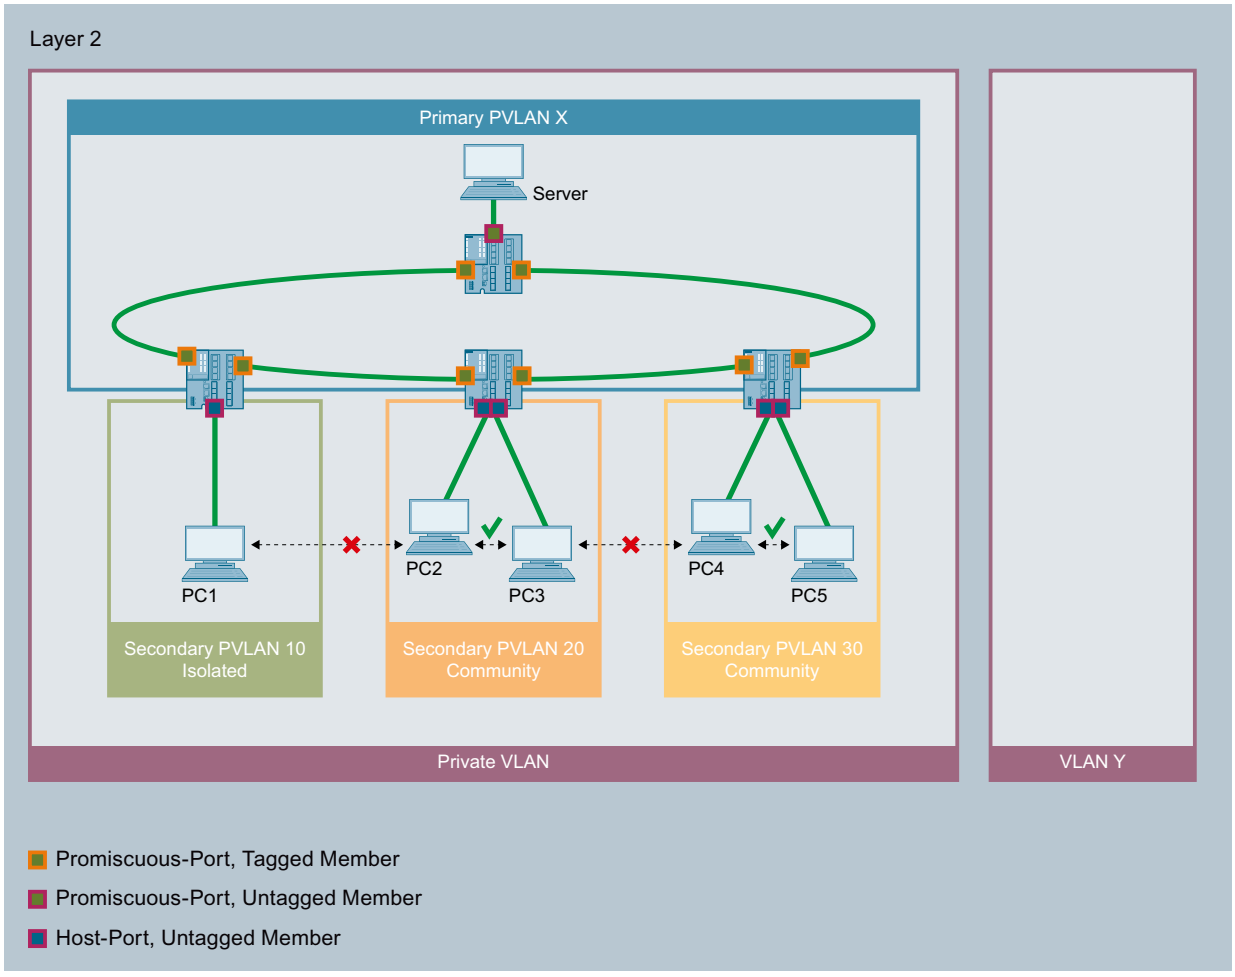
VLAN ID

In the 12-bit data field, up to 4096 VLAN IDs can be formed. The following conventions apply:

VLAN ID	Meaning
0	The frame contains only priority information (priority tagged frames) and no valid VLAN identifier.
1- 4094	Valid VLAN identifier, the frame is assigned to a VLAN and can also include priority information.
4095	Reserved

Private VLAN

With a private VLAN (PVLAN) you can divide up the layer 2 broadcast domains of a VLAN.



A private VLAN consists of the following units:

- A primary private VLAN (primary PVLAN)
  The VLAN that is divided up is called primary private VLAN.
- secondary private VLANs (secondary PVLAN)
  Secondary PVLANs exist only within a primary PVLAN. Every secondary PVLAN has a specific VLAN ID and is connected to the primary PVLAN.
  Secondary PVLANs are divided into the following types:
  - Isolated Secondary PVLAN
    Devices within an isolated secondary PVLAN cannot communicate with each other via layer 2.
  - Community Secondary PVLAN
    Devices within a community secondary PVLAN can communicate with each other directly via layer 2. The devices cannot communicate with devices in other communities of the PVLAN via layer 2.

Note

VALAN ID with secondary PVLANs

If you use the same VLAN ID for secondary PVLANs on different IE switches, the end devices in these secondary PVLANs can communicate with other via layer 2 across the different switches.

In this example, the ports of the IE switches that connect them to other IE switches are promiscuous ports. These network ports are tagged members in all PVLANs: Primary PVLAN and all secondary PVLANs.

The ports to which the PCs are connected are host ports. The host ports are all untagged members in the primary PVLAN and in their secondary PVLAN.

The port to which the server is connected is a promiscuous port. This promiscuous port ports is an untagged member in all PVLANs: Primary PVLAN and all secondary PVLANs.

In this example all PCs can communicate with the server. The server can communicate with all PCs. PC1 cannot communicate with any other PC. The PCs within a community secondary PVLAN can communicate with each other but not with the PCs in another secondary PVLAN.

SNMP

Introduction

With the aid of the Simple Network Management Protocol (SNMP), you monitor and control network components from a central station, for example routers or switches. SNMP controls the communication between the monitored devices and the monitoring station.

Tasks of SNMP:

- Monitoring of network components
- Remote control and remote parameter assignment of network components
- Error detection and error notification

In versions v1 and v2c, SNMP has no security mechanisms. Each user in the network can access data and also change parameter assignments using suitable software.

For the simple control of access rights without security aspects, community strings are used.

The community string is transferred along with the query. If the community string is correct, the SNMP agent responds and sends the requested data. If the community string is not correct, the SNMP agent discards the query. Define different community strings for read and write permissions. The community strings are transferred in plain text.

Standard values of the community strings:

- public
  has only read permissions
- private
  has read and write permissions

Note

Because the SNMP community strings are used for access protection, do not use the standard values "public" or "private". Change these values following the initial commissioning.

Further simple protection mechanisms at the device level:

- Allowed Host
  The IP addresses of the monitoring systems are known to the monitored system.
- Read Only
  If you assign "Read Only" to a monitored device, monitoring stations can only read out data but cannot modify it.

SNMP data packets are not encrypted and can easily be read by others.

The central station is also known as the management station. An SNMP agent is installed on the devices to be monitored with which the management station exchanges data.

The management station sends data packets of the following type:

- GET
  Request for a data record from the SNMP agent
- GETNEXT
  Calls up the next data record.
- GETBULK (available as of SNMPv2c)
  Requests multiple data records at one time, for example several rows of a table.
- SET
  Contains parameter assignment data for the relevant device.

The SNMP agent sends data packets of the following type:

- RESPONSE
  The SNMP agent returns the data requested by the manager.
- TRAP
  If a certain event occurs, the SNMP agent itself sends traps.

SNMPv1/v2c/v3 use UDP (User Datagram Protocol) and use the UDP ports 161 and 162. The data is described in a Management Information Base (MIB).

SNMPv3

Compared with the previous versions SNMPv1 and SNMPv2c, SNMPv3 introduces an extensive security concept.

SNMPv3 supports:

- Fully encrypted user authentication
- Encryption of the entire data traffic
- Access control of the MIB objects at the user/group level

With the introduction of SNMPv3 you can no longer transfer user configurations to other devices without taking special action, e.g. by loading a configuration file or replacing the C-PLUG.

According to the standard, the SNMPv3 protocol uses a unique SNMP engine ID as an internal identifier for an SNMP agent. This ID must be unique in the network. It is used to authenticate access data of SNMPv3 users and to encrypt it.

Depending on whether you have enabled or disabled the “SNMPv3 User Migration” function, the SNMP engine ID is generated differently.

Restriction when using the function

Use the "SNMPv3 User Migration" function only to transfer configured SNMPv3 users to a substitute device when replacing a device.
Do not use the function to transfer configured SNMPv3 users to multiple devices. If you load a configuration with created SNMPv3 users on several devices, these devices use the same SNMP engine ID. If you use these devices in the same network, your configuration contradicts the SNMP standard.

Compatibility with predecessor products

You can only transfer SNMPv3 users to a different device if you have created the users as migratable users. To create a migratable user the "SNMPv3 User Migration" function must be activated when you create the user.

Redundancy mode

Spanning Tree

Avoiding loops on redundant connections

The spanning tree algorithm allows network structures to be created in which there are several connections between two IE switches / bridges. Spanning tree prevents loops being formed in the network by allowing only one path and disabling the other (redundant) ports for data traffic. If there is an interruption, the data can be sent over an alternative path. The functionality of the spanning tree algorithm is based on the exchange of configuration and topology change frames.

Definition of the network topology using the configuration frames

The devices exchange configuration frames known as BPDUs (Bridge Protocol Data Units) with each other to calculate the topology. The root bridge is selected and the network topology created using these frames. BPDUs also bring about the status change of the root ports.

The root bridge is the bridge that controls the spanning tree algorithm for all involved components.

Once the root bridge has been specified, each device sets a root port. The root port is the port with the lowest path costs to the root bridge.

Response to changes in the network topology

If nodes are added to a network or drop out of the network, this can affect the optimum path selection for data packets. To be able to respond to such changes, the root bridge sends configuration messages at regular intervals. The interval between two configuration messages can be set with the "Hello Time" parameter.

Keeping configuration information up to date

With the "Max Age" parameter, you set the maximum age of configuration information. If a bridge has information that is older than the time set in "Max Age", it discards the message and initiates recalculation of the paths.

New configuration data is not used immediately by a bridge but only after the period specified in the "Forward Delay" parameter. This ensures that operation is only started with the new topology after all the bridges have the required information.

RSTP, MSTP, CIST

Rapid Spanning Tree Protocol (RSTP)

One disadvantage of STP is that if there is a disruption or a device fails, the network needs to reconfigure itself: The devices start to negotiate new paths only when the interruption occurs. This can take up to 30 seconds. Fur this reason, STP was expanded to create the "Rapid Spanning Tree Protocol" (RSTP, IEEE 802.1w). This differs from STP essentially in that the devices are already collecting information about alternative routes during normal operation and do not need to gather this information after a disruption has occurred. This means that the reconfiguration time for an RSTP controlled network can be reduced to a few seconds.
This is achieved by using the following functions:

- Edge ports (end node port)
  Edge ports are ports connected to an end device.
  A port that is defined as an edge port is activated immediately after connection establishment. If a spanning tree BPDU is received at an edge port, the port loses its role as edge port and it takes part in (R)STP again. If no further BPDU is received after a certain time has elapsed (3 x hello time), the port returns to the edge port status.
- Point-to-point (direct communication between two neighboring devices)

  By directly linking the devices, a status change (reconfiguration of the ports) can be made without any delays.
- Alternate port (substitute for the root port)

  A substitute for the root port is configured. If the connection to the root bridge is lost, the device can establish a connection over the alternate port without any delay due to reconfiguration.
- Reaction to events

  Rapid spanning tree reacts to events, for example an aborted connection, without delay. There is no waiting for timers as in spanning tree.
- Counter for the maximum bridge hops
  The number of bridge hops a package is allowed to make before it automatically becomes invalid.

In principle, therefore with rapid spanning tree, alternatives for many parameters are preconfigured and certain properties of the network structure taken into account to reduce the reconfiguration time.

Multiple Spanning Tree Protocol (MSTP)

The Multiple Spanning Tree Protocol (MSTP) is a further development of the Rapid Spanning Tree Protocol. Among other things, it provides the option of operating several RSTP instances within different VLANs or VLAN groups and, for example, making paths available within the individual VLANs that the single Rapid Spanning Tree Protocol would globally block.

Common and Internal Spanning Tree (CIST)

CIST identifies the internal instance used by the switch that is comparable in principle with an internal RSTP instance.

HRP

HRP - High Speed Redundancy Protocol

HRP is the name of a redundancy method for networks with a ring topology. The switches are interconnected via ring ports. One of the switches is configured as the redundancy manager (RM). The other switches are redundancy clients. Using test frames, the redundancy manager checks the ring to make sure it is not interrupted. The redundancy manager sends test frames via the ring ports and checks that they are received at the other ring port. The redundancy clients forward the test frames.

If the test frames of the RM no longer arrive at the other ring port due to an interruption, the RM switches through its two ring ports and informs the redundancy clients of the change immediately. The reconfiguration time after an interruption of the ring is a maximum of 0.3 seconds.

Standby redundancy

Standby redundancy is a method with which rings each of which is protected by high-speed redundancy can be linked together redundantly. In the ring, a master/slave device pair is configured and these monitor each other via their ring ports. If a fault occurs, the data traffic is redirected from one Ethernet connection (standby port of the master or standby server) to another Ethernet connection (standby port of the slave).

Requirements

- HRP is supported in ring topologies with up to 50 devices. Exceeding this number of devices can lead to a loss of data traffic.
- For HRP, only devices that support this function can be used in the ring.
- All devices must be interconnected via their ring ports.
- Devices that do not support HRP must be linked to the ring using special devices with HRP capability. Up to the ring, this connection is not redundant.

Standby

General

SCALANCE X switches support not only ring redundancy within a ring but also redundant linking of rings or open network segments (linear bus). In the redundant link, rings are connected together over Ethernet connections. This is achieved by configuring a master/slave device pair in one ring so that the devices monitor each other and, in the event of a fault, redirect the data traffic from the normally used master Ethernet connection to the substitute (slave) Ethernet connection.

Standby redundancy

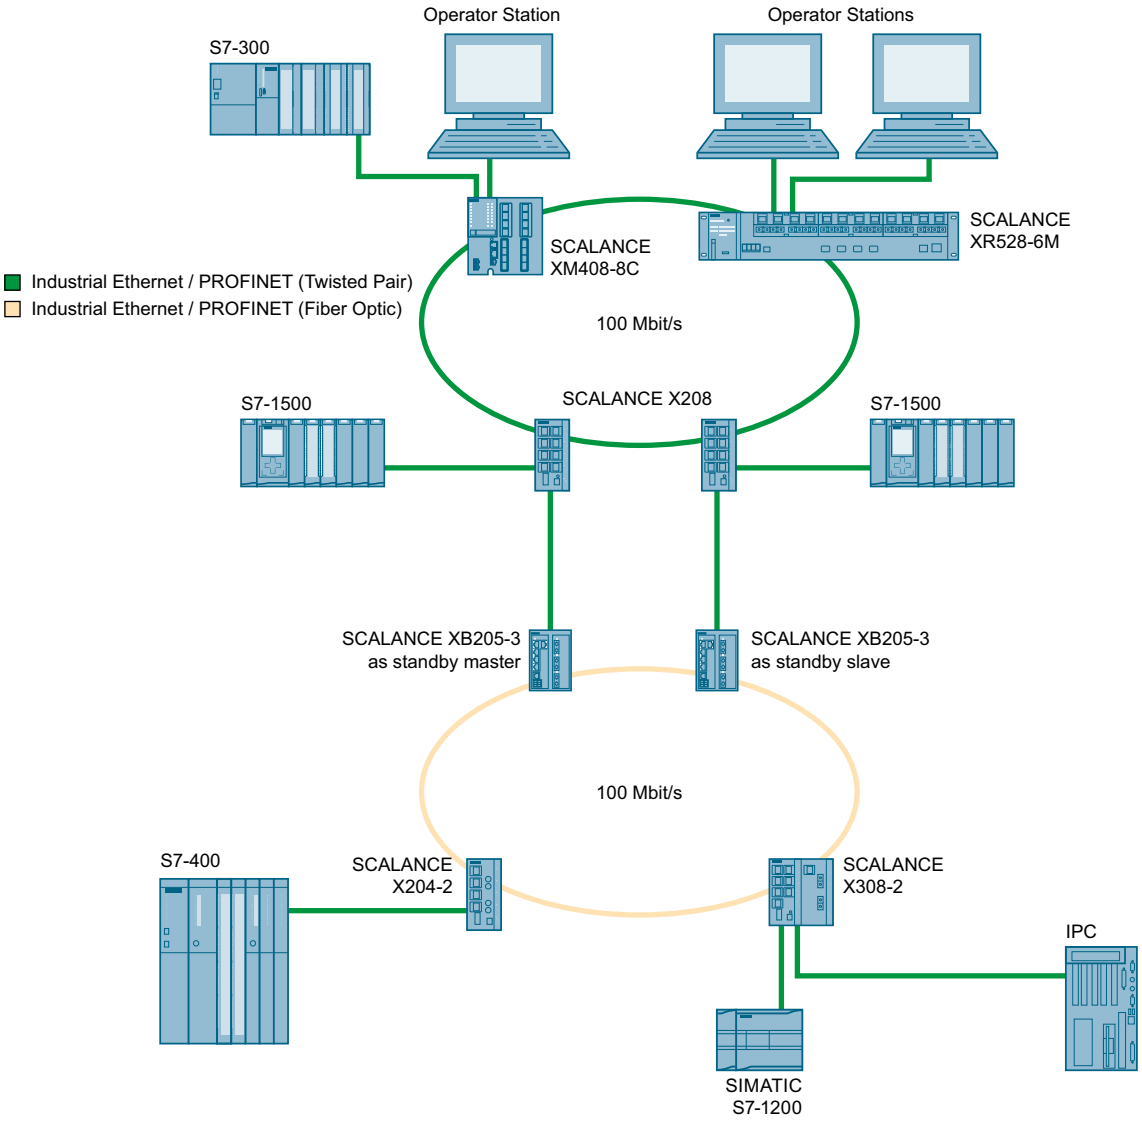


Figure 10-15 Example of a redundant link between rings

For a redundant link as shown in the figure, two devices must be configured as standby redundancy switches within a network segment. In this case, network segments are rings with a redundancy manager. Instead of rings, network segments might also be linear.

The two standby redundancy switches connected in the configuration exchange data frames with each other to synchronize their operating statuses (one device is master and the other slave). If there are no problems, only the link from the master to the other network segment is active. If this link fails (for example due to a link-down or a device failure), the slave activates its link as long as the problem persists.

MRP

MRP - Media Redundancy Protocol

The "MRP" method conforms to the Media Redundancy Protocol (MRP) specified in the following standard:

IEC 62439-2 Release 1.0 (2010-02) Industrial communication networks - High availability automation networks Part 2: Media Redundancy Protocol (MRP)

The reconfiguration time after an interruption of the ring is a maximum of 200 ms.

Topology

The following figure shows a possible topology for devices in a ring with MRP.

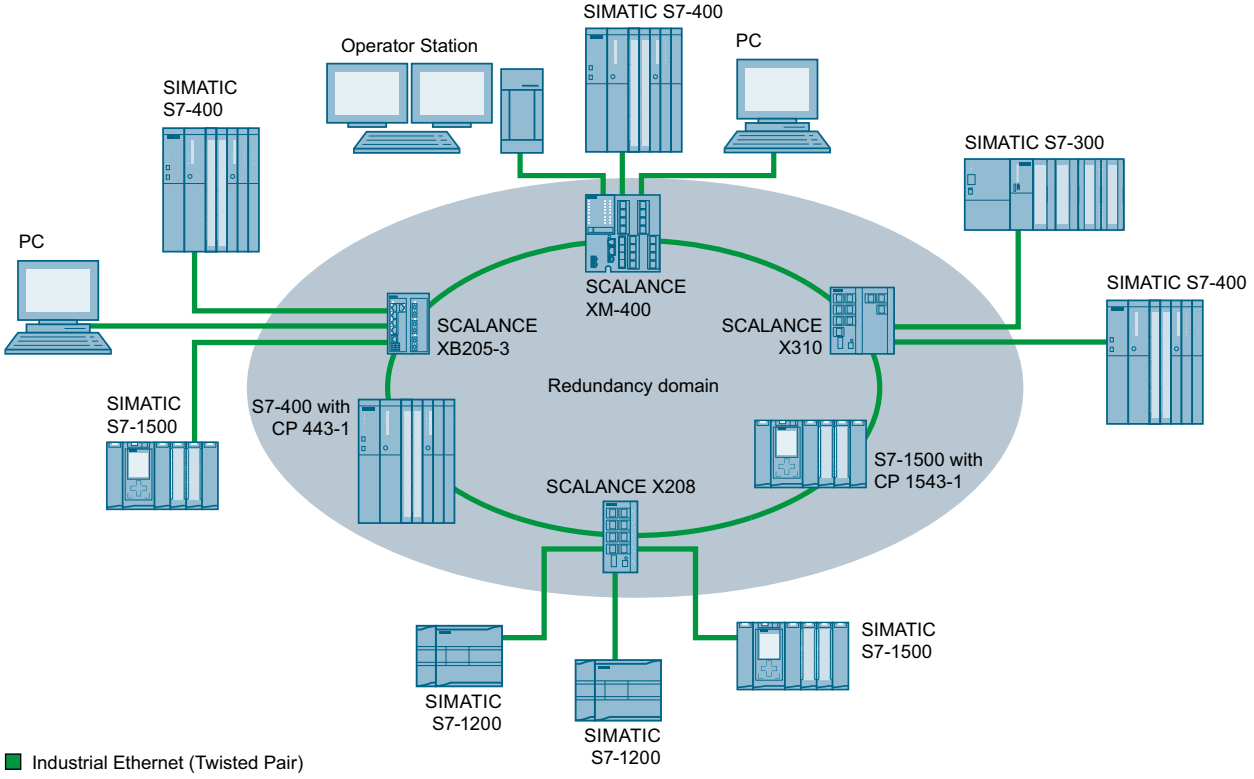

Figure 10-16 Example of a ring topology with the MRP media redundancy protocol

The following rules apply to a ring topology with media redundancy using MRP:

- All the devices connected within the ring topology are members of the same redundancy domain.
- One device in the ring is acting as redundancy manager.
- All other devices in the ring are redundancy clients.

Non MRP-compliant devices can be connected to the ring via a SCALANCE X switch or via a PC with a CP capable of MRP.

Requirements

Requirements for problem-free operation with the MRP media redundancy protocol are as follows:

- MRP is supported in ring topologies with up to 50 devices.
  Exceeding this number of devices can lead to a loss of data traffic.
- The ring in which you want to use MRP may only consist of devices that support this function. These include, for example, some of the Industrial Ethernet SCALANCE X switches, some of the communications processors (CPs) for SIMATIC S7 and PG/PC or non-Siemens devices that support this function.
- All devices must be interconnected via their ring ports.
  Multimode connections up to 3 km and single mode connections up to 26 km between two SCALANCE X IE switches are possible. At greater distances, the specified reconfiguration time may be longer.
- "MRP" must be enabled for all devices in the ring.
- The connection settings (transmission medium / duplex) must be set to full duplex and at least 100 Mbps for all ring ports. Otherwise there may be a loss of data traffic.
  - STEP 7: Set all the ports involved in the ring to "Automatic settings" in the "Options" tab of the properties dialog.
  - WBM: If you configure with Web Based Management, the ring ports are set automatically to autonegotiation.

See also

Configuration in STEP 7 (Page 1256)

Note

Number of devices

Except in PROFINET IO systems, topologies with up to 100 SCALANCE X-200 and SCALANCE X-300 IE switches were tested successfully.

Configuration in WBM

Role

The choice of role depends on the following use cases:

- You want to use MRP in a ring topology only with Siemens devices:
  - For at least one device in the ring select "Automatic Redundancy Detection" or "MRP Auto Manager".
  - For all other devices in the ring select "MRP Client" or "Automatic Redundancy Detection".
- You want to use MRP in a ring topology that also includes non-Siemens devices:
  - For exactly one device in the ring select the role "MRP Auto Manager".
  - For all other devices in the ring topology, select the role of "MRP client".

Note

The use of "Automatic Redundancy Detection" is not possible when using non-Siemens devices.

- You configure the devices in an MRP ring topology partly with WBM and partly with STEP 7:
  - With the devices you configure using WBM, select "MRP Client" for all devices.
  - With the devices that you configure using STEP 7, select precisely one device as "Manager" or "Manager (Auto)" and "MRP Client" for all other devices.

Note

If a device is assigned the role of "Manager" with STEP 7, all other devices in the ring must be assigned the "MRP Client" role. If there is a device with the "Manager" role and a device with the "Manager (Auto)"/"MRP Auto-Manager" in a ring, this can lead to circulating frames and therefore to failure of the network.

Configuration

In WBM, you configure MRP on the following pages:

- AUTOHOTSPOT
- AUTOHOTSPOT

Configuration in STEP 7

Configuration in STEP 7

To create the configuration in STEP 7, select the parameter group "Media redundancy" on the PROFINET interface.

Set the following parameters for the MRP configuration of the device:

- Domain
- Role
- Ring port
- Diagnostic interrupts

These settings are described below.

Note

Valid MRP configuration

In the MRP configuration in STEP 7, make sure that all devices in the ring have a valid MRP configuration before you close the ring. Otherwise, there may be circulating frames that will cause a failure in the network.

One device in the ring needs to be configured as "redundancy manager" and all other devices in the ring as "clients".

Note

Note factory settings

MRP is disabled and spanning tree enabled for the following brand new IE switches and those set to the factory settings:

- SCALANCE XB-200 (Ethernet/IP variants)
- SCALANCE XP-200 (Ethernet/IP variants)
- SCALANCE XM-400
- SCALANCE XR-500

To load a PROFINET configuration into one of the specified devices, first disable spanning tree on the device.

Note

Reconfiguration only when the ring is open

First open the ring before you

- change the MRP role or
- reconfigure ring ports

Note

Starting up and restarting

The MRP settings are still effective after a restart of the device or a power failure and hot restart as long as the power failure does not occur within 90 seconds after the configuration change.

Note

Prioritized startup

If you configure MRP in a ring, you cannot use the "prioritized startup" function in PROFINET applications on the devices involved.

If you want to use the "prioritized startup" function, then disable MRP in the configuration.

In the STEP 7 configuration, set the role of the relevant device to "Not a node in the ring".

Domain

Single MRP rings

If you want to configure a single MRP ring, leave the factory setting "mrpdomain 1" in the "Domain" drop-down list.

All devices configured in a ring with MRP must belong to the same redundancy domain. A device cannot belong to more than one redundancy domain in a single ring.

Multiple MRP rings

If you configure multiple single MRP rings, the nodes of the ring will be assigned to the individual rings with the "Domain" parameter. Set the same domain for all devices within a ring. Set different domains for different rings. Devices that do not belong to the same ring must have different domains.

If you want to configure MRP multiple rings, as the central redundancy manager for up to four rings select a device that is capable of multiple rings. Specify different domains for all ring instances and assign these to the corresponding ring ports of the redundancy manager. Configure the other devices as clients. The same domain must be set for all devices within a ring.

Role

Note

Reconfiguration only when the ring is open!

The choice of role depends on the following use cases.

- You want to use MRP in a topology with **one ring** only with Siemens devices and without monitoring diagnostic interrupts:
  Assign all devices to the "mrpdomain-1" domain and the role "Manager (Auto)".
  The device that actually takes over the role of redundancy manager, is negotiated by Siemens devices automatically.
- You want to use MRP in a topology with **multiple rings** only with Siemens devices and without monitoring diagnostic interrupts (MRP multiple rings):
  - Assign all instances of the device that connects the rings the role of "Manager".
  - For all other devices in the ring topology, select the role of "Client".

- You want to use MRP in a ring topology that also includes non-Siemens devices or you want to receive diagnostic interrupts relating to the MRP status from a device (see "Diagnostic interrupts"):
  - Assign precisely one device in the ring the role of "Manager (Auto)".
  - For all other devices in the ring topology, select the role of "Client".
- You want to disable MRP:
  Select the option "Not node in the ring" if you do not want to operate the device within a ring topology with MRP.

Note

Role after resetting to factory settings

With brand new Siemens devices and those reset to the factory settings the following MRP role is set:

- "Manager (Auto)"
  CPs
- "Automatic Redundancy Detection"
  - SCALANCE X-200
  - SCALANCE XC-200
  - SCALANCE XB-200 (PROFINET variants)
  - SCALANCE XP-200 (PROFINET variants)
  - SCALANCE X-300
  - SCALANCE X-400

If you are operating a non-Siemens device as the redundancy manager in the ring, this may cause loss of the data traffic.

MRP is disabled and spanning tree enabled for the following brand new IE switches and those set to the factory settings:

- SCALANCE XB-200 (Ethernet/IP variants)
- SCALANCE XP-200 (Ethernet/IP variants)
- SCALANCE XM-400
- SCALANCE XR-500

Ring port 1 / ring port 2

Here, select the port you want to configure as ring port 1 and ring port 2.

With devices with more than 8 ports, not all ports can be selected as ring port.

The drop-down list shows the selection of possible ports for each device type. If the ports are specified in the factory, the boxes are grayed out.

NOTICE
Ring ports after resetting to factory settings If you reset to the factory settings, the ring port settings are also reset. If other ports were used previously as ring ports before resetting, with the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

Note

Reconfiguration only when the ring is open

First open the ring before you reconfigure the ring ports of a multiple ring manager.

Diagnostic interrupts

Enable the "Diagnostic interrupts" option, if you want diagnostic interrupts relating to the MRP status on the local CPU to be output.

The following diagnostic interrupts can be generated:

- Wiring or port error
  Diagnostic interrupts are generated if the following errors occur at the ring ports:
  - Connection abort on a ring port
  - A neighbor of the ring port does not support MRP.
  - A ring port is connected to a non-ring port.
  - A ring port is connected to the ring port of another MRP domain.
- Status change active/passive (redundancy manager only)
  If the status changes (active/passive) in a ring, a diagnostics interrupt is generated.

Parameter assignment of the redundancy is not set by STEP 7 (redundancy alternatives)

This option only affects SCALANCE X switches. Select this option if you want to set the properties for media redundancy using alternative mechanisms such as WBM, CLI or SNMP.

If you enable this option, existing redundancy settings are retained and are not overwritten. The parameters in the "MRP configuration" box are then reset and grayed out. The entries then have no meaning.

Parallel Redundancy Protocol

Parallel Redundancy Protocol

The "Parallel Redundancy Protocol" (PRP) is a redundancy protocol for Ethernet networks. It is defined in Part 3 of the IEC 62439 standard. This redundancy method allows data communication to be maintained without interruption/reconfiguration time if there are interruptions in the network.

The PRP method is supported, for example, by the devices of the SCALANCE X-200RNA product line.

Overlong frames

When sending PRP frames, the IE switch expands the frame with a PRP trailer. With frames with the maximum length, appending the PRP trailer results in an overlong frame that exceeds the maximum permitted frame length (according to the IEEE 802.3 standard).

To prevent data loss with overlong frames, all network components located in a PRP network must support a frame length of at least 1528 bytes.

The devices described in this manual can be used in PRP networks, see also section "Configuration limits (Page 1233)".

Routing function

Introduction

The term routing describes the specification of routes for communication between different networks; in other words, how does a data packet from subnet A get to subnet B.

SCALANCE X supports the following routing functions:

- Static routing
  With static routing, the routes are entered manually in the routing table.
- Router redundancy
  With standardized VRRP (Virtual Router Redundancy Protocol), the availability of important gateways is increased by redundant routers.
  - VRRPv2 (IPv4)
  - VRRPv3 (IPv4 / IPv6)
- Dynamic routing
  The entries in the routing table are dynamic and are updated continuously. The entries are created with one of the following dynamic routing protocols:
  - OSPFv2 (IPv4)
  - OSPFv3 (IPv6)
  - RIPv2 (IPv4)
  - RIPng (IPv6)

VRRP

VRRPv2

Router redundancy with VRRP

With the Virtual Router Redundancy Protocol (VRRP), the failure of a router in a network can be countered.

VRRP can only be used with virtual IP interfaces (VLAN interfaces) and not with router ports.

Several VRRP routers in a network segment are put together as a logical group representing a virtual router (VR). The group is defined using the virtual ID (VRID). Within the group, the VRID must be the same. The VRID can no longer be used for other groups.

The virtual router is assigned a virtual IP address and a virtual MAC address. One of the VRRP routers within the group is specified as the master router. The master router has priority 255. The other VRRP routers are backup routers. The master router assigns the virtual IP address and the virtual MAC address to its network interface. The master router sends VRRP packets (advertisements) to the backup routers at specific intervals. With the VRRP packets, the master router signals that it is still functioning. The master router also replies to the ARP queries.

If the virtual master router fails, a backup router takes over the role of the master router. The backup router with the highest priority becomes the master router. If the priority of the backup routers is the same, the higher MAC address decides. The backup router becomes the new virtual master router.

The new virtual master router adopts the virtual MAC and IP address. This means that no routing tables or ARP tables need to be updated. The consequences of a device failure are therefore minimized.

You configure VRRP in "Layer 3 (IPv4) > VRRP".

VRRP3

Version 3 of VRRP is based on version 2.

Note

- Enable routing to be able to use VRRPv3.
- You can only use VRRPv3 in conjunction with VLAN interfaces. Router ports are not supported.
- Simultaneous operation of VRRP and VRRPv3 is not possible.
- VRRPv3 supports IPv4 and IPv6. Both can be configured and operated at the same time with VRRP3.

You configure VRRPv3 in:

IPv4: Layer 3 (IPv4)> VRRPv3

IPv6: Layer 3 (IPv6)> VRRPv3

OSPF

OSPFv2

Dynamic routing with OSPFv2

OSPF (Open Shortest Path First) is a cost-based routing protocol. To calculate the shortest and most cost-effective route, the Short Path First algorithm by Dijkstra is used. OSPF was developed by the IETF (Internet Engineering Task Force).

You configure OSPFv2 in "Layer 3 (IPv4) > OSPFv2".

OSPFv2 divides an autonomous system (AS) into different areas.

Areas in OSPF

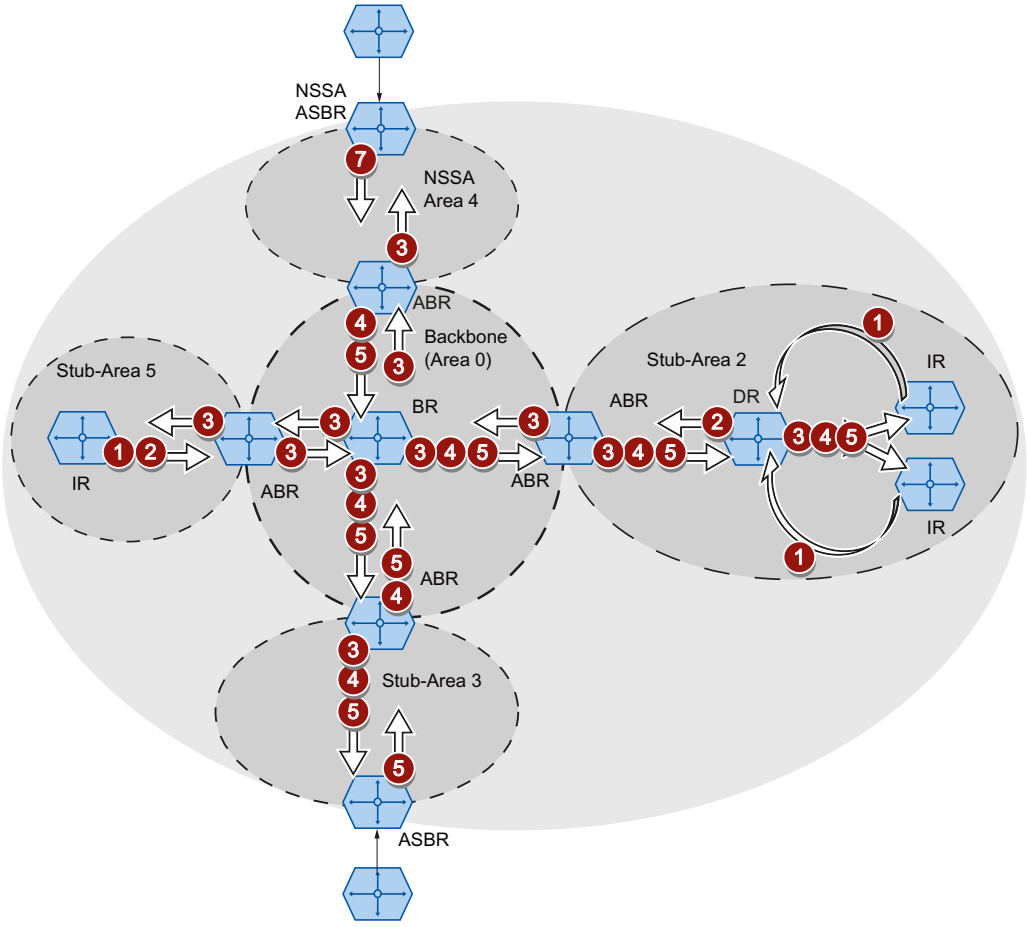
The following areas exist:

- Backbone
  The backbone area is area 0.0.0.0. All other areas are connected to this area. The backbone area is connected either directly or via virtual connections with other areas.
  All routing information is available in the backbone area. As a result, the backbone area is responsible for forwarding information between different areas.
- Stub Area
  This area contains the routes within its area within the autonomous system and the standard route out of the autonomous system. The destinations outside this autonomous system are assigned to the standard route.
- Totally Stubby Area
  This area knows only the routes within its area and the standard route out of the area.
- Not So Stubby Area (NSSA)
  This area can forward (redistribute) packets from other autonomous systems into the areas of its own autonomous system. The packets are further distributed by the NSSA router.

Routers of OSPF

OSPF distinguishes the following router types:

- Internal router (IR)
  All OSPF interfaces of the router are assigned to the same area.
- Area Border Router (ABR)
  The OSPF interfaces of the router are assigned to different areas. One OSPF interface is assigned to the backbone area. Where possible, routes are grouped together.
- Backbone Router (BR)
  At least one of the OSPF interfaces is assigned to the backbone area.
- Autonomous System Border Router (ASBR)
  One interface of the router is connected to a different AS, for example an AS that uses the routing protocol RIP.



Virtual connection

Each area must be connected to the backbone area. In some situations a direct physical connection is not possible. In this case, a router of the relevant area must be connected to a backbone router via a virtual connection.

LSA types

Within the autonomous system, packets are exchanged that contain information about the connections of a router and the connection status message. The packets are also known as LSAs (Link State Advertisements). The LSAs are always sent from the router to the neighbor router.

If there are changes in the network, LSAs are sent to all routers in the network. The information depends on the LSA type.

1. **Router LSA (LSA Type 1)**
   The LSA Type 1 is only sent within an area. For each active connection of the router that belongs to the area in consideration, an LSA Type 1 is generated. The LSA Type 1 contains information about the status and the costs of the connection, for example IP address, network mask, network type
2. **Network LSA (LSA Type 2)**
   The LSA Type 2 is sent only within an area. For each network that belongs to the relevant area, the router generates an LSA Type 2. If several routers are interconnected in a network, the LSA Type 2 is sent by the designated router (DR). The LSA Type 2 includes the network address, the network mask and a list of routers that are connected to the network
3. **Summary LSA (LSA Type 3 / LSA Type 4)**
   The Summary LSA is generated by the area border router and sent into the area. The
4. Summary LSA contains information about routes outside the area but inside the AS. Where possible, the routes are grouped together.
   - Summary LSA (LSA Type 3)
     The LSA Type 3 describes the routes to the networks and advertises the standard route to the areas.
   - AS Summary LSA (LSA Type 4)
     The LSA Type 4 describes the routes to the ASBR.
5. **External LSA (LSA Type 5 / LSA Type 7)**
   The External LSA is generated by the ASBR. The LSA type depends on the area.
7. - AS External LSA (LSA Type 5)
     The LSA Type 5 is sent by the AS border router into the areas of the autonomous system except the Stub and NSSA areas. The LSA contains information about routes to a network in another AS. The routes are either created manually or learned externally. The ASBR uses LSA Type 5 to distribute standard routes to the backbone area.
   - NSSA External LSA (LSA Type 7)
     The LSA Type 7 is generated by the AS border router of an NSSA. The router is also known as the NSSA ASBR. The LSA Type 7 is sent only within the NSSA. If the P bit in LSA Type 7 = 1, these LSAs are converted to LSA Type 5 by the ABR and sent to the backbone area.

Establishing the neighborhood

The router runs through the following statuses to establish a connection to the neighbor router.

1. Attempt state / Init state
   The router activates OSPF and begins to send and receive Hello packets. Based on the received Hello packets, the router learns which OSPF routers are in its vicinity. The router checks the content of the Hello packet. The Hello packet also contains the list of the neighbor routers (neighbor table) of the "sender".
2. Two way state
   If, for example, the ID of the area, the area type and the settings for the times match, a connection (adjacency) can be established to the neighbor. In a point-to-point network, the connection is established directly. If several neighbor routers can be reached in a network, the designated router (DR) and the designated backup router (DBR) are identified based on Hello packets. The router with the highest router priority becomes the designated router. If two routers have the same router priority, the router with the highest router ID becomes the designated router. The router establishes a connection to the designated router.
3. Exchangestart state
   The neighbor routers decide which router starts communication. The router with the higher router ID becomes the designated router.
4. Exchange state
   The neighbor routers send packets that describe the content of their neighborhood database. The neighborhood database (link state database - LSDB) contains information on the topology of the network.
5. Loading state
   The router completes the received information. If the router still has questions relating to the status of a specific connection, it sends a link state request. The neighbor router sends a response (link state update). The response contains a suitable LSA. The router confirms receipt of the response (link state acknowledge).
6. Full State
   The information exchange with the neighbor router is completed. The neighborhood database of the neighbor router is the same. Based on the Short Path First algorithm, the router calculates a route to every destination. The route is entered in the routing table.

Check the neighborhood

The Hello packets are only used to establish the neighborhood relations. Hello packets are used to check the connection to the neighbor router by sending them cyclically. If no Hello packet is received within a certain interval (dead interval), the connection to the neighbor is marked as "down". The relevant entries are deleted.

Updating the neighborhood database

Once the neighborhood database is established, LSAs are sent to all routers in the network if there are changes in the topology.

OSPFv3

Version 3 of OSPF is based on version 2 and is only used with IPv6. A large part of the routing mechanisms was adopted. OSPFv3 is defined in the RFCs 2740 and 5340.

You configure OSPFv3 under "Layer 3 (IPv6) > OSPFv3".

The following has not changed:

- The statuses that a router runs through to establish a connection to the neighbor router.
- The areas : Backbone, Stub Area, Totally Stubby Area, Not So Stubby Area (NSSA)
- The router types: Internal Router (IR), Area Border Router (ABR), Backbone Router (BR), Autonomous System Area Border Router (ASBR), Designated Router (DR)
- The router ID, the area ID and the ID of the LSA are entered in the IPv4 address format: x.x.x.x

What has changed?

Terms

The terms network or subnet are replaced by link.

Authentication

The authentication was removed. Instead OSPFv3 uses IPsec, that is implemented in IPv6.

Neighbor routers

The neighbor routers are identified via the router ID.

Neighbor database

The neighbor database (link state database - LSDB) is divided into different areas of application:

- Link scope LSDB
  Contains the link LSA
- Area scope LSDB
  contains the following LSAs
  - Router LSA
  - Network LSA
  - Inter-area prefix LSA
  - Inter area router LSA
  - Intra area prefix LSA
- AS scope LSDB
  Contains the AS external LSA

LSA types

Two new LSA types were defined for OSPFv3.

OSPFv2		OSPFv3		Who	Within	Description
1	Router LSA	0x2001	Router LSA	every router	Area	No longer contains address information. This is contained in the new LSA type 2009.
2	Network LSA	0x2002	Network LSA	DR	Area	No longer contains address information. This is contained in the new LSA type 2009.
3	Summary LSA	0x2003	Inter-area prefix LSA	ABR	Area	Same function as in OSPFv2, simply renamed
4	AS Summary LSA	0x2004	Inter-Area Router LSA	ABR	Area	Same function as in OSPFv2, simply renamed
5	AS External LSA	0x4005	AS External LSA	ASBR	AS	Same function as in OSPFv2, simply renamed
7	NSSA External LSA	0x2007	Type 7 LSA	NSSA ASBR	NSSA	Same function as in OSPFv2, simply renamed
		0x2008	Link LSA	every router	Link	The LSA is sent by the router to every router linked to it. The LSA contains the link local address of the router and a list with IPv6 prefixes configured on the link.
		0x2009	Intra area prefix LSA	every router	Area	The LSA is sent only within an area. The LSA contains the IPv6 prefixes connected to the router or network.

In contrast to OSPFv2, OSPFv3 can forward unknown LSA types. Previously these were deleted and not distributed further.

RIP

RIPv2

Dynamic routing with RIPv2

The Routing Information Protocol (RIPv2) is used to create routing tables automatically. RIPv2 is used in autonomous systems (AS) with a maximum of 15 routers. It is based on the Distance-Vector algorithm.

RIPv2 was developed by the IETF (Internet Engineering Task Force) and is described in RFC 2453.

You configure RIPv2 in "Layer 3 (IPv4) > RIPv2".

Setting up a routing table

Since a router initially only knows its directly connected networks, it sends a request to its direct neighbor routers. As the reply, it receives the routing tables of the neighbor routers. Based on the information it receives, the router set up its own routing table.

The routing table contains entries for all possible destinations. Each entry includes the distance to the destination and the first router on the route.

The distance is also known as the metric. This indicates the number of routers to be passed through on the route to the destination (hop count). The maximum distance is 15 routers (hops).

Updating the routing table

Once the routing table is set up, the router sends its routing table to each direct neighbor router via the UDP port 520 at intervals of 30 seconds.

The router compares new routing information with its existing routing table. If the new information includes shorter routes, the existing routes are overwritten. The router only keeps the shortest route to a destination.

Checking neighbor routers

If a router does not receive messages from a neighbor router for longer than 180 seconds, it marks the router as being invalid. The router assigns the metric 16 for the neighbor router.

RIPng

RIPng (RIP next generation) is only used with IPv6 and is defined in RFC 2080. As with RIP (IPv4), RIPng is based on the distance vector algorithm of Bellman-Ford.

In contrast to RIPv2, RIPng is activated directly on the layer 3 interface (VLAN interface / router port) and not globally on the device.

RIPng uses the UDP port 521 and RIP the UDP port 520.

You configure RIPng in "Layer 3 (IPv6) > RIPng".

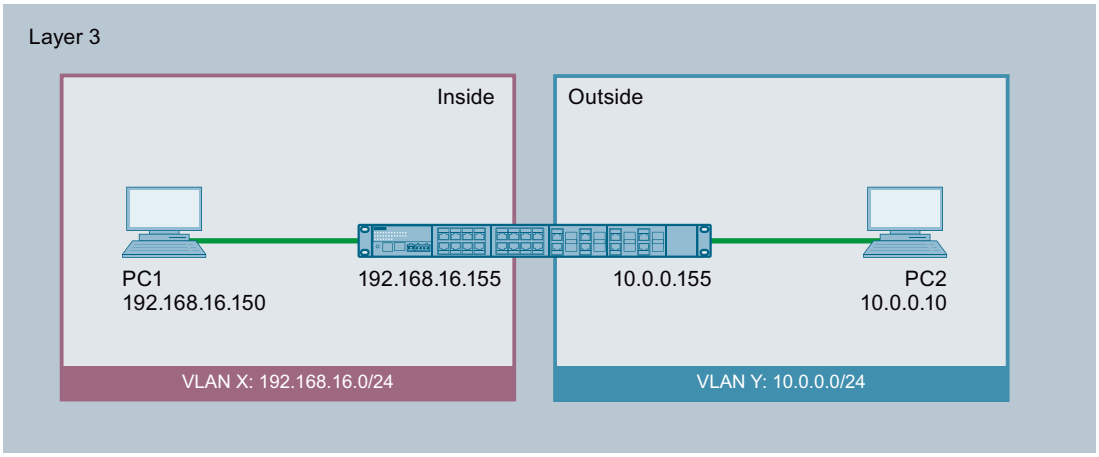
NAT/NAPT

Note

NAT/NAPT is possible only on layer 3 of the ISO/OSI reference model. To use the NAT function, the networks must use the IP protocol.

When using the ISO protocol that operates at layer 2, it is not possible to use NAT.

In Network Address Translation (NAT) IP subnets are divided into "Inside" and "Outside". The division is from the perspective of a NAT interface. All networks reachable via the NAT interface itself count as "Outside" for this interface. All networks reachable via other IP interfaces of the same device count as "Inside" for the NAT interface.



If there s routing via the NAT interface, the source or destination IP addresses of the transferred data packets are changed at the transition between "Inside" and "Outside". Whether or not the source or destination IP address is changed depends on the communications direction. It is always the IP address of the communications node that is located "Inside" that is adapted.

Depending on the perspective the IP address of a communications node is always designated as "Local" or "Global".

		Perspective	
		Local	**Global**
Position	**Inside**	An actual IP address that is assigned to a device in the internal network. This address cannot be reached from the external network.	An IP address at which an internal device can be reached from the external network.
	Outside	An actual IP address that is assigned to a device in the external network. Since only "Inside" addresses are converted, there is no distinction made between outside local and outside global.	

Example

In the example two IP subnets are connected together via an IE switch. The division is from the perspective of the NAT interface 10.0.0.155. The communication of PC2 with PC1 is implemented via NAT/NAPT.

The actual IP address of PC1 (inside local) is implemented statically with NAT. For PC2, PC1 can be reached at the inside global address.

		Perspective	
		Local	**Global**
Position	**Inside**	192.168.16.150	10.0.0.7
	Outside	10.0.0.10	

The actual IP address of PC1 (inside local) is implemented statically with NAPT. For PC2, PC1 can be reached at the inside global address.

		Perspective	
		Local	**Global**
Position	**Inside**	192.168.16.150:80	10.0.0.7:80
	Outside	10.0.0.10:1660	

Computing capacity

Due to the load limitation of the CPU packet receipt of the device is limited to 300 packets a second. This corresponds to a maximum data through of 1.7 Mbps. This load limitation does not apply per interface but generally for all packets going the CPU.

The entire NAT communication runs via the CPU and therefore represents competition for IP communication going to the CPU, e.g. WBM and Telnet.

Note that a large part of the computing capacity is occupied if you use NAT.

NAT

With Network Address Translation (NAT), the IP address in a data packet is replaced by another. NAT is normally used on a gateway between an internal network and an external network.

With source NAT, the inside local source address of an IP packet from a device in the internal network is rewritten by a NAT device to an inside global address at the gateway.

With destination NAT, the inside global source address of an IP packet from a device in the external network is rewritten by a NAT device to an inside local address at the gateway.

To translate the internal into the external IP address and back, the NAT device maintains a translation list. The address assignment can be dynamic or static. You configure NAT in "Layer 3 (IPv4) > NAT (Page 1470)".

NAPT

In "Network Address Port Translation" (NAPT), several internal source IP addresses are translated into the same external IP address. To identify the individual nodes, the port of the internal device is also stored in the translation list of the NAT device and translated for the external address.

If several internal devices send a query to the same external destination IP address via the NAT device, the NAT device enters its own external source IP address in the header of these forwarded frames. Since the forwarded frames have the same external source IP address, the NAT device assigns the frames to the devices using a different port number.

If a device from the external network wants to use a service in the internal network, the translation list for the static address assignment needs to be configured. You configure NAPT in "Layer 3 (IPv4) > NAT > NAPT (Page 1473)".

NAT/NAPT and IP routing

You can enable NAT/NAPT and IP routing at the same time. In this case, you need to regulate the reachability of internal addresses from external networks with ACL rules.

Link aggregation

Link aggregation

With link aggregation, several parallel physical connections with the same transmission speed are grouped together to form a logical connection with a higher transmission speed. This method based on IEEE 802.3ad is also known as port trunking or channel bundling.

Link aggregation works only with full duplex connections with the same transmission speed in point-to-point mode. This achieves multiplication of the bandwidth or transmission speed. If part of the connection fails, the data traffic is handled via the remaining parts of the connection.

To control and monitor, the Link Aggregation Control Layer (LACL) and the Link Aggregation Control Protocol (LACP) are used.

Quality of service

Quality of Service (QoS) is a method to allow efficient use of the existing bandwidth in a network.

QoS is implemented by prioritization of the data traffic. Incoming frames are sorted into a Queue according to a certain prioritization and further processed. This gives certain frames priority.

The different QoS methods influence each other and are therefore taken into account in the following order:

1. The switch first checks whether the incoming frame is a broadcast or agent frame.
   → When the first condition is met, the switch takes into account the priority set on the "General (Page 1389)" page.
   The switch sorts the frame into a queue according to the assignment on page "CoS Map (Page 1390)".
2. If the first condition is not met the switch checks whether the frame contains a VLAN tag.
   → If the second condition is met the switch checks the settings for the priority on the "General (Page 1389)" page. The switch checks whether a value other than "Do not force" is set for the priority.
   If the priority is set the switch sorts the frame into a queue according to the assignment on page "CoS Map (Page 1390)".
3. If the second condition is also not met the frames are further processed according to the Trust mode. You configure the Trust mode on the page "QoS Trust (Page 1391)".

General (Page 1394)

Authentication

Overview of user management

Access to the device is managed by configurable user settings. Set up users with a password for authentication. Assign a role with suitable rights to the users.

The authentication of users can either be performed locally by the device or by an external RADIUS server. You configure how the authentication is handled on the "Security > AAA > General" page.

When you transfer the configuration of a device to TIA, the configured users, roles and groups are not transferred.

Compatibility with predecessor versions

With firmware version 5.1, user management was expanded by the RADIUS authorization mode "Vendor Specific". To ensure compatibility with firmware versions ≤ 5.0, the default setting was selected so that following a firmware update the earlier authentication mode "conventional" continues to be used.

Local login

The local logging in of users by the device runs as follows:

1. The user logs in with user name and password on the device.
2. The device checks whether an entry exists for the user.
   → If an entry exists, the user is logged in with the rights of the associated role.
   → If no corresponding entry exists, the user is denied access.

Login via an external RADIUS server

RADIUS(Remote Authentication Dial-In User Service) is a protocol for authenticating and authorizing users by servers on which user data can be stored centrally.

Depending on the RADIUS authorization mode you have selected on the "Security > AAA > RADIUS Client" page, the device evaluates different information of the RADIUS server.

RADIUS authorization mode "conventional"

If you have set the authorization mode "conventional", the authentication of users via a RADIUS server runs as follows:

1. The user logs in with user name and password on the device.
2. The device sends an authentication request with the login data to the RADIUS server.
3. The RADIUS server runs a check and signals the result back to the device.
   - The RADIUS server reports a successful authentication and for the "Service Type" attribute returns the value "Administrative User" to the device
     → The user is logged in with administrator rights.
   - The RADIUS server reports a successful authentication and returns a different or even no value to the device for the attribute "Service Type".
     → The user is logged in with read rights.
   - The RADIUS server reports a failed authentication to the device:
     → The user is denied access.

RADIUS authorization mode "Vendor Specific"

Requirement

For the RADIUS authorization mode "Vendor Specific" the following needs to be set on the RADIUS server:

- Manufacturer code: 4196
- Attribute number: 1
- Attribute format: Character string (group name)

Procedure

If you have set the authorization mode "Vendor Specific", the authentication of users via a RADIUS server runs as follows:

1. The user logs in with user name and password on the device.
2. The device sends an authentication request with the login data to the RADIUS server.
3. The RADIUS server runs a check and signals the result back to the device.
   Case A: The RADIUS server reports a successful authentication and returns the group assigned to the user to the device.
   - The group is known on the device and the user is not entered in the table "External User Accounts"
     → The user is logged in with the rights of the assigned group.
   - The group is known on the device and the user is entered in the table "External User Accounts"
     → The user is assigned the role with the higher rights and logged in with these rights.
   - The group is not known on the device and the user is entered in the table "External User Accounts"
     → The user is logged in with the rights of the role linked to the user account.
   - The group is not known on the device and the user is not entered in the table "External User Accounts"
     → The user is logged in with the rights of the role "Default".

   Case B: The RADIUS server reports a successful authentication but does not return a group to the device.
   - The user is entered in the table "External User Accounts":
     → The user is logged in with the rights of the linked role.
   - The user is not entered in the table "External User Accounts":
     → The user is logged in with the rights of the role "Default".

   Case C: The RADIUS server reports a failed authentication to the device:
   - The user is denied access.

Authentication method

You can configure the authentication methods "802,1X" and "MAC Authentication" as well as the "Guest VLANGuest VLAN" option separately for each port.

The functions have a hierarchical order. If all three functions are enabled, an attempt is made initially to authenticate the end device using "802.1x". If this authentication is unsuccessful, "MAC Authentication" is started. If this authentication is also unsuccessful, the end device is enabled for communication in the "Guest VLAN". "Guest VLAN" can only be used if at least one authentication method is active.

The two authentication methods depend on the end device. If the end device supports EAP (Extensible Authentication Protocol), it can be authenticated using the "802.1X" method. If the end device does not support EAP, it can be authenticated using "MAC Authentication". In this case, the IE switch adopts the role of the end device and uses the MAC address of the device as the authentication parameter.

802.1X

The "802.1X" authentication method works as follows:
An end device that supports EAP sends authentication information to the IE switch. The IE switch forwards the information to the authentication server. The authentication server checks the information and allows or denies the end device access to the network.

MAC Authentication

The "MAC Authentication" authentication method works as follows:
As soon as the IE switch receives a frame from the end device, the IE switch sends a query to the RADIUS server to allow or deny the end device access to the network.

Assignment of a VLAN via RADIUS or guest VLAN

Authentication with a change to the VLAN configuration

If during authentication a port is assigned to a VLAN dynamically using the function "RADIUS VLAN Assignment Allowed" or "Guest VLAN" the following happens:

- If the VLAN that is to be assigned has not been created on the device, the authentication is rejected.
- If the VLAN that is to be assigned has been created on the device:
  - The port becomes an untagged member in the assigned VLAN if it was not already.
  - The PVID of the port is changed to the ID of the assigned VLAN.

Note

If the port is only to be assigned to one VLAN, you need to adapt the VLAN configuration manually. As default, all ports are untagged members in "vlan 1".

If the authentication is canceled, e.g. by link down, the dynamic changes are canceled.

- The port is no longer a member in the assigned VLAN.
- The PVID of the port is reset to the value it had prior to authentication.

Authentication without a change to the VLAN configuration

If during authentication no VLAN is assigned either by the function "RADIUS VLAN Assignment Allowed" or by "Guest VLAN", the existing VLAN configuration of the port remains unchanged.

Editing properties and parameters

Editing options

You have the following options for editing properties and parameters:

- Hardware and network editor
  Once you have inserted the network component, you can edit the properties and parameters, for example the device name. You will find more detailed information in "Hardware and network editor".
- Web Based Management (WBM)
  The parameters and properties are accessible using the supplied HTML pages (WBM pages). Each WBM page has its own help page that describes the properties and parameters. For further information, refer to the configuration manuals:
  - "SCALANCE XB-200/XC-200/XP-200 Web Based Management"
    You will find the configuration manual on the Internet pages of Siemens Industry Online Support inSCALANCE XB-200 (https://support.industry.siemens.com/cs/ww/en/ps/15291/man), SCALANCE XC-200 (https://support.industry.siemens.com/cs/ww/en/ps/15291/man) and SCALANCE XP-200 (https://support.industry.siemens.com/cs/ww/en/ps/21869/man).
  - "SCALANCE XM-400/XR-500 Web Based Management"
    You will find this configuration manual on the Internet pages of Siemens Industry Online Support in SCALANCE XM-400 (https://support.industry.siemens.com/cs/ww/en/ps/15315/man) and SCALANCE XR-500 (https://support.industry.siemens.com/cs/ww/en/ps/15317/man).
- Command Line Interface
  All the configuration settings for the device can be made using the CLI. The CLI provides the same options as Web Based Management (WBM). For further information, refer to the configuration manuals:
  - "SCALANCE XB-200/XC-200/XP-200 Command Line Interface"
    You will find the configuration manual on the Internet pages of Siemens Industry Online Support inSCALANCE XB-200 (https://support.industry.siemens.com/cs/ww/en/ps/15291/man), SCALANCE XC-200 (https://support.industry.siemens.com/cs/ww/en/ps/15291/man) and SCALANCE XP-200 (https://support.industry.siemens.com/cs/ww/en/ps/21869/man).
  - "SCALANCE XM-400/XR-500 Command Line Interface"
    You will find this configuration manual on the Internet pages of Siemens Industry Online Support in SCALANCE XM-400 (https://support.industry.siemens.com/cs/ww/en/ps/15315/man) and SCALANCE XR-500 (https://support.industry.siemens.com/cs/ww/en/ps/15317/man).

Availability

The availability of the settings depends

- on the port type
- on the configuration mode

SCALANCE X distinguishes the following port types:

- Switch port
- Router port

The following configuration modes are available:

- Offline configuration
  You can configure a PC station the first time offline. In this mode only the settings that require no connection to the device are available.
- Online configuration mode
  If there is a connection to the device, there are additional pages available in the Inspector window. These pages include the note "This page is only available if there is an online connection to the device". With some settings, the additional information "only available online" is included.

Creating and deleting an entry

As an example, an entry will be created and deleted on the Syslog client. The procedure is valid on all pages.

Creating a new entry

1. Select the device in the network or device view.
2. Open the properties of the device in the Inspector window.
3. In the Inspector window go to System > Syslog client.
4. Enter the IP address for the Syslog server.
5. Click in the table.
6. Select the entry "New entry" in the shortcut menu.
   A new entry is created in the table.

Deleting an entry

1. Select the required entry in the table.
2. Select the "Delete" entry in the shortcut menu.

Buttons you require often

- **Refresh the display with "Refresh"**
  Pages that display current parameters have a "Refresh" button at the lower edge of the page. Click this button to request up-to-date information from the device for the current page.
- **Save settings for all ports with "Transfer to table"**
  Pages on which you can configure several ports have 2 tables. In the first table, you can make the settings for all ports and transfer these to the second table. In the last column of the first table, there is the "Transfer to table" button. Click this button to save the settings you have made for all ports.

Assigning the IP address

Configuration options

When shipped and after restoring to the factory settings, the device does not have an IP address.

The following options are available to assign an IP address to the device:

- DHCP (default setting)
- Primary Setup Tool
  For further information, refer to the configuration manual "Primary Setup Tool". You will find the MIB at Siemens Industry Automation and Drives Service & Support on the Internet under the entry ID 19440762 (http://support.automation.siemens.com/WW/view/en/19440762).
- STEP 7
- CLI via the serial interface
  For further information, refer to the configuration manual "SCALANCE XM-400/XR-500 Command Line Interface". You will find the configuration manual on the Internet pages of Siemens Industry Automation and Drives Service & Support (http://support.automation.siemens.com/WW/view/en/48805144/133300).

Requirement

- "Set IP address on device" is enabled in the properties of the device. You will find more detailed information in "Addressing PROFINET devices".

Uploading the configuration data with a PROFINET IO device

With a SCALANCE device that is assigned to a PROFINET IO controller, you must distinguish between the data of the PROFINET IO device configuration and the SCALANCE configuration:

- The PROFINET IO device configuration can only be supplied by the PROFINET IO controller.
- The SCALANCE configuration relates only to the data that is configurable in the Web Based Management (WBM) (System, Layer 2, Layer 3, Security).

Follow the steps below to load the entire configuration of a SCALANCE device:

1. Download the PROFINET IO device configuration via the PROFINET IO controller:
   - Select the PROFINET IO controller in the project tree.
   - Select the command "Online" > "Load device as new station (hardware and software)" in the toolbar.
   - See also the section "Loading project data from a device"
2. Load the SCALANCE configuration as a local upload via the device:
   - Select the SCALANCE device in the network view.
   - In the shortcut menu of the selected device select the command "SCALANCE configuration > Upload to PG/PC".
   - See also section "Configuring deevices".

Show information

Versions

Note

The page is only available if there is an online connection to the device.

This page shows the versions of the hardware and software of the device.

Description

Table 1 has the following columns:

- **Hardware**
  - Basic device
    Shows the basic device.
  - PX.X
    X.X = port in which the SFP module is inserted.
  - Slot X
    X = slot number: Module plugged into this slot.
- **Name**
  Shows the name of the device or module.
- **Revision**
  Shows the hardware version of the device.
- **Order number**
  Shows the order number of the device or described module.

Table 2 has the following columns:

- **Software**
  - Firmware
    Shows the current firmware version. If a new firmware file was downloaded and the device has not yet restarted, the firmware version of the downloaded firmware file is displayed here. After the next restart, the downloaded firmware is activated and used.
  - Bootloader
    Shows the version of the boot software stored on the device.
- **Description**
  Shows the short description of the software.
- **Version**
  Shows the version number of the software version.
- **Date**
  Shows the date on which the software version was created.

I&M

Note

The page is only available if there is an online connection to the device.

This page contains information about device-specific vendor and maintenance data such as the article number, serial number, version number etc. You cannot configure anything on this page.

Description of the displayed values

The table has the following rows:

- **Manufacturer ID**
  Shows the manufacturer ID.
- Article number
  Shows the article number.
- **Serial number**
  Shows the serial number.
- **Hardware revision**
  Shows the hardware version.
- **Software version**
  Shows the software version.
- **Revision counter**
  Shows the revision counter: Counter for revisions since the initial commissioning
- **Revision Date**
  Date and time of the last revision

- **Function tag**
  Shows the function tag (plant designation) of the device. The plant designation (HID) is created during configuration of the device with HW Config of STEP 7.
- **Location tag**
  Shows the location tag of the device. The location identifier (LID) is created during configuration of the device with HW Config of STEP 7.
- **Date**
  Shows the date created during configuration of the device with HW Config of STEP 7.
- **Description**
  Shows the description created during configuration of the device with HW Config of STEP 7.

ARP / neighbor table

ARP table

Note

The page is only available if there is an online connection to the device.

Assignment of MAC address and IP address

With the Address Resolution Protocol (ARP), there is a unique assignment of MAC address to IPv4 addresses. This assignment is kept by each network node in its own separate ARP table. The page shows the ARP table of the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the interface via which the row entry was learnt.
- **MAC Address**
  Shows the MAC address of the destination or source device.
- **IP address**
  Shows the IP address of the target device.
- **Media Type**
  Shows the type of connection.
  - Dynamic
    The device recognized the address data automatically.
  - Static
    The addresses were entered as static addresses

IPv6 Neighbor Table

Assignment of MAC address and IPv6 address

Via the IPv6 neighbor table, there is a unique assignment of MAC address to IPv6 address. This assignment is kept by each network node in its own separate neighbor table.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Displays the interface via which the row entry was learnt.
- **MAC Address**
  Shows the MAC address of the destination or source device.
- **IP Address**
  Shows the IPv6 address of the destination device.
- **Media Type**
  Shows the type of connection.
  - Dynamic
    The device recognized the address data automatically.
  - Static
    The addresses were entered as static addresses.

Log table

Logging events

Note

The page is only available if there is an online connection to the device.

The device allows you to log events that occur, some of which you can specify in " System > Events". This, for example, allows you to record when an authentication attempt failed or when the connection status of a port has changed. The content of the events log table is retained even when the device is turned off.

Settings

- **Severity Filter**
  You can filter the entries in the table according to severity. Select the required entries in the check boxes above the table.
  - Info
    Information
  - When this parameter is enabled, all entries of the category "Info" are displayed.
  - Warning
    Warning
    When this parameter is enabled, all entries of the category "Warning" are displayed.
  - Critical
    Critical
    When this parameter is enabled, all entries of the category "Critical" are displayed.

  The table has the following columns:

  - **Restart**
    Counts the number of restarts since you last reset to factory settings and shows the device restart after which the corresponding event occurred.
  - **System Up Time**
    Shows the time the device has been running since the last restart when the described event occurred.
  - **System Time**
    Shows the date and time when the described event occurred.
    If the system time is set, the time is also displayed at which the event occurred.
  - **Severity**
    Shows the severity of the message.
  - **Log Message**
    Displays a brief description of the event that has occurred. You will find the list of possible messages in Appendix D of the configuration manual.

Buttons

- **Delete**
  Click this button to delete the content of the event log file. All entries are deleted regardless of what you have selected under "Severity Filters".
  The display is also cleared. The restart counter is only reset after you have restored the device to the factory settings and restarted the device.

  Note

  The table can contain 400 entries for each severity. The number of entries in this table is restricted to 1200. When this number is reached, the oldest entries of the relevant severity are discarded. The table remains permanently in memory.

Fault

Error status

Note

The page is only available if there is an online connection to the device.

if an error occurs, it is shown on this page. On the device, errors are indicated by red fault LED lighting up.

Internal errors of the device and errors that you configure on the following pages are indicated:

- System > Events"
- "System" > Fault Monitoring"

Errors of the "Cold/Warm Start" event can be deleted by a confirmation.

The calculation of the time of an error always begins after the last system start.

If there are no errors present, the fault LED switches off.

Description of the displayed values

- **No. of Signaled Faults**
  Shows the number of reported faults.

The table contains the following columns:

- **Fault Time**
  Shows the time the device has been running since the last restart when the described error/ fault occurred.
- **Fault Description**
  Displays a brief description of the fault/error that has occurred.
- **Clear Fault State**
  If the "Clear Fault State" button is enabled, you can delete the fault.
- "Reset Counters" button
  Click "Reset Counters" to reset all counters. The counters are reset by a restart.

Redundancy

Spanning Tree

Note

The page is only available if there is an online connection to the device.

The page shows the current information about the Spanning Tree and the settings of the root bridge.

Displayed values

- **Spanning Tree Mode**
  Shows the set mode. You specify the mode in "Layer 2 > Spanning Tree > General".
  The following values are possible:
  - '-'
  - STP
  - RSTP
  - MSTP
- **Instance ID**
  Shows the number of the instance. The parameter depends on the configured mode.
- **Bridge Priority / Root Priority**
  Which device becomes the root bridge is decided by the bridge priority. The bridge with the highest priority (in other words, with the lowest value for this parameter) becomes the root bridge. If several devices in a network have the same priority, the device whose MAC address has the lowest numeric value will become the root bridge. Both parameters, bridge priority and MAC address together form the bridge identifier. Since the root bridge manages all path changes, it should be located as centrally as possible due to the delay of the frames. The value for the bridge priority is a whole multiple of 4096.
- **Bridge address / root address**
  The bridge address shows the MAC address of the device and the root address shows the MAC address of the root bridge.
- **Root Cost**
  Shows the path costs from the device to the root bridge.
- **Bridge Status**
  Shows the status of the bridge, e.g. whether or not the device is the root bridge.
- **Regional root priority** (available only with MSTP)
  For a description, see Bridge priority / Root priority.
- **Regional root address** (available only with MSTP)
  Shows the MAC address of the device.
- **Regional Root Cost** (only available with MSTP)
  The path costs from this device to the regional root bridge.

The table has the following columns:

- **Port**
  Shows the port via which the device communicates.
- **Role**
  Shows the status of the port. The following values are possible:
  - Disabled
    The port was removed manually from the spanning tree and will no longer be taken into account by the spanning tree.
  - Designated
    The ports leading away from the root bridge.
  - Alternate
    The port with an alternative route to a network segment
  - Backup
    If a switch has several ports to the same network segment, the "poorer" port becomes the backup port.
  - Root
    The port that provides the best route to the root bridge.
  - Master
    This port points to a root bridge located outside the MST region.
- **Status**
  Displays the current status of the port. The values are only displayed. The parameter depends on the configured protocol. The following statuses are possible:
  - Discarding
    The port receives BPDU frames. Other incoming or outgoing frames are discarded.
  - Listening
    The port receives and sends BPDU frames. The port is involved in the spanning tree algorithm. Other outgoing and incoming frames are discarded.
  - Learning
    The port actively learns the topology; in other words, the node addresses. Other outgoing and incoming frames are discarded.
  - Forwarding
    Following the reconfiguration time, the port is active in the network. The port receives and sends data frames.
- **Oper. Version**
  Shows which Spanning Tree protocol is used by the port.
- **Priority**
  If the path calculated by the spanning tree is possible over several ports of a device, the port with the highest priority (in other words the lowest value for this parameter) is selected. A value between 0 and 240 can be entered for the priority in steps of 16. If you enter a value that cannot be divided by 16, the value is automatically adapted.

- **Path Cost**
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected. If several ports of a device have the same value, the port with the lowest port number will be selected.
  If the value "Cost Calc." is "0", the automatically calculated value is shown. Otherwise, the value of "Cost Calc." is displayed.
  The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000.

  You configure the "Cost. Calc." on the pages "Layer 2 > Spanning Tree > CIST Port" and "Layer 2 > Spanning Tree > MST Port".
- **Edge type**
  Shows the type of the connection. The following values are possible:
  - Edge Port

    An edge port is connected to this port.
  - No Edge Port
    There is a spanning tree device at this port.
- **P.t.P. Type**
  Shows the type of point-to-point link. The following values are possible:
  - P.t.P.
    With half duplex, a point-to-point link is assumed.
  - Shared Media

    With a full duplex connection, a point-to-point link is not assumed.

VRRP statistics

Introduction

Note

The page is only available if there is an online connection to the device.

This page shows the statistics of the VRRP protocol and all configured virtual routers.

Description of the displayed values

The following fields are displayed:

- VRID errors
  Shows how many VRRP frames containing an unsupported VRID were received.
- Version errors
  Shows how many VRRP frames containing an invalid version number were received.
- Checksum errors
  Shows how many VRRP frames containing an invalid checksum were received.

The table has the following columns:

- Interface
  Interface to which the settings relate.
- VRID
  Shows the ID of the virtual router.
- Change to master status
  Shows how often this virtual router changed to the "Master" role.
- Advertisements recd.
  Shows how often a VRRP frame was received that contained a bad address list.
- Advertisement Interval Errors
  Shows how many bad VRRP packets were received whose interval does not match the value set locally.
- IP TTL errors
  Shows how many bad VRRP packets were received whose TTL (Time to live) value in the IP header is incorrect.
- Prio 0 received
  Shows how many VRRP packets with priority 0 were received. VRRP packets with priority 0 are sent when a master router is shut down. These packets allow a fast handover to the relevant backup router.
- Prio 0 sent
  Shows how many VRRP packets with priority 0 were sent. Packets with priority 0 are sent when a master router is shut down. These packets allow a fast handover to the relevant backup router.
- Invalid Type
  Shows how many bad VRRP packets were received whose authentication type was not 0. Type 0 means "no authentication".
- Address List Errors
  Shows how many bad VRRP packets were received whose address list does not match the locally configured list.
- Invalid Auth. Type
  Shows how many bad VRRP packets were received whose authentication type was not type 0. Type 0 means "no authentication".

- **Auth. Type Mismatch**
  Shows how many bad VRRP frames were received whose authentication type does not match.
- **Frame length error**
  Shows how many bad VRRP frames were received whose length is not correct.

VRRP Statistics

Introduction

This page shows the statistics of the VRRPv3 protocol and all configured virtual routers.

Note

The page is only available if there is an online connection to the device.

Displayed values

The following fields are displayed:

- **VRID Errors**
  Shows how many VRRPv3 packets containing an unsupported VRID were received.
- **Version Errors**
  Shows how many VRRPv3 packets containing an invalid version number were received.
- **Checksum Errors**
  Shows how many VRRPv3 packets containing an invalid checksum were received.

The table has the following columns:

- **Interfaces**
  Interface to which the settings relate.
- **VRID**
  Shows the ID of the virtual router. Valid values are 1 ... 255.
- **Type**
  Shows the version of the IP protocol.
- **Become Master**
  Shows how often this virtual router changed to the "Master" status.
- **Advertisements Received**
  Shows how many VRRPv3 packets were received.
- **Advertisement Interval Errors**
  Shows how many bad VRRPv3 packets were received whose interval does not match the value set locally.
- **IP TTL Errors**
  Shows how many bad VRRPv3 packets were received whose TTL (Time to live) value in the IP header is incorrect.

- **Prio 0 received**
  Shows how many VRRPv3 packets with priority 0 were received. VRRPv3 packets with priority 0 are sent when a master router is shut down. These packets allow a fast handover to the relevant backup router.
- **Prio 0 sent**
  Shows how many VRRPv3 packets with priority 0 were sent. Packets with priority 0 are sent when a master router is shut down. These packets allow a fast handover to the relevant backup router.
- **Invalid Type**
  Shows how many bad VRRPv3 packets were received whose value in the "Type" field of the IP header is invalid.
- **Address List Errors**
  Shows how many bad VRRPv3 packets were received whose address list does not match the locally configured list.
- **Packet Length Errors**
  Shows how many bad VRRPv3 packets were received whose length is not correct.

Ring Redundancy

Note

The page is only available if there is an online connection to the device.

Automatic Redundancy Detection (ARD) is the default when the device ships. If you want to use the previous High Speed Redundancy Protocol (HRP), HRP must be configured.

- Reconfiguration time of the frame traffic following a failover in MRP: 200 ms
- Reconfiguration time of the frame traffic following a failover in HRP: 300 ms

This page informs you about the values currently set for the device.

Description

The following fields are displayed:

- **Redundancy Function**
  The "Redundancy Function" column shows the role of the device within the ring:
  - no Ring Redundancy
    The IE switch is operating without redundancy function.
  - HRP Client
    The IE switch is operating as an HRP client.
  - HRP manager
    The IE switch is operating as an HRP manager.
  - MRP Client
    The IE switch is operating as an MRP client.
  - MRP manager
    The IE switch is operating as an MRP manager. Using STEP 7, the role "Manager" was set for the device.
  - MRP Auto-Manager
    The IE switch is operating as an MRP manager. Using WBM or CLI the role "MRP Auto-Manager" or using STEP 7 the role "Manager (Auto)" was set.
- **RM Status**
  The "RM Status" column shows whether or not the IE switch is operating as redundancy manager and whether it has opened or closed the ring in this role.
  - Passive
    The IE switch is operating as redundancy manager and has opened the ring; in other words, the line of switches connected to the ring ports is operating problem free. The "Passive" status is also displayed if the IE switch is not operating as the redundancy manager (Redundancy manager disabled).
  - Active
    The IE switch is operating as redundancy manager and has closed the ring; in other words, the line of switches connected to the ring ports is interrupted (problem). The redundancy manager connects its ring ports through and restores an uninterrupted linear topology.
  - "-"
    The redundancy function is disabled.
- **Observer Status**
  Shows the current status of the observer.
- **Ring Port 1 and Ring Port 2**
  The "Ring Port 1" and "Ring Port 2" columns show the ports being used as ring ports.

- **No. of Changes to RM Active State**
  Shows how often the device as redundancy manager switched to the active status, i.e. closed the ring.
  If the redundancy function is disabled or the device is not the HRP/MRP manager, the text "Redundancy manager disabled" appears.
- **Max. delay of the RM test frames [ms]**
  Shows the maximum delay for test frames of the redundancy manager.
  If the redundancy function is disabled or the device is not the HRP/MRP manager, the text "Redundancy manager disabled" appears.

Standby

Note

The page is only available if there is an online connection to the device.

On this page, you obtain information about the status of the device in terms of standby redundancy. The text boxes on this page are read-only.

Note

Device with the higher MAC address becomes master

When linking HRP rings redundantly, two devices are always configured as a master/slave pair. This also applies to interrupted HRP rings = linear buses. When operating normally, the device with the higher MAC address adopts the role of master. This type of assignment is important in particular when a device is replaced. Depending on the MAC addresses, the previous device with the slave function can take over the role of the standby master.

The Standby tab shows the status of the standby function:

Description

The following fields are displayed:

- **Standby ports**
  Shows the standby port.
- **Standby name**
  Standby connection name

- **Standby Function**
  Shows whether the standby connection is activated or deactivated.
  - Master
    The device has a connection to the partner device and is operating as master. In normal operation, the standby port of this device is active.
  - Slave
    The device has a connection to the partner device and is operating as slave. In normal operation, the standby port of this device is inactive.
  - Disabled
    The standby link is disabled. The device is operating neither as master nor slave. The port configured as a standby port works as a normal port without standby function.
  - Connection establishment
    No connection has yet been established to the partner device. The standby port is inactive. In this case, either the configuration on the partner device is inconsistent (for example incorrect connection name, standby link disabled) or there is a physical fault (for example device failure, link down).
  - Connection lost
    The existing connection to the partner device has been lost. In this case, either the configuration on the partner device was modified (for example a different connection name, standby link disabled) or there is a physical fault (for example device failure, link down).
- **Standby status**
  Shows the status of the standby port:
  - Active
    The standby port of this device is active; in other words is enabled for frame traffic.
  - Passive
    The standby port of this device is inactive; in other words is blocked for frame traffic.
  - "-"
    The standby function is disabled.
- **No. of Changes to Standby Active State**
  Shows how often the IE switch has changed the standby status from "Passive" to "Active". If the connection of a standby port fails on the standby master, the IE switch changes to the "Active" status. If the standby function is disabled, the text "Standby Disabled" appears in this box.
  Following each restart on the device, the counters are automatically reset.

Ethernet Statistics

Interface statistics

Interface statistics

The page shows the statistics from the interface table of the Management Information Base (MIB).

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **In Octet**
  Shows the number of received bytes.
- **Out Octet**
  Shows the number of sent bytes.
- **In Unicast**
  Shows the number of received unicast frames.
- **In Non Unicast**
  Shows the number of received frames that are not of the type unicast.
- **Out Unicast**
  Shows the number of sent unicast frames.
- **Out Non Unicast**
  Shows the number of sent frames that are not of the type unicast.
- **In Errors**
  Shows the number of all possible RX errors, refer to the tab "Packet Error".

Packet Size

Frames sorted by length

This page displays how many frames of which size were sent and received at each port.

Note

The page is only available if there is an online connection to the device.

The displayed values are transferred by RMON.

On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.

  Note
  Display of frame statistics

  In the statistics relating to frame lengths, note that both incoming and outgoing frames are counted.

- **Frame lengths**
  The other columns after the port number contain the absolute numbers of frames according to their frame length.
  The following frame lengths are distinguished:
  - 64 bytes
  - 65 - 127 bytes
  - 128 - 255 bytes
  - 256 - 511 bytes
  - 512 - 1023 bytes
  - 1024 - max.

Note
Data traffic on blocked ports

For technical reasons, data packets can be indicated on blocked ports.

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

Frame type

Received frames sorted by type

This page displays how many frames of the type "unicast", "multicast", and "broadcast" were received at each port.

You cannot configure anything on this page.

The displayed values are transferred by RMON. On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.
- **Unicast / Multicast / Broadcast**
  The other columns after the port number contain the absolute numbers of the incoming frames according to their frame type "unicast", "multicast" and "broadcast".

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

Packet Errors

Received bad frames

This page shows how many bad frames were received per port.

You cannot configure anything on this page.

The displayed values are transferred by RMON. On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations.
- **Error types**
  The other columns after the port number contain the absolute numbers of the incoming frames according to their error type.
  In the columns of the table, a distinction is made according to the following error types:
  - CRC

    Packets whose content does not match the CRC checksum.
  - Undersize
    Packets with a length less than 64 bytes.
  - Oversize
    Frames discarded because they were too long.
  - Fragments

    Packets with a length less than 64 bytes and a bad CRC checksum.
  - Jabbers
    VLAN-tagged packets with an incorrect CRC checksum that were discarded because they were too long.
  - Collisions
    Collisions that were detected.

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

History

Samples of the statistics

The page shows samples from each port with information from the statistics.

On the page "Layer 2 > RMON > History", you can set the ports for which samples will be taken.

Note

The page is only available if there is an online connection to the device.

Settings

- **Port**
  Select the port for which the history will be displayed.

Displayed values

- **Entries**
  Maximum number of samples that can be saved at the same time.
- **Interval [s]**
  Interval after which the current status of the statistics will be saved as a sample.

The table has the following columns:

- **Sample**
  Number of the sample
- **Time for the Sample**
  System up time at which the sample was taken.
- **Unicast**
  Number of received unicast frames.
- **Multicast**
  Number of received multicast frames.
- **Broadcast**
  Number of received broadcast frames.
- **CRC**
  Number of frames with a bad CRC checksum.
- **Undersize**
  Number of frames that are shorter than 64 bytes.
- **Oversize**
  Number of frames discarded because they were too long.
- **Fragments**
  Number of frames that are shorter than 64 bytes and have a bad CRC checksum.
- **Jabbers**
  Number of frames with a VLAN tag that have a bad CRC checksum and will be discarded because they are too long.
- **Collisions**
  Number of collisions of received frames.
- **Utilization**
  Utilization of the port during a sample.

Unicast

This page shows the current content of the unicast filter table. This table lists the source addresses of unicast address frames. Entries can be made either dynamically when a node sends a frame to a port or statically by the user setting parameters.

Description

- **VLAN ID**
  Shows the VLAN-ID assigned to this MAC address.
- **MAC Address**
  Shows the MAC address of the node that the device has learned or the user has configured.
- **Status**
  Shows the status of each address entry:
  - Learnt
    The specified address was learned by receiving a frame from this node and will be deleted when the aging time expires if no further packets are received from this node.

    Note

    If there is a link down, learned MAC entries are deleted.

  - Static
    Configured by the user. Static addresses are stored permanently; in other words, they are not deleted when the aging time expires or when the switch is restarted.
- **Port**
  Shows the port via which the node with the specified address can be reached. Frames received by the device whose destination address matches this address will be forwarded to this port.

Multicast

This table shows the multicast frames currently entered in the multicast filter table and their destination ports. The entries can be dynamic (the device has learned them) or static (the user has set them).

Description

- **VLAN ID**
  Shows VLAN ID of the VLAN to which the MAC multicast address is assigned.
- **MAC Address**
  Shows the MAC multicast address that the device has learned or the user has configured.

- **Status**
  Shows the status of each address entry. The following information is possible:
  - Static
    The address was entered statically by the user. Static addresses are stored permanently; in other words, they are not deleted when the aging time expires or when the device is restarted. These must be deleted by the user.
  - IGMP
    The destination port for this address was obtained by IGMP configuration.
  - MLD
    The destination port for this address was determined by MLD configuration.
  - GMRP
    The destination port for this address was registered by a received GMRP frame.
- **List of ports**
  There is a column for each slot. Within a column, the multicast group to which the port belongs is shown:
  - M (Member)
    Multicast frames are sent via this port.
  - R (Registered)
    Member of the multicast group, registration was by an GMRP frame.
  - I (IGMP/MLD)
    Member of the multicast group, registration was by an IGMP/MLD frame.
  - –
    Not a member of the multicast group. No multicast frames with the defined multicast MAC address are sent via this port.
  - F (Forbidden)
    Not a member of the multicast group. Moreover, this address must not be an address learned dynamically with GMRP or IGMP/MLD.

LLDP

Note

The page is only available if there is an online connection to the device.

Status of the neighborhood table

This page shows the current content of the neighborhood table. This table stores the information that the LLDP agent has received from connected devices. You set the interfaces via which the LLDP agent receives or sends information in the following section: "Layer 2 > LLDP".

Description of the displayed values

The table contains the following columns:

- **System name**
  System name of the connected device.
- **Device ID**
  Device ID of the connected device.
- **Local interface**
  Port at which the IE switch received the information.
- **Hold Time**
  An entry remains stored in the MIB for the time specified here. If the IE switch does not receive any new information from the connected device during this time, the entry is deleted.
- **Property**
  Shows the properties of the connected device:
  - Router
  - Bridge
  - Telephone
  - DOCSIS Cable Device
  - WLAN Access Point
  - Repeater
  - Station
  - Other
- **Port ID**
  Port of the device with which the IE switch is connected.

DHCP Server

This page shows whether IPv4 addresses were assigned to the devices by the DHCP server.

Note

The page is only available if there is an online connection to the device.

Description

- **IP Address**
  Shows the IPv4 address assigned to the DHCP client.
- **Pool ID**
  Shows the number of the IPv4 address band.
- **Identification method**
  Shows the method according to which the DHCP client is identified.

- **Identification value**
  Shows the MAC address or he client ID of the DHCP client.
- **Remote ID**
  Shows the remote ID of the DHCP client.
- **Circuit ID**
  Shows the circuit ID of the DHCP client.
- **Assignment method**
  Shows whether the IPv4 address was assigned statically or dynamically. You configure the static entries in "System > DHCP > Static Leases".
- **Assignment status**
  Shows the status of the assignment.
  - Assigned
    The assignment is used.
  - Not used
    The assignment is not used.
  - Probing
    The assignment is being checked.
  - Unknown
    The status of the assignment is unknown.
- **Expire Time**
  Shows how long the assigned IPv4 address is still valid. Once this period has elapsed, the DHCP client must either request a new IPv4 address or extend the lease time of the existing IPv4 address.

Diagnostics

This page shows the diagnostics values of internal and external modules of the device. The modules are only shown if they make diagnostics information available. If you add or remove a module, the display is automatically adapted.

If the diagnostic value falls below or exceeds the displayed threshold values, the status changes accordingly.

On the "System > Events > Configuration" page, you can specify how the device signals the status change.

Description

The Usage Table contains the following columns:

- **Name**
  Shows the name of the module.
- **Status**
  Depending on the relationship between the threshold values and the current temperature the following statuses are displayed in ascending priority.
  - OK
    The temperature value is within the preset threshold values.
  - WARNING
    The lower or upper threshold value of the severity level "Warning" was exceeded.
  - CRITICAL
    The lower or upper threshold value of the severity level "Critical" was exceeded.
  - INVALID
    The value could not be read out or is invalid. The "Power [%] box shows "-".
  - INITIAL
    No data has been read out yet. "-" is displayed in all boxes.
- **Power [%]**
  Shows the current value of the power. The display is updated at regular intervals.
- **High Warning Threshold [%]**
  If the value exceeds this value, the status changes to "WARNING". You can configure that you are informed by a message.
- **High Critical Threshold [%]**
  If the value exceeds this value, the status changes to "CRITICAL". You can configure that you are informed by a message.

The Temperature Table contains the following columns:

- **Name**
  Shows the name of the module.
  The information in the row "Chassis" relates to the inner temperature of the housing.
  With modular devices, the port is also specified.
- **State**
  Depending on the relationship between the threshold values and the current temperature the following statuses are displayed in ascending priority.
  - OK
    The temperature value is within the preset threshold values.
  - WARNING
    The lower or upper threshold value of the severity level "Warning" was exceeded.
  - CRITICAL
    The lower or upper threshold value of the severity level "Critical" was exceeded.
  - INVALID
    The value could not be read out or is invalid. In the "Temperature [°C]" box "-" is displayed.
  - INITIAL
    No data has been read out yet. "-" is displayed in all boxes.
- **Temperature [°C]**
  Shows the current value of the temperature. The display is updated at regular intervals. The value can have a tolerance of +/- 3 °C
- **Lower Threshold [°C] (Critical)**
  If the value falls below this value, the status changes to "CRITICAL". You can configure that you are informed by a message.
- **Lower Threshold [°C] (Warning)**
  If the value falls below this value, the status changes to "WARNING". You can configure that you are informed by a message.
- **Upper Threshold [°C] (Warning)**
  If the value exceeds this value, the status changes to "WARNING". You can configure that you are informed by a message.
- **Upper Threshold [°C] (Critical)**
  If the value exceeds this value, the status changes to "CRITICAL". You can configure that you are informed by a message.

FMP

Monitoring optical links

With Fiber Monitoring, you can monitor optical links. The table shows the current status of the ports.

You set the values to be monitored on the following page: "Layer 2 > FMP".

Note

The page is only available if there is an online connection to the device.

Displayed values

- **Port**
  Shows the available optical ports.
- **Rx Power State**
  - disabled
    Fiber monitoring is disabled.
  - ok
    The value for the received power of the optical link is within the set limits
  - maint. req.
    Check the link.
    A warning is signaled.
  - maint. dem.
    The link needs to be checked.
    An alarm is signaled and the fault LED is lit.
  - link down
  - The connection is interrupted.

- **RX Power**
  Shows the current value of the received power. The value can have a tolerance of +/- 3 dB. If there is no connection (link down) or fiber monitoring is disabled, "-" is displayed. If fiber monitoring is not enabled on the partner port, the value 0.0 is displayed.
- **Power Loss State**
  To be able to monitor the power loss of the connection, the port requires a link to another port with FM enabled.
  - disabled
    FM is disabled.
  - ok
    The value for the power loss of the optical link is OK.
  - maint. req.
    Check the link.
    A warning is signaled.
  - maint. dem.
    The link needs to be checked.
    An alarm is signaled and the fault LED is lit.
  - idle
    The port has no connection to another port with fiber monitoring enabled.
    If no diagnostics information is received from the optical port of the connection partner for 5 cycles, the fiber monitoring connection is assumed to be interrupted. A cycle lasts 5 seconds.
- **Power Loss [dB]**
  Shows the current value of the power loss. The value can have a tolerance of +/- 3 dB. If there is no connection (link down), fiber monitoring is disabled or the partner port does not support fiber monitoring, "-" is displayed.

IPv4 routing

Routing table

This page shows the routes currently being used.

Description

The table has the following columns:

- **Destination network**
  Shows the destination address of this route.
- **Subnet mask**
  Shows the subnet mask of this route.
- **Gateway**
  Shows the gateway for this route.
- **Interface**
  Shows the interface for this route.

- **Metric**
  Shows the metric of the route. The higher value, the longer the packets require to their destination.
- **Routing protocol**
  Shows the routing protocol from which the entry in the routing table originates. The following entries are possible:
  - Connected: Connected routes
  - Static: Static routes
  - RIP: Routes via RIP
  - OSPF: Routes via OSPF
  - other: Other routes

OSPFv2 interfaces

Overview

Note

The page is only available if there is an online connection to the device.

This page shows the configuration of the OSPF interface.

Description of the displayed values

The table has the following columns:

- **IP Address**
  Shows the IPv4 address of the OSPF interface
- **Area ID**
  Shows the Area ID to which the OSPF interface belongs.

- **Interface Status**
  Shows the status of the WLAN interface:
  - Down
    The interface is not available.
  - Loopback
    Loopback interface
  - Waiting
    Startup and negotiation of the interface.
  - Point to Point
    Point-to-point connection
  - Designated Router
    The router is a designated router and generates a network LSA.
  - Backup D. Router
    The router is backup for the designated router.
  - Other D. Router
    The interface is started up. The router is neither a designated router nor a backup designated router.
- **OSPF status**
  Shows the status of OSPF.
  - Enabled: OSPF is enabled on the interface.
  - Disabled: OSPF is disabled on the interface.
- **Designated Router**
  Shows the IPv4 address of the designated router for this OSPF interface.
- **Backup Designated Router**
  Shows the IPv4 address of the designated backup router for this OSPF interface.
- **Events**
  Shows the number of status changes of OSPF.

OSPFv2 neighbors

Note

The page is only available if there is an online connection to the device.

This page shows the dynamically detected neighbor routers in the relevant networks.

Description of the displayed values

The table has the following columns:

- **IP Address**
  Shows the IPv4 address of the neighbor router in this network.
- **Router ID**
  Shows the ID of the neighbor router. The two addresses can match.

- **Status**
  Shows the status of the neighbor router. The status can adopt the following values:
  - unknown
    Status of the neighbor router is unknown.
  - down
    The neighbor router cannot be reached.
  - attemptand init
    Short-lived statuses during initialization
  - two-way
    Two-way receipt of Hello packets. Specification of the designated router and the designated backup router.
  - exchangestart, exchange and loading
    Status during exchange of the LSAs
  - full
    The database is complete and synchronized within the area. The routes can now be detected.

    Note

    Normal status

    If the partner router is a designated router or a designated backup router, the status is "full". Otherwise the status is "two-way".

- **Assoc. Area Type**
  Shows the area type via which the neighbor-neighbor relation is maintained. The following area types exist:
  - Normal
  - Stub
  - NSSA
  - Backbone
- **Priority**
  Shows the priority of the neighbor router. This is only significant when selecting the designated router on a network. For virtual neighbor routers, this information is irrelevant.
- **Hello suppr**
  Shows the suppressed Hello packets to the neighbor router. This field normally displays "no".
- **Hello Queue**
  Shows the length of the queue with Hello packets still to be transmitted.
- **Events**
  Shows the number of status changes.

OSPFv2 virtual neighbors

Note

The page is only available if there is an online connection to the device.

This page shows the configured virtual neighbor routers.

Overview

The table has the following columns:

- **IP Address**
  Shows the IPv4 address of the virtual neighbor router in this network.
- **Router ID**
  Shows the router ID of the virtual neighbor router.
- **Status**
  Shows the status of the neighbor router. The status can adopt the following values:
  - unknown
    Status of the neighbor router is unknown.
  - down
    The neighbor router cannot be reached.
  - attemptand init
    Short-lived statuses during initialization
  - two-way
    Two-way receipt of Hello packets. Specification of the designated router and the designated backup router.
  - exchangestart, exchange and loading
    Status during exchange of the LSAs
  - full
    The database is complete and synchronized within the area. The routes can now be detected.

    Note

    Normal status

    If the partner router is a designated router or a designated backup router, the status is "full". Otherwise the status is "two-way".
- **Transit Area ID**
  Shows the ID of the area via which the virtual neighborhood relation exists.
- **Hello Suppr.**
  Shows whether there are suppressed Hello packets to the virtual neighbor router.
  - no: There are no suppressed Hello packets (default)
  - yes: There are suppressed Hello packets.

- **Hello Queue**
  Shows the length of the queue with Hello packets still to be transmitted.
- **Events**
  Shows the number of status changes.

OSPFv2 LSDB

Overview

Note

The page is only available if there is an online connection to the device.

The link state database is the central database for managing all links within an area. It consists of the link state advertisements (LSAs). The most important data of these LSAs is shown on the this WBM page.

Description of the displayed boxes

The table has the following columns:

- **Area ID**
  Shows the ID of the area to which the LSA belongs. If the LSA is an external connection, '-' is displayed.
- **LSA type**
  Shows the LSA type. The following values are possible:
  - unknown
    LSA type is unknown.
  - Router
    The router LSA (Type 1) is sent by the OSPF router within an area. The LSA contains information about the status of all router interfaces.
  - Network
    The network LSA (Type 2) is sent by the designated router within an area. The LSA contains a list of routers connected to the network.
  - NSSA External
    The NSSA external LSA (Type 7) is sent by the NSSA-ASBR within an NSSA. The NSSA-ASBR receives LSAs of Type 5 and converts the information to LSAs of Type 7. The NSSA router can forward these LSAs within an NSSA.
  - Summary
    The summary LSA (Type 3) is sent by the ABR within an area. The LSA contains information about routes to other networks.
  - AS Summary
    The AS summary LSA (Type 4) is sent by the area border router within an area. The LSA contains information about routes to other autonomous systems.
  - AS External
    The AS external LSA (Type 5) is sent by the AS border router within an autonomous system. The LSA contains information about routes from one network to another.
- **Link State ID**
  Shows the ID of the LSA.
- **Router ID**
  Shows the ID of the router that sent this LSA.
- **Sequence number**
  Shows the sequence number of the LSA. Each time an LSA is renewed, this sequence number is incremented by one.

RIPv2 statistics

Overview

Note

The page is only available if there is an online connection to the device.

This page shows the statistics of the RIP interface.

Description of the displayed values

The table has the following columns:

- **IP address**
  Shows the IP address of the RIPv2 interface
- **Bad packets**
  Number of received RIP packets that were deleted and therefore ignored.
- **Bad Routes**
  Number of routes of valid RIP packets that could not be taken into consideration.
- **Updates Sent**
  Shows how often the router has sent its routing table to its neighbor routers.

NAT Translations

Overview

This page displays the active NAT connections.

Description of the displayed values

The table has the following columns:

- **Interface**
  Shows the IP interface.
- **Inside Local Address**
  Shows the actual address of the device that should be reachable from external.
- **Inside Local Port**
  Shows the port that is assigned to the Inside Local Address.
- **Inside Global Address**
  Shows the address at which the device can be reached from external.
- **Inside Global Port**
  Shows the port that is assigned to the Inside Global Address.
- **Outside Local/Global Address**
  Shows the address of the communications partner.
- **Outside Local/Global Port**
  Displays the port of the external communications partner.
- **Last Use Time**
  Shows the time at which the last packet was transferred.

IPv6 routing

Routing table

Introduction

This page shows the IPv6 routes currently being used.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Destination Network**
  Shows the destination address of this route.
- **Prefix Length**
  Shows the prefix length of this route.
- **Gateway**
  Shows the gateway for this route.
- **Interface**
  Shows the interface for this route.
- **Metric**
  Shows the metric of the route. The higher value, the longer packets require to their destination.
- **Routing Protocol**
  Shows the routing protocol from which the entry in the routing table originates. The following entries are possible:
  - connected: Connected routes
  - Static: Static routes
  - RIPng: Routes via RIPng
  - OSPFv3: Routes via OSPFv3
  - other: Other routes

OSPFv3 Interfaces

Overview

This page shows the configuration of the OSPFv3 interface.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the interface to which the settings relate.
- **Area ID**
  Shows the Area ID to which the OSPF interface belongs.
- **Interface Status**
  Shows the status of the interface.
  - Down
    The interface is not available.
  - Loop back
    Loop back interface
  - Waiting
    Startup and negotiation of the interface.
  - Point to Point
    Point-to-point connection
  - Designated Router
    The router is a designated router and generates network LSAs.
  - Backup D. Router
    The router is the backup router for the designated router.
  - S D. Router
    The Interface has started up. The router is neither a designated nor a designated backup router.
- **OSPF Status**
  Shows the status of OSPF.
  - Enabled: OSPF is enabled on the interface.
  - Disabled: OSPF is disabled on the interface.
- **Designated Router**
  Shows the IPv6 address of the designated router for this OSPFv3 interface.

- **Backup Designated Router**
  Shows the IPv6 address of the designated backup router for this OSPFv3 interface.
- **Events**
  Shows the number of status changes of OSPFv3.

OSPFv3 neighbors

Overview

This page shows the dynamically detected neighbor routers in the relevant networks.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Displays the OSPFv3 interface via which the neighbor router can be reached.
- **Router ID**
  Shows the ID of the neighbor router.
- **Status**
  Shows the status of the neighbor router. The status can adopt the following values:
  - unknown
    Status of the neighbor router is unknown.
  - down
    The neighbor router cannot be reached.
  - attempt und init
    Short-lived status during initialization
  - two-way
    Two-way receipt of Hello packets. Specification of the designated router and the designated backup router.
  - exchangestart, exchange und loading
    Status during exchange of the LSAs
  - full
    The database is complete and synchronized within the area. The routes can now be detected.

    Note

    Normal status

    If the partner router is a designated router or a designated backup router, the status is "full". Otherwise the status is "two-way".

- **Assoc. Area Type**
  Shows the area type via which the neighbor-neighbor relation is maintained. The following area types exist:
  - Standard
  - Stub
  - NSSA
  - Backbone
- **Priority**
  Shows the priority of the neighbor router. This is only significant when selecting the designated router on a network. For virtual neighbor routers, this information is irrelevant.
- **Hello suppr**
  Shows the suppressed Hello packets to the neighbor router. This field normally displays "no".
- **Retrans Queue**
  Shows the length of the queue with Hello packets still to be transmitted.
- **Events**
  Shows the number of status changes.

OSPFv3 Virtual Neighbors

Overview

This page shows the configured virtual neighbors.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Displays the OSPFv3 interface via which the neighbor router can be reached.
- **Router ID**
  Shows the ID of the virtual neighbor router.

- **Status**
  Shows the status of the virtual neighbor router. The status can adopt the following values:
  - unknown
    Status of the neighbor router is unknown.
  - down
    The neighbor router cannot be reached.
  - attempt und init
    Short-lived status during initialization
  - two-way
    Two-way receipt of Hello packets. Specification of the designated router and the designated backup router.
  - exchangestart, exchange und loading
    Status during exchange of the LSAs
  - full
    The database is complete and synchronized within the area. The routes can now be detected.

  Note

  Normal status

  If the partner router is a designated router or a designated backup router, the status is "full". Otherwise the status is "two-way".

- **Trans. Area-ID**
  Shows the ID of the area via which the virtual neighborhood relation exists.
- **Hello suppr**
  Shows the suppressed Hello packets to the neighbor router. This field normally displays "no".
- **Retrans Queue**
  Shows the length of the queue with Hello packets still to be transmitted.
- **Events**
  Shows the number of status changes.

OSPFv3 AS-Scope LSDB

Overview

The AS-Scope LSDB consists of AS external LSAs. The most important data of these LSAs is shown on this page.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Link State Type**
  - AS External
    The AS external LSA (Type 0x4005) is sent by the AS border router within an autonomous system. The LSA contains information about routes from one network to another.
- **Link State ID**
  Shows the ID of the LSA.
- **Router ID**
  Shows the ID of the router that sent this LSA.
- **Sequence Number**
  Shows the sequence number of the LSA. Each time an LSA is renewed, this sequence number is incremented by one.

OSPFv3 Area-Scope LSDB

Overview

The Area-Scope LSDB is the central database for managing all links within an area. The most important data of the LSAs is shown on this page.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Area ID**
  Shows the ID of the area to which the LSA belongs. If the LSA is an external connection, '-' is displayed.
- **Link State Type**
  Shows the LSA type. The following values are possible:
  - Router
    The router LSA (Type 0x2001) is sent by the OSPF router within an area. The LSA contains information about the status of all router interfaces. However, no longer contains address information. This is contained in the new LSA type 0x2009.
  - Network
    The network LSA (Type 0x2002) is sent by the designated router within an area. The LSA contains a list of routers connected to the network. However, no longer contains address information. This is contained in the new LSA type 2009.
  - Inter-Area Prefix
    the inter-area prefix LSA (Type 0x2003) is sent by the ABR within an area. The LSA contains information about routes to other networks.
  - Inter-Area Router
    The inter-area router LSA (Type 0x2004) is sent by the area border router within an area. The LSA contains information about routes to other autonomous systems.
  - Type 7
    The Type 7 LSA (Type 0x2007) is sent by the NSSA-ASBR within an NSSA. The NSSA-ASBR receives LSAs of Type 0x4005 and converts the information to LSAs of Type 0x2007. The NSSA router can forward these LSAs within an NSSA.
  - Intra-Area Prefix
    The intra-area prefix LSA (Type 0x2009) is only sent within an area. It contains the IPv6 prefixes connected to the router or network.
- **Link State ID**
  Shows the ID of the LSA.
- **Router ID**
  Shows the ID of the router that sent this LSA.
- **Sequence Number**
  Shows the sequence number of the LSA. Each time an LSA is renewed, this sequence number is incremented by one.

OSPFv3 Link Scope LSDB

Overview

The link scope LSDB consists of the link LSAs. The most important data of these LSAs is shown on this page.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the OSPFv3 interface to which the link LSA belongs.
- **Link State Type**
  - Link
    The link LSA (Type 0x2009) is sent by the router to every router linked to it. It contains the link local address of the router and a list with IPv6 prefixes configured on the link.
- **Link State ID**
  Shows the ID of the LSA.
- **Router ID**
  Shows the ID of the router that sent this LSA.
- **Sequence Number**
  Shows the sequence number of the LSA. Each time an LSA is renewed, this sequence number is incremented by one.

RIPng Statistics

Overview

This page shows the statistics of the RIPng interfaces.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the RIPng interface.
- **Status**
  Shows the status of the RIPng interface.
  - up
  - down
- **Messages Received**
  Shows how often the router has received messages.
- **Requests Received**
  Shows how often the router has received requests.
- **Responses Received**
  Shows how often the router has received responses.
- **Unknown Commands**
  Shows how many RIPng packets were received whose value in the "Commands" field of the RIPng header is unknown. Known values are 1 for requests and 2 for responses.
- **Other version**
  Shows how many RIPng packets were received whose value in the "Version" field is not 1.
- **Discards**
  Shows how often the router has discarded RIPng packets.
- **Messages Sent**
  Shows how often the router has sent messages.
- **Requests Sent**
  Shows how often the router has sent requests.
- **Responses Sent**
  Shows how often the router has sent responses.
- **Updates Sent**
  Shows how often the router has sent its routing table to its neighbor routers.

Security

Overview

This page shows the security settings and the local and external user accounts.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the rights of the logged-on user.

Displayed values

Services

The "Services" list shows the security settings.

- **Telnet Server**
  You configure the setting in "System > Configuration".
  - Enabled: Unencrypted access to the CLI.
  - Disabled: No unencrypted access to the CLI.
- **SSH Server**
  You configure the setting in "System > Configuration".
  - Enabled: Encrypted access to the CLI.
  - Disabled: No encrypted access to the CLI.
- **Web Server**
  You configure the setting in "System > Configuration".
  - HTTP/HTTPS: Access to the WBM is possible with HTTP and HTTPS.
  - HTTPS: Access to the WBM is now only possible with HTTPS.
- **SNMP**
  You can configure setting in "System > SNMP > General".
  - "-" (SNMP disabled)
    Access to device parameters via SNMP is not possible.
  - SNMPv1/v2c/v3
    Access to device parameters is possible with SNMP versions 1, 2c or 3.
  - SNMPv3
    Access to device parameters is possible only with SNMP version 3.
- **Management ACL**
  You configure the setting in "Security > Management ACL".
  - Disabled: No access restriction
    The access control is disabled.
  - Enabled: No access restriction
    The access control is enabled but no access rules have been defined.
  - Enabled: Restricted access only
    The access control is enabled and access rules have been defined.

- **Login Authentication**
  You configure the setting in "Security > AAA > General".
  - Local
    The authentication must be made locally on the device.
  - RADIUS
    The authentication must be handled via a RADIUS server.
  - Local and RADIUS
    The authentication is possible both with the users that exist on the device (user name and password) and via a RADIUS server.
    The user is first searched for in the local database. If the user does not exist there, a RADIUS query is sent.
  - RADIUS and fallback local
    The authentication must be handled via a RADIUS server.
    A local authentication is performed only when the RADIUS server cannot be reached in the network.
- **Password Policy**
  Shows which password policy is currently being used.

Local and external user accounts

You configure local user accounts and roles in "Security > User Accounts"

When you create a local user account an external user account is generated automatically. Local user accounts involve users each with a password for logging in on the device.

In the table "External User Accounts" a user is linked to a role, for example the user "Observer" with the role "user" In this case, the user is defined on a RADIUS server. The roll is defined locally on the device. When a RADIUS server authenticates a user, the corresponding group however is unknown or does not exist, the device checks whether or not there is an entry for the user in the table "External User Accounts". If an entry exists, the user is logged in with the rights of the associated role. If the corresponding group is known on the device, both tables are evaluated. The user is assigned the role with the higher rights.

Note

The table "External User Accounts" is only evaluated if you have set "Vendor Specific" in the RADIUS Authorization Mode".

With CLI you can access external user accounts.

The table "Local User Accounts" has the following columns:

- **User Account**
  Shows the name of the local user.
- **Role**
  Shows the role of the user. You can obtain more information on the function rights of the role in "Information > Security > Roles".

The table "External User Accounts" has the following columns:

- **User Account**
  Shows the name of the user on the RADIUS server.
- **Role**
  Shows the role assigned to the user on the device. You can obtain more information on this in "Information > Security > Roles".

Supported Function Rights

The page shows the function rights available locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

- **Function Right**
  Shows the number of the function right. Different rights relating to the device parameters are assigned to the numbers.
- **Description**
  Shows the description of the function right.

Groups

This page shows which group is linked to which role. The group is defined on a RADIUS server. The roll is defined locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

The table has the following columns:

- **Group**
  Shows the name of the group. The name matches the group on the RADIUS server.
- **Role**
  Shows the role. Users who are authenticated with the linked group on the RADIUS server receive the rights of this role locally on the device.
- **Description**
  Shows a a description for the link.

Roles

The page shows the roles valid locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

This table contains the following columns:

- **Role**
  Shows the role.
- **Function Right**
  Shows the function rights of the role:
  - 1
    Users with this role can read device parameters but cannot change them.
  - 15
    Users with this role can both read and change device parameters.
  - 0
    This is a role that the device assigns internally when the user could not be authenticated. The user is denied access to the device.
- **Description**
  Shows a description of the role.

Configuring system functions

Configuration

The page contains the configuration overview of the access options of the device. Specify the services that access the device. With some services, there are further configuration pages on which more detailed settings can be made.

Settings

- **Telnet Server**
  Enable or disable the "Telnet Server" service for unencrypted access to the CLI.
- **SSH server**
  Enable or disable the "SSH Server" service for encrypted access to the CLI.
- **HTTPS server only**
  If this function is enabled, you can only access the device via HTTPS.

- **DNS client**
  Enable or disable depending on whether the IE switch should operate as a DNS client. You can configure other settings in "System > DNS Client".
- **SMTP Client**
  Enable or disable the SMTP client. You can configure other settings in "System > SMTP Client".
- **Syslog Client**
  Enable or disable the Syslog client. You can configure other settings in "System > Syslog client".
- **DCP Server**
  Specify whether or not the device can be accessed with DCP (Discovery and Configuration Protocol):
  - "-" (disabled)
    DCP is disabled. Device parameters can neither be read nor modified.
  - Read/write access
    With DCP, device parameters can be both read and modified.
  - Read-Only
    With DCP, device parameters can be read but cannot be modified.
- **Time**
  Select the required setting. The following settings are possible:
  - Manual
    The system time is set manually. You can configure other settings in "System > System Time > Manual Setting".
  - SNTP Client
    The system time is set via an SNTP server. You can configure other settings in "System > System time > SNTP client".
  - NTP Client
    The system time is set via an NTP server. You can configure other settings in "System > System time > NTP client".
  - SIMATIC Time
    The system time is set using a SIMATIC time transmitter. You can configure other settings in "System > System Time SIMATIC Time Client".
  - PTP Client(SCALANCE XR528-6M and XR552-12M only)
    The system time is set via a PTP server. You can configure other settings in "System > System Time > PTP Client".

- **SNMP**
  Select the required protocol. The following settings are possible:
  - "-" (SNMP disabled)
    Access to device parameters using SNMP is not possible.
  - SNMPv1/v2c/v3
    Access to device parameters is possible with SNMP versions 1, 2c or 3. You can configure other settings in "System > SNMP > General".
  - SNMPv3
    Access to device parameters is possible with SNMP version 3. You can configure other settings in "System > SNMP > General".
- **SNMPv1/v2 Read-Only**
  Enable or disable write access to SNMP variables with SNMPv1/v2c.
- **SNMPv1 traps**
  Enable or disable the sending of SNMP traps (alarm frames). You can configure other settings in "System > SNMP > Traps".
- **SINEMA configuration interface**
  If the SINEMA configuration interface is enabled, you can download configurations to the IE switch via the TIA Portal.
- **NFC** (only with SCALANCE XM-400)
  Enable or disable the "NFC" function.
  You will find further information on NFC in the "SCALANCE XM400" Operating Instructions.
- **Configuration mode**
  Select the required operating mode. The following modes are possible:
  - Automatic save
    Automatic backup mode. Approximately 1 minute after the last parameter change or when you restart the device, the configuration is automatically saved.
  - Trial
    In the "Trial" configuration mode, although changes are adopted, they are not saved in the configuration file (startup configuration).
    To save changes in the configuration file, use the "Write startup config" button. The "Write startup config" button is displayed when you set trial mode. The display area also shows the message "Trial Mode Active – Click the "Write Startup Config" button to make your settings persistent" as soon as there are unsaved modifications. This message can be seen on every page until the changes made have either been saved or the device has been restarted.

General

Device

This page contains the general device information.

Settings

- **Current System Time**(Only available online)
  Shows the current system time. The system time is either set by the user or by a time-of-day frame: either SINEC H1 time-of-day frame, NTP or SNTP. (readonly)
- **System Up Time**(only available online)
  Shows the operating time of the device since the last restart. (readonly)
- **Device Type**(only available online)
  Shows the type designation of the device. (readonly)
- **System Name**
  You can enter the name of the device. The entered name is displayed in the selection area. A maximum of 255 characters are possible. The system name is also displayed in the CLI input prompt. The number of characters in the CLI input prompt is limited. The system name is truncated after 16 characters.
- **System Contact**
  You can enter the name of a contact person responsible for managing the device.
- **Location**
  You can enter the location of the device. The entered installation location is displayed in the selection area.

Note

The ASCII characters 0x20 to 0x7e are used in the input boxes.

At the start and end of the input boxes"System name", "System Contact" and "System Location", the characters "<", ">" and "space" are not permitted.

Coordinates

On this page, you configure the geographic coordinates (latitude, longitude and the height above the ellipsoid according to WGS84). These boxes are purely for information with a maximum length of 32 characters.

Getting the coordinates

Use suitable maps for obtaining the geographic coordinates of the device.

The geographic coordinates can also be obtained using a GPS receiver. The geographic coordinates of these devices are normally displayed directly and only need to be entered in the input boxes of this page.

Settings

- **Latitude**
  Enter the north or south latitude for the location of the device.
  For example, +49° 1´ 31.67" means that the device is located at 49 degrees, 1 arc minute and 31.67 arc seconds north latitude.
  A south latitude is shown by a preceding minus character.
  You can also append the letters N (north latitude) or S (south latitude) to the numeric information (49° 1´ 31.67" N).
- **Longitude**
  Enter the value of the eastern or western longitude of the location of the device.
  For example, +8° 20´ 58.73" means that the device is located at 8 degrees, 20 minutes and 58.73 seconds east.
  A western longitude is indicated by a preceding minus sign.
  You can also add the letter E (eastern longitude) or W (western longitude) to the numeric information (8° 20´ 58.73" E).
- **Height**
  Enter the value of the height above sea level in meters.
  For example, 158 m means that the device is located at a height of 158 m above sea level.
  Heights below sea level (for example the Dead Sea) are indicated by a preceding minus sign.

Agent IP

Configuration of the IP addresses

Note

The page is only available if there is an online connection to the device.

On this page, you specify the IP configuration for the device.

With devices with more than one IP interface, this call references the "Subnets > Configuration" menu item in the "Layer 3 (IPv4)" menu and the configuration of the TIA interface there.

Settings

The page contains the following boxes:

- **IP Assignment Method**
  Shows how the IP address is assigned.
  - Static
    The IP address is static. You enter the IP settings in the input boxes "IP Address" and "Subnet Mask".
  - Dynamic (DHCP)
    The device obtains a dynamic IP address from a DHCP server.
- **IP Address**
  Enter the IP address of the device.
  After clicking the "Set Values" button, this IP address is also displayed in the address bar of the Internet browser. If this does not take place automatically, you will need to enter the IP address in the address bar of the Internet browser manually.
- **Subnet Mask**
  Enter the subnet mask of the device.
- **Default gateway**
  Enter the IP address of the default gateway to be able to communicate with devices in another subnet, for example diagnostics stations, e-mail server.
- **Agent VLAN ID**
  Select the VLAN ID from the drop-down list. You can only select VLANs that have already been configured.
  In the mode "802.1D Transparent Bridge", this drop-down list is grayed out, see also "Layer 2 > VLAN > General".

  Note

  Changing the Agent VLAN ID

  If the configuration PC is connected directly to the device via Ethernet and you change the Agent VLAN ID , the device is no longer reachable via Ethernet following the change.
- **MAC Address**
  Shows the MAC address of the device. The MAC address is linked to the hardware and cannot be modified.

DNS client

On this page, you can configure up to 3 DNS servers. If there is more than one server, the order in the table specifies the order in which the servers are queried. The top server is queried first.

The DNS () server (Domain Name System) assigns a domain name to an IP address so that a device can be uniquely identified.

If this function is enabled, the IE switch can communicate with a DNS server as a DNS client. You have the option of entering names in IP address boxes.

Note

The DNS client function can only be used if there is a DNS server in the network.

Settings

The page contains the following boxes:

- **DNS Client**
  Enable or disable depending on whether the IE switch should operate as a DNS client.
- **Used DNS Servers**
  Specify which DNS server the device uses:
  - learned only
    The device uses only the DNS servers assigned by DHCP.
  - manual only
    The device uses only the manually configured DNS servers. The DNS servers must be connected to the Internet. A maximum of three DNS servers can be configured.
  - all
    The device uses all available DNS servers.
- **DNS Server IP Address**
  Enter the IP address of the DNS server.
- **Origin**
  Shows whether the DNS server was configured manually or was assigned by DHCP.

The table contains the following columns:

- **DNS Server Address**
  Shows the IP address of the DNS server.
- **Origin**
  Shows whether the DNS server was configured manually or was assigned by DHCP.

Restart

On this page, there is a button with which you can restart the device and the option of resetting to the factory settings.

Note

The page is only available if there is an online connection to the device.

Restart

Note the following points about restarting a device:

- You can only restart the device with administrator privileges.
- A device should only be restarted with the buttons of this menu or with the appropriate CLI commands and not by a power cycle on the device.
- Any modifications you have made only become active on the device after clicking the "Set values" button on the relevant WBM page. If the device is in "Trial" mode, configuration modifications must be saved manually before a restart. In "Automatic Save" mode, the last changes are saved automatically before a restart.

Reset to Factory Defaults

By resetting all the settings to the factory settings, the IP address and the passwords are also lost. Following this, the device can only be accessed via the serial interface, using the Primary Setup Tool or using DHCP.

NOTICE
With the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

Resetting to defaults (profiles)

The profiles provide a preconfiguration for various use cases of the devices.

When you start a device with the default settings of a profile, the settings are reset to the factory settings and some parameters are set so that they are designed for a use case. In contrast to resetting to the factory settings. the users and passwords are retained after the restart. The configured IP address is lost so that device can then only be accessed via the serial interface, using the Primary Setup Tool or using DHCP.

NOTICE
With the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

Which settings were set specially for the profile are displayed before the restart.

The profiles can be used independently of the factory setting of the device.

Settings

Note

Note the effects of the individual functions described in the sections above.

To restart the device, the buttons on this page provide you with the following options:

- **Restart**
  Click this button to restart the system. You must confirm the restart in a dialog box. During a restart, the device is reinitialized, the internal firmware is reloaded, and the device runs a self-test. The settings of the start configuration are retained, e.g. the IP address of the device. The learned entries in the address table are deleted. You can leave the browser window open while the device restarts. After the restart you will need to log in again.
- **Restore Factory Defaults and Restart**
  Click this button to restore the factory defaults of the device and to restart the device. You must confirm the restart in a dialog box.
  The factory settings depend on the device.

To restart the device with a predefined profile, the buttons on this page provide you with the following options:

- **PROFINET Defaults**
  Click this button to restore the default settings of the PROFINET profile and to restart the device. You must confirm the restart in a dialog box. The dialog box displays the settings specially made for operation with the PROFINET protocol.
- **EtherNet/IP Defaults**
  Click this button to restore the default settings of the EtherNet/IP profile and to restart the device. You must confirm the restart in a dialog box. The dialog box displays the settings specially made for operation with the EtherNet/IP protocol.
- **Industrial Ethernet Defaults**
  Click this button to restore the default settings of the Industrial Ethernet profile and to restart the device. You must confirm the restart in a dialog box. The dialog box displays the settings specially made for operation in the Industrial Ethernet environment.

Load & save

File types

Overview of the file types

File type	Description
Config	This file contains the start configuration. Among other things, this device contains the definitions of the users, roles, groups and function rights. The passwords are stored the file "Users".
ConfigPack	Detailed configuration information. for example, start configuration, users, certificates ZIP file consisting of the Config, Users and LSYS fle.
Debug	This file contains information for Siemens Support. It is encrypted and can be sent by e-mail to Siemens Support without any security risk.
EDS	Electronic Data Sheet (EDS) Electronic data sheets for describing devices in the EtherNet/IP mode

File type	Description
Firmware	The firmware is signed and encrypted. This ensures that only firmware created by Siemens can be downloaded to the device.
GSDML	PROFINET information on the device properties
HTTPSCert	Default HTTPS certificates including key The preset and automatically created HTTPS certificates are self-signed. We strongly recommend that you create your own HTTPS certificates and make them available. We recommend that you use HTTPS certificates signed either by a reliable external or by an internal certification authority. The HTTPS certificate checks the identity of the device and controls the encrypted data exchange. Certificates with a different format cannot be copied in.
LogFile	File with entries from the event log table
MIB	Private MSPS MIB file
RunningCLI	Text file with CLI commands This file contains an overview of the current configuration in the form of CLI commands. You can download the text file. The file is not intended to be uploaded again unchanged.
Script	Text file with CLI commands You can upload a script file in a device. The CLI commands it contains are executed appropriately.
StartupInfo	Startup log file This file contains the messages that were entered in the log during the last startup.
Users	This file contains the assignment of the user names to the corresponding passwords.
WBMFav	WBM favorite pages This file contains the favorites that you created in the WBM.. You can download this file and upload it in other devices.

Uploading and saving using HTTP

Loading and saving data via HTTP

This page allows you to store device data in an external file on your client PC or to load such data from an external file from the client PC to the devices.
This means, for example, that you can also load new firmware from a file located on your client PC.

Note

The page is only available if there is an online connection to the device.
This page is available both for connections using HTTP and for connections using HTTPS.

Firmware

The firmware is signed and encrypted. This ensures that only firmware created by Siemens can be downloaded to the device.

Note

Incompatibility with predecessor versions

During the installation of a previous version, the configuration data and log files can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

Incompatibility with previous firmware versions with/without PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

In this situation, if a PLUG is inserted in the device, following the restart, this has the status "Not Accepted" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data. If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using the WBM page "System > PLUG".

Configuration files

Note

Configuration files and trial mode/automatic save mode

In "Automatic Save" mode, the data is saved automatically before the configuration files (ConfigPack and Config) are transferred.
In trial mode, although the changes are adopted, they are not saved in the configuration files (ConfigPack and Config). Use the "Write Startup Config" button on the "System > Configuration" WBM page to save changes in the configuration file.

CLI script file

You can download existing CLI configurations (RunningCLI) and upload your own CLI scripts (Script).

Note

The downloadable CLI script is not intended to be uploaded again unchanged.

Settings

The table has the following columns:

- **Type**
  Shows the designation of the file.
- **Description**
  Shows the short description of the file type.

- **Load**
  With this button, you can upload files to the device. The button can be enabled, if this function is supported by the file type.
- **Save**
  With this button, you can save files from the device. The button can only be enabled if this function is supported by the file type and the file exists on the device.
- **Delete**
  With this button, you can delete files from the device. The button can only be enabled if this function is supported by the file type and the file exists on the device.

Note

Following a firmware update, delete the cache of your Internet browser.

Uploading and saving using TFTP

Loading and saving data via a TFTP server

On this page, you can configure the TFTP server and the file names. You can also store device data in an external file on a TFTP server or load such data from an external file from the TFTP server to the devices. This means, for example, that you can also load new firmware from a file located on a TFTP server.

Firmware

The firmware is signed and encrypted. This ensures that only firmware created by Siemens can be downloaded to the device.

Note

Incompatibility with predecessor versions

During the installation of a previous version, the configuration data and log files can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

Incompatibility with previous firmware versions with/without PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

In this situation, if a PLUG is inserted in the device, following the restart, this has the status "Not Accepted" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data. If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using the WBM page "System > PLUG".

Configuration files

Note

Configuration files and Trial mode/Automatic Save

In "Automatic Save" configuration mode, the data is saved automatically before the configuration files (ConfigPack and Config) are transferred.
In trial mode , although the changes are adopted, they are not saved in the configuration files (ConfigPack and Config). Use the "Write Startup Config" button on the "System > Configuration" WBM page to save changes in the configuration files.

CLI script file

You can download existing CLI configurations (RunningCLI) and upload your own CLI scripts (Script).

Note

The downloadable CLI script is not intended to be uploaded again unchanged.

Settings

- **TFTP Server IP Address**
  Enter the IP address or the FQDN of the TFTP server with which you exchange data.
- **TFTP Server Port**
  Here, enter the port of the TFTP server via which data exchange will be handled. If necessary, you can change the default value 69 to your own requirements.

The table has the following columns:

- **File type**
  Shows the designation of the file.
- **Description**
  Shows the short description of the file type.

- **File name**
  A file name is preset here for every file type.

  Note

  Changing the file name

  You can change the file name preset in this column. After clicking the "Set Values" button, the changed name is stored on the device and can also be used with the Command Line Interface.

- **Select action** (only available online)
  Select the required action. The selection depends on the selected file type, for example you can only save the log file.
  The following actions are possible:
  - Save file
    With this selection, you save a file on the TFTP server.
  - Load file
    With this selection, you load a file from the TFTP server.

Passwords

There are files to which access is password protected. To load the file on the device, enter the password specified for the file on the WBM page.

Settings

The table has the following columns:

- **Type**
  Shows the file type.
- **Description**
  Shows the short description of the file type.
- **Enabled**
  When selected, the password is used. Can only be enabled if the password is configured.
- **Password**
  Enter the password for the file.

- **Password Confirmation**
  Confirm the new password.
- **Status**
  Shows whether the current settings for the file match the device.
  - Valid
    the "Enabled" setting is selected and the password matches the certificate.
  - Invalid
    the "Enabled" setting is selected but the password does not match the certificate or no certificate has been loaded yet.
  - '-'
    The password cannot be evaluated or is not yet being used. The "Enabled" check box is not selected.

Events

Configuration

On this page, you specify how the device reacts to system events. By enabling the appropriate options, you specify how the device reacts to events. To enable or disable the options, click the relevant settings of the columns.

Settings

- **Signaling Contact Response**
  Select the behavior of the signaling contact. The following reactions are possible:
  - conventional
    Default setting for the signaling contact. An error/fault is displayed by the fault LED and the signaling contact is opened. When the error/fault state no longer exists, the fault LED goes off and the signaling contact is closed.
  - User-defined
    The way the signaling contact works does not depend on the error/fault that has occurred. The signaling contact can be opened or closed as required by user actions.
- **Signaling Contact Status**
  Select the status of the signaling contact from the drop-down list. The following statuses are possible:
  - close
    Signaling contact is closed.
  - open
    Signaling contact is opened.

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2.
- **E-mail/Trap/Log table/Syslog/Errors**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Event**
  The "Event" column contains the following values:
  - Cold/Warm Start
    The device was turned on or restarted by the user.
  - Link Change
    This event occurs only when the port status is monitored and has changed, see "System > Fault Monitoring > Link Change".
  - Authentication Failure
    This event occurs when attempting access with a bad password.
  - RMON Alarm
    An alarm or event has occurred relating to the remote monitoring of the system.
  - Power Supply Switchover
    This event occurs only when power supply lines 1 and 2 are monitored. It indicates that there was a change to line 1 or line 2, see System > Fault Monitoring > Power Supply".
  - RM status change
    The redundancy manager has recognized an interruption or restoration of the ring and has switched the line over or back.
  - Spanning Tree Change
    The STP or RSTP or MSTP topology has changed.
  - Fault State Change
    The fault state has changed. The fault state can relate to the activated port monitoring, the response of the signaling contact or the power supply monitoring.
  - Standby State Change
    A device with an established standby connection (master or slave) has activated or deactivated the link to the other ring (standby port). The data traffic was redirected from one Ethernet connection (standby port of the master) to the other Ethernet connection (standby port of the slave).
  - VRRP State Change (only with routing using VRRP)
    The status of the virtual router has changed
  - Loop Detection
    A loop was detected in the network segment.
  - OSPF State Change
    The status of OSPF has changed.
  - Pnac Port Authentication State Change
    Port authentication
  - PoE State Change
    The status of PoE has changed.
  - Diagnostics Alarms
    The diagnostics value has fallen below or exceeded a certain limit.
  - FMP Status Change
    The value of the received power or the power loss has fallen below a certain limit.
- **E-mail**

The device sends an e-mail. This is only possible if the SMTP server is set up and the "SMTP client" function is enabled.

- **Trap**
  The device sends an SNMP trap. This is only possible if "SNMPv1 traps" is enabled in "System > Configuration".
- **Log table**
  The device writes an entry in the event log table, see "Information > Log Table"
- **Syslog**
  The device writes an entry to the system log server. This is only possible if the system log server is set up and the "Syslog client" function is enabled.
- **Fault**
  The device triggers a fault. The error LED lights up

Severity filter

On this page, set the threshold levels for sending system event notifications.

Settings

The table has the following columns:

- **Client Type**
  Select the client type for which you want to make settings:
  - E-mail
    Sending system event messages by e-mail
  - Log table
    Entry of system events in the log table.
  - Syslog
    Entering system events in the Syslog file
  - WLAN Authentication Log
    Forwarding of the entries from the WLAN Authentication Log to the system protocol server.
    Can only be configured with SCALANCE W770 and SCALANCE W780
- **Severity**
  Select the required level. The following settings are possible:
  - Info
    System events are processed as of the severity level "Info".
  - Warning
    System events are processed as of the severity level "Warning".
  - Critical
    System events are processed as of the severity level "Critical".

SMTP client

The device provides the option of automatically sending an e-mail if an alarm event occurs (for example to the network administrator). The e-mail contains the identification of the sending device, a description of the cause of the alarm in plain language, and a time stamp. This allows centralized network monitoring to be set up for networks with few nodes based on an E-mail system. When an e-mail error message is received, the WBM can be started by the Internet browser using the identification of the sender to read out further diagnostics information.

On this page, you can configure up to three SMTP servers and the corresponding e-mail addresses.

Settings

- **SMTP Client**
  Enable or disable the SMTP client.
- **Sender Email Address**
  Enter the name of the sender to be included in the e-mail, for example the device name. This setting applies to all configured SMTP servers.
- **Send Test Mail**
  Send a test e-mail to check your configuration.
- **SMTP Port**
  Enter the port via which your SMTP server can be reached.
  Factory settings: 25
  This setting applies to all configured SMTP servers.
- **SMTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the SMTP server.

This table contains the following columns:

- **SMTP Server Address**
  Shows the IP address or the FQDN (Fully Qualified Domain Name) of the SMTP server.
- **Email address of the recipient**
  Enter the e-mail address to which the device sends an e-mail if a fault occurs.

Syntax of email addresses

The following conditions apply to e-mail addresses:

- Alphanumeric characters are permitted.
- The following special characters are permitted:
  - @
  - _ (underscore)
  - - (hyphen)
  - . (period)
- A @ character must be included.

- Only one @ may be used.
- The characters "@" and the "." must not be the first or last character.

DHCP

DHCP client

If the device is configured as a DHCP client, it starts a DHCP query. As the reply to the query the device receives an IPv4 address from the DHCP server. The server manages an address range from which it assigns IPv4 addresses. It is also possible to configure the server so that the client always receives the same IPv4 address in response to its request.

Settings

- **DHCP client configuration file request (opt 66, 67)**
  Select this option if you want the DHCP client to use options 66 and 67 to download and then enable a configuration file.
- **DHCP Mode**
  Select the DHCP mode. The following modes are possible:
  - via MAC Address
    Identification is based on the MAC address.
  - via DHCP Client ID
    Identification is based on a freely defined DHCP client ID.
  - Via System Name
    Identification is based on the system name. If the device name is 255 characters long, the last character is not used for identification.
  - via PROFINET Name of Station
    Identification is based on the PROFINET name of the station.

This table contains the following columns:

- **Interface**
  Interface to which the setting relates.
- **DHCP**
  Enable or disable the DHCP client for the relevant interface.

DHCP Server

You can operate the device as a DHCP server. This allows IP addresses to be assigned automatically to the connected devices. The IP addresses are either distributed dynamically from an address band (pool) you have specified or a specific IP address is assigned to a particular device.

On this page, specify the address band from which the connected device receives any IP address. You configure the static assignment of the IP addresses in "Static Leases".

Requirement

- The connected devices are configured so that they obtain the IP address from a DHCP server.

Description

The page contains the following boxes:

- **DHCP Server**
  Enable or disable the DHCP server on the device.

  Note

  To avoid conflicts with IPv4 addresses, only one device may be configured as a DHCP server in the network.

- **Probe address with ICMP echo before offer**
  When selected, the DHCP server checks whether or not the IP address has already been assigned. To do this the DHCP server sends ICMP echo messages (ping) to the IPv4 address. If no reply is received, the IPv4 address is assigned.

  Note

  If there are devices in your network on which the echo service is disabled as default, there may be conflicts with the IPv4 addresses. To avoid this, assign these devices an IPv4 address outside the IPv4 address band.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Pool ID**
  Shows the number of the IPv4 address band. If you click the "Create" button, a new row with a unique number is created (pool ID).
- **Interface**
  Select a VLAN IP interface. The IPv4 addresses are assigned dynamically via this interface. The requirement for the assignment is that the IPv4 address of the interface is located in the subnet of the IPv4 address band. If this is not the case, the interface does not assign any IPv4 addresses.
- **Enable**
  Specify whether or not this IPv4 address band will be used.

  Note

  If you enable the IPv4 address band, its settings in this and the other DHCP tabs are grayed out and can no longer be edited.

- **Subnet**
  Enter the network address range that will be assigned to the devices. Use the CIDR notation.
- **Lower IP Address**
  Enter the IPv4 address that specifies the start of the dynamic IPv4 address band. The IPv4 address must be within the network address range you configured for "Subnet".

- **Upper IP address**
  Enter the IPv4 address that specifies the end of the dynamic IPv4 address band. The IPv4 address must be within the network address range you configured for "Subnet".
- **Lease Time (sec)**
  Specify for how many seconds the assigned IPv4 address remains valid. When half the period of validity has elapsed. the DHCP client can extend the period of the assigned IPv4 address. When the entire time has elapsed, the DHCP client needs to request a new IPv4 address.

Port Range

On this page, you define the ports via which the IPv4 addresses of an address band are assigned.

After you have created an IPv4 address band in the "DHCP Server" tab, a new line is created in this tab and all ports selected that are currently located in the corresponding VLAN. If you add ports to the VLAN later, the ports are not automatically enabled in this tab.

Description

This table contains the following columns:

- **Pool ID**
  Shows the number of the IPv4 address band. A line is created for every address band.
- **Interface**
  Shows the assigned VLAN IP interface.
- **All ports**
  Select the setting from the drop-down list. You have the following setting options:
  - Enabled
    The check box is enabled for all ports.
  - Disabled
    The check box is disabled for all ports.
  - No Change
    The table remains unchanged.
- **Px.y**
  Specify the ports via which IPv4 addresses of the address band will be assigned.
  You can only select ports located in the corresponding VLAN.

DHCP Options

On this page you specify which DHCP options the DHCP server supports. The various DHCP options are defined in RFC 2132.

The DHCP options 1, 3, 6, 66 and 67 are created automatically when the IPv4 address band is created. With the exception of DHCP option 1, the options can be deleted. With DHCP option 1 the subnet mask is set automatically that you entered for the address band in "DHCP Server". With the DHCP option 3, you can set the internal IPv4 address of the device as a DHCP parameter using a check box.

Description

The page contains the following boxes:

- **Pool ID**
  Select the required IPv4 address band.
- **Option Code**
  Enter the number of the required DHCP option. The various DHCP options are defined in RFC 2132. The supported DHCP options are listed in the following paragraph.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Pool ID**
  Shows the number of the IPv4 address band.
- **Option Code**
  Shows the number of the DHCP option.
- **Use Interface IP**
  If you enable the check box, the IPv4 address is used as the default gateway that is assigned to the VLAN IP address. If the check box is disabled, you can enter an IPv4 address.
- **Value**
  Enter the DHCP parameter that is transferred to the DHCP client. The content depends on the DHCP option.
  - DHCP option 3 (default gateway):
    Enter the DHCP parameter as an IPv4 address, e.g. 192.168.100.2.
  - DHCP option 6 (DNS):
    Enter the DHCP parameter as an IPv4 address, e.g. 192.168.100.2. You can specify up to three IPv4 addresses separated by commas.
  - DHCP option 66 (TFTP Server):
    Enter the DHCP parameter as an IPv4 address, e.g. 192.168.100.2.
  - DHCP option 67 (boot file name)
    Enter the name of the boot file in the string format.
  - DHCP option 12 (host name)
    Enter the host name in the string format.

DHCP options supported

The following DHCP options are supported:

- Option 1
- Option 3
- Option 6
- Option 12
- Option 66
- Option 67

Relay Agent Information

On this page you define that devices with a certain remote ID and circuit ID are assigned the IPv4 addresses from a specific address band.

If you create such an entry for an address band, the ports of the address band only react to DHCP queries via a DHCP relay agent (option 82). You can create further address bands for the same VLAN IP interfaces so that ports react to different requests.

Note

Extension or release of an IPv4 address assigned via a relay agent.

With address assignments via a relay agent "Renew" and "Release" messages going directly from the DHCP client to the DHCP server are ignored by the server.

- The extension of the period for an IPv4 address assigned via a relay agent is achieved using a "Rebinding" message that the client sends automatically as a broadcast.
- To speed up the release of an IPv4 address assigned via a relay agent, configure a shorter period of validity.

Description

The page contains the following boxes:

- **Pool ID**
  Select the required IPv4 address band.
- **Remote ID**
  Enter the remote ID.
- **Circuit ID**
  Enter the circuit ID.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Pool ID**
  Shows the number of the IPv4 address band.
- **Remote ID**
  Shows the remote ID.
- **Circuit ID**
  Shows the circuit ID.

Static Leases

On this page you define that DHCP clients are assigned a preset IPv4 address depending on their client ID or MAC address.

Description

The page contains the following boxes:

- **Pool ID**
  Select the required IPv4 address band.
- **Client identification method**
  Select the method according to which a client is identified.
  - Ethernet MAC
    The client is identified by its MAC address.
  - Client ID
    The client is identified by a freely defined DHCP client ID.
- **Value**
  Enter the MAC address (Ethernet MAC) or the client ID of the client.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Pool ID**
  Shows the number of the IPv4 address band.
- **Identification method**
  Shows whether the client is identified by its MAC address or the client ID.
- **Value**
  Shows the MAC address or client ID of the client.
- **IP Address**
  Specify the IPv4 address that will be assigned to the client. The IPv4 address must be within the IPv4 address band.

SNMP

General

On this page, you make the basic settings for SNMP. Enable the options according to the function you want to use.

Settings

- **SNMP**
  Select the SNMP protocol. The following settings are possible:
  - "-" (disabled)
    SNMP is disabled.
  - SNMPv1/v2c/v3
    SNMPv1/v2c/v3 is supported.
  - SNMPv3
    Only SNMPv3 is supported.
- **SNMPv1/v2 Read-Only**
  If you enable this option, SNMPv1/v2c can only read the SNMP variables.

  Note

  Community String

  For security reasons, do not use the standard values "public" or "private". Change the community strings following the initial installation.

- **SNMPv1/v2c Read Community String**
  Enter the community string for access of the SNMP protocol.
- **SNMPv1/v2c Read/Write Community String**
  Enter the community string for read and write access of the SNMP protocol.
- **SNMPv1 Traps**
  Enable or disable the sending of SNMP traps (alarm frames). On the "Trap" tab, specify the IP addresses of the devices to which SNMP traps will be sent.
- **SNMPv1/v2c Trap Community String**
  Enter the community string for sending SNMPv1/v2 messages.
- **SNMPv3 User Migration**
  - **Enabled**
    If the function is enabled, an SNMP engine ID is generated that can be migrated. You can transfer configured SNMPv3 users to a different device.
    If you enable this function and load the configuration of the device on another device, configured SNMPv3 users are retained.
  - **Disabled**
    If the function is disabled, a device-specific SNMP engine ID is generated. To generate the ID, the agent MAC address of the device is used. You cannot transfer this SNMP user configuration to other devices.
    If you load the configuration of the device on another device, all configured SNMPv3 users are deleted.
- **SNMP Engine ID**
  Shows the SNMP engine ID.

Traps

If an alarm event occurs, a device can send SNMP traps (alarm frames) to up to ten different management stations at the same time. Traps are only sent if the events specified in "Events" occur.

Note

SNMP traps are sent only when the "SNMPv1 Traps" setting was selected in "SNMP > General".

Settings

- **Trap Receiver Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the station to which the device sends SNMP traps. You can specify up to ten different recipients.

The table has the following columns:

- **Trap Receiver Address**
  If necessary, change the IP addresses or the FQDN of the stations.
- **Trap**
  Enable or disable the sending of SNMP traps. Stations that are entered but not selected do not receive SNMP traps.

v3 Groups

Security settings and assigning permissions

SNMP version 3 allows permissions to be assigned, authentication, and encryption at protocol level. The security levels and read/write permissions are assigned according to groups. The settings automatically apply to every member of a group.

Settings

- **Group Name**
  Enter the name of the group. The maximum length is 32 characters.
- **Security Level**
  Select the security level (authentication, encryption) valid for the selected group. You have the following options for the security levels:
  - no Auth/no Priv
    No authentication enabled / no encryption enabled.
  - Auth/no Priv
    Authentication enabled / no encryption enabled.
  - Auth/Priv
    Authentication enabled / encryption enabled.

The table has the following columns:

- **Group Name**
  Shows the defined group names.

  Note

  Once a group name and the security level have been specified, they can no longer be modified after the group is created. If you want to change the group name or the security level , you will need to delete the group and recreate it and reconfigure it with the new name.

- **Security Level**
  Shows the configured security level.
- **Read**
  Enable or disable read access for the required group.
- **Write**
  Enable or disable write access for the required group.

  Note

  For write access to work, you also need to enable read access.

- **Persistence**
  Shows whether or not the group is assigned to an SNMPv3 user. If the group is not assigned to an SNMPv3 user, no automatic saving is triggered and the configured group is deleted after restarting the device.
  - Yes
    The group is assigned to an SNMPV3 user.
  - No
    The group is not assigned to an SNMPV3 user.

v3 users

User-specific security settings

On the WBM page, you can create new SNMPv3 users and modify or delete existing users. The user-based security model works with the concept of the user name; in other words, a user ID is added to every frame. This user name and the applicable security settings are checked by both the sender and recipient.

Settings

- **User name**
  Enter a freely selectable user name. After you have entered the data, you can no longer modify the name.

The table has the following columns:

- **User name**
  Shows the created users.
- **Group Name**
  Select the group to which the user will be assigned.
- **Authentication Protocol**
  Specify the authentication protocol for which a password will be stored.
  The following settings are available:
  - None
  - MD5
  - SHA
- **Encryption Protocol**
  Specify whether or not a password should be stored for encryption with the DES algorithm. Can only be enabled when an authentication protocol has been selected.
- **Authentication Password**
  Enter the authentication password. This password must have at least 6 characters, the maximum length is 32 characters.
- **Confirm authentication password**
  Confirm the password by repeating the entry.
- **Encryption Password**
  Enter your encryption password. This password must have at least 6 characters, the maximum length is 32 characters.
- **Confirm Encryption Password**
  Confirm the encryption password by repeating the entry.
- **Persistence**
  Shows whether or not the user is assigned to an SNMPv3 group. If the user is not assigned to an SNMPv3 group, no automatic saving is triggered and the configured user is deleted after restarting the device.
  - Yes
    The user is assigned to an SNMPv3 group.
  - No
    The user is not assigned to an SNMPv3 group.

System time

Manual time setting

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

On this page, you set the date and time of the system. For this setting to be used, enable "Manual time setting".

Note

The page is only available if there is an online connection to the device.

Settings

- **Time Manually**
  Enable or disable the manual time setting. If you enable the option, the "System Time" input box can be edited.
- **System Time**
  Enter the date and time in the format "MM/DD/YYYY HH:MM:SS".
- **Use PC Time**
  Click the button to use the time setting of the PC.
- **Last Synchronization Time**
  Shows when the last time-of-day synchronization took place.
  If no time-of-day synchronization was possible, the box displays "Date/time not set".
- **Last Synchronization Mechanism**
  This box displays how the last time-of-day synchronization was performed.
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame.
  - PTP
    Automatic time-of-day synchronization with PTP

DST overview

On this page, you can create new entries for the daylight saving time changeover.

The table provides an overview of the existing entries.

Settings

- **DST No.**
  Shows the number of the entry.
  If you create a new entry, a new line with a unique number is created.
- **Name**
  Shows the name of the entry.
- **Year**
  Shows the year for which the entry was created.
- **Start Date**
  Shows the month, day and time for the start of daylight saving time.
- **End Date**
  Shows the month, day and time for the end of daylight saving time.
- **Recurring Date**
  With an entry of the type "Rule", the period in which daylight saving time is active is displayed consisting of week, day, month and time of day. With an entry of the type "Date" a "-" is displayed.
- **State**
  Shows the status of the entry:
  - enabled
    The entry was created correctly.
  - invalid
    The entry was created new and the start and end date are identical.
- **Type**
  Shows how the daylight saving time changeover is made:
  - Date
    A fixed date is entered for the daylight saving time changeover.
  - Recurring
    A rule was defined for the daylight saving time changeover.

DST configuration

On this page, you can configure the entries for the daylight saving time changeover. As result of the changeover to daylight saving or standard time, the system time for the local time zone is correctly set.

You can define a rule for the daylight saving time changeover or specify a fixed date.

Settings

Note

The content of this page depends on the selection in the "Type" box.

The boxes "DST No.", "Type" and "Name" are always shown.

- **DST No.**
  Select the type of the entry.
- **Type**
  Select how the daylight saving time changeover is made:
  - Date
    You can set a fixed date for the daylight saving time changeover.
    This setting is suitable for regions in which the daylight saving time changeover is not governed by rules.
  - Recurring
    You can define a rule for the daylight saving time changeover.
    This setting is suitable for regions in which the daylight saving time always begins or ends on a certain weekday.
- **Name**
  Enter a name for the entry.

Settings with "Date" selected

You can set a fixed date for the start and end of daylight saving time.

- **Year**
  Enter the year for the daylight saving time changeover.
- **Start Date**
  Enter the following values for the start of daylight saving time:
  - Day
    Specify the day.
  - Hour
    Specify the hour.
  - Month
    Specify the month.
- **End Date**
  Enter the following values for the end of daylight saving time:
  - Day
    Specify the day.
  - Hour
    Specify the hour.
  - Month
    Specify the month.

Settings with "Recurring" selected

You can create a rule for the daylight saving time changeover.

- **Start Date**
  Enter the following values for the start of daylight saving time:
  - Hour
    Specify the hour.
  - Month
    Specify the month.
  - Week
    Specify the week.
    You can select the 1st to 4th or the last week of the month.
  - Weekday
    Specify the weekday.
- **End Date**
  Enter the following values for the end of daylight saving time:
  - Hour
    Specify the hour.
  - Month
    Specify the month.
  - Week
    Specify the week.
    You can select the 1st to 4th or the last week of the month.
  - Weekday
    Specify the weekday.

SNTP client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

SNTP (Simple Network Time Protocol) is used for synchronizing the time in the network. The appropriate frames are sent by an SNTP server in the network.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **SNTP Client**
  Enable or disable automatic time-of-day synchronization using SNTP.
- **Current System Time** (only available online)
  Shows the current date and current normal time received by the IE switch. If you specify a time zone, the time information is adapted accordingly.

- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.
- **Last Synchronization Mechanism** (only available online)
  Shows how the last time-of-day synchronization was performed. The following methods are possible:
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP
- **Time Zone**
  Enter the time zone you are using in the format "+/- HH:MM". The time zone relates to UTC standard world time.
  The time in the "Current System Time" box is adapted accordingly.
- **Daylight Saving Time**
  Shows whether the daylight saving time changeover is active.
  - active (offset +1 h)
    The system time was changed to daylight saving time; in other words an hour was added. The normal time including the time zone continues to be displayed in the "Current System Time" box.
    The normal time including the time zone continues to be displayed in the "Current System Time" box.
  - inactive (offset +0 h)
    The current system time is not changed.
- **SNTP Mode**
  Select the synchronization mode. The following types of synchronization are possible:
  - Poll
    If you select this protocol type, the input boxes "SNTP Server Address", "SNTP Server Port" and "Poll Interval[s]" are displayed to allow further configuration. With this type of synchronization, the device is active and sends a time query to the SNTP server.
  - Listen
    With this type of synchronization, the device is passive and "listens" for SNTP frames that deliver the time of day.
- **Poll Interval[s]**
  Here, enter the interval between two-time queries. In this box, you enter the query interval in seconds. Possible values are 16 to 16284 seconds.

- **SNTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the SNTP server.
- **SNTP Server Port**
  Enter the port of the SNTP server.
  The following ports are possible:
  - 123 (standard port)
  - 1025 to 36564
- **Primary**
  The check mark is set for the SNTP server that you create first. If several SNTP servers have been created, the primary server is queried first.

NTP client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

If you require time-of-day synchronization using NTP, you can make the relevant settings here.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **NTP Client**
  Enable or disable automatic time-of-day synchronization using NTP.
- **Current System Time** (only available online)
  Shows the current date and current normal time received by the IE switch. If you specify a time zone, the time information is adapted accordingly.
- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.

- **Last Synchronization Mechanism** (only available online)
  This box displays how the last time-of-day synchronization was performed. The following methods are possible:
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP
- **Time Zone**
  Enter the time zone you are using in the format "+/- HH:MM". The time zone relates to UTC standard world time.
  The time in the "Current System Time" box is adapted accordingly.
- **Daylight Saving Time**
  Shows whether the daylight saving time changeover is active.
  - active (offset +1 h)
    The system time was changed to daylight saving time; in other words an hour was added. The normal time including the time zone continues to be displayed in the "Current System Time" box.
  - inactive (offset +0 h)
    The current system time is not changed.
- **NTP Server Index**
  Select the index of the NTP server. The server with the lowest index is queried first.
- **NTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the NTP server.
- **NTP Server Port**
  Enter the port of the NTP server.
  The following ports are possible:
  - 123 (standard port)
  - 1025 to 36564
- **Poll Interval[s]**
  Here, enter the interval between two time queries. In this box, you enter the poll interval in seconds. Possible values are 64 to 1024 seconds.

SIMATIC Time Client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

On this page, you configure time synchronization with the SIMATIC Time Client.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **SIMATIC Time Client**
  Enable or disable the SIMATIC time client.
- **Current System Time** (only available online)
  Shows the current system time.
- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.
- **Last Synchronization Mechanism** (only available online)
  This box displays how the last time-of-day synchronization was performed.
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP

PTP Client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

If you require time-of-day synchronization using PTP, you can make the relevant settings here.

The following devices support time-of-day synchronization with PTP:

- SCALANCE XR528-6M
- SCALANCE XR552-12M

Settings

- **PTP Client**
  Enable or disable time synchronization using PTP. You can configure other settings in "Layer 2 > PTP".
- **Current System Time** (only available online)
  Shows the current date and current normal time obtained due to time synchronization in the network. If you specify a time zone, the time information is adapted accordingly.
- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place. If no time-of-day synchronization was possible, the box displays "Date/time not set".
- **Last Synchronization Mechanism** (only available online)
  This box displays how the last time-of-day synchronization was performed.
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP
- **Time Zone**
  Enter the time zone you are using in the format "+/- HH:MM". The time zone relates to UTC standard world time.
  The time in the "Current System Time" box is adapted accordingly.
- **Daylight Saving Time**
  Shows whether the daylight saving time changeover is active.
  - active (offset +1 h)
    The system time was changed to daylight saving time; in other words an hour was added. The normal time including the time zone continues to be displayed in the "Current System Time" box.
  - inactive (offset +0 h)
    The current system time is not changed.

Auto logout

On this page, set the times after which there is an automatic logout from WBM or the CLI following user in activity. If you have been logged out automatically, you will need to log in again.

Settings

- **Web Based Management [s]**
  Enter the time in seconds for the automatic logout from WBM. If you enter the value 0, the automatic logout is disabled.
- **CLI (TELNET, SSH, Serial) [s]**
  Enter the time in seconds for the automatic logout from the CLI. If you enter the value 0, the automatic logout is disabled.

Button

The "Select/Set" button has the following functions:

- Change display mode
- Enable redundancy manager
- Restore to factory defaults
- Fault mask and LED display

You will find a detailed description of the individual functions available with the buttons in the device operating instructions.

On this page, the functionality of the SELECT/SET button can be restricted or fully disabled.

Settings

- **Restore Factory Defaults**
  Enable or disable the "Restore Factory Defaults" function with the Select/Set button.

  CAUTION

  Button function "Restore Factory Defaults" active during startup

  If you have disabled this function in your configuration, disabling is only valid during operation. When restarting, for example after power down, the function is active until the configuration is loaded so that the device can inadvertently be reset to the factory settings. This may cause unwanted disruption in network operation since the device needs to be reconfigured if this occurs. An inserted PLUG is also deleted and returned to the status as shipped

- **Redundancy Manager**
  Enable or disable the redundancy manager function.
- **Set Fault Mask**
  Enable or disable the function "Define fault mask via the LED display" with the Select/set button. This function only works in display mode D.

Syslog client

Syslog according to RFC 3164 is used for transferring short, unencrypted text messages over UDP in the IP network. This requires a system log server.

Requirements for sending log entries:

- The Syslog function is enabled on the device.
- The Syslog function is enabled for the relevant event.
- There is a Syslog server in your network that receives the log entries. Since this is a UDP connection, there is no acknowledgment to the sender.
- The IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server is entered in the device.

Settings

- **Syslog Client**
  Enable or disable the Syslog function.
- **Syslog Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server.

The table contains the following columns:

- **Syslog Server Address**
  Shows the IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server.
- **Server Port**
  Enter the port of the Syslog server being used.

Ports

Port overview

The page shows the configuration for the data transfer for all ports of the device.

You cannot configure anything on this page.

Settings

- **Port**
  Shows the configurable ports.
- **Port name**
  Shows the name of the port.
- **Port Type** (only with routing)
  Shows the type of the port. The following types are possible:
  - Router Port
  - Switch Port VLAN Hybrid
  - Switch-Port VLAN Trunk
  - Switch Port VLAN Host
  - Switch-Port PVLAN Promiscuous

- **Combo Port Media Type**
  The values are only available with combo ports. Shows the mode of the combo port:
  - auto
  - rj45
  - sfp
- **Status**
  Shows whether the port is on or off. Data traffic is possible only over an enabled port.
- **OperState**
  Displays the current operational status. The operational status depends on the configured "Status" and the "Link". The available options are as follows:
  - up
    You have configured the status "enabled" for the port and the port has a valid connection to the network.
  - down
    You have configured the status "disabled" or "Link down" for the port or the port has no connection.
  - not present
    With modular devices, this status is displayed when, for example, no media module is inserted.
- **Link** (only available online)
  Shows the connection status to the network. With the connection status, the following is possible:
  - Up
    The port has a valid link to the network, a link integrity signal is being received.
  - Down
    The link is down, for example because the connected device is turned off.
- **Mode** (only available online)
  Shows the transfer parameters of the port
- **MTU** (Maximum Transmission Unit)
  Shows the maximum packet size.
- **Negotiation**
  Shows whether the automatic configuration is enabled or disabled.
- **Flow Ctrl. Type**
  Shows whether flow control is enabled or disabled for the port.
- **Flow Ctrl.**
  Shows whether or not flow control is working on this port.

- **MAC Address** (only available online)
  Shows the MAC address of the port.
- **Blocked by**
  Shows why the port is in the "blocked" status:
  - -
    The analysis of the port status Is not supported.
  - forwarding
    The port is not blocked.
  - ring redundancy
    The port belongs to a redundancy manager. When the redundancy manager is in the "Passive status, one of the ring ports is in the "blocking" status.
  - spanning tree
    The port has the status "Discarding" in the spanning tree. The port is part of a spanning tree, however it is located on a redundant path and is deactivated for data traffic.
  - loop detection
    A loop was detected and as the reaction to a loop, the status "disable" was configured for the port.
  - down-in-bundle
    The port is part of a link aggregation and was deactivated by LACP.
  - la-loop-detection
    The port is part of a link aggregation. A loop was detected and as the reaction to a loop, the status "disable" was configured for the link aggregation.
  - la-spanning-tree
    The port is part of a link aggregation. The link aggregation was switched to the status "Discarding" by the spanning tree.
  - admin-down
    The status "disabled" is configured for the port, see "System > Ports > Configuration".
  - link down
    The status "enabled" is configured for the port but there is no connection, see "System > Ports > Configuration".
  - power-down
    The status “Link down" is configured for the port, see "System > Ports > Configuration".
  - standby
    Standby redundancy is enabled on the device. The port is a standby port with the status "Passive".

Differing display of the transmission parameters with combo ports. In the connection status "down", the displayed transmission parameters do not match the actual values of the combo port. In the connection status "up", the correct values are displayed.

Initial situation

A pluggable transceiver is plugged into the combo port with the following settings:

- Combo Port Media Type: auto
- Status: enabled
- Link: down display of the transmission parameters with 100 Mbps pluggable transceivers

- Actual response: Mode: 1G HD
- Expected response: Mode: 100M FD with 1 Gbps pluggable transceivers
- Actual response: Mode: 1G HD
- Expected response: Mode: 1G FD

Configuration

With this page, you can configure all the ports of the device.

Settings

- **Port**
  Select the port to be configured. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.
- **Status**
  Specify whether the port is enabled or disabled.
  - enabled
    The port is enabled. Data traffic is possible only over an enabled port.
  - disabled
    The port is disabled but the connection remains.
  - Link down
    The port is disabled and the connection to the partner device is terminated.
- **Port name**
  Enter a name for the port.
- **MAC Address** (only available online)
  Shows the MAC address of the port.
- **Mode Type**(only available online)
  Select the transmission speed and the transmission method of the port. If you set the mode to "Autonegotiation", these parameters are automatically negotiated with the connected end device. This must also be in the "Autonegotiation" mode.

  Note

  Before the port and partner port can communicate with each other, the settings must match at both ends.

  Note

  "Mode Type" with combo ports

  To be able to set the "Mode Type" of a combo port, change the "Combo Port Media Type" to "rj45". If "auto" is set for the "Combo Port Media Type" and the RJ-45 port is used, you cannot set the "Mode Type".

- **Mode** (only available online)
  Shows the transmission speed and mode of the port.
  The transmission speed can be 10 Mbps, 100 Mbps, 1000 Mbps or 10 Gbps.
  As the transmission mode, full duplex (FD) or half duplex (HD) can be configured.

- **Negotiation**
  Shows whether the automatic configuration of the connection to the partner port is enabled or disabled.
- **Flow Ctrl. Type**
  Enable or disable flow control for the port.

  Note

  Turning flow control on/off with autonegotiation

  Flow control can only be enabled or disabled if the "autonegotiation" function is turned off. The function cannot enabled again afterwards.

- **Flow Ctrl.**
  Shows whether flow control is working on this port.
- **MTU**
  Enter the packet size.
- **Port Type** (only with routing)
  Select the type of the port:
  - Router Port
    The port is an IP interface. It does not support layer 2 functions.
  - Switch Port VLAN Hybrid
    The port sends tagged and untagged frames. It is not automatically a member of a VLAN.
  - Switch-Port VLAN Trunk
    The port only sends tagged frames and is automatically a member of all VLANs.
  - Switch Port VLAN Host
    Host ports belong to a secondary PVLAN. Connect devices to host ports that are only intended to communicate with certain devices of the PVLAN.
  - Switch-Port PVLAN Promiscuous
    Promiscuous ports belong to a primary PVLAN. Connect devices to promiscuous ports that are intended to communicate all devices of the PVLAN.
- **Combo Port Media Type**
  Specify the mode of the combo port:
  - auto
    If you select this mode, the SFP transceiver port has priority. As soon as an SFP transceiver is plugged in, an existing connection at the fixed RJ-45 port is terminated. If no SFC transceiver is plugged in, a connection can be established via the fixed RJ-45 port.
  - rj45
    If you select this mode, the fixed RJ-45 port is used regardless of the SFP transceiver port. If a pluggable transceiver is plugged in, it is disabled and the power turned off.
  - sfp
    If you select this mode, the SFP transceiver port is used regardless of the built-in RJ-45 port. If an RJ-45 connection is established, it is terminated because the power of the RJ-45 port is turned off.

  The factory setting for the combo ports is the auto mode.

- **OperState**
  Displays the current operational status. The operational status depends on the configured "Status" and the "Link". The available options are as follows:
  - up
    You have configured the status "enabled" for the port and the port has a valid connection to the network.
  - down
    You have configured the status "disabled" or "Link down" for the port or the port has no connection.
  - not present
    With modular devices, this status is displayed when, for example, no media module is inserted.

- **Link** (only available online)
  Shows the connection status to the network. The available options are as follows:
  - Up
    The port has a valid link to the network, a link integrity signal is being received.
  - Down
    The link is down, for example because the connected device is turned off.
- **Blocked by**
  Shows why the port is in the "blocked" status:
  - -
    The analysis of the port status Is not supported.
  - forwarding
    The port is not blocked.
  - ring-redundancy
    The port belongs to a redundancy manager. When the redundancy manager is in the "Passive status, one of the ring ports is in the "blocking" status.
  - spanning-tree
    The port has the status "Discarding" in the spanning tree. The port is part of a spanning tree, however it is located on a redundant path and is deactivated for data traffic.
  - loop-detection
    A loop was detected and as the reaction to a loop, the status "disable" was configured for the port.
  - down-in-bundle
    The port is part of a link aggregation and was deactivated by LACP.
  - la-loop-detection
    The port is part of a link aggregation. A loop was detected and as the reaction to a loop, the status "disable" was configured for the link aggregation.
  - la-spanning-tree
    The port is part of a link aggregation. The link aggregation was switched to the status "Discarding" by the spanning tree. - admin-down The status "disabled" is configured for the port, see "System > Ports > Configuration".
  - link-down
    The status "enabled" is configured for the port but there is no connection, see "System > Ports > Configuration".
  - power-down
    The status “Link down" is configured for the port, see "System > Ports > Configuration".
  - standby
    Standby redundancy is enabled on the device. The port is a standby port with the status "Passive".

Changing the port configuration

Note

Optical ports only work with the full duplex mode and at maximum transmission rate. As a result, the following settings cannot be made for optical ports:

- Automatic configuration
- Transmission speed
- Transmission technique

Note

With various automatic functions, the device prevents or reduces the effect on other ports and priority classes (Class of Service) if a port is overloaded. This can mean that frames are discarded even when flow control is enabled.

Port overload occurs when the device receives more frames than it can send, for example as the result of different transmission speeds.

Fault Monitoring

Power supply

Configure whether or not the power supply should be monitored by the messaging system. Depending on the hardware variant, there are one or two power connectors (Supply 1 / Supply 2). With a redundant power supply, configure the monitoring separately for each individual feed-in line.

If there is no power on one of the monitored lines (Supply 1 or Supply 2) or when the voltage is too low, a fault is signaled by the signaling system.

Note

You will find the permitted operating voltage limits in the compact operating instructions of the device.

A fault causes the signaling contact to trigger and the fault LED on the device to light up and, depending on the configuration, can trigger a trap, an e-mail, or an entry in the event log table.

Settings

- **Line 1**
  Enable or disable the monitoring of power connector 1.
- **Line 2**
  Enable or disable the monitoring of power connector 2.

Link Change

On this page, you configure whether or not an error message is triggered if there is a status change on a network connection.

If connection monitoring is enabled, an error is signaled

- when there should be a link on a port and this is missing.
- or when there should not be a link on a port and a link is detected.

An error causes the signaling contact to trigger and the fault LED to light up on the device. Depending on the configuration, the error may trigger a trap, an e-mail or an entry in the event log table.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns

- **Port**
  Shows the available ports.
- **Setting**
  Select the setting. You have the following options:
  - Up
    Error handling is triggered when the port changes to the active status.
    (From "Link down" to "Link up")
  - Down
    Error handling is triggered when the port changes to the inactive status.
    (From "Link up" to "Link down")
  - "-" (disabled)
    The error handling is not triggered.

Redundancy

On this page, you configure whether or not an error message is triggered if there is a status change on a network connection.

Setting

- **Redundancy loss (HRP only)**
  Enable or disable connection monitoring. If the redundancy of the connection is lost, an error is signaled.

PROFINET

This page shows the PROFINET IO AR status and the device name.

Settings

- **PNIO Device Diagnostics**
  Shows whether PNIO is enabled ("On") or disabled ("Off").
- **PNIO Device Diagnostics for next boot**
  Set whether PNIO will be enabled ("On") or disabled ("Off") after the next device restart.

  Note

  PNIO and EtherNet/IP

  When PNIO is turned on, EtherNet/IP is turned off. The switchover from PNIO and EtherNet/IP has no effect on DCP.

  Note

  PNIO AR Status

  If a PROFINET connection is established; in other words the PNIO AR status is "Online", you cannot disable PNIO.

- **PNIO AR Status**
  This box shows the status of the PROFINET IO connection; in other words whether the device is connected to a PROFINET IO controller "Online " or "Offline".
  Here, online means that a connection to a PROFINET IO controller exists, that this has downloaded its configuration data to the device and that the device can send status data to the PROFINET IO controller. In this status known as "in data exchange", the parameters set via the PROFINET IO controller cannot be configured.
- **PNIO Name of Station**
  This box displays the PROFINET IO device name according to the configuration in HW Config of STEP 7.
- **Restore PROFINET IO Defaults and Restart**
  Click this button to restore the default settings of the PROFINET IO profile and to restart the device. You must confirm the restart in a dialog box. The dialog box displays the settings specially made for operation with the PROFINET protocol.

NOTICE
By resetting the settings to the default settings of a profile, the IP address is also lost. Following this, the device can only be accessed via the serial interface, using the Primary Setup Tool or using DHCP. With the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

- **Allow PNIO Data Exchange**(only with SCALANCE XB-200)
  Enable or disable PNIO data exchange
- **Simulate PNIO Data Exchange**(only with SCALANCE XB-200)
  Enable or disable the simulation of PNIO data exchange.

EtherNet/IP

EtherNet/IP

On this page, you configure the mode of EtherNet/IP.

Description of the displayed boxes

The page contains the following boxes:

- **EtherNet/IP Device Diagnostics**
  Shows whether EtherNet/IP is enabled ("On") or disabled ("Off").
- **EtherNet/IP Device Diagnostics for next boot**
  Set whether EtherNet/IP will be enabled ("On") or disabled ("Off") after the next device restart.

  Note

  EtherNet/IP and PROFINET

  When EtherNet/IP is turned on, PROFINET is turned off. The switchover from EtherNet/IP and PROFINET has no effect on DCP.

  Note

  PROFINET AR Status

  If a PROFINET connection is established; in other words the PROFINET AR status is "Online", you cannot enable EtherNet/IP.

- **Restore EtherNet/IP Defaults and Restart**
  Click this button to restore the default settings of the EtherNet/IP profile and to restart the device. You must confirm the restart in a dialog box. The dialog box displays the settings specially made for operation with the EtherNet/IP protocol.

  NOTICE

  Loss of the IP address

  By resetting the settings to the default settings of a profile, the IP address is also lost. Following this, the device can only be accessed via the serial interface, using the Primary Setup Tool or using DHCP.

  With the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

PLUG

PLUG configuration

Note

The page is only available if there is an online connection to the device.

NOTICE
Do not remove or insert a C-PLUG / KEY-PLUG during operation! A PLUG may only be removed or inserted when the device is turned off. The device checks whether or not a PLUG is present at one second intervals. If it is detected that the PLUG was removed, there is a restart. If a valid KEY-PLUG was inserted in the device, the device changes to a defined error state following the restart.

Information about the configuration of the C-PLUG / KEY-PLUG

This page provides detailed information about the configuration stored on the C-PLUG or KEY-PLUG. It is also possible to reset the PLUG to "factory defaults" or to load it with new contents.

Note

The action is only executed after you click the "Set Values" button.

The action cannot be undone.

If you decide against executing the function after making your selection, click the "Refresh" button. As a result the data of this page is read from the device again and the selection is canceled.

Note

Incompatibility with previous versions with PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed. In this situation, if a PLUG is inserted in the device, following the restart, this has the status "NOT ACCEPTED" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data.

If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using "System > PLUG".

Settings

The table has the following rows:

- **Status**
  Shows the status of the PLUG. The following are possible:
  - ACCEPTED
    There is a PLUG with a valid and suitable configuration in the device.
  - NOT ACCEPTED
    Invalid or incompatible configuration on the inserted PLUG.
  - NOT PRESENT
    There is no C-PLUG or KEY-PLUG inserted in the device.
  - FACTORY
    PLUG is inserted and does not contain a configuration. This status is also displayed when the PLUG was formatted during operation.
  - MISSING
    There is no PLUG inserted. Functions are configured on the device for which a license is required.
- **Device Group**
  Shows the SIMATIC NET product line that used the C-PLUG or KEY-PLUG previously.
- **Device Type**
  Shows the device type within the product line that used the C-PLUG or KEY-PLUG previously.
- **Configuration Revision**
  The version of the configuration structure. This information relates to the configuration options supported by the device and has nothing to do with the concrete hardware configuration. This revision information does not therefore change if you add or remove additional components (modules or extenders), it can, however, change if you update the firmware.
- **File System**
  Displays the type of file system on the PLUG.

NOTICE
New file system UBI As of firmware version 3.0, UBI is the standard file system for the C-PLUG or KEY-PLUG. If a C-PLUG with the previous file system IECP is detected in such a device, this C-PLUG will be formatted for the UBI file system and the data will be rewritten to the C-PLUG. This change in the file system also occurs following a firmware update to V3.0. A downgrade to the previous version of the firmware then presents a problem. The firmware can neither read nor write the C-PLUG or KEY-PLUG and it is not even possible to "Erase PLUG to factory default".

- **File System Size [bytes]**
  Shows the maximum storage capacity of the file system on the C-PLUG.
- **File System Usage**
  Displays the storage space in use in the file system of the C-PLUG.

- **Info String**
  Shows additional information about the device that used the PLUG previously, for example, article number, type designation, and the versions of the hardware and software. The displayed software version corresponds to the version in which the configuration was last changed. With the "NOT ACCEPTED" status, further information on the cause of the problem is displayed.
- **Modify PLUG**
  Select the required setting. You have the following options for changing the configuration on the C-PLUG or KEY-PLUG:
  - Write current configuration to PLUG
    This option is available only if the status of the PLUG is "NOT ACCEPTED" or FACTORY. The configuration in the internal flash memory of the device is copied to the PLUG.
  - Erase PLUG to factory default
    Deletes all data from the C-PLUG and triggers low-level formatting.

PLUG license

Note

The page is only available if there is an online connection to the device.

NOTICE
Do not remove or insert a C-PLUG / KEY-PLUG during operation! A PLUG may only be removed or inserted when the device is turned off. The device checks whether or not a PLUG is present at one second intervals. If it is detected that the PLUG was removed, there is a restart. If a valid KEY-PLUG was inserted in the device, the device changes to a defined error state following the restart. If the device was configured at some time with a PLUG, the device can no longer be used without this PLUG. To be able to use the device again, reset the device to the factory settings.

Note

Incompatibility with previous versions with PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed. In this situation, if a PLUG is inserted in the device, following the restart, this has the status "NOT ACCEPTED" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data.

If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using "System > PLUG".

Information about the license of the KEY-PLUG

A C-PLUG can only store the configuration of a device. In addition to the configuration, a KEY-PLUG also contains a license that enables certain functions of your SIMATIC NET device.

This page provides detailed information about the license on the KEY-PLUG.

Displayed values

- **Status**
  Shows the status of the KEY-PLUG. The following are possible:
  - ACCEPTED
    The KEY-PLUG in the device contains a suitable and valid license.
  - NOT ACCEPTED
    The license of the inserted KEY-PLUG is not valid.
  - NOT PRESENT
    No KEY-PLUG is inserted in the device.
  - MISSING
    There is no KEY-PLUG or a C-PLUG with the status "FACTORY" inserted in the device. Functions are configured on the device for which a license is required.
  - WRONG
    The inserted KEY-PLUG is not suitable for the device.
  - UNKNOWN
    Unknown content of the KEY-PLUG.
  - DEFECTIVE
    The content of the KEY-PLUG contains errors.
- **Order ID**
  Shows the order number of the KEY-PLUG. The KEY-PLUG is available for various functional enhancements and for various target systems.
- **Serial Number**
  Shows the serial number of the KEY-PLUG.
- **Info String**
  Shows additional information about the device that used the KEY-PLUG previously, for example, order number, type designation, and the versions of the hardware and software. The displayed software version corresponds to the version in which the configuration was last changed. With the "NOT ACCEPTED" status, further information on the cause of the problem is displayed.

Note

When you save the configuration, the information about whether or not a KEY-PLUG was inserted in the device at the time is also saved. This configuration can then only work if a KEY-PLUG with the same article number / license is inserted.

Ping

Reachability of an address in an IP network

Note

The page is only available if there is an online connection to the device.

With the ping function, you can check whether a certain IPv4 address is reachable in the network.

Settings

- **IP Address**
  Enter the IPv4 address of the device.
- **Repeat**
  Enter the number of ping requests.
- **Ping**
  Click this button to start the ping function.
- **Ping Output**
  This box shows the output of the ping function.
- **Delete**
  Click this button to delete the ping output.

PoE

General

Note

The menu item “PoE” is only displayed for devices that support PoE

On this page, you see information about the power that the IE switch supplies with PoE.

The SCALANCE X-500 represents a PSE (Power Sourcing Equipment).

With the SCALANCE XM400, each group of four ports with PoE capability is known as a PSE.

The displayed values apply only to the corresponding PSE.

Setting

- **PSE**
  Shows the number of the PoE power supply.
- **Maximum Power**
  Maximum power that a PSE provides to supply PoE devices.

- **Allocated Power**
  Sum of the power reserved by the PoE devices according to the "Classification".
- **Used power**
  Sum of the power used by the end devices.
- **Usage Threshold [%]**
  When the power being used by the end devices exceeds the percentage shown here, an event is triggered.

Power over Ethernet with SCALANCE XM-400

With a SCALANCE XM-400, you can use the "Power over Ethernet" function via the port extender PE408PoE. PoE power supply The connection of the PoE power supply is external. You can connect 2 PoE power supplies with each PE408PoE port extender. Each PE408PoE therefore has 2 PSE units (Power Sourcing Equipment) each with 4 ports.

Port

Settings for the ports

For each individual PoE port, you can specify whether or not the power will be supplied via Ethernet. You can also set a priority for each connected powered device (PD). Devices for which a high priority was set, take preference over other devices for the power supply.

Settings

Table 1 has the following columns:

- **Port**
  Shows that the settings are valid for all ports.
- **Setting**
  Select the required setting. Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Priority**
  Select the required priority of the port. Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Type**
  Enter a string that describes the connected device in greater detail. The maximum length is 255 characters.
- **Copy to Table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the configurable PoE ports.
  The port is made up of the port number and the slot number, for example port 0.1 is slot 0, port 1.
- **Setting**
  Enable the PoE power supply for this port or interrupt it.
- **Priority**
  Select which priority this port will have for the power supply.
  The following settings are possible, in ascending order of relevance:
  - low
    low priority
  - high
    medium priority
  - critical
    high priority

  If the same priority is set for two ports, the port with the lower port number will be preferred when necessary.
- **Type**
  Here, you can enter a string to describe the connected device in greater detail.
- **Classification**
  The classification specifies the class of the device. From this, it is possible to recognize the maximum power of the device.
- **Status**
  Shows the current status of the port.
  The following states are possible:
  - disabled
    The PoE power supply is deactivated for this port.
  - delivering
    The PoE power supply is activated for this port and a device is connected.
  - searching
    The PoE power supply is activated for this port but there is no device connected.

  Note

  If a device is connected to a port with PoE capability, a check is made to determine whether the power of the port is adequate for the connected device. If the power of the port is inadequate, although PoE is enabled in "Setting", the port nevertheless has the status "disabled". This means that the port was disabled by the PoE power management.

- **Power [mW]**
  Shows the power that the SCALANCE provides at this port.

- **Voltage [V]**
  Shows the voltage applied to this port.
- **Current [mA]**
  Shows the current with which a device connected to this port is supplied.

Port diagnostics

Cable tester

Note

The page is only available if there is an online connection to the device.

With this page, each individual Ethernet port can run independent fault diagnostics on the cable. This test is performed without needing to remove the cable, connect a cable tester and install a loopback module at the other end. Short-circuits and cable breaks can be localized to within a few meters.

Note

Please note that this test is permitted only when no data connection is established on the port to be tested.

Settings

- **Port**
  Select the required port from the drop-down list.
- **Run Test**
  Activates error diagnostics. The result is shown in the table.

This table contains the following columns:

- **Pair**
  Shows the wire pair in the cable.

  Note
  Wire pairs

  Wire pairs 4-5 and 7-8 of 10/100 Mbps network cables are not used.

  In 1000 Mbps or gigabit Ethernet, all 4 wire pairs are used.

  The wire pair assignment - pin assignment is as follows (DIN 50173):

  Pair 1 = pin 4-5

  Pair 2 = pin 1-2

  Pair 3 = pin 3-6

  Pair 4 = pin 7-8

- **Status**
  Displays the status of the cable.
- **Distance [m]**
  Displays the distance to the cable end, cable break, or short-circuit.

SFP diagnostics

On this page, you run independent error diagnostics for each individual SFP port. This test is performed without needing to remove the cable, connect a cable tester or install a loopback module at the other end.

Note

Please note that this test is permitted only when no data connection is established on the port to be tested.

If, however, there is a data connection to the port to be tested, this is briefly interrupted.

Automatic re-establishment of the connection can fail and then needs to be done manually.

Description

The page contains the following boxes:

- **Port**
  Select the required port from the drop-down list.

The values are shown in the following boxes:

- **Name**
  Shows the name of the interface.
- **Model**
  Shows the type of interface.

- **Revision**
  Shows the hardware version of the SFP.
- **Serial**
  Shows the serial number of the SFP.
- **Nominal Bit Rate [Mbps]**
  Shows the nominal bit rate of the interface.
- **Max. Link (50.0/125um) [m]**
  Shows the maximum distance in meters that is possible with this medium.
- **Max. Link (62.5/125um) [m]**
  Shows the maximum distance in meters that is possible with this medium.

The following table shows the values of the SFP transceiver used in this port:

- **Temperature [°C]**
  Shows the temperature of the interface.
- **Voltage [V]**
  Shows the voltage applied to the interface [V].
- **Current [mA]**
  Shows the current consumption of the interface [mA].
- **RX Power [mW]**
  Shows the receive power of the interface [mW].
- **Tx Power [mW]**
  Shows the transmit power of the interface [mW].
- **Current**
  Shows the current value.
- **Low**
  Shows the lowest value.
- **High**
  Shows the highest value.

Configuring layer 2 functions

Configuration

On this page, you create a basic configuration for the functions of layer 2. On the configuration pages of these functions, you can make more detailed settings. You can also check the settings on the configuration pages.

Settings

- **Protocol Based VLAN**
  Enable or disable protocol-based VLAN. You can configure other settings in "Layer 2 > VLAN".
- **Subnet Based VLAN**
  Enable or disable subnet-based VLAN. You can configure other settings in "Layer 2 > VLAN".
- **Dynamic MAC Aging**
  Enable or disable the "Aging" mechanism. You can configure other settings in "Layer 2 > Dynamic MAC Aging".
- **Redundancy Type**
  The following settings are available:
  - **"-" (disabled)**
    The redundancy function is disabled.
  - **Spanning Tree**
    If you select this option, you specify the required redundancy mode in "Redundancy Mode".
  - **Ring**
    Enables ring redundancy. You can configure other settings in "Layer 2 > Ring Redundancy > Ring".
  - **Ring with RSTP**
    If you select this option, the compatibility mode for spanning tree is set permanently to RSTP. In the "Redundancy Type" drop-down list, you specify the redundancy mode of the ring redundancy. You can change the current setting in the "Ring Redundancy" and "Spanning Tree" menus.

    Note

    Restriction relating to ports with the "Ring with RSTP" option

    If you have enabled the "Ring with RSTP" option, the following ports must not be included in the spanning tree:
    - Ring ports
    - Standby ports
    - Standby coupling ports

- **Redundancy Mode**
  If you select "Spanning Tree" for the "Redundancy Type", the following options are then available:
  - **STP**
    Enables the Spanning Tree Protocol (STP). Typical reconfiguration times with spanning tree are between 20 and 30 seconds. You can configure other settings in "Layer 2 > Spanning Tree".
  - **RSTP**
    Enables the Rapid Spanning Tree Protocol (RSTP). If a spanning tree frame is detected at a port, this port reverts from RSTP to spanning tree. You can configure other settings in "Layer 2 > Spanning Tree".

    Note

    When using RSTP (Rapid Spanning Tree Protocol), loops involving duplication of frames or frames being overtaken may occur briefly. If this is not acceptable in your particular application, use the slower standard spanning tree mechanism.

  - **MSTP**
    Enables the Multiple Spanning Tree Protocol (MSTP). You can configure other settings in "Layer 2 > Spanning Tree".

  If you select "Ring" or "Ring with RSTP" for the "Redundancy Type", the following options are then available:

  - Automatic Redundancy Detection
    Select this setting to create an automatic configuration of the redundancy mode.
    In the Automatic Redundancy Detection mode, the device automatically detects whether or not there is a device with the "HRP Manager" role in the ring. If there is, the device adopts the role "HRP Client" client.
    If no HRP manager is found, all devices with the "Automatic Redundancy Detection" or "MRP Auto Manager" setting negotiate among themselves to establish which device adopts the role of "MRP Manager". The device with the lowest MAC address will always become "MRP Manager". The other devices automatically set themselves to "MRP Client" mode.
  - MRP Auto-Manager
    In the "MRP Auto Manager" mode, the devices negotiate among themselves to establish which device will adopt the role of "MRP Manager". The device with the lowest MAC address will always become "MRP Manager". The other devices automatically set themselves to "MRP Client" mode.
    In contrast to the setting "Automatic Redundancy Detection", the devices are not capable of detecting whether or not an HRP manager is in the ring.

    Note

    MRP configuration in STEP 7

    If you set the role "Manager (Auto)" or "Manager" for the device in STEP 7, in both cases, "MRP Auto Manager" is displayed on this WBM page. In the display in the CLI, a distinction is made between the two roles.

  - MRP Client
    The device adopts the role of MRP client.

  - HRP Client
    The device adopts the role of HRP client.
  - HRP Manager
    The device adopts the role of HRP manager.
    When you configure an HRP ring, one device must be set as HRP manager. For all other devices, "HRP Client" or "Automatic Redundancy Detection" must be set.

- **Standby**
  Enable or disable the "Standby redundancy" function. You can configure other settings in "Layer 2 > Ring Redundancy > Standby".
- **Passive Listening**
  Enable or disable the "passive listening" function.
- **RMON**
  If you select this check box, Remote Monitoring (RMON) allows diagnostics data to be collected on the device, prepared and read out using SNMP by a network management station that also supports RMON. This diagnostic data, for example port-related load trends, allow problems in the network to be detected early and eliminated.
- **Dynamic Multicast**
  The following settings are possible:
  - **"-" (disabled)**
  - **IGMP Snooping**
    Enables IGMP (Internet Group Management Protocol). You can configure other settings in "Layer 2 > Multicast > IGMP".
  - **MLD Snooping**
    Enables MLD. You can configure other settings in "Layer 2 > Multicast > MLD".
  - **IGMP and MLD Snooping**
    Enables IGMP and MDL.
  - **GMRP**
    Enables GMRP (GARP Multicast Registration Protocol). You can configure other settings in "Layer 2 > Multicast > GMRP".

    Note

    GMRP and IGMP cannot operate at the same time.

- **GVRP**
  Enable or disable "GVRP" (GARP VLAN Registration Protocol). You can configure other settings in "Layer 2 > VLAN > GVRP".
- **Mirroring**
  Enable or disable port mirroring. You can configure other settings in "Layer 2 > Mirroring > Port".

- **Loop Detection**
  Enable or disable loop detection. You can configure other settings in "Layer 2 > Loop Detection".
- **PTP**
  Specify how the device will process PTP messages. You can configure other settings in "Layer 2 > PTP".
  - off
    The device does not process any PTP messages. PTP messages are, however, forwarded according to the rules of the switch.
  - transparent
    The device adopts the function of a transparent clock and forwards PTP messages to other nodes while at the same time making entries in the correction field of the PTP message.

QoS

General

Transmission priorities

On this page, you can specify the priorities of different frames. In addition to this, depending on the priority you can set the method according to which the processing order of the frames is specified. You should also refer to the section "Basics (Page 1272)".

Description of the displayed values

The page contains the following boxes:

- **Broadcast Priority**
  Specify the priority of broadcast frames. The switch sorts the frame into a queue according to this prioritization . You configure the assignment of the priority to a queue on the page ""Layer 2 > QoS > CoS Map".
- **Agent Priority**
  Specify the priority of agent frames. The switch sorts the frame into a queue according to this prioritization . You configure the assignment of the priority to a queue on the page ""Layer 2 > QoS > CoS Map".
- **Scheduling Mode**
  Select the order in which the frames are processed in the queues.
  The higher the queue number, the higher the processing priority.
  - Strict Queueing
    As long as there are frames with high priority in the queue, only these high-priority frames are processed.
  - Weighted Fair Queueing
    Even if there are frames with high priority in the queue, frames with a lower priority will be processed occasionally.

CoS Map

On this page, you can assign CoS priorities to different Queues.

Settings

- **CoS**
  Shows the CoS priority of the incoming packets.
- **Queue**
  From the drop-down list, select the queue that is assigned to the CoS priority.
  The higher the number of the queue, the higher the processing priority.
  With queues 1 - 6 frames with a lower priority are occasionally processed even if there are frames with high priority in the queue.
  With queues 7 - 8 only frames with a high priority are processed as long as there are frames with high priority in the queue.

The service classes (CoS) are assigned to the queues as follows:

SCALANCE XB-200/XP-200	SCALANCE XM-400/XR-500
CoS 0 → Queue 2	CoS 0 → Queue 2
CoS 1 → Queue 1	CoS 1 → Queue 1
CoS 2 → Queue 1	CoS 2 → Queue 3
CoS 3 → Queue 2	CoS 3 → Queue 4
CoS 4 → Queue 3	CoS 4 → Queue 5
COo 5 → Queue 3	CoS 5 → Queue 6
CoS 6 → Queue 4	CoS 6 → Queue 7
CoS 7 → Queue 4	CoS 7 → Queue 8

DSCP Mapping

On this page, you can assign DSCP priorities to different Queues.

Settings

- **DSCP**
  Shows the DSCP priority of the incoming packets.
- **Queue**
  From the drop-down list, select the queue that is assigned to the DSCP priority. The higher the queue number, the higher the send priority.
  With queues 1 - 6 frames with a lower priority are occasionally processed even if there are frames with high priority in the queue.
  With queues 7 - 8 only frames with a high priority are processed as long as there are frames with high priority in the queue.

The DSCP codes are assigned to the queues as follows:

SCALANCE XB-200/XP-200	SCALANCE XM-400/XR-500
DSCP codes 0 - 15 → Queue 1	DSCP codes 0 - 7 → Queue 2
DSCP codes 16 - 31 → Queue 2	DSCP codes 8 - 15 → Queue 1
DSCP codes 32 - 47 → Queue 3	DSCP codes 16 - 23 → Queue 3
DSCP codes 48 - 63 → Queue 4	DSCP codes 24 - 31 → Queue 4
	DSCP codes 32 - 39 → Queue 5
	DSCP codes 40 - 47 → Queue 6
	DSCP codes 48 - 55 → Queue 7
	DSCP codes 56 - 63 → Queue 8

QoS Trust

Specifying the subnet priority

On this page you can set the method according to which frames to be forwarded are prioritized port by port.

Description of the displayed values

Table 1 has the following columns:

- 1st column
  Shows that the setting is valid for all ports of table 2.
- Trust Mode
  Select the required setting. If "No setting" is selected, the entry in table 2 remains unchanged.
- Transfer to table
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the configurable PoE ports.
  The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.
- **Trust Mode**
  Select the required mode from the drop-down list:
  - No Trust
    The switch sorts the incoming frames into a queue according to the prioritization of the receiving port.
    If there is a DSCP value in the IP header, this is ignored. If a VLAN tag exists, it is replaced by the priority value of the receiving port.
  - Trust COS
    If an incoming frame contains a VLAN tag, the switch sorts it into a queue according to this prioritization.
    If the frame does not contain a VLAN tag, the switch sorts the frame into a queue according to the prioritization of the receiving port.
    If there is a DSCP value in the IP header, this is ignored.
  - Trust DSCP
    If an incoming frame contains a DSCP prioritization, the switch sorts it into a queue according to this prioritization.
    If the frame does not contain a DSCP prioritization, the switch sorts the frame into a queue according to the prioritization of the receiving port.
    If the frame contains a VLAN tag, this is ignored.
  - Trust COS-DSCP
    With an incoming frame, there is a sequential check to determine which prioritization it contains.
    If the frame contains a DSCP prioritization, it is handled as in the "Trust DSCP" mode.
    If the frame contains no DSCP prioritization, the switch checks whether the frame contains a VLAN tag. If it contains a VLAN tag, the switch sorts it into a queue according to this prioritization.
    If the frame contains neither a DSCP prioritization nor a VLAN tag, the switch sorts the frame into a queue according to the prioritization of the receiving port.

CoS Port Remap

Changing priority when sending

On this page depending on the priority when receiving, you can change the priority of a frame with which it is sent.

Description of the displayed boxes

The page contains the following boxes:

- **CoS Remap**
  Enable or disable frames being sent with changed priorities according to Table 2.

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2.
- **Priority 0 - 7**
  The priority in the column stands for the priority with which a frame is received.
  - 0 - 7
    Select the priority with which a frame will be sent.
  - No Change
    No change in table 2.
- **Copy to Table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows all available ports. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.
- **Priority 0 - 7**
  The priority in the column stands for the priority with which a frame is received.
  In the drop-down list select the priority with which a frame will be sent.

Rate Control

Limiting the transfer rate of incoming and outgoing data

On this page, you configure the load limitation (maximum number of data packets per second) for the individual ports. You can specify the category of frame for which these limit values will apply.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports.
- **Limit Ingress Unicast (DLF) / Limit Ingress Broadcast / Limit Ingress Multicast**
  Select the required setting. Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Total Ingress Rate [pkts/s]**
  Specify the maximum number of incoming packets processed by the device. If "No Change" is entered, the entry in table 2 remains unchanged
- **Egress Rate [Kb/s]**
  Specify the data rate for all outgoing frames. If "No Change" is entered, the entry in table 2 remains unchanged
- **Transfer to table**
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the port to which the settings relate.
- **Limit Ingress Unicast (DLF)**
  Enable or disable the data rate for limiting incoming unicast frames with an unresolvable address (Destination lookup failure).
- **Limit Ingress Broadcast**
  Enable or disable the data rate for limiting incoming broadcast frames.
- **Limit Ingress Multicast**
  Enable or disable the data rate for limiting incoming multicast frames.
- **Total Ingress Rate [pkts/s]**
  Specify the maximum number of incoming packets processed by the device.
- **Egress Rate [Kb/s]**
- Specify the data rate for all outgoing frames.

Note

Rounding of the values, deviation from desired value

When you enter the values for transmission rates, note that the WBM rounds to correct values.

If values are configured for total ingress transmission rate and egress transmission rate, the actual values in operation can exceed or fall below the set values by 10%.

VLAN

General

On this page, you define the VLAN and specify the use of the ports.

Note

Changing the "Agent VLAN ID"

If the configuration PC is connected directly to the device via Ethernet and you change the "agent VLAN ID", the device is no longer reachable via Ethernet following the change.

Important rules for VLANs

With SCALANCE XB-200 the rules of the Base Bridge mode apply "802.1Q VLAN Bridge".

Make sure you keep to the following rules when configuring and operating your VLANs:

- Frames with the VLAN ID "0" are handled as untagged frames but retain their priority value.
- As default, all ports on the device send frames without a VLAN tag to ensure that the end node can receive these frames.
- With SCALANCE X devices, the VLAN ID "1" is the default on all ports.

- If an end node is connected to a port, outgoing frames should be sent without a tag (static access port). If, however, there is a further switch at this port, the frame should have a tag added (trunk port).
- With a trunk port, the VLAN assignment is dynamic. Static configurations can only be created if, in addition to the trunk port property, the port is also entered statically as a member in the VLANs involved. An example of a static configuration is the assignment of the multicast groups in certain VLANs.

Settings

- **VLAN ID**
  Enter the VLAN ID.

The table has the following columns:

- **VLAN ID**
  Shows the VLAN ID. The VLAN ID is assigned once when you create a new data record and can then no longer be changed. To make a change, the entire data record must be deleted and created again.
- **Base Bridge mode (only with SCALANCE XB-200)**
  Specify the base bridge mode.

  Note

  Changing base bridge mode

  Note the section "Changing base bridge mode". This section describes how a change affects the existing configuration.

  - 802.1Q VLAN Bridge
    Sets the mode "VLAN-aware" for the device. In this mode, VLAN information is taken into account.
    Default setting with EtherNet/IP variants
  - 802.1D transparent bridge
    Sets the mode "VLAN-unaware" for the device. In this mode, VLAN tags are not taken into account or changed but are forwarded transparently. In this mode, you cannot create any VLANs. Only a management VLAN is available: VLAN 1:
    Default setting with PROFINET variants
- **Name**
  Enter a name for the VLAN. The name only provides information and has no effect on the configuration.
  The VLAN name can be a maximum of 32 characters long.
- **Status**
  Shows the status of the entry. Here, static means that the address was entered as a static address by the user. The entry GVRP means that the configuration was registered by a GVRP frame. This is, however, only possible if GVRP was enabled for the device.
- **Private VLAN Type**
  Shows the type of the PVLAN.
- **Primary VLAN ID**
  , With secondary PVLANs shows the ID of the corresponding primary PVLAN.

- Transparent(only with SCALANCE XM-400/XR-500)
  If you enable these settings, you switch a VLAN to the transparent mode. Ports that were assigned to this VLAN as members or untagged members now become transparent ports. This means the following:
  - The port VLAN ID of the transparent port is set to the ID of this VLAN.
  - Untagged frames that are received at these ports are forwarded to all other transparent ports once again without tag as long as they are not forwarded to a standard VLAN by a protocol or subnet rule.
  - Frames tagged with VLAN ID "0" and that are received at these ports are forwarded to all other transparent ports once again tagged with VLAN ID "0" as long as they are not forwarded to a standard VLAN by a protocol or subnet rule.
  - Frames tagged with the VLAN ID of the transparent VLAN and that are received at these ports are forwarded to all transparent ports once again tagged with the VLAN ID of the transparent VLAN.
  - Other frames are forwarded according to the normal VLAN rules and a transparent port behaves like an untagged member in this VLAN.
  - All ports that were not members or untagged members in the relevant VLAN are automatically set to the "Forbidden" status.
  - As long as a VLAN is configured as a transparent VLAN, the ports belonging to this VLAN cannot be modified.
  - You can only configure one a transparent VLAN.
- List of ports
  Specify the use of the port. The following options are available:
  - "-"
    The port is not a member of the specified VLAN.
    With a new definition, all ports have the identifier "-".
  - M
    The port is a member of the VLAN. Frames sent in this VLAN are forwarded with the corresponding VLAN tag.
  - R
    The port is a member of the VLAN. A GVRP frame is used for the registration.
  - U (upper case)
    The port is an untagged member of the VLAN. Frames sent in this VLAN are forwarded without the VLAN tag. Frames without a VLAN tag are sent from this port.
  - u (lower case)
    The port is an untagged member of the VLAN, but the VLAN is not configured as a port VLAN. Frames sent in this VLAN are forwarded without the VLAN tag.
  - F
    The port is not a member of the specified VLAN and it is not possible for the VLAN to be registered dynamically at this port using GVRP. You can configure other settings in "Layer 2 > VLAN > Port-based VLAN".

– T
This option is only displayed and cannot be selected in the WBM. This port is a trunk port making it a member in all VLANs. You configure this function in the CLI (Command Line Interface) using the "`switchport mode trunk`" command.

Changing Base Bridge mode with SCALANCE XB-200

VLAN-unaware (802.1D transparent bridge) → VLAN-aware (802.1Q VLAN bridge)

If you change the Base bridge mode from VLAN-unaware to VLAN aware, this has the following effects

- All static and dynamic unicast entries are deleted.
- All static and dynamic multicast entries are deleted.

VLAN-aware (802.1Q VLAN bridge) → VLAN-unaware (802.1D transparent bridge)

If you change the Base bridge mode from VLAN-aware to VLAN-unaware, this has the following effects

- All static and dynamic VLAN information is deleted.
- A management VLAN is created: VLAN 1:
- All static and dynamic unicast entries are deleted.
- All static and dynamic multicast entries are deleted.

GVRP

Configuration of GVRP functionality

Using GVRP frame, a different device can register at the port of the device for a specific VID. A different device, can, for example be an end device or a switch. The device can also send GVRP frames via this port. On this page, you can enable each port for GVRP functionality.

Settings

- **GVRP**
Enable or disable the "GVRP" function.

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2.
- **Setting**
  Select the setting. You have the following setting options:
  - Enabled
    Enables the sending of GVRP frames.
  - Disabled
    Disables the sending of GVRP frames.
  - No Change
    No change in table 2.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Enable or disable the sending GVRP frames.

Port-based VLAN

Processing received frames

On this page, you specify the configuration of the port properties for receiving frames.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports.
- **Priority / Port VID / Acceptable Frames / Ingress Filtering**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports and link aggregations.
- **Priority**
  Select the priority assigned to untagged frames.
  The CoS priority (Class of Service) used in the VLAN tag. If a frame is received without a tag, it will be assigned this priority. This priority specifies how the frame is further processed compared with other frames.
  There are a total of eight priorities with values 0 to 7, where 7 represents the highest priority (IEEE 802.1p Port Priority).
- **Port VID**
  Select the VLAN ID. Only VLAN IDs defined on the "VLAN > General" page can be selected.
  If a received frame does not have a VLAN tag, it has a tag with the VLAN ID specified here added to it and is sent according to the rules at the port.
- **Acceptable Frames**
  Specify which types of frames will be accepted. The following alternatives are possible:
  - Tagged Frames Only
    The device discards all untagged frames. Otherwise, the forwarding rules apply according to the configuration.
  - All
    The device forwards all frames
- **Ingress Filtering**
  Specify whether the VID of received frames is evaluated.
  The following options are available:
  - Enabled
    The VLAN ID of received frames decides whether they are forwarded: To forward a VLAN tagged frame, the receiving port must be a member in the same VLAN. Frames from unknown VLANs are discarded at the receiving port.
  - Disabled
    All frames are forwarded.

Protocol-based VLAN group

On this page, you specify groups and assign a protocol to them.

Settings

- **Protocol Based VLAN**
  Enable or disable the protocol-based VLAN assignment.
- **Protocol Value**
  Enter the hexadecimal protocol value.
  A few examples are shown below:
  - PROFINET: 88:92
  - IP: 08:00
  - Novell: 81:37
  - netbios: f0:f0
  - appletalk: 80:9b
- **Group ID**
  Enter the ID of the group.

The table has the following columns:

- **Protocol Value**
  Shows the file value.
- **Group ID**
  Shows the group ID.

Protocol-based VLAN port

On this page, you specify which protocol and which VLAN is assigned to the individual port.

Settings

- **Port**
  Select the required port. All available ports and the link aggregations can be selected.
- **Group ID**
  Select the group ID from the drop-down list. Specify the ID in "Layer 2 > VLAN > Protocol Based VLAN Group".

The table has the following columns:

- **Port**
  All available ports and the link aggregations are shown.
- **Group ID**
  Shows the group ID assigned to the port.
- **VLAN ID**
  Select the required VLAN ID to be assigned to the port.

IPv4 subnet-based VLAN

On this page, you specify which VLAN ID is assigned to the subnet.

Settings

- **Subnet Based VLAN**
  Enable or disable the subnet-based VLAN assignment.
- **Port**
  Select the port. All available ports and the link aggregations can be selected.
- **Subnet Address**
  Enter the IP address of the subnet.
  Example: 192.168.10.0 for the network 192.168.10.x with nodes 192.168.10.1 to 192.168.10.254.
- **Subnet Mask**
  Enter the subnet mask.

The table has the following columns:

- **Port**
  All available ports and the link aggregations are shown.
- **Subnet Address**
  Shows the subnet assigned to the port.
- **Subnet Mask**
  Shows the subnet mask.
- **VLAN ID**
  Select the VLAN ID you want to assign to the port or the subnet.

Private VLAN

General

Private VLAN configuration page

On this page you define the types of the PVLANs and assign secondary PVLANs to a primary PVLAN.

Note

All secondary PVLANs must be known on all devices of a PVLAN. Even if a device has no host port in a secondary PVLAN, the secondary PVLAN must be known on the device.

Description of the displayed boxes

The table has the following columns:

- **VLAN ID**
  Shows the VLAN ID.
- **Private VLAN Type**
  Specify the type of PVLAN:
  - Primary
    Mit diesem Typ definieren Sie ein Primary PVLAN. In a PVLAN you can only define one primary PVLAN. The primary PVLAN uses the VLAN ID of the VLAN.
  - Isolated
    With this type, you define a secondary PVLAN. Only one device can exist in this secondary PVLAN. The secondary PVLAN has a specific VLAN ID.
  - Community
    With this type, you define a secondary PVLAN. The devices in this secondary PVLAN can communicate with each other via layer 2. The secondary PVLAN has a specific VLAN ID.
- **Primary VLAN ID**
  With secondary PVLANs select the VLAN ID of the primary PVLAN.

IP Interface Mapping

VLAN configuration page

On this page you specify from which secondary PVLANs the IP interface of the primary PVLAN will be reachable.

Description of the displayed boxes

The page contains the following boxes:

- **Interface**
  Select a primary PVLAN with an IP interface.
- **Secondary VLAN ID**
  Select a secondary VLAN ID from which the IP interface of the primary PVLAN will be reachable.

The table has the following columns:

- **Select**
  Select the row you want to delete.
- **Interface**
  Shows the IP interface.
- **Secondary VLAN-ID**
  Shows the secondary VLAN-ID of the secondary PVLAN from which the IP interface of the primary PVLAN is reachable.

Mirroring

Basics

Mirroring

The device provides the option of simultaneously channeling incoming or outgoing data streams via other interfaces for analysis or monitoring. This has no effect on the monitored data streams. This procedure is known as mirroring. In this menu section, you enable or disable mirroring and set the parameters.

Mirroring ports

Mirroring a port means that the data traffic at a port (mirrored port) of the IE switch is copied to another port (monitor port). You can mirror one or more ports to a monitor port.

If a protocol analyzer is connected to the monitor port, the data traffic at the mirrored port can be recorded without interrupting the connection. This means that the data traffic can be investigated without being affected. This is possible only if a free port is available on the device as the monitor port.

General

Mirroring in general

On this page, you can enable or disable the mirroring function and make the basic settings.

Note

Mirroring a port does not work beyond switch core boundaries. Refer to the operating instructions of the device.

Note

You need to disable port mirroring if you want to connect a normal end device to the monitor port. This does not apply to the function extender BUS ANALYZER Agent XM-400.

Note the data rate

If the maximum data rate of the mirrored port is higher than that of the monitor port, data may be lost and the monitor port no longer reflects the data traffic at the mirrored port. Several ports can be mirrored to one monitor port at the same time.

RSPAN

With RSPAN (Remote Switched Port Analyzer) you can forward the data traffic of a mirroring session to the monitor port via a VLAN. On the RSPAN VLAN, the mirrored data traffic is not disturbed by other data.

Frames addressed directly to the mirroring source cannot be mirrored on the RSPAN destination port.

Settings

- **Mirroring**
  Enable or disable mirroring of the data traffic.
- **Monitor Barrier**
  Enable or disable the setting to restrict communication via the monitor port.

Note

Effects of monitor barrier

If you enable this setting, the management of the switch via the monitor port is no longer reachable. The following port-specific functions are changed:

- DCP forwarding is turned off
- LLDP is turned off
- Unicast, multicast and broadcast blocking is turned on

The previous statuses of these functions are no longer restored after disabling monitor barrier again. They are reset to the default values and may need to be reconfigured.

You can reconfigure these functions manually even if monitor barrier is turned on. The data traffic on the monitor port is also allowed again. If you do not require this, make sure that only the data traffic you want to monitor is forwarded to the interface.

If mirroring is disabled, the listed port-specific functions are reset to the default values. This reset takes place regardless of whether the functions were configured manually or automatically by enabling "Monitor Barrier".

Note

Function extender BUS ANALYZER Agent XM-400

If the destination port is a port of the function extender BUS ANALYZER Agent XM-400 the monitor barrier option is always activated. It is activated regardless of whether the check box was disabled or enabled.

- **RSPAN VLAN ID**
  Select a VLAN.

This table has the following columns:

- **Session ID**
  The Session ID is assigned automatically when a new entry is created.
- **Session Type**
  Select the required entry:
  - '-'
    None
  - Port-based
    Port-based mirroring
  - VLAN
    VLAN-based mirroring.
  - MAC ACL
    Mirroring of the MAC Access Control List.
  - IP ACL
    Mirroring of the IP Access Control List.

  Note

  If you have created a session of the type "VLAN" "MAC ACL" or "IP ACL", you cannot create any further sessions. You can create up to 7 sessions of the type "Port-based".

  If you change the "Session Type" of an existing session, all previous configurations of this session are lost.

- **Status**
  Shows whether or not mirroring is active.
- **Hardware Index**
  If in a VLAN you select more than one source port for the port-based egress mirroring, unknown unicast and multicast frames as well as broadcast frames are forwarded only once to the destination port. With several sessions, the corresponding frames are only visible in one session. They are only mirrored on the one destination port with the lowest hardware index.
- **Dest. Port**
  Select the destination port to be mirrored to in this session.

  Note

  Function extender BUS ANALYZER Agent XM-400

  If you connect a function extender BUS ANALYZER Agent XM-400 with a SCALANCE XM-400 basic device as of firmware version 5.1, you can select up to four ports of the function extender BUS ANALYZER Agent XM-400 as destination ports. Function extender BUS ANALYZER Agent XM-400 supports port-based, VLAN-based, MAC ACL-based and IP ACL-based mirroring.

- **RSPAN**
  Enable or disable RSPAN for a session.

Port

Mirroring ports

You can only configure the settings on this page if you have already generated a session ID with the session type "Port-based" on the "General" tab.

Settings

- **Session ID**
  Select the session you want to monitor. Up to 7 parallel sessions are possible and their ports must not overlap.

The table has the following columns:

- **Port**
  Shows the port to be monitored.
- **Ingress Mirroring**
  Enable or disable listening in on incoming packets at the required port.
- **Egress Mirroring**
  Enable or disable listening in on outgoing packets at the required port.

VLAN

VLAN sources of the port mirroring

You can only configure the settings on this page if you have already generated a session ID with the session type "VLAN" on the "General" tab.

On this page, you specify the VLAN whose incoming data traffic will be mirrored to the monitor port.

It can happen that data packets are visible on the monitor port that were not received in the defined VLAN. These data packets come from functions that are enabled on the device, e.g. SIMATIC time client. To avoid these data packets when VLAN mirroring, disable the relevant functions on the device before a recording.

Settings

- **Session ID**
  Select the session you want to monitor. Only one session is possible.
- **VLAN ID**
  Enter the VLAN ID in the "VLAN ID" input box.

The table "Ingress Mirroring " has the following columns:

- **VLAN-ID**
  Shows the VLAN ID for which the incoming frames are mirrored. The VLAN ID can only be assigned once when you create a new data record and can then no longer be changed. To make a change, the entire data record must be deleted and created again.

MAC Flow

You can only configure the settings on this page if you have already generated a session ID with the session type "MAC ACL" on the "General" tab.

The MAC ACL filter decides which data is available at the monitor port.

Settings

- **Session ID**
  Select the session number of the port mirroring.

The table has the following columns:

- **ACL Filter Number**
  Shows the number of the ACL filter. You configure the MAC ACL filter in "Security > MAC ACL".
- **Ingress Mirroring**
  Shows whether incoming packets are mirrored.

  Note

  Rules

  The selected rule only becomes active when you specify with which ACL rules the incoming packets will be filtered for at least one interface. You configure the settings in "Security > MAC ACL > Ingress Rules".

- **Source MAC**
  Shows the MAC address of the sender.
- **Dest. MAC**
  Shows the MAC address of the recipient.
- **Ingress Interfaces**
  Shows all interfaces to which this rule applies. The ACL filter decides which incoming data streams are mirrored on the monitor port (destination port).
- **Egress Interfaces**
  Shows all interfaces to which this rule applies.

IP Flow

You can only configure the settings on this page if you have already generated a session ID with the session type "IP ACL" on the "General" tab.

The ACL filter decides which data is available at the monitor port.

Settings

- **Session ID**
  Select the session ID. Only session IDs of the session type "IP ACL" are available.

The table has the following columns:

- **ACL Filter Number**
  Shows the number of the ACL filter.
- **Ingress Mirroring**
  Shows whether incoming packets are mirrored.

  Note

  Rules

  The selected rule only becomes active when you specify with which ACL rules the incoming packets will be filtered for at least one interface. You configure the settings in "Security > IP ACL > Ingress Rules".

- **Source IP**
  Shows the IPv4 address of the sender.
- **Source Subnet Mask**
  Shows the subnet mask of the sender.
- **Dest. IP**
  Shows the IPv4 address of the recipient.
- **Dest. Subnet Mask**
  Shows the subnet mask of the recipient.
- **Ingress Interfaces**
  Shows all interfaces to which this rule applies. The ACL filter decides which incoming data streams are mirrored on the monitor port (destination port).
- **Egress Interfaces**
  Shows all interfaces to which this rule applies. The ACL filter decides which outgoing data streams are mirrored on the monitor port (destination port).

Dynamic MAC Aging

The device automatically learns the source addresses of the connected nodes.

This information is used to forward data frames to the nodes specifically involved. The network load for the other nodes is reduced.
If a device does not receive a frame whose source address matches a learnt address within a certain time, the learnt address is deleted. This mechanism is known as aging. Aging prevents frames being forwarded incorrectly, for example when an end device (for example a programming device) is connected to a different port. If the check box is not enabled, a device does not delete learned addresses automatically.

Settings

- **Dynamic MAC Aging**
  Enable or disable the function for automatic aging of learned MAC addresses:
- **Aging Time [s]**
  Enter the time in seconds. After this time, a learned address is deleted if the device does not receive any further frames from this sender address.

Ring Redundancy

Ring

Rules for ring redundancy

Factory settings

- The factory setting defines MSTP as the redundancy method.
- With SCALANCE XM-400, the factory setting defines ports P1.1 and P1.2 as ring ports.
- With SCALANCE XM-500, the factory setting defines ports P0.1 and P0.2 as ring ports.
  Ring ports

Ring ports

The predefined ring ports of SCALANCE XR-500 are 10 Gbps ports. If a 1000 Mbps pluggable transceiver is plugged into one of the 10 Gbps ring ports, you cannot enable ring redundancy. Remove the 1000 Mbps pluggable transceiver.

Enabling ring redundancy

You can enable ring redundancy as follows:

- using the WBM
- using the CLI
- using the SELECT/SET button
- using a PNIO configuration download

Settings

- **Ring Redundancy**
  If you enable the "Ring Redundancy" check box, you turn ring redundancy on. The ring ports set on this page are used.
- **Ring redundancy mode**
  Specify the ring redundancy mode. The following options are available:
  - **"-" (disabled)**
    The redundancy function is disabled.
  - **Automatic Redundancy Detection**
    Select this setting to create an automatic configuration of the redundancy mode.
    In the "Automatic Redundancy Detection" mode, the device automatically detects whether or not there is a device with the "HRP Manager" role in the ring. If this is the case, the device adopts the role of "HRP Client". If no HRP manager is found, all devices with the "Automatic Redundancy Detection" or "MRP Auto Manager" setting negotiate among themselves to establish which device adopts the role of "MRP Manager". The device with the lowest MAC address will always become "MRP Manager". The other devices automatically set themselves to "MRP Client" mode.
  - **MRP Auto Manager**
    Automatic media redundancy manager
  - **MRP Client**
    Media redundancy client
  - **HRP Client**
    High Speed Redundancy Protocol client
  - **HRP Manager**
    High Speed Redundancy Protocol manager
- **Ring ports**
  Specify the ports to be used as ring ports in media redundancy in ring topologies.
  The ring port you select in the left-hand drop-down menu is the "Isolated Port" in HRP.

Note

If you restore the factory defaults, the default redundancy mode "Automatic Redundancy Detection" becomes active.

The ring port configuration is also reset to the factory default ports. If other ports were used previously as ring ports, with the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

- **Observer**
  Enable or disable the observer. The "Observer" function is only available in HRP rings. The ring port selected in the left-hand drop-down menu is connected to the "Isolated Port" of an HRP manager.
  The observer monitors malfunctions of the redundancy manager or incorrect configurations of an HRP ring.
  If the observer is enabled, it can interrupt the connected ring if errors are detected. To do this, the observer switches a ring port to the "blocking" status. When the error is resolved, the observer enables the port again.
- **Restart Observer** (only available online)
  If numerous errors occur in quick succession, the observer no longer enables its port automatically. The ring port remains permanently in the "blocking" status. This is signaled by the error LED and a message text.
  After the errors have been eliminated, you can enable the port again using the "Restart Observer" button.

Restoring factory settings

If you have restored the factory defaults (Restore Factory Defaults and Restart), ring redundancy is disabled and the default ports are used as the ring ports. This can lead to circulating frames and failure of the data traffic if other settings were used in a previous configuration.

Changing over the status of the ring ports with the redundancy manager

If you configure a redundancy manager, set the status of the ring ports. The first ring port changes to the “blocking" status and the second ring port to the “forwarding" status. As long as ring redundancy is enabled, you cannot change the status of these ring ports.

Note

Make sure that you first open the ring so that there are no circulating frames.

Standby

Redundant linking of rings

Standby redundancy allows the redundant linking of HRP rings. To establish a standby connection, configure two neighboring devices within a ring as standby master or standby slave. The standby master and the standby slave must be connected via parallel cables to two devices in another ring. In problem-free operation, messages are exchanged between the two rings via the master. If the master's line is disturbed, the slave takes over the forwarding of messages between the two rings. Enable standby redundancy for both standby partners and select the ports via which the device is connected to the rings you want to link to. For the "Standby Connection Name", a name unique within the ring must be assigned for both partners. This identifies the two devices as standby partners that belong together.

Note

To be able to use the function, HRP must be activated.

The standby manager always requires an activated HRP client or HRP manager.

Note

Standby master coupling with an optical 100 Mbps connection

While the coupling partner of a standby master with an optical 100 Mbps connection starts up again, physically disconnect the connection between the standby master and its coupling partner.

Settings

- **Standby**
  Enable or disable this function.
- **Standby Port**
  Select the port to be standby port. The link to the other ring is via the standby port.
  Note

  Note

  Standby ports in the spanning tree

  Before you enable the port as the standby port, you need to disable the port in the spanning tree.

  1. Change to the page "Layer 2 > Spanning Tree > CIST Port".

  2. Disable the ports in the spanning tree you want to configure as standby ports.

  The standby port is involved in the redirection of data traffic. In there are no problems, only the standby port of the master is enabled and handles the data traffic into the connected HRP ring or HRP bus.
  If the master or the Ethernet connection (link) of one of the standby ports of the master fails, the standby port of the master will be disabled and the standby port of the slave enabled. As a result, a functioning Ethernet connection to the connected network segment (HRP ring or HRP linear bus) is restored.

- **Standby Connection Name**
  This name defines the master/slave device pair. Both devices must be located in the same ring.
  Here, enter the name for the standby connection. This must be identical to the name entered on the standby partner. You can select any name to suit your purposes, however, you can only use the name for one pair of devices in the entire network.
- **Force device to Standby Master**
  When selected, the device is configured as standby master regardless of its MAC address.
  - If this check box is not selected for either of the devices for which the standby master is enabled, then assuming that no error has occurred, the device with the higher MAC address adopts the role of standby master.
  - If the option is selected for both devices or if the "Force device to Standby Master" property is supported by only one device, the standby master is also selected based on the MAC address.

  This type of assignment is important in particular when a device is replaced. Depending on the MAC addresses, the previous device with the slave function can take over the role of the standby master.

  Note

  If two devices are linked by the standby function, the "Standby" function must be enabled on both devices.

- **Wait for Standby Partner**
  - Enabled
    A standby connection is enabled only after the standby master and the standby slave as well as their standby partners have established a connection. This ensures that the redundant connection is really available before communication via a standby connection is enabled.
  - Disabled
    A standby connection is enabled even if the standby master has not yet established a connection to the standby slave.
    This can lead to circulating frames and failure of the data traffic if another standby connection has already been enabled. Multiple standby connections can, for example, result due to configuration errors if different standby connection names were assigned to the standby master and standby slave.

Spanning Tree

General

General settings of MSTP

On this page, you configure the settings for MSTP. As default, Rapid Spanning Tree is enabled that can be set to the MSTP, RSTP or STP compatible mode with a switch.

On the configuration pages of these functions, you can make detailed settings.

Depending on the compatibility mode, you can configure the corresponding function on the relevant configuration page.

Settings

- **Spanning Tree**
  Enable or disable Spanning Tree.
- **Protocol Compatibility**
  Select the compatibility mode of MSTP. For example if you select RSTP, MSTP behaves like RSTP.
  The following settings are available:
  - STP
  - RSTP
  - MSTP

See also

Link aggregation (Page 1424)

MST port (Page 1419)

MST General (Page 1419)

CIST general/ST general

The page consists of the following parts.

- The left-hand side of the page shows the configuration of the device.
- The central part shows the configuration of the root bridge that can be derived from the spanning tree frames received by a device.
- The right-hand side shows the configuration of the regional root bridge that can be derived from the MSTP frames. The displayed data is only visible if you have enabled "Spanning Tree" on the "General" page and if "MSTP" is set for "Protocol Compatibility". This also applies to the "Bridge Max Hop Count" parameter. If the device is a root bridge, the information on the left and right matches.

Settings

- **Bridge Priority / Root Priority** (only available online)
  Which device becomes the root bridge is decided based on the bridge priority. The bridge with the highest priority becomes the root bridge. The lower the value, the higher the priority. If several devices in a network have the same priority, the device whose MAC address has the lowest numeric value will become the root bridge. Both parameters, bridge priority and MAC address together form the bridge identifier. Since the root bridge manages all path changes, it should be located as centrally as possible due to the delay of the frames.
- **Bridge Address / Root Address**(only available online)
  The bridge address shows the MAC address of the device and the root address shows the MAC address of the root bridge.

- **Root Port** (only available online)
  Shows the port via which the switch communicates with the root bridge.
- **Root Cost** (only available online)
  The path costs from this device to the root bridge.
- **Topology Changes** / **Last Topology Change** (only available online)
  The entry for the device shows the number of reconfigurations due to the spanning tree mechanism since the last startup. For the root bridge, the time since the last reconfiguration is displayed as follows:
  - Seconds: sec unit after the number
  - Minutes: min unit after the number
  - Hour: hr unit after the number
- **Bridge Hello Time [s] / Root Hello Time[s]** (only available online)
  Each bridge regularly sends configuration frames (BPDUs). The interval between two such frames is the Hello time. The default for this parameter is 2 seconds.
- **Bridge Forward Delay [s] / Root Forward Delay [s]**
  New configuration data is not used immediately by a bridge but only after the period specified in the parameter. This ensures that operation is only started with the new topology after all the bridges have the required information.
- **Bridge Max Age / Root Max Age** (only available online)
  When the max age timer elapses the received BPDU is discarded to be accepted as valid by the switch.
- **Bridge Max Hop Count**
  This parameter specifies how many MSTP nodes a BPDU may pass through. If an MSTP BPDU is received and has a "Bridge Max Hop Count" that exceeds the value configured here, it is discarded.
- **Regional root priority** (only available online)
  For a description, see Bridge Priority / Root Priority
- **Regional root address** (only available online)
  The MAC address of the device.
- **Regional root costs** (only available online)
  Shows the path costs from this device to the regional root bridge.
- **Region Name**
  Enter the name of the MSTP region to which this device belongs. As default, the MAC address of the device is entered here. This value must be the same on all devices that belong to the same MSTP region.
- **Region Version**
  Enter the version number of the MSTP region in which the device is located. This value must be the same on all devices that belong to the same MSTP region.
- **Reset Counter** (only available online)
  Click this button to reset the counters on this page to zero.

CIST Port/ST Port

MSTP-CIST port configuration

When the page is called, the table displays the current status of the configuration of the port parameters.

To configure them, click the relevant cells in the port table.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Spanning Tree Status**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.

Table 2 has the following columns:

- **Port**
  Shows the available ports and interfaces.
  - Port X
  - WLAN X
  - VAP X.Y
  - WDS X.Y
- **Spanning Tree Status**
  Specify whether or not the port is integrated in the spanning tree.

  Note

  If you disable the "Spanning Tree Status" setting for a port, this may cause the formation of loops. The topology must be kept in mind.

- **Priority**
  Enter the priority of the port. The priority is only evaluated when the path costs are the same. The value must be divisible by 16. If the value that cannot be divided by 16, the value is automatically adapted.
- **Cost Calc.**
  Enter the path cost calculation. If you enter the value "0" here, the automatically calculated value is displayed in the "Path Costs" box.

- **Path Costs** (only available online)
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected as the path. If several ports of a device have the same value for the path costs, the port with the lowest port number is selected.
  If The "Cost Calc." is "0", the automatically calculated value is shown. Otherwise, the value of the "Cost Calc." box is displayed. The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000

  The values can, however, also be set individually.
- **Status** (only available online)
  Displays the current status of the port. The values are only displayed and cannot be configured. The "Status" parameter depends on the configured protocol. The following is possible for status:
  - Disabled

    The port only receives and is not involved in STP, MSTP and RSTP.
  - Discarding
    In the "Discarding" mode, BPDU frames are received. Other incoming or outgoing frames are discarded.
  - Listening

    In this status, BPDUs are both received and sent. The port is involved in the spanning tree algorithm.
  - Learning

    Stage prior to the forwarding status, the port is actively learning the topology (in other words, the node addresses).
  - Forwarding

    Following the reconfiguration time, the port is active in the network; it receives and forwards data frames.

- **Fwd. Trans** (only available online)
  Specifies the number of changes from the "Discarding" status to the "Forwarding" status
- **Edge type**
  Specify the type of edge port. You have the following options:
  - "-"
    Edge port is disabled. The port is treated as a "no edge port".
  - Admin
    Select this option when there is always an end device on this port. Otherwise a reconfiguration of the network will be triggered each time a connection is changed.
  - Auto
    Select this option if you want a connected end device to be detected automatically at this port. When the connection is established the first time, the port is treated as a "no Edge Port".
  - Admin/Auto
    Select these options if you operate a combination of both on this port. When the connection is established the first time, the port is treated as an Edge Port.
- **Edge** (only available online)
  Shows the status of the port.
  - Enabled

    An edge port is connected to this port.
  - Disabled
    There is a spanning tree or rapid spanning tree device at this port.

  With an end device, a switch can change over the port faster without taking into account spanning tree frames. If a spanning tree frame is received despite this setting, the port automatically changes to the "Disabled" setting for switches.
- **P.t.P. Type**
  Select the required option. The selection depends on the port that is set.
  - "-"
    Point to point is calculated automatically. If the port is set to half duplex, a point-to-point link is not assumed.
  - P.t.P.

    Even with half duplex, a point-to-point link is assumed.
  - Shared Media

    Even with a full duplex connection, a point-to-point link is not assumed.

  Note

  Point-to-point connection means a direct connection between two devices. A shared media connection is, for example, a connection to a hub.

- **P.t.P.**
  - Enabled
    Shows that a point-to-point link exists.
  - Disabled
    Shows that no point-to-point link exists.
- **Hello Time**
  Enter the interval after which the bridge sends configuration BPDUs

Note

The port-specific setting of the Hello time is only possible in MSTP compatible mode.

MST General

Multiple Spanning Tree configuration

With MSTP, in addition to RSTP, several VLANs can be managed in a LAN with separate RSTP trees.

Settings

- **MSTP Instance ID**
  Enter the number of the MSTP instance.

The table has the following columns:

- **Select**
  Select the line to be deleted.
- **MSTP Instance ID**
  Shows the number of the MSTP instance.
- **Root Address**
  Shows the MAC address of the root bridge
- **Root Priority**
  Shows the priority of the root bridge.
- **Bridge Priority**
  Enter the bridge priority. The value for the bridge priority is a whole multiple of 4096.
- **VLAN ID**
  Enter the VLAN ID. Here, you can also specify ranges with Start ID, "-", End ID. Several ranges or IDs are separated by ",".

MST port

Configuration of the Multiple Spanning Tree port parameters

On this page, you set the parameters for the ports of the configured multiple spanning tree instances.

Settings

- **MSTP Instance ID**
  Select the ID of the MSTP instance.

Table 1 has the following columns

- **1st column**
  Shows that the setting is valid for all ports.
- **MSTP Status**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2

Table 2 has the following columns:

- **Port**
  Shows all available ports and link aggregations.
- **MSTP Instance ID**
  ID of the MSTP instance.
- **MSTP Status**
  Enable or disable MSTP for this port.
- **Priority**
  Enter the priority of the port. The priority is only evaluated when the path costs are the same. The value must be divisible by 16. If the value that cannot be divided by 16, the value is automatically adapted.
- **Cost Calc.**
  Enter the path cost calculation in the input box. If you enter the value "0" here, the automatically calculated value is displayed in the next box "Path Costs".
- **Path Costs** (only available online)
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected as the path. If several ports of a device have the same value for the path costs, the port with the lowest port number is selected.
  If the value for the Cost Calc is "0" the automatically determined value is displayed. Otherwise, the value of the "Cost Calc box is displayed. The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000

  The values can, however, also be set individually.

- **Status** (only available online)
  Displays the current status of the port. The values are only displayed and cannot be configured. The following is possible for status:
  - Discarding
    The port exchanges MSTP information but is not involved in the data traffic.
  - Blocked
    In the blocking mode, BPDU frames are received.
  - Forwarding
    The port receives and sends data frames.
- **Fwd. Trans**(only available online)
  Specifies the number of status changes Discarding - Forwarding or Forwarding - Discarding for a port.

Enhanced Passive Listening Compatibility

Enabling the function

On this page, you can enable passive listening compatibility.

Settings

- **Enhanced Passive Listening Compatibility**
  Enable or disable this function for the entire device.

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Displays the port of the device.
- **Setting**
  - Enabled
    Enables the function.
  - Disabled
    Disables the function.

Loop detection

With the "Loop Detection" function, you specify the ports for which loop detection will be activated. The ports involved send special test frames - the loop detection frames. If these frames are sent back to the device, there is a loop.

A "local loop" involving this device means that the frames are received again at a different port of the same device. If the sent frames are received again at the same port, there is a "remote loop" involving other network components.

Note

A loop is an error in the network structure that needs to be eliminated. The loop detection can help to find the errors more quickly but does not eliminate them. The loop detection is not suitable for increasing network availability by deliberately including loops.

Note

Note that loop detection is only possible at ports that were not configured as ring ports or standby ports.

Settings

- **Loop Detection**
  Enable or disable loop detection.
- **VLAN Loop Detection**
  Enable or disable loop detection in a VLAN.

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2
- **Threshold / Remote Reaction / Local Reaction**
  Select the required settings. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Specify how the port handles loop detection frames.

  Note

  Test frames create additional network load. We recommend that you only configure individual switches, for example at branch points of the ring, as "sender" and the others as "forwarder".

  – sender
    Loop detection frames are sent out and forwarded.
  – forwarder
    Loop detection frames from other devices are forwarded.
  – blocked
    The forwarding of loop detection frames is blocked.
- **Threshold**
  By entering a number, specify the number of received loop detection frames as of which a loop is assumed.
- **Remote Reaction**
  Specify how the port will react if a remote loop occurs.
  – no action
    A loop has no effect on the port.
  – disable
    The port is blocked.
- **Local Reaction**
  Specify how the port will react if a local loop occurs.
  – no action
    A loop has no effect on the port.
  – disable
    The port is blocked
- **Status** (only available online)
  This box shows whether loop detection is enabled or disabled for this port.
- **Source Port** (only available online)
  Shows the receiving port of the loop detection frame that triggered the last reaction
- **Source VLAN** (only available online)
  Shows the VLAN ID of the loop detection frame that triggered the last reaction.
  This requires that the "VLAN Loop Detection" setting is selected.
- **Reset** (only available online)
  After a loop in the network has been eliminated, click this button to reset the port again.

Note

Changing the configured port status with loop detection

The configuration of the port status can be changed with the "Loop Detection" function. If, for example, the administrator has disabled a port, the port can be enabled again after a device restart with "Loop Detection" (enabled). The port status "link down" is not changed by "Loop Detection".

Note

Effects of configuration using STEP 7

The configuration of Spanning Tree can be changed if you configure "Loop Detection" using STEP 7.

If you enable "Loop Detection" on a port with STEP 7, Spanning Tree is automatically disabled on this port. If you disable "Loop Detection" for the port again with STEP 7 Spanning Tree is not automatically enabled. Enable Spanning Tree with the WBM or CLI.

Link aggregation

Bundling network connections for redundancy and higher bandwidth

A link aggregation according to IEEE 802.3ad allows several connections between neighboring devices to be bundled to achieve higher bandwidths and to protect against failure.

Ports on both partner devices are included in link aggregations and the devices are then connected via these ports. To assign ports (in other words links) correctly to a partner device, the Link Aggregation Control Protocol (LACP) from the IEEE 802.3ad standard is used.

Note

When a port is assigned to a link aggregation but is not active (e.g. link down), the values displayed may differ from the values configured for the link aggregation. If the port in the link aggregation becomes active, individual port configurations such as DCP forwarding are overwritten with the configured values of the link aggregation.

Settings

The table has the following columns:

- **Port**
  Shows the virtual port number of this link aggregation. This identifier is assigned internally by the firmware.
- **Link Aggregation Name**
  Enter a name for the link aggregation. This name can be specified by the user during configuration. The name is not absolutely necessary but can be useful to distinguish between the various link aggregations.

- **MAC Address**
  Shows the MAC address.
- **Status**
  Enable or disable link aggregation.
- **MTU**
  Specify the packet size.
- **LACP**
  - on
    Enables the sending of LACP frames.
  - off
    Disables the sending of LACP frames.
- **Frame Distribution**
  Set the type of distribution of packets on the individual links of an aggregation.
  - Destination&Source Mac
    The distribution is based on a combination of the destination and source MAC address.
  - Destination&Source IP-MAC
    The distribution is based on a combination of the destination and source IP address and MAC address.

- **VLAN Mode**
  Specify how the link aggregation is entered in a VLAN:
  - Hybrid
    The link aggregation sends tagged and untagged frames. It is not automatically a member of a VLAN.
  - Trunk
    The link aggregation only sends tagged frames and is automatically a member of all VLANs.
- **Port**
  Shows the ports that belong to this link aggregation. The following values can be selected from the drop-down list:
  - "-" (disabled)
    Link aggregation is disabled.
  - "a" (active)
    The port sends LACP frames and is only involved in the link aggregation when LACP frames are received.
  - "p" (passive)
    The port is only involved in the link aggregation when LACP frames are received.
  - o" (on)
    The port is involved in the link aggregation and does not send any LACP frames.

Note

Within a "link aggregation", only ports with the following configuration are possible:

- all ports with "o"
- all ports with "a" or "p".

Note

If you add a configured port to a link aggregation, the port adopts the configuration of the link aggregation. If you take the port out of the link aggregation, the settings of the port are reset to the factory settings.

See also

General (Page 1413)

DCP forwarding

Applications

The DCP protocol is used by STEP 7 and the PST Tool for configuration and diagnostics. When shipped, DCP is enabled on all ports; in other words, DCP frames are forwarded at all ports. With this option, you can disable the sending of these frames for individual ports, for example to prevent individual parts of the network from being configured with the PST Tool or to divide the full network into smaller parts for configuration and diagnostics.

Note

PNIO configuration

Since DCP is a PROFINET protocol, the configuration created here is only effective with the VLAN associated with the TIA interface.

All the ports of the device are displayed on this page. After each displayed port, there is a drop-down list for function selection.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Specify whether the port should block or forward outgoing DCP frames. The following options are available:
  - forward
    DCP frames are forwarded at this port.
  - block
    No outgoing DCP frames are forwarded at this port. It is nevertheless still possible to receive via this port.

LLDP

Identifying the network topology

LLDP (Link Layer Discovery Protocol) is defined in the IEEE 802.AB standard.

LLDP is a method used to discover the network topology. Network components exchange information with their neighbor devices using LLDP.

Network components that support LLDP have an LLDP agent. The LLDP agent sends information about itself and receives information from connected devices at periodic intervals. The received information is stored in the MIB.

Applications

PROFINET uses the LLDP protocol for topology diagnostics. In the default setting, LLDP is enabled for all ports; in other words, LLDP frames are sent and received on all ports. With this function, you have the option of enabling or disabling sending and/or receiving per port.

Settings

Table 1 has the following columns:

- 1st column
  Shows that the setting is valid for all ports of table 2.
- Setting
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- Transfer to table
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- Port
  Shows the port.
- Setting
  Select whether or not the port will send or receive LLDP frames. The following options are available:
  - Rx
    This port can only receive LLDP frames.
  - Tx
    This port can only send LLDP frames.
  - Rx & Tx
    This port can receive and send LLDP frames.
  - "-" (disabled)
    This port can neither receive nor send LLDP frames.

FMP

Requirements

- To be able to use the Fiber Monitoring (FM) function, enable LLDP. The FM information is appended to the LLDP packets.
- You can only use Fiber Monitoring with transceivers capable of diagnostics. Devices and modules with transceivers capable of diagnostics have the supplement "FM" in the name.

Monitoring optical links

With Fiber Monitoring, you can monitor optical links.

If you enable FM on an optical port, diagnostics information is sent via the port. In addition to sending, there is also a check to establish whether information is being received.

Regardless of whether the IE switch receives diagnostics information, it monitors the received power and compares it with selectable power limits.

If you connect two IE switches via optical ports with FM enabled, they exchange their diagnostics information. This also allows a power loss to be calculated. The power loss is also compared with selectable power limits.

If the value of the received power or the power loss falls below a specified limit, an event is triggered. In "System > Events > Configuration", you can specify how the IE switch indicates the event.

Settings

- **Port**
  Shows the available optical ports that support fiber monitoring. This depends on the transceivers.
- **State**
  Enable or disable FM. As default, the function is enabled.
- **Rx Power [dBm] maintenance required (warning)**
  Specify the value at which you are informed of the deterioration of the received power by a message of the severity level “Warning"
  The default value depends on the relevant pluggable transceiver.
- **Rx Power [dBm] maintenance demanded (critical)**
  Specify the value at which you are informed of the deterioration of the received power by a message of the severity level “Critical"
  The default value depends on the relevant pluggable transceiver.
- **Power Loss [dB] maintenance required (warning)**
  Enter the value at which you want to be informed about the power loss of the connection the first time.
- **Power Loss [dB] maintenance demanded (critical)**
  Enter the value at which you want to be informed about the power loss of the connection the second time.

Unicast

Filter

Address filtering

This page shows the current content of the unicast filter table. This table lists the source addresses of unicast address frames. The displayed entries were made statically, in other words, the user set them.

On this page, you also define the static unicast filters.

Settings

- **VLAN ID**
  Select the VLAN ID in which you configure a new static MAC address. If nothing is set, "VLAN1" is set as the basic setting.
- **MAC Address**
  Enter the MAC address here.

This table contains the following columns:

- **VLAN ID**
  Shows the VLAN-ID assigned to this MAC address.
- **MAC Address**
  Shows the MAC address of the node that the device has learned or the user has configured.
- **Status**
  Shows the status of each address entry:
  - static
    Configured by the user. Static addresses are stored permanently; in other words, they are not deleted when the aging time expires or when the switch is restarted.
- **Port**
  Shows the port via which the node with the specified address can be reached. Frames received by the device whose destination address matches this address will be forwarded to this port.

Note

You can only specify **one** port for unicast addresses.

Learning

Starting/stopping learning

Note

The page is only available if there is an online connection to the device.

With the automatic learning function, all connected devices are automatically entered in the unicast filter table. As long as the "Start learning" function is enabled, all learned unicast addresses are created immediately as static unicast entries.
The learning process is ended only after clicking the "Stop learning" button. With this method, learning can take a few minutes or several hours in larger networks before all nodes have really been learned. Only nodes that send packets during the learning phase are found.
By subsequently enabling the Port Lock function, only packets from the nodes known after the end of the learning phase (static unicast entries) will be accepted at the relevant ports.

Note

If the Port Lock function was already active on individual ports prior to the automatic learning phase, no addresses will be learned on these ports. This makes it possible to restrict learning to certain ports. To do this, first enable the Port Lock function of the ports that are not intended to learn addresses.

Settings

- **Start learning**
  Click the "Start learning" button to start the learning phase.
  The device now enters the addresses of connected devices until you stop the function.
- **Stop learning**
  Click the "Stop Learning" button to stop the learning phase.
  The learned entries are stored.
- **Deleting all static unicast addresses**
  Click the "Clear all static unicast addresses" button to delete all static entries.
  In large networks with numerous nodes, automatic learning may lead to a lot of undesired static entries. To avoid having to delete these individually, this button can be used to delete all static entries. This function is disabled during automatic learning.

  Note

  Depending on the number of entries involved, deleting may take some time.

Locked ports

Activating the access control

On this page, you can block individual ports for unknown nodes.

If the Port Lock function is enabled, packets arriving at this port from unknown MAC addresses are discarded immediately. Packets from known nodes are accepted by the port.
Since ports with the port lock function enabled cannot learn any MAC addresses, learned addresses on these ports are automatically deleted after the port lock function is enabled.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Enable or disable access the port lock function for the port.

Blocking

Blocking forwarding of unknown unicast frames

On this page, you can block the forwarding of unknown unicast frames for individual ports.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Enable or disable the blocking of unicast frames

Multicast

Groups

Multicast applications

In the majority of cases, a frame is sent with a unicast address to a particular recipient. If an application sends the same data to several recipients, the amount of data can be reduced by sending the data using one multicast address. For some applications, there are fixed multicast addresses (NTP, IETF1 Audio, IETF1 Video etc.).

Reducing network load

In contrast to unicast frames, multicast frames represent a higher load for the device. Generally, multicast frames are sent to all ports. There are three ways of reducing the load caused by multicast frames:

- Static entry of the addresses in the multicast filter table.
- Dynamic entry of the addresses by listening in on IGMP parameter assignment frames (IGMP Configuration).
- Active dynamic assignment of addresses by GMRP frames.

The result of all these methods is that multicast frames are sent only to ports for which an appropriate address is entered.

“Information > Multicast" shows the multicast frames currently entered in the filter table and their destination ports. The displayed entries were made statically, in other words, the user set them.

Settings

- VLAN ID
  Select the VLAN ID to be assigned to the MAC multicast address.
- MAC Address
  Here you enter a new MAC multicast address you want to configure.

The table has the following columns:

- VLAN ID
  Shows VLAN ID of the VLAN to which the MAC multicast address is assigned.
- MAC Address
  Shows the MAC multicast address that the device has learned or the user has configured.

- **Status**
  Shows the status of each address entry.
  - Static
    The address was entered statically by the user. Static addresses are stored permanently; in other words, they are not deleted when the aging time expires or when the device is restarted. These must be deleted by the user.
- **List of ports**
  There is a column for each slot. Within a column, the multicast group to which the port belongs is shown. The following selections are possible:
  - M (Member)
    Multicast frames are sent via this port.
  - F (Forbidden)
    Not a member of the multicast group. Moreover, this address must not be an address learned dynamically with GMRP or IGMP/MLD.
  - -
    Not a member of the multicast group. No multicast frames with the defined multicast MAC address are sent via this port

IGMP

Function

IE switches support "IGMP snooping" and the IGMP querier function. If "IGMP snooping" is enabled, IGMP frames are evaluated and the multicast filter table is updated with this information. If "IGMP Querier is also enabled, IE switches also send IGMP queries that trigger responses from IGMP-compliant nodes.

IGMP Snooping Aging Time

In this menu, you can configure the aging time for IGMP Configuration. When the time elapses, entries created by IGMP are deleted from the address table if they are not updated by a new IGMP frame.

This applies to all ports; a port-specific configuration is not possible.

IGMP Snooping Aging Time depending on the querier

SCALANCE XR500 as IGMP querier:

If a SCALANCE XR500 is used as an IGMP querier, the query interval is 125 seconds. For the "IGMP Snooping Aging Time", set at least 250 seconds.

Other IGMP queriers

If a different IGMP querier is used, the value of the "IGMP Snooping Aging Time" should be at least twice as long as the query interval.

Settings

- **IGMP Snooping**
  Enable or disable IGMP (Internet Group Management Protocol). The function allows the assignment of IP addresses to multicast groups. If the check box is selected, IGMP entries are included in the table and IGMP frames are forwarded.
- **IGMP Snooping Aging Time**
  Enter the value for the aging time in seconds in this box.
- **IGMP Querier**
  Enable or disable "IGMP Querier". The device sends IGMP queries.

GMRP

Enabling GMRP

By selecting the check box, you specify whether or not GMRP is used for each individual port. If "GMRP" is disabled for a port, no registrations are made for it and it cannot send GMRP frames.

Settings

- **GMRP**
  Enable or disable the GMRP function.

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports and the link aggregations.
- **Setting**
- Enable or disable GMRP for the port or for the link aggregation.

Blocking

On this page, you can block the forwarding of unknown multicast frames for individual ports.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  Enable or disable the blocking of multicast frames.

MLD

Mulitcast Listener Discovery

Devices support "MLD snooping" and the "MLD querier" function. If "MLD snooping" is enabled, MLD frames are evaluated and the multicast filter table is updated with this information. If "IGMP querier is also enabled, IE switches also send MLD queries that trigger responses from MLD-compliant nodes.

With MLD snooping, MLD frames are only forwarded to the intended multicast listeners instead of being flooded to all ports.

For MLD snooping to work, you need to enable the function globally and in the VLANs.

MLD Snooping Aging Time

On this page, you can configure the aging time for MLD configuration. When the time elapses, entries created by MLD are deleted from the address table if they are not updated by a new MLD packet.

This applies to all VLANS; a VLAN-specific configuration is not possible.

Settings

- **MLD Snooping**
  Enable or disable MLD on the device.
- **MLD Snooping Aging Time**
  Enter the time after which entries generated by MLD are deleted from the multicast filter table. Assuming that this is not updated by a new MLD packet.
  This applies to all VLANS; a VLAN-specific configuration is not possible

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all VLANs of table 2.
- **Snooping / Querier**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Copy to Table**
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- **VLAN**
  Shows the VLAN to which the settings relate
- **Snooping**
  Enable or disable MLD for the required VLAN. When enabled, the MLD entries are included the multicast filter table and MLD packets are forwarded.
- **Querier**
  Enable or disable sending of MLD queries

Broadcast

Blocking the forwarding of broadcast frames

On this page, you can block the forwarding of broadcast frames for individual ports.

Note

Some communication protocols work only with the support of broadcast. In these cases, blocking can lead to loss of data communication. Block broadcast only when you are sure that you do not need it.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  All available ports and the link aggregations are shown.
- **Setting**
  Enable or disable the blocking of broadcast frames.

PTP

General

Note

The following devices support time-of-day synchronization with PTP:

- SCALANCE XR528-6M
- SCALANCE XR552-12M

IEEE 1588 with SCALANCE devices

The IEEE 1588v2 standard defines mechanisms with which highly precise time-of-day synchronization of devices in a network can be achieved. SCALANCE devices with suitable hardware support time synchronization according to IEEE 1588v2.

The functionality is disabled on these devices when they are shipped and following a "Reset to factory defaults". To be able to use PTP, enable this function and configure every port that is on the synchronization path as well as ports that are blocked due to redundancy mechanisms. PTP can also be used with redundancy mechanisms in the ring such as HRP, standby linking of rings, MRP and RSTP.

Setting

- **1588 Mode**
  You can make the following settings:
  - **off**
    The device does not process any PTP messages. PTP messages are, however, forwarded according to the rules of the device.
  - **transparent**
    The device adopts the function of a transparent clock and forwards PTP messages to other nodes while at the same time making entries in the correction field of the PTP message.

TC general

1588 Transparent Clock

On this page, you specify the general settings for PTP.

Settings

- **Delay Mechanism**
  Specify the delay mechanism the device will work with:
  - End-to-end(delay request response mechanism will be used)

    Note

    With end-to-end synchronization with more than 2 slaves, freak values > 100 ns can occur in the offset.

  - Peer-to-peer (peer delay mechanism will be used)
- **Domain Number**
  Enter the domain number for the device. The device ignores PTP messages with a different domain number. A SCALANCE device can only be assigned to one synchronization domain.

TC port

On this page, you specify the ports that can process PTP messages.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports of table 2.
- **Setting / Transport Mechanism**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports.
- **Setting**
  The port status. The following entries are possible:
  - Enabled
    The port is not involved in PTP.
  - Disabled
    The port processes PTP messages.

- **Faulty Flag**
  Shows error status relating to PTP.
  - true
    An error occurred.
  - false
    No error has occurred on this port.
- **Transport Mechanism**
  Specifies the protocol for transferring the PTP messages. This protocol must also be supported by the communications partner of the port
  - Ethernet
  - UDP IPv4

RMON

Statistics

Statistics

On this page you can specify the ports for which RMON statistics are displayed. The RMON statistics are shown on the page “Information > Ethernet Statistics” in “Packet Size”, “Frame Type” and “Packet Errror”.

Settings

- **RMON**
  When enabled, Remote Monitoring (RMON) allows diagnostics data to be collected on the device, prepared and read out using SNMP by a network management station that also supports RMON. This diagnostic data, for example port-related load trends, allow problems in the network to be detected early and eliminated.

  Note

  If you disable RMON, these statistics are not deleted but retain their last status.

- **Port**
  Select the ports for which statistics will be displayed.

The table has the following columns:

- **Port**
  Shows the ports for which statistics will be displayed.

History

Samples of the statistics

On this page, you can specify whether or not samples of the statistics are saved for a port. You can specify how many entries should be saved and at which intervals samples should be taken.

Settings

Table 1 has the following columns:

- 1st column
  Shows that the settings are valid for all ports.
- Setting/Buckets/Interval
  Select the required settings. If "No Change" is selected, the entry in table 2 remains unchanged.
- Transfer to table
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- Port
  Shows the port to which the settings relate.
- Setting
  Enable or disable the recording of the history on the relevant port.
- Entries
  Enter the maximum number of samples to be stored at the same time.
- Interval [s]
  Enter the interval after which the current status of the statistics will be saved as a sample.

Configuring layer 3 functions for IPv4

Configuration

The page contains the overview of the layer 3 functions for IPv4 of the device. On this page, you enable or disable the required layer 3 function.

The functions "Routing", "VRRP", "RIP" and "OSPF" are only available with layer 3.

Settings

- **Routing**(only available with devices with a layer 3 license)
  - Enabled
    IPv4 routing is enabled. You can only enable the routing function if DHCP is disabled on all configured interfaces.
  - Disabled
    IPv4 routing is disabled. If IPv6 routing is enabled on the device, this is also disabled.
- **DHCP Relay Agent**
  Enable or disable the DHCP relay agent. You can configure other settings in "Layer 3 (IPv4)> DHCP Relay Agent".
- **VRRP** (only available with devices with a layer 3 license)
  Enable or disable routing using VRRP. To use VRRP, first enable the routing function. You can configure other settings in "Layer 3 (IPv4) > VRRP".
- **OSPF** (only available with devices with a layer 3 license)
  Enable or disable routing using VRRP. To use VRRP, first enable the routing function. You can configure other settings in "Layer 3 (IPv4) > VRRP".
- **RIP** (only available with devices with a layer 3 license)
  Enable or disable routing using RIP. To use RIP , first enable the routing function. You can configure other settings in "Layer 3 (IPv4) > RIP".

Subnets

Overview (IPv4)

Subnet

The page shows the subnets for the selected interface. If more than one subnet is available on an interface, the first entry of this interface is of the address type "Primary". All other subnets have the address type "Secondary".

A subnet always relates to an interface. You configure the interface in "Layer 3 (IPv4) > Configuration".

Settings

- **Interface**
  Select the interface on which you want to configure another subnet.

The table has the following columns:

- **Interface**
  Shows the interface.
- **TIA Interface**
  Shows whether or not the entry is a TIA interface.
- **Interface Name**
  Shows the name of the interface.

- **MAC Address**
  Shows the MAC address.
- **IP Address**
  Shows the IPv4 address of the subnet.
- **Subnet Mask**
  Shows the subnet mask.
- **Address Type**
  Shows the address type. The following values are possible:
  - Primary
    The first IPv4 address that was configured on an IP interface.
  - Secondary
    All other IPv4 addresses that were configured on an interface.
- **IP Assignment Method**
  Shows how the IPv4 address is assigned.
  - Static
    The IP address is static. You enter the IP settings in "IP Address" and "Subnet Mask".
  - Automatic (DHCP)
    The device obtains a dynamic IPv4 address from a DHCP server.
- **Address Collision Detection Status**
  If new IPv4 addresses become active in the network, this function checks whether this can result in address collisions. With this function, IPv4 addresses that will be assigned twice can be detected.
  Shows the status of the "Detection of address collisions" function.

  Note

  The function does not run a cyclic check.

  - Idle
    The interface is not enabled and does not have an IP address.
  - Starting
    This status indicates the start-up phase. In this phase, the device initially sends a query as to whether the planned IP address already exists. If the address is not yet been assigned, the device sends the message that it is using this IP address as of now.
  - Conflict
    The interface is not enabled. The interface is attempting to use an IP address that is already been assigned.
  - Defending
    The interface uses a unique IP address. Another interface is attempting to use the same IP address.
  - Active
    The interface uses a unique IP address. There are no collisions.
  - Not supported
    The function for detection of address collisions is not supported.

Configuration

On this page, you configure the subnet. You create the subnet in "Layer 3 > Subnets > Overview".

Settings

- **Interface (Name)**
  Select the required interface.
- **Interface Name**
  Enter a name for the interface.
- **MAC Address** (only available online)
  Shows the MAC address of the selected interface
- **DHCP**
  Enable or disable the DHCP client for this IPv4 interface.

  Note

  If you want to operate the device as a router with several interfaces, disable DHCP on all interfaces.

- **IP Address**
  Enter the IPv4 address of the subnet. The IPv4 address must not be used more than once.
- **Subnet Mask**
  Enter the subnet mask of the subnet you are creating. Subnets on different interfaces must not overlap.
- **Address Type**
  Shows the address type. The following values are possible:
  - Primary
    The first subnet of the interface.
  - Secondary
    All other subnets of the interface.
- **TIA Interface**
  Enable or disable the setting.
  The following conditions apply to the TIA interface:
  - Only interfaces with the address type "Primary" can be enabled as the TIA interface.
  - There must only ever be one TIA interface.
  - There can only be one TIA interface.
  - A TIA interface is always a VLAN interface.

TIA interface and PROFINET interface

The IP address of the TIA interface is linked to the IP address located in the parameter group "Properties > General > PROFINET interface > Ethernet addresses".

Both IP addresses always have the same value. If you change the value of one IP address, the other IP address changes accordingly.

TIA Interface

The TIA interface is the interface via which all PROFINET functions of the IE switch are handled.

TIA interface is the name of the IP address for PROFINET from the perspective of the IE switch.

PROFINET interface

You make the IP setting of the PROFINET device in TIA under PROFINET interface.

PROFINET interface is the name of the IP address for PROFINET from the perspective of the TIA Portal.

Static Routes (IPv4)

Static route

On this page, you create the static IPv4 routes.

Settings

- **Destination Network**
  Enter the network address of the destination that can be reached via this route.
- **Subnet Mask**
  Enter the corresponding subnet mask.
- **Gateway**
  Enter the IPv4 address of the gateway via which this network address is reachable.
- **Metric**
  Enter the metric for the route. The metric corresponds to the quality of a connection, for example speed, costs. If there are several equal routes, the route with the lowest metric value is used.

The table has the following columns:

- **Destination Network**
  Shows the network address of the destination.
- **Subnet Mask**
  Shows the corresponding subnet mask.
- **Gateway**
  Shows the IPv4 address of the next gateway.
- **Interface** (only available online)
  Shows the Interface of the route.
- **Metric**
  Enter the metric for the route. When creating the route, "not used" is entered automatically. The metric corresponds to the quality of a connection, for example speed, costs. If there are several equal routes, the route with the lowest metric value is used.
- **State** (only available online)
  Shows whether or not the route is active.

Route maps

General (IPv4)

Route maps

With route maps, you control how routing information is further processed. You can filter routing information and specify whether the information is further processed, modified or discarded.

Route maps operate according to the following principle:

- Routing information is compared with the filters of the route maps.
- The comparison is continued until the filters of a route map match the properties of an item of information.
- The information is then processed according to the route map settings:
  - The routing information is discarded.
  - The properties of the routing information are changed.

Settings

- **Name**
  Enter the name for the route map.
- **Sequence No**
  Enter a number for the route map.
  You can create several route maps with the same name but with different sequence numbers. The sequence numbers then specify the order in which the route maps are processed.

The table has the following columns:

- **Name**
  Shows the name of the route map.
- **Sequence No**
  Shows the sequence number of the route map.
- **Action**
  Specify what happens to the routing information that matches the settings of the route map:
  - permit
    The routing information is further processed according to the settings you make on the "Set" page.
  - deny
    The routing information is discarded.

Interface & Value Match (IPv4)

On this page, you specify whether or not the routing information for a route map is filtered according to interfaces, metric or tags.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.
  The created route maps are available to you.
- **Type**
  Select the basis for the filtering:
  - Interface
  - Metric
  - Tag
- **Interface**
  Select an interface.
  Only active if you have selected the "Interface" entry for "Type".
- **Metric**
  Enter a value for the metric.
  Only active if you have selected the "Metric" entry for "Type".
- **Tag**
  Enter a value for the tag.
  Only active if you have selected the "Tag" entry for "Type".
- **Route Type**
  Select the type of the route.
  - Local
    The routing information for the route map is filtered according to directly connected routes (local interfaces).
  - Remote
    The routing information for the route map is filtered according to learned or statically configured routes.

  This box is active only if i you have selected the entry "Route Type in the "Type" drop-down list.

The table has the following columns:

- **Type**
  Shows the selected type:
  - Interface
  - Metric
  - Tag
  - Route Type
- **Value**
  Shows the selected interface, the value of the metric or of the tag.

Destination Match (IPv4)

On this page, you specify whether or not the routing information for a route map is filtered based on the destination IPv4 address.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.
- **IP Address**
  Enter the IPv4 address of the destination on which the filtering is based.
- **Subnet Mask**
  Enter the subnet mask of the destination on which the filtering is based.

The table has the following columns:

- **IP Address**
  Shows the IPv4 address of the destination.
- **Subnet mask/prefix**
  Shows the subnet mask of the destination.

Next Hop Match (IPv4)

On this page, you specify whether or not the filtering for a route map will be based on the router to which the routing information is sent next.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.
- **IP Address**
  Enter the IP address of the router to which the routing information will be sent next.

The table has the following columns:

- **IP Address**
  Shows the IP address of the next router.

Set (IPv4)

On this page, you specify whether or not the routing information will be changed by a route map.

If, for example, you have filtered based on a certain metric, you can change the value of the metric here. The routing information is then forwarded with the new value. You can only change the information of a "Permit" route map.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.

The table has the following columns:

- **Name**
  Shows the name of the route map.
- **Sequence No**
  Shows the sequence number of the route map.
- **Metric**
  Enter the new value for the metric with which the routing information will be forwarded.
- **Tag**
  Enter the new value for the tag with which the routing information will be forwarded.

DHCP Relay Agent

General

If the DHCP server is in a different network, the device cannot reach the DHCP server. The DHCP relay agent intercedes between a DHCP server and the device. The DHCP relay agent forwards the port number of the device with the DHCP query to the DHCP server. If a DHCP server is unreachable, the device can switch to a different DHCP server.

Settings

- **DHCP Relay Agent (Opt. 82)**
  Enable or disable the DHCP relay agent.
- **Server IP Address**
  Enter the IPv4 address of the DHCP server.

The table has the following columns:

- **Server IP Address**
  Shows the IPv4 address of the DHCP server.

Option

Parameters of the DHCP relay agent

On this page, you can specify parameters for the DHCP server, for example the circuit ID. The circuit ID describes the origin of the DHCP query, for example which port received the DHCP query.

You specify the DHCP server on the "General" tab.

Settings

Global configuration

- **Circuit ID router index**
  Enable or disable the setting. When enabled, the router index is added to the generated circuit ID.
- **Circuit ID recipient VLAN ID**
  Enable or disable the setting. When enabled, the VLAN ID is added to the generated circuit ID.
- **Circuit ID receiving port**
  Enable or disable the setting. When enabled, the receiving port is added to the generated circuit ID.

  Note

  You need to select a least one option.

- **Remote ID**
  Shows the device ID.

Interface-specific configuration

- **Interface**
  Select the required IPv4 interface.

The table has the following columns:

- **Interface**
  Shows the interface.

  Note

  If you have not created an interface-specific configuration, the global configuration with the MAC address is used as the device ID.

- **Remote ID type**
  Select the type of the device ID. You have the following options:
  - IP Address
    The IPv4 address of the device is used as the device ID.

    Note

    No automatic updating

    There is no link between the "Remote ID" box and the currently set IP address.

    If the IP address is changed, the new IP address is not entered in the "Remote ID" box automatically. Only the value of the "Remote ID Type" box changes to "Free Text". To use the current IP address again, select "IP Address" again in the "Remote ID Type" box.

  - MAC Address
    The MAC address of the device is used as the device ID.
  - Free Text
    If you use "Free Text", you can enter the device name as the device identifier in the "Remote ID" box.
- **Remote ID**
  Enter the device name. Can only be edited if you select the entry "Free Text" for "Remote ID Type".
- **Circuit ID Type**
  Select the type of circuit ID from the drop-down list. You have the following options:
  - Predefined
    The circuit ID is created automatically based on the router index, VLAN ID or port.
  - Free Number
    If you use "Free Number", you can enter the ID for "Circuit ID".
- **Circuit ID**
  Enter the circuit ID. Can only be edited if you select the "Free Number" entry for the "Circuit ID Type".

VRRP

Router

On this page, you create virtual routers. You can configure other parameters in "Layer 3 (IPv4) > VRRP > Configuration".

Note

- VRRP is available only on layer 3.
- VRRP can only be used in conjunction with VLAN interfaces. Router ports are not supported.
- Simultaneous operation of VRRP and VRRPv3 is not possible.
- Select "VRRP" to configure VRRP

Settings

The following settings are available:

- **VRRP**
  Enable or disable routing using VRRP.
- **Reply to pings on virtual interfaces**
  When enabled, the virtual IPv4 addresses also reply to the ping.
- **Track**
  Enable or disable VRID tracking.
  When enabled, all interfaces of a VRID are monitored. When the link of an interface changes from "up" to "down", the priority of all VRRP interfaces with the same VRID is reduced to the value "0".
  When the link of an interface changes back from "down" to "up", the original priority of the VRRP interfaces is restored.
- **Interface**
  Select the required VLAN interface operating as virtual router.
- **VRID**
  Enter the ID of the virtual router. This ID defines the group of routers that form a virtual router (VR). In the group, this is the same. it can no longer be used for other groups.

The table has the following columns:

- **Interface**
  Shows the Interface that functions as the virtual router.
- **VRID**
  Shows the ID of the virtual router.
- **Virtual MAC Address**
  Shows the virtual MAC address of the virtual router.
- **Primary IP Address**
  Shows the numerically lowest IPv4 address in this VLAN. The entry 0.0.0.0 means that the "Primary" address on this VLAN is used. Otherwise all IPv4 addresses configured in this VLAN in "Layer 3 (IPv4) > Subnets" are valid values.

- **Router Status**
  Shows the current status of the virtual router. Possible values are as follows:
  - Master
    The router is the master router and handles the routing functionality for all assigned IP addresses.
  - Backup
    The router is the backup router. If the master router fails, the backup router takes over the tasks of the master router.
  - Initialize
    The virtual router has just been turned on. It will soon change to the "Master" or "Backup" status.
- **Master IP Address** (only available online)
  Shows the IPv4 address of the master router.
- **Priority**
  Shows the priority of the virtual router.
  If an IPv4 address is assigned to the VRRP router that is also actually configured on the local IPv4 interface, the value 255 is entered automatically. All other priorities can be distributed freely among the VRRP routers. The higher the priority, the earlier the VRRP router becomes "Master".
- **Advert. Interval**
  Shows the interval at which the master router sends VRRP packets.
- **Preempt**
  Shows the precedence of a router when changing roles between backup and master.
  - yes
    This router has precedence when changing roles.
  - no
    This router does not have precedence when changing roles.

Configuration

Introduction

On this page, you configure the virtual router.

Note

VRRP is available only on layer 3.

Description of the displayed values

The page contains the following boxes:

- **Interface / VRID**
  Select the ID of the virtual router to be configured.
- **Primary IP Address**
  Select the numerically lowest IPv4 address: If the router becomes master router, the router uses this IPv4 address.

  Note

  If you only configure one subnet on this VLAN, no entry is necessary. The entry is then 0.0.0.0.
  If you configure more than one subnet on the VLAN and you want a specific IPv4 address to be used as the source address for VRRP packets, select the IPv4 address from the drop-down list. Otherwise, the numerically lowest IPv4 address will be used.

- **Master**
  If this option is enabled, the numerically lowest IPv4 address is entered for "Associated IP Address". This means that the highest priority IPv4 address of the VRRP router is used as the virtual IP address of the virtual master router. The backup routers in this group must disable the option and use the IPv4 address of the router in "Associated IP address".
- **Priority**
  Enter the priority of this virtual router.
  If an IPv4 address is assigned to the VRRP router that is also actually configured on the local IPv4 interface, the value 255 is entered automatically. All other priorities can be distributed freely among the VRRP routers. The higher the priority, the earlier the VRRP router becomes "Master".
- **Advertisement Interval**
  Enter the interval in seconds after which a master router sends a VRRP packet again.
- **Preempt lower priority Master**
  Allow the precedence when changing roles between backup and master based on the selection process.
- **Track ID**
  Select a track ID.
- **Decrement Priority**
  Enter the value by which priority of the VRRP interface will be reduced.
- **Current Priority**
  Shows the priority of the VRRP interface after the monitored interface has changed to the "down" status.

Address overview

Overview

This page shows which IPv4 addresses the virtual router monitors.

Note

VRRP is available only on layer 3.

Settings

The table has the following columns:

- **Interface**
  Shows the Interface that functions as the virtual router.
- **VRID**
  Shows the ID of this virtual router.
- **Number of Addresses**
  Shows the number of IPv4 addresses.
- **Associated IP Address (1) ... Associated IP Address (4)**
  Shows the router IPv4 addresses monitored by this virtual router. If a router takes over the role of master, the routing function is taken over by this router for all these IPv4 addresses.

Address configuration

Note

VRRP is available only on layer 3.

Settings

The following settings are possible:

- **Interface / VRID**
  Select the required virtual router.
- **Associated IP Address**
  Enter the IPv4 address that the virtual router will monitor.

The table has the following columns:

- **Associated IP Address**
  Shows the IPv4 addresses that the virtual router monitors.

Interface Tracking

Introduction

On this page, you configure the monitoring of interfaces.

When the link of a monitored interface changes from "up" to "down", the priority of the assigned VRRP interface is reduced. You configure the value by which the priority is reduced on the page "Layer 3 > VRRP/VRRPv3 > Configuration".

When the link of the interface changes back from "down" to "up", the original priority of the VRRP interface is restored.

Note

This function is available only with layer 3.

Description of the displayed values

The page contains the following boxes:

- **Interface**
  From the drop-down list, select the interface to be monitored.
- **Track ID**
  Enter a track ID.
- **Track ID**
  Select a track ID.
- **Track Interface Count**
  Enter how many monitored interfaces need to change to the "down" status, before the priority is changed.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Track ID**
  Shows the track ID.
- **Interface**
  Shows the interface that is being monitored.

VRRPv3

Router (IPv4)

Introduction

On this page, you create new virtual routers. You can configure other parameters in "Layer 3 (IPv4) > VRRPv3 > Configuration".

Note

- This function is available only with layer 3.
- Simultaneous operation of VRRP and VRRPv3 is not possible.
- Select the "VRRPv3" check box to configure VRRPv3.
- You can use VRRPv3 on VLAN interfaces. Router ports are not supported.

Settings

- **VRRPv3**
  Enable or disable routing using VRRPv3. Can only be enabled when "Layer 3 (IPv6) > Configuration" "IPv6 Routing" is enabled.
- **Reply to pings on virtual interfaces**
  When enabled, the virtual IPv4 addresses also reply to the ping.
- **Track**
  Enable or disable VRID tracking.
  When enabled, all interfaces of a VRID are monitored. When the link of an interface changes from "up" to "down", the priority of all VRRP interfaces with the same VRID is reduced to the value "0".
  When the link of an interface changes back from "down" to "up", the original priority of the VRRP interfaces is restored.
- **Interface**
  Select the required VLAN interface operating as virtual router.
- **VRID**
  Enter the ID of the virtual router. This ID defines the group of routers that form a virtual router (VR). In the group, this is the same. It can no longer be used for other groups.

The table has the following columns:

- **Interface**
  Shows the IPv4 interface that functions as the virtual router.
- **VRID**
  Shows the ID of the virtual router.
- **Virtual MAC Address**
  Shows the virtual MAC address of the virtual router.

- **Primary IP Address**
  Shows the numerically lowest IPv4 address in this VLAN. The entry 0.0.0.0 means that the "Primary" address on this VLAN is used. Otherwise all IPv4 addresses configured on this VLAN in the "Layer 3 (IPv4) > Subnets" menu are valid values.
- **Router State**
  Shows the current status of the virtual router. Possible values are:
  - Master
    The router is the master router and handles the routing functionality for all assigned IPv4 addresses.
  - Backup
    The router is the backup router. If the master router fails, the backup router takes over the tasks of the master router.
  - Initialize
    The virtual router has just been turned on. It will soon change to the "Master" or "Backup" state.
- **Master IP Address**
  Shows the IPv4 address of the master router.
- **Priority**
  Shows the priority of the virtual router.
  If an IPv4 address is assigned to the VRRP router that is also actually configured on the local IPv4 interface, the value 255 is entered automatically. All other priorities can be distributed freely among the VRRP routers. The higher the priority, the earlier the VRRP router becomes "Master".
- **Advert. Interval**
  Shows the interval at which the master router sends VRRPv3 packets.
- **Preempt**
  Shows the precedence of a router when changing roles between backup and master.
  - yes
    This router has precedence when changing roles.
  - no
    This router does not have precedence when changing roles.

Configuration (IPv4)

Introduction

On this page, you configure the virtual router.

Note

This function is available only with layer 3.

Settings

The page contains the following:

- **Interface / VRID**
  Select the ID of the virtual router to be configured.
- **Primary Address**
  Select the primary IPv4 address. If the router becomes master router, the router uses this IPv4 address.

  Note

  If you only configure one subnet on this VLAN, no entry is necessary. The entry is then 0.0.0.0.
  If you configure more than one subnet on the VLAN and you want a specific IPv4 address to be used as the source address for VRRP packets, select the IPv4 address. Otherwise, the numerically lowest IPv4 address will be used.
- **Master**
  If enabled, the numerically lowest IPv4 address is entered for "Associated IP Address". This means that the numerically lowest IPv4 address of the VRRP router is used as the virtual IP address of the virtual master router. The backup routers in this group must disable the option and use the IPv4 address of the router in "Associated IP address".
- **Priority**
  Enter the priority of this virtual router. Valid values are 1-254.
  If an IPv4 address is assigned to the VRRPv3 router that is also actually configured on the local IPv4 interface, the value 255 is entered automatically. All other priorities can be distributed freely among the VRRPv3 routers. The higher the priority, the earlier the VRRPv3 router becomes "Master".
- **Advertisement interval**
  Enter the interval in seconds after which a master router sends a VRRPv3 packet again.
- **Preempt lower priority Master**.
  Allow precedence when changing roles between backup and master based on the selection process.
- **VRRP Compatible Mode**
  When enabled, the VRRPv3 router also sends and receives VRRPv2 frames in addition to VRRPv3 frames for configured IPv4 addresses. Only necessary when some VRRP routers do not support VRRPv3
- **Track ID**
  Select a track ID.
- **Decrement Priority**
  Enter the value by which priority of the VRRP interface will be reduced.
- **Current Priority**
  Shows the priority of the VRRP interface after the monitored interface has changed to the "down" status.

Addresses Overview (IPv4)

Overview

This page shows which IPv4 addresses the virtual router monitors. Each virtual router can monitor a maximum of 10 IPv4 addresses.

Note

This function is available only with layer 3.

Settings

The table has the following columns:

- **Interface**
  Shows the Interface that functions as the virtual router.
- **VRID**
  Shows the ID of this virtual router.
- **Number of Addresses**
  Shows the number of IPv4 addresses.
- **Associated IP Address (1) ...Associated IP Address (10)**
  Shows the router IPv4 addresses monitored by this virtual router. If a router takes over the role of master, the routing function is taken over by this router for all these IPv4 addresses.

Addresses Configuration (IPv4)

Creating or changing the monitored IP addresses

On this page, you can create, modify or delete the IPv4 addresses to be monitored.

Note

This function is available only with layer 3.

Settings

The page contains the following:

- **Interface / VRID**
  Select the ID of the virtual router.
- **Associated IP Address**
  Enter the IPv4 address that the virtual router will monitor.

The table has the following columns:

- **Associated IP Address**
  Shows the IPv4 addresses that the virtual router monitors.

Interface Tracking (IPv4)

Introduction

On this page, you configure the monitoring of interfaces.

When the link of a monitored interface changes from "up" to "down", the priority of the assigned VRRP interface is reduced. You configure the value by which the priority is reduced on the page "Layer 3 > VRRP/VRRPv3 > Configuration".

When the link of the interface changes back from "down" to "up", the original priority of the VRRP interface is restored.

Note

This function is available only with layer 3.

Description of the displayed values

The page contains the following boxes:

- **Interface**
  From the drop-down list, select the interface to be monitored.
- **Track ID**
  Enter a track ID.
- **Track ID**
  Select a track ID.
- **Track Interface Count**
  Enter how many monitored interfaces need to change to the "down" status, before the priority is changed.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Track ID**
  Shows the track ID.
- **Interface**
  Shows the interface that is being monitored.

OSPFv2

Configuration

Introduction

On this page, you configure routing with OSPF.

Note

OSPF is available only on layer 3.

Settings

- **OSPFv2**
  Enable or disable routing using OSPFv2.
- **Router ID**
  Enter the name of one of the OSPFv2 interfaces. The name is entered in the IP address format and does not need to match the local IP address.
- **OSPFv2 RFC1583 Compatibility**
  Enable the option if you still have old OSPFv2 routers in operation that are not compatible with RFC 2328.
- **Border Router**
  Displays the status of the OSPFv2 router. If the local system is an active member in at least 2 areas, this is an area border router.
- **AS Border Router**
  Specify whether the router is an AS border router. An AS border router intercedes between multiple autonomous systems, for example if you have an additional RIP network. An AS border router is also necessary to add and to distribute static routes.
- **New LSA Received** (only available online)
  Shows the number of received LSAs.
  Updates and local LSAs are not counted.
- **New LSA Configured** (only available online)
  Number of different LSAs sent by this local system.
- **External LSA Maximum**
  To limit the number of entries of external LSAs in the database, enter the maximum number of external LSAs.
- **Exit Interval [s]**
  Enter the interval after which the OSPFv2 router once again attempts to come out of the overflow status. A 0 means that the OSPFv3 router attempts to exit the overflow status only following a restart.
- **Inbound Filter**
  Select a route map that filters inbound routes.

- **Redistribute Routes**
  Specify which known routes are distributed using OSPFv2. You can make different decisions for the route types Default, Connected and Static.

  Note

  The settings can only be enabled on an AS border router. Enabling the Default and Static options, in particular, can cause problems if they are enabled at too many points in the network, for example, forwarding loops.

- **Route Map**
  Select a route map that filters which routes are forwarded using OSPFv2.

Areas

Overview

An autonomous system can be divided into smaller areas.

On this page, you can view, create, modify or delete the areas of the router.

Note

OSPF is available only on layer 3.

Settings

- **Area ID**
  Enter the designation of the area. The database is synchronized for all routers of an area. The area ID must be unique in the network.
  The area identifier is a 32-bit number with the following format: x.x.x.x where x = 0 ... 255
  The area ID 0.0.0.0 is reserved for the backbone area and cannot be deleted.

This table contains the following columns:

- **Area ID**
  Shows the ID of the area.
- **Area Type**
  Select the area type from the drop-down list.
  - Normal
  - Stub
  - NSSA
  - Backbone
- **Summary**
  Specify whether summary LSAs are generated for this area.
  - Summary: Summary LSAs are sent to the area.
  - No Summary: Summary LSAs are not sent to the area.

- **Metric**
  Displays the costs for the OSPFv2 interface.
- **Updates**
  Shows the number of recalculations of the routing tables.
- **LSA Count**
  Shows the number of LSAs in the database.
- **Area BR**
  Shows the number of reachable area border routers (ABR) within this area.
- **AS BR**
  Shows the number of reachable autonomous system border routers (ASBR) in this area.

Area range

Creating a new OSPFv2 area range

On this page, networks can be grouped together under one area ID. The method is used only with area border routers. This means that an area border router only advertises one route for grouped areas to the outside.

Note

OSPF is available only on layer 3.

Settings

- **Area ID**
  Select the area ID of the area. You configure the ID in "Layer 3 > OSPFv2 > Areas".
- **Subnet Address**
  Enter the IPv4 address of the network that will be grouped.
- **Subnet Mask**
  Enter the subnet mask of the network that will be grouped.

This table contains the following columns:

- **Area ID**
  Shows the ID of the area.
- **Subnet Address**
  Shows the IPv4 address of the network that will be grouped with other networks.
- **Subnet Mask**
  Shows the subnet mask of the network that will be grouped with other networks.
- **Advertise**
  Enable this setting to advertise the grouped network.

Interfaces

Overview

On this page, you can configure OSPFv2 interfaces.

Note

OSPF is available only on layer 3.

Settings

- **IP Address**
  Select the IPv4 address of the OSPFv2 interface.
- **Area ID**
  Select the area ID of the area with which the OSPFv2 interface is connected.

  Note

  For the secondary interface select the same Area ID as for the corresponding primary interface.
  The information whether a primary or secondary interface is involved can be found in the "Address Type" column on the "Layer 3 (IPv4) > Subnets > Overview" page.

This table contains the following columns:

- **IP Address**
  Shows the IPv4 address of the OSPFv2 interface
- **Area ID**
  Select the area ID of the area with which the OSPFv2 interface is connected.
- **OSPF Status**
  Specify whether or not OSPFv2 is active on the interface.
  - Enabled: OSPFv2 is enabled on the interface.
  - Disabled: OSPFv2 is disabled on the interface.
- **Metric**
  Enter the costs for the OSPFv2 interface.
- **Priority**
  Enter the router priority. The priority is only relevant for selecting the designated router or designated border router. This parameter can be selected differently on routers within the same subnet.
- **Trans. Delay**
  Enter the required delay when sending a connection update.
- **Retrans. Delay**
  Enter the time after which an OSPFv2 packet is transferred again if no confirmation was received.

- **Hello Interval**
  Enter the interval between two Hello packets.
- **Dead Interval**
  Enter the interval after which the neighbor router is marked as "failed" if no more Hello packets are received from it during this time.

Interface authentication

Configuring the interface login

On this page, you define the authentication of the interface.

Note

OSPF is available only on layer 3.

Settings

- **OSPF Interface**
  Select the OSPFv2 interface for which you want to configure authentication.
- **Authentication type**
  Select the authentication method of the OSPF interface. You have the following options:
  - None: No authentication
  - simple: Authentication using an unencrypted password
  - MD5: Authentication using MD5

Simple authentication

- **Password**
  Enter a password.
- **Confirmation**
  Confirm the entered password.

MD5 authentication

- **Authentication Key ID**
  Enter the identifier of the MD5 authentication key.
  Enter the ID for MD5 authentication with which the password will be used as a key. Since the key ID is transferred with the protocol, the same key must be stored under the same key ID on all neighboring routers.

The table has the following columns:

- **Authentication Key ID**
  Can only be edited if you set the MD5 authentication method. It is only possible to use several keys there.
- **MD5 Key**
  Enter the MD5 key.

- **Confirm MD5 Key**
  Confirm the entered key.
- **Youngest Key ID** (only available online)
  Shows whether or not the MD5 key is the latest key ID.

Virtual links

Overview

Due to the protocol, each area border router must have access to the backbone area. If a router is not connected directly to the backbone area, a virtual link to it is created.

Note

OSPF is available only on layer 3.

Note

Note that when creating a virtual link both the transit area and the backbone area must already be configured.

the virtual link must be configured identically at both ends.

Settings

- **Virtual links are not effective unless the device is an ABR.** (only available online)
  This is displayed when at least one virtual link entry is configured and the device is not an area border router.
- **Neighbor Router ID**
  Enter the ID of the neighbor router at the other end of the virtual connection.
- **Transit Area ID**
  Select the ID of the area that connects the two routers.

This table contains the following columns:

- **Transit Area ID**
  Shows the ID via which the two routers are connected.
- **Neighbor Router ID**
  Shows the ID of the neighbor router at the other end of the virtual connection.
- **Virt. Link Status**
  Specify the status of the virtual link. The following statuses are possible:
  - down: The virtual link is inactive.
  - point-to-point: The virtual link is active.
- **Trans. Delay**
  Enter the required delay when sending a link update packet.
- **Retrans. Delay**
  Enter the time after which a packet is transferred again if no confirmation was received.

- **Hello Interval**
  Enter the interval between two Hello packets.
- **Dead Interval**
  Enter the interval after which the neighbor router counts as "failed" if no more Hello packets are received from it during this time.

Virtual Link Authentication

Configuring the virtual link login

On this page, you define the authentication for the virtual link.

Note

OSPF is available only on layer 3.

Settings

- **Virtual Link (Area/Neighbor)**
  Select the virtual link for which you want to configure authentication.
- **Authentication type**
  Select the authentication method of the OSPF interface. You have the following options:
  - None: No authentication
  - simple: Authentication using an unencrypted password.
  - MD5: Authentication using MD5

Simple authentication

- **Password**
  Enter the password.
- **Confirmation**
  Confirm the entered password.

MD5 authentication

- **Authentication Key ID**
  Enter the identifier of the MD5 authentication key.
  Enter the ID for MD5 authentication with which the password will be used as a key.
  Since the key ID is transferred with the protocol, the same key must be stored under the same key ID on all neighboring routers.

The table has the following columns:

- **Authentication Key ID**
  Can only be edited if you set the MD5 authentication method. It is only possible to use several keys there.
- **MD5 Key**
  Enter the MD5 key.

- **Confirm MD5 Key**
  Confirm the entered key.
- **Youngest Key ID**
  Shows whether or not the MD5 key is the latest key ID.

RIPv2

Configuration

On this page, you configure routing with RIP.

Note

RIPv2 is available only on layer 3.

Settings

- **RIPv2**
  Enable or disable routing using RIPv2.
- **Inbound Filter**
  Select a route map that filters inbound routes.
- **Redistribute Routes**
  Specify which known routes are distributed using RIPv2.
  The following types of route exist:
  - Static Default
  - Connected
  - Static
  - OSPF
- **Route Map**
  Select a route map that filters which routes are forwarded using RIPv2.

Interfaces

Overview

On this page, you can configure RIPv2 interfaces.

Note

RIPv2 is available only on layer 3.

Settings

- **IP Address**
  Select the IPv4 address of the RIPv2 interface.

This table contains the following columns:

- **IP Address**
  Shows the IPv4 address of the RIPv2 interface
- **Send Updates**
  Select the way in which updates are sent:
  - no send
    No updates are sent.
  - RIPv1
    Updates for RIPv1 are sent.
  - RIPv1-compat.
    RIPv2 updates are sent as broadcasts according to the rules of RIPv1.
  - RIPv2
    Updates for RIPv2 are sent as multicasts.
  - RIPv1 demand/RIPv2 demand
    RIP packets are sent only as a response to an explicit query.
- **Receive Updates**
  Select the form in which received updates are accepted:
  - no receive
    No updates are received.
  - RIPv1
    Only updates of RIPv1 are received.
  - RIPv2
    Only updates of RIPv2 are received.
  - RIPv1/v2
    Updates of RIPv1 and RIPv2 are received.
- **Default Metric**
  Enter the costs for the RIPv2 interface.

NAT

NAT

On this WBM page, you specify the basic settings for NAT.

Description

The page contains the following boxes:

- **NAT**
  Enable or disable NAT/NAPT for the entire device. When enabled, the device operates as a NAT router.
- **Idle Timeout [s]**
  Enter the required time. If no data exchange takes place, when this time has elapsed ...
- **TCP Timeout [s]**
  Enter the required time. If no data exchange takes place, the TCP connection is deleted from the "NAT Translations" table when this time has elapsed.
- **UDP Timeout [s]**
  Enter the required time. If no data exchange takes place, the UDP connection is deleted from the "NAT Translations" table when this time has elapsed.
- **Interface**
  Select the an IP interface from the drop-down list:
- **NAT**
  Enable or disable NAT for an IP interface.
  An entry is created automatically in the "Pool" tab. The device can be reached from the external network using the IP address of the IP interface.
  If you disable NAT for an IP interface and there are no configurations on the NAT interface, the entry is automatically deleted from the table.
  NAPT
  Enable or disable NAPT for an IP interface.

The table has the following columns:

- **Interface**
  Interface to which the setting relates.
- **NAT**
  Shows whether NAT is enabled or disabled for the selected IP interface.
  NAT is only enabled, when you have enabled NAT for the entire device.
- **NAPT**
  Shows whether NAPT is enabled or disabled for the selected IP interface.
  NAPT is only enabled, when you have enabled NAT for the entire device.
  If you do not create further configurations for NAPT, the dynamic port translation is enabled. As default, the device cannot be reached from an external network. If the device wants to communicate in an external network, the inside local address and the IP address of the IP interface have a port added and the device is assigned as inside local and inside global address. Using this inside global address, the device can be reached from the external network until the timer of the connection elapses.

Static

On this WBM page, you configure static address translatiions.

You specify which inside global address the inside local address of a device will be converted to and vice versa. This variant allows connection establishment in both directions. The device in the internal network can be reached from the external network.

Description

The page contains the following boxes:

- **Interface**
  Select the an IP interface from the drop-down list:
- **Inside Local Address**
  Enter the actual address of the device that should be reachable from external.
- **Inside Global Address**
  Enter the address at which the device can be reached from external.

The table has the following columns:

- **1st column**
  Select the check box in the row to be deleted.
- **Interface**
  Interface to which the setting relates.
- **Inside Local Address**
  Shows the actual address of the device that should be reachable from external.
- **Inside Global Address**
  Shows the address at which the device can be reached from external.

Pool

On this WBM page, you configure static address translations.

As default, the device cannot be reached from an external network. If the device wants to communicate in an external network, an inside global address is assigned to it dynamically. Using this inside global address, the device can be reached from the external network until the timer of the connection elapses.

Description

The page contains the following boxes:

- **Interface**
  Select the an IP interface from the drop-down list:
- **Inside Global Address**
  Enter the start address for the dynamic assignment of addresses at which devices will be reachable from external.
- **Inside Local Address Mask**
  Enter the address mask of the external subnet.

The table has the following columns:

- **1st column**
  Select the check box in the row to be deleted.
- **Interface**
  Interface to which the setting relates.

- **Inside Global Address**
  Shows the start address for the dynamic assignment of addresses at which devices will be reachable from external.
- **Inside Local Address Mask**
  Shows the address mask of the external subnet.

NAPT

On this WBM page, you configure static address translations.

Description

The page contains the following boxes:

- **Interface**
  Select the an IP interface from the drop-down list:
- **Inside Local Address**
  Enter the actual address of the device that should be reachable from external.
- **Service**
  Select the service for which the port translation is valid.
  When you select a service, the same port is entered in the Start Port and End Port boxes.
  if you change the start port, the end port is changed accordngly.
  if you select the entry "-", you can enter the start and end port freely.
- **Start Port**
  Enter a port.
- **End Port**
  Depending on your selection in the "Service" drop down list, you can enter a port or a port is displayed.
  If you enter different ports in the Start Port and End Port boxes, the same port range is entered in the Inside Global Port box. A port range can only be translated to the same port range.
  If you enter the same port in the Start Port and End Port boxes, you can enter any Inside Global Port.
- **Inside Global Port**
  Depending on your selection in the "Service" drop down list, you can enter a port or a port is displayed.
- **Protocol**
  Select the protocol for which the port translation is valid.
- **Description**
  Enter a description for the port translation.

The table has the following columns:

- **1st column**
  Select the check box in the row to be deleted.
- **Interface**
  Interface to which the setting relates.

- **Inside Local Address**
  Shows the actual address of the device that should be reachable from external.
- **Start Port**
  Shows the start port that will be assigned to the inside local address.
- **End Port**
  Shows the end port that will be assigned to the inside local address.
- **Protocol**
  Shows the protocol for which the port translation applies.
- **Inside Global Address**
  Shows the address at which the device will be reached from external.
- **Inside Global Port**
  Shows the port that will be assigned to the Inside Global Address.
- **Description**
  Shows a a description for the port translation.

Configuring layer 3 functions for IPv6

Configuration

Introduction

The page contains the overview of the layer 3 functions for IPv6. On this page, you enable or disable the required layer 3 function.

The functions "IPv6 Routing", "VRRPv3" and "OSPFv3" are only available with Layer 3 (IPv6).

Settings

- **IPv6 Routing** (only available with devices with a layer 3 license)
  - Enabled
    IPv6 routing is enabled. If IPv4 routing is not enabled on the device this is also enabled with this function.
  - Disabled
    IPv6 routing is disabled.
- **VRRPv3** (only available with devices with a layer 3 license)
  Enable or disable routing using VRRPv3. To use VRRPv3 , first enable the IPv6 routing function. You can configure other settings in "Layer 3 (IPv6) > VRRPv3".
- **OSPFv3** (only available with devices with a layer 3 license)
  Enable or disable routing using OSPFv3. You can configure other settings in "Layer 3 (IPv6) > OSPFv3".

Subnets (IPv6)

Connected Subnets

On this page, you can enable IPv6 on the interface. The interface is also called an IPv6 interface. An IPv6 interface can have several IPv6 addresses.

Settings

The page contains the following:

- **Interface**
  Select the IP interface for which IPv6 will be enabled.
- **IPv6 Enable**
  Enable or disable IPv6 for this interface.

  Note

  Disabling IPv6

  As soon as IPv6 is enabled on the IP interface, IPv6 can only be disabled by removing the interface.

- **IPv6 Address**
  Enter the IPv6 address. The entry depends on the selected address type.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix
- **IPv6 Address Type**
  Select the address type.
  - Unicast
  - Anycast
  - Link Local IPv6 address is only valid on the link

The table has the following columns:

- **Interface Name**
  Shows the name of the interface.
- **IPv6 Address**
  Shows the IPv6 address of the subnet.
- **Prefix Length**
  Shows the prefix length.
- **IPv6 Address Type**
  Displays the address type. The following values are possible:
  - Unicast
  - Anycast
  - Link Local

DHCPv6 client

DHCPv6 client

On this page, you specify whether the DHCPv6 client receives not only the configuration settings but also the IPv6 address or supports the "prefix delegation" function.

Prefix delegation

The DHCPv6 server delegates the distribution of the IPv6 prefix to the DHCPv6 client. To do this an IPv6 interface must be configured on the DHCPv6 client as a PD client. Via the PD client, the DHCPv6 client obtains an IPv6 prefix from the DHCPv6 server and stores it under a prefix name. The IPv6 interfaces of the DHCPv6 client the should adopt the prefix are configured as so-called PD sub clients.

You configure the PD sub-clients in "Layer 3 (IPv6)" > "DHCPv6 Client" > "DHCPv6 PD Sub Client".

Settings

- **Interface**
  Select the IP interface via which the DHCPv6 client functions.
- **Enable**
  Enable or disable the DHCPv6 client for the relevant interface.
- **Mode**
  Specify the procedure.
  - Status dependent Obtains the IPv6 address and the configuration file from the DHCPv6 server
  - Stateless: Obtains only the configuration file from the DHCPv6 server
  - Prefix Delegation: The DHCPv6 client takes over the distribution of the IPv6 prefix
- **Prefix Name**
  Enter the prefix name that will be further distributed by the DHCPv6 router. Can only be edited with the "Prefix Delegation" procedure. The DHCPv6 router stores IPv6 prefix of the DHCPv6 server under this name.
- **Rapid Commit**
  When enabled the procedure for the IPv6 address assignment is shortened. Instead of 4 DHCPv6 messages (SOLICIT, ADVERTISE , REQUEST, REPLY) only 2 DHCPv6 messages (SOLICIT, REPLY) are used. You will find further information on the messages in RFC 3315.

DHCPv6 PD Sub Client

On this page you specify which IPv6 interfaces of the DHCPv6 client will adopt the prefix.

This achieved by assigning the prefix name followed by a prefix and the required prefix length to them as the IP address. Here, the first bits of the configured prefix are replaced by the values stored in the prefix name.

The PD sub client forms the IPv6 address from the prefix name, prefix and prefix length.

Example:

Under the prefix name "test", the following IPv6 prefix is stored: 2001:DB8:1234::/48

Prefix = 2002:AF9:5678::1

Prefix length = 64

From these settings the PD sub client forms the following IPv6 address: 2001:DB8:1234::1

Settings

- **Interface**
  Select the interface that functions as the PD sub client. Only IP interfaces can be selected.
- **Prefix Name**
  Enter the prefix name that will be further distributed by the PD router. The PD router stores IPv6 prefix of the DHCPv6 server under this name.
- **Prefix**
  Specify the network identifier of the host.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix

This table contains the following columns

- **Interface Name**
  Shows the name of the interface
- **Prefix Name**
  Shows the name of the prefix.
- **Prefix**
  Shows the prefix.
- **Prefix Length**
  Shows the prefix length.
- **Generated Address** (only available online)
  Shows the IPv6 address formed from the prefix name, prefix and prefix length.

Static Routes (IPv6)

On this page, you configure static IPv6 routes.

Settings

The page contains the following:

- **Destination Network**
  Enter the network address of the destination that can be reached via this route.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix
- **Gateway**
  Enter the IPv4 address of the gateway via which this network address is reachable.

- **Metric**
  Enter the metric for the route. The metric corresponds to the quality of a connection, based for example on speed or costs. If there are several equal routes, the route with the lowest metric value is used.
- **Interface**
  Specify the IPv6 interface via which the network address of the destination is reached.

This table contains the following columns:

- **Destination Network**
  Shows the IPv6 network address of the destination.
- **Prefix Length**
  Shows the prefix length.
- **Gateway**
  Shows the IPv6 address of the next gateway.
- **Interface**
  Shows the Interface of the route.
- **Metric**
  Enter the metric for the route. When creating the route, "not used" is entered automatically. The metric corresponds to the quality of a connection, based for example on speed or costs. If there are several equal routes, the route with the lowest metric value is used.
- **Status**
  Shows whether or not the route is active.

Route maps

General (IPv6)

Route maps

With route maps, you control how routing information is further processed. You can filter routing information and specify whether the information is further processed, modified or discarded.

Route maps operate according to the following principle:

- Routing information is compared with the filters of the route maps.
- The comparison is continued until the filters of a route map match the properties of an item of information.
- The information is then processed according to the route map settings:
  - The routing information is discarded.
  - The properties of the routing information are changed.

Settings

- **Name**
  Enter the name for the route map.
- **Sequence No**
  Enter a number for the route map.
  You can create several route maps with the same name but with different sequence numbers. The sequence numbers then specify the order in which the route maps are processed.

The table has the following columns:

- **Name**
  Shows the name of the route map.
- **Sequence No**
  Shows the sequence number of the route map.
- **Action**
  Specify what happens to the routing information that matches the settings of the route map:
  - permit
    The routing information is further processed according to the settings you make on the "Set" page.
  - deny
    The routing information is discarded.

Interface & Value Match (IPv6)

On this page, you specify whether or not the routing information for a route map is filtered according to interfaces, metric or tags.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.
  The created route maps are available to you.
- **Type**
  Select the basis for the filtering:
  - Interface
  - Metric
  - Tag
- **Interface**
  Select an interface.
  Only active if you have selected the "Interface" entry for "Type".
- **Metric**
  Enter a value for the metric.
  Only active if you have selected the "Metric" entry for "Type".

- **Tag**
  Enter a value for the tag.
  Only active if you have selected the "Tag" entry for "Type".
- **Route Type**
  Select the type of the route.
  - Local
    The routing information for the route map is filtered according to directly connected routes (local interfaces).
  - Remote
    The routing information for the route map is filtered according to learned or statically configured routes.

  This box is active only if i you have selected the entry "Route Type in the "Type" drop-down list.

The table has the following columns:

- **Type**
  Shows the selected type:
  - Interface
  - Metric
  - Tag
  - Route Type
- **Value**
  Shows the selected interface, the value of the metric or of the tag.

Destination Match (IPv6)

On this page, you specify whether or not the routing information for a route map is filtered based on the destination IPv6 address.

Settings

- **Route Map (Name/Seq. No.)**
  Select a route map.
- **IP Address**
  Enter the IPv6 address of the destination on which the filtering is based.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix

The table has the following columns:

- **IP Address**
  Shows the IPv6 address of the destination.
- **Prefix Length**
  Shows the prefix length.

Next Hop Match (IPv6)

On this page, you specify whether or not the filtering for a route map will be based on the router to which the routing information is sent next.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.
- **IP Address**
  Enter the IP address of the router to which the routing information will be sent next.

The table has the following columns:

- **IP Address**
  Shows the IP address of the next router.

Set (IPv6)

On this page, you specify whether or not the routing information will be changed by a route map.

If, for example, you have filtered based on a certain metric, you can change the value of the metric here. The routing information is then forwarded with the new value. You can only change the information of a "Permit" route map.

Settings

- **Route Map (name/seq. no.)**
  Select a route map.

The table has the following columns:

- **Name**
  Shows the name of the route map.
- **Sequence No**
  Shows the sequence number of the route map.
- **Metric**
  Enter the new value for the metric with which the routing information will be forwarded.
- **Tag**
  Enter the new value for the tag with which the routing information will be forwarded.

DHCPv6 Relay Agent

Interfaces

A DHCPv6 relay agent forwards the DHCP queries of the DHCPv6 client to the DHCPv6 server. When forwarding the remote ID is inserted in the DHCP query. The remote ID is the identifier of the interface. With this, the DHCPv6 agent can send the reply of the DHCPv6 server to the required DHCPv6 client.

Settings

- **Remote ID (Opt. 37)**
  When enabled the DHCP relay agent option 37 (Remote ID) is used. Specify the type of identifier in "Remote ID Type".
- **Interface**
  Select the IPv6 interface.

The table has the following columns:

- **Interface**
  Interface to which the settings relate.
- **Current Remote ID**
  Shows which remote ID is currently being used.
- **Remote ID Type**
  Select hat is used as the identifier for the IPv6 interface. The following options are available:
  - DUID
    DHCP Unique Identifier
  - System Name
    System name of the device
  - Management IP
    Management IPv6 address of the device
  - User Defined
    User-defined entry
- **DHCP Unique Identifier**
  Enter the DUID (DHCP Unique Identifier).
- **User Defined**
  Enter a user-defined entry as the identifier.

Server Addresses

On this page you enable the DHCPv6 relay agent on the interface. You also specify which DHCPv6 server can be reached via it.

Settings

- **Relay Interface**
  Select the interface on which the DHCPv6 relay agent accepts DHCPv6 requests.
- **Server IP Address**
  Enter the IPv6 address of the DHCPv6 server to which the DHCPv6 requests will be forwarded. The address can be either the unicast or the link local multicast address. With the link local multicast address you need to specify an interface, via which the DHCPv6 server can be reached. You configure the interface in "Layer 3 (IPv6) > DHCPv6 Relay Agent > Outgoing Interfaces".

The table has the following columns:

- **Server IP Address**
  Shows the IP64 address of the DHCPv6 server.

Outgoing Interfaces

Outgoing Interfaces

The link local multicast address (ff02::1:2) of the DHCPv6 server can only be reached by devices located on the same link. On this page, you specify the IPv6 interface via which this DHCPv6 server can be reached.

Settings

- **Relay Interface**
  Select the IPv6 interface on which the DHCPv6 relay agent accepts DHCPv6 requests.
- **Server IP Address**
  Select the IPv6 address of the DHCPv6 server.
- **Outgoing Interface**
  Select the interface via which the DHCPv6 server can be reached.

The table has the following columns:

- **Server IP Address**
  Shows the IPv6 address of the DHCPv6 server.
- **Outgoing Interface**
  Shows the IPv6 interface via which the DHCPv6 server can be reached.

VRRPv3

Router (IPv6)

Introduction

On this page, you create new virtual routers. You can configure other parameters in "Layer 3 (IPv6) > VRRPv3 > Configuration".

Note

- This function is available only with layer 3.
- Simultaneous operation of VRRP and VRRPv3 is not possible.
- Select the "VRRPv3" check box to configure VRRPv3.
- You can use VRRPv3 on VLAN interfaces. Router ports are not supported.

Settings

- **VRRPv3**
  Enable or disable routing using VRRPv3. Can only be enabled when "Layer 3 (IPv6) > Configuration" "IPv6 Routing" is enabled.
- **Track**
  Enable or disable VRID tracking.
  When enabled, all interfaces of a VRID are monitored. When the link of an interface changes from "up" to "down", the priority of all VRRP interfaces with the same VRID is reduced to the value "0".
  When the link of an interface changes back from "down" to "up", the original priority of the VRRP interfaces is restored.
- **Interface**
  Select the required VLAN interface operating as virtual router.
- **VRID**
  Enter the ID of the virtual router. This ID defines the group of routers that form a virtual router (VR). In the group, this is the same. It can no longer be used for other groups.

The table has the following columns:

- **Interface**
  Shows the Interface that functions as the virtual router.
- **VRID**
  Shows the ID of the virtual router.
- **Virtual MAC Address** (only available online)
  Shows the virtual MAC address of the virtual router.
- **Primary IP Address**
  Shows the numerically lowest IPv6 address in this VLAN. The entry "::" means that the "Primary" address is used on this VLAN. Otherwise all IPv6 addresses configured on this VLAN in the "Layer 3 (IPv6) > Subnets" menu are valid values.
- **Router State** (only available online)
  Shows the current status of the virtual router. Possible values are:
  - Master
    The router is the master router and handles the routing functionality for all assigned IPv4 addresses.
  - Backup
    The router is the backup router. If the master router fails, the backup router takes over the tasks of the master router.
  - Initialize
    The virtual router has just been turned on. It will soon change to the "Master" or "Backup" state.
- **Master IP Address** (only available online)
  Shows the IPv6 address of the master router.
- **Priority** (only available online)
  Shows the priority of the virtual router.
  The current master router is automatically given 255. All other priorities can be distributed freely among the VRRPv3 routers. The higher the priority, the earlier the VRRPv3 router becomes "Master".

- **Advert. Internal**
  Shows the interval at which the master router sends VRRPv3 packets.
- **Preempt**
  Shows the precedence of a router when changing roles between backup and master.
  - yes
    This router has precedence when changing roles.
  - no
    This router does not have precedence when changing roles.
- **Reply to pings on virtual interfaces (Accept Mode)**
  Shows the precedence of a router when changing roles between backup and master.
  - Yes
    Virtual IP addresses also reply to pings.
  - No
    Virtual IP addresses do not reply to pings.

Configuration (IPv6)

Introduction

On this page, you configure the virtual router.

Note

This function is available only with layer 3.

Settings

- **Interface / VRID**
  Select the ID of the virtual router to be configured.
- **Primary Address**
  Select the primary IPv6 address. If the router becomes master router, the router uses this IPv4 address.

  Note

  If you only configure one subnet on this VLAN, no entry is necessary. The entry is then **::**. If you configure more than one subnet on the VLAN and you want a specific IPv6 address to be used as the source address for VRRPv3 packets, select the IPv6 address. Otherwise, the IPv6 address with priority will be used.
- **Master**
  If this option is enabled, the numerically lowest IPv6 address is entered for "Associated IP Address". This means that the highest priority IPv6 address of the VRRP router is used as the virtual IPv6 address of the virtual master router. The backup routers in this group must disable the option and use the IPv6 address of the router in "Associated IP Address".

- **Priority**
  Enter the priority of this virtual router.
  The current master router is always given 255. All other priorities can be distributed freely among the redundant routers. The higher the priority, the earlier the router becomes "Master".
- **Advertisement interval**
  Enter the interval in seconds after which a master router sends a VRRPv3 packet again.
- **Preempt lower priority Master**.
  Allow precedence when changing roles between backup and master based on the selection process.
- **Reply to pings on virtual interfaces (Accept Mode)**
  When enabled, the virtual IPv6 addresses also reply to the ping.
- **Track ID**
  Select a track ID.
- **Decrement Priority**
  Enter the value by which priority of the VRRP interface will be reduced.
- **Current Priority**
  Shows the priority of the VRRP interface after the monitored interface has changed to the "down" status.

Addresses Overview (IPv6)

Overview

This page shows which IPv6 addresses the virtual router monitors.

Note

This function is available only with layer 3.

Displayed values

The table has the following columns:

- **Interface**
  Shows the Interface that functions as the virtual router.
- **VRID**
  Shows the ID of this virtual router.
- **Number of Addresses**
  Shows the number of IPv6 addresses.
- **Associated IP Address (1) ...Associated IP Address (10)**
  Shows the router IPv6 addresses monitored by this virtual router. If a router takes over the role of master, the routing function is taken over by this router for all these IPv6 addresses.

Addresses Configuration (IPv6)

Creating or changing the monitored IP addresses

On this page, you can create, modify or delete the IPv4 addresses to be monitored.

Note

This function is available only with layer 3.

Settings

- **Interface / VRID**
  Select the ID of the virtual router.
- **Associated IP Address**
  Enter the IPv6 address that the virtual router will monitor.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted
- **Associated IP Address**
  Shows the IPv6 addresses that the virtual router monitors.

Interface Tracking (IPv6)

Introduction

On this page, you configure the monitoring of interfaces.

When the link of a monitored interface changes from "up" to "down", the priority of the assigned VRRP interface is reduced. You configure the value by which the priority is reduced on the page "Layer 3 > VRRP/VRRPv3 > Configuration".

When the link of the interface changes back from "down" to "up", the original priority of the VRRP interface is restored.

Note

This function is available only with layer 3.

Description of the displayed values

The page contains the following boxes:

- **Interface**
  From the drop-down list, select the interface to be monitored.
- **Track ID**
  Enter a track ID.

- **Track ID**
  Select a track ID.
- **Track Interface Count**
  Enter how many monitored interfaces need to change to the "down" status, before the priority is changed.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Track ID**
  Shows the track ID.
- **Interface**
  Shows the interface that is being monitored.

OSPFv3

Configuration

Introduction

On this page, you configure the routing using OSPFv3.

Note

This function is available only with layer 3.

Settings

- **OSPFv3**
  Enable or disable routing using OSPFv3.
- **Router ID**
  Enter the name of one of the OSPFv3 interfaces. The router ID is specified in IPv4 format and must be unique in the network.
- **Border Router**
  Displays the status of the OSPFv3 router. If the local system is an active member in at least 2 areas, this is an area border router.
- **AS Border Router**
  Specify whether the router is an AS border router. An AS border router intercedes between multiple autonomous systems, for example if you have an additional RIP network. An AS border router is also necessary to add and to distribute static routes.
- **New LSA Received**
  Shows the number of received LSAs. Updates and its own LSAs are not counted.
- **New LSA Configured**
  Shows the number of different LSAs sent by this local system.

- **External LSA Maximum**
  To limit the number of entries of external LSAs in the database, enter the maximum number of external LSAs.
- **Exit Interval [s]**
  Enter the interval after which the OSPFv3 router once again attempts to come out of the overflow status. A 0 means that the OSPFv3 router attempts to exit the overflow status only following a restart.
- **Inbound Filter**
  Select a route map that filters inbound routes.
- **Redistribute Routes**
  Specify which known routes are distributed using OSPFv3. You make different decisions for the route types Connected, Static and RIPng.

  Note

  The options can only be enabled on an AS border router. Enabling the Default and Static options, in particular, can cause problems if they are enabled at too many points in the network, for example, forwarding loops.

- **Route Map**
  Select a route map that filters which routes are forwarded using RIPng.

Areas

Overview

An autonomous system can be divided into smaller areas.

On this page, you can view, create, modify or delete the areas of the router.

Note

This function is available only with layer 3.

Settings

- **Area ID**
  Enter the designation of the area. The database is synchronized for all routers of an area. The area identifier must be unique in the network.
  The area identifier is a 32-bit number with the following format: x.x.x.x where x = 0 ... 255
  The area identifier 0.0.0.0 is reserved for the backbone area and cannot be deleted.

This table contains the following columns:

- **Area ID**
  Shows the ID of the area.
- **Area Type**
  Specify the type of area.
  - Normal
  - Stub
  - NSSA
  - Backbone
- **Summary**
  Specify whether summary LSAs are generated for this area.
  - Summary: Summary LSAs are generated and sent to the area.
  - No Summary: Summary LSAs are not generated and sent to the area.
- **Metric**
  Displays the costs for the OSPFv3 interface.
- **Updates**
  Shows the number of recalculations of the IPv6 routing tables.
- **LSA Count**
  Shows the number of LSAs in the database.
- **Area BR**
  Shows the number of reachable area border routers (ABR) within this area.
- **AS BR**
  Shows the number of reachable autonomous system border routers (ASBR) in this area.

Area Range

Creating a new OSPFv3 area range

On this page, you can group up to 4 networks under one area ID. The method is used only with area border routers. This means that an area border router only advertises one route for grouped areas to the outside.

Note

This function is available only with layer 3.

Settings

- **Area ID**
  Select the ID of the area. You specify the ID in "Areas".
- **Prefix**
  Enter the IPv6 address of the network that will be grouped.
- **Prefix Length**
  Enter the number of bits belonging to the prefix that will be grouped.

This table contains the following columns:

- **Area ID**
  Shows the ID of the area.
- **Prefix**
  Shows the IPv6 address of the network that will be grouped.
- **Prefix Length**
  Enter the number of bits that will belong to the prefix.
- **Advertise**
  Enable this option to advertise the grouped network.

Interfaces

Overview

On this page, you can configure OSPFv3 interfaces.

Note

This function is available only with layer 3.

Settings

- **Interface**
  Select the IPv6 interface on which OSPFv3 will be enabled.
- **Area ID**
  Select the area ID of the area with which the OSPFv3 interface is connected.

  Note

  For the secondary interface select the same Area ID as for the corresponding primary interface.
  The information whether a primary or secondary interface is involved can be found in "Layer 3 (IPv6) > Subnets".

This table contains the following columns:

- **Interface**
  Shows the OSPFv3 interface.
- **Area ID**
  Select the area ID of the area with which the OSPFv3 interface is connected.
- **OSPF Status**
  Specify whether or not OSPFv3 is active on the interface.
  - Enabled: OSPFv3 is enabled on the interface.
  - Disabled: OSPFv3 is disabled on the interface.
- **Metric**
  Enter the costs for the OSPFv3 interface.
- **Priority**
  Enter the router priority. The priority is only relevant for selecting the designated router or designated border router. This parameter can be selected differently on routers within the same subnet.
- **Trans. Delay**
  Enter the required delay when sending a connection update.
- **Retrans. Interval**
  Enter the time after which an OSPFv3 packet is transferred again if no confirmation was received.
- **Hello Interval**
  Enter the interval between two Hello packets.
- **Dead Interval**
  Enter the interval after which the neighbor router is marked as "failed" if no more Hello packets are received from it during this time.

Virtual links

Overview

Due to the protocol, each area border router must have access to the backbone area. If a router is not connected directly to the backbone area, a virtual link to it is created.

Note

This function is available only with layer 3.

Note

Note that when creating a virtual link both the transit area and the backbone area must already be configured.

A virtual link must be configured identically at both ends.

Settings

- **Neighbor Router ID**
  Enter the ID of the neighbor router at the other end of the virtual connection.
- **Transit Area ID**
  Select the ID of the area that connects the two routers.

This table contains the following columns:

- **Transit Area ID**
  Shows the ID via which the two routers are connected.
- **Neighbor Router ID**
  Shows the ID of the neighbor router at the other end of the virtual connection.
- **Virt. Link Status**
  Specify the status of the virtual link. The following states are possible:
  - down: The virtual link is inactive.
  - point-to-point: The virtual link is active.
- **Trans. Delay**
  Enter the required delay when sending a connection update.
- **Retrans. Interval**
  Enter the time after which a packet is transferred again if no confirmation was received.
- **Hello Interval**
  Enter the interval between two Hello packets.
- **Dead Interval**
  Enter the interval after which the neighbor router counts as "failed" if no more Hello packets are received from it during this time.

RIPng

Configuration

On this page, you configure routing with RIPng.

Note

This function is available only with layer 3.

Settings

- **Inbound Filter**
  Select a route map that filters inbound routes.
- **Redistribute Routes**
  Specify which known routes are distributed using RIPng.
  The following types of route exist:
  - Connected
  - Static
  - OSPFv3
- **Route Map**
  Select a route map that filters which routes are forwarded using RIPng.

Interfaces

Overview

On this page, you specify the interfaces that support RIPng.

Note

This function is available only with layer 3.

Settings

This table contains the following columns:

- **Interface**
  Shows the available IPv6 interface.
- **Admin State**
  Enable or disable the RIPng routing for the interface.
- **Default Metric**
  Enter the costs for the RIPng interface.

Configuring security functions

Users

Local Users

Note

The page is only available if there is an online connection to the device.

Local users

On this page, you create local users with the corresponding rights.

When you create or delete a local user this change is also made automatically in the table "External User Accounts". If you want to make change explicitly for the internal or external user table, use the CLI commands.

Note

You can create up to 16 additional user accounts.

Note

The values displayed depend on the rights of the logged-in user.

Settings

- **User Account**
  Enter the name for the user. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 255 characters long.
  - The following characters must not be included: § ? " ; : < =

  Note

  User name cannot be changed

  After creating a user, the user name can no longer be modified.

  If a user name needs to be changed, the user must be deleted and a new user created.

  Deleting users

  The preset users as well as logged in users cannot be deleted or changed.

- **Password Policy**
  Shows which password policy is being used.
- **Password**
  Enter the password for the user.

  Note

  Password Policy: high

  Note the following password policies:
  - Password length: at least 8 characters, maximum 128 characters
  - At least 1 uppercase letter
  - At least 1 special character
  - At least 1 number

- **Password Confirmation**
  Enter the password again to confirm it.
- **Role**
  Select a role.
  You can choose between system-defined and self-defined roles, refer to the page "Security > Users > Roles.".

The table contains the following columns:

- **User Account**
  Shows the user name.
- **Role**
  Shows the role of the user.
- **Description**
  Displays a description of the user account. The description text can be up to 100 characters long.

Roles

Note

The page is only available if there is an online connection to the device.

Roles

On this page, you create roles that are valid locally on the device.

Note

The values displayed depend on the rights of the logged-in user.

Note

You can create up to 28 additional roles.

Settings

- **Role Name**
  Enter the name for the role. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 64 characters long.

  Note

  Role name cannot be changed

  After creating a role, the name of the role can no longer be changed.

  If a name of a role needs to be changed, the role must be deleted and a new role created.

  Deleting roles

  Predefined roles and assigned roles cannot be deleted or modified.

The table contains the following columns:

- **Role**
  Shows the name of the role.
- **Function Right**
  Select the function rights of the role.
  - 1
    Users with this role can read device parameters but cannot change them.
  - 15
    Users with this role can both read and change device parameters.

  Note

  Function right cannot be changed

  If you have assigned a role, you can no longer change the function right of the role.

  If you want to change the function right of a role, follow the steps outlined below:

  1. Delete all assigned users.
  2. Change the function right of the role:
  3. Assign the role again.

- **Description**
  Enter a description for the role. With predefined roles a description is displayed. The description text can be up to 100 characters long.

Groups

Note

The page is only available if there is an online connection to the device.

User Groups

On this page you link a group with a role.

In this example the group "Administrators" is linked to the "admin"role: The group is defined on a RADIUS server. The role is defined locally on the device. When a RADIUS server authenticates a user and assigns the user to the "Administrators" group, this user is given rights of the "admin" role.

Note

You can create up to 32 groups.

Settings

- **Group Name**
  Enter the name of the group. The name must match the group on the RADIUS server. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 64 characters long.

The table contains the following columns:

- **Group**
  Shows the name of the group.
- **Role**
  Select a role. Users who are authenticated with the linked group on the RADIUS server receive the rights of this role locally on the device.
  You can choose between system-defined and self-defined roles, refer to the page "Security > Users > Roles.".
- **Description**
  Enter a description for the link of the group.to a role.

Passwords

Passwords

Note

The page is only available if there is an online connection to the device.

On this page, you can change passwords. If you are logged on with the "admin" role, you can change the passwords for all user accounts. If you are logged on with the "user" role, you can only change your own password.

Note

If you log on the first time or log on after a "Reset to factory defaults and restart", you will be prompted to change the password.

Note

If you are logged in via a RADIUS server, you cannot change any local device passwords.

Note

Changing the password in "Trial" configuration mode

Even if you change the password in "Trial" configuration mode, this change is saved immediately.

Note

The factory settings for the passwords when the devices ship are as follows:

- admin: admin

When you log in for the first time or following a "Restore Factory Defaults and Restart", with the preset user "admin" you will be prompted to change the password.

Settings

- **Current User**
  Shows the user that is currently logged in.
- **Current User Password**
  Enter the password for the currently logged in user.
- **User Account**
  Select the user whose password you want to change.
- **Password Policy**
  Shows which password policy is being used when assigning new passwords.
  - High
    Password length: at least 8 characters, maximum 128 characters
    at least 1 uppercase letter
    at least 1 special character
    at least 1 number
  - Low
    Password length: at least 6 characters, maximum 128 characters
- **New Password**
  Enter the new password again to confirm it.
- **Password Confirmation**
  Enter the new password again to confirm it.

Options

On this page you specify which password policy will be used when assigning new passwords.

Description

- **Password Policy**
  Shows which password policy is currently being used
- **New Password Policy**
  Select the required setting from the drop-down list.
  - High
    Password length: at least 8 characters, maximum 128 characters
    at least 1 uppercase letter
    at least 1 special character
    at least 1 number
  - Low
    Password length: at least 6 characters, maximum 128 characters

AAA

General

The term "AAA" used in the menu stands for "Authentication, Authorization, Accounting" and is used to identify and allow network nodes, to provide them with the appropriate services and to determine the amount of use.

On this page, you configure the login.

Settings

Note

To be able to use the login authentication "RADIUS", "Local and RADIUS" or "RADIUS and fallback Local" a RADIUS server must be stored and configured for user authentication.

- **Login Authentication**
  Specify how the login is made:
  - Local
    The authentication must be made locally on the device.
  - RADIUS
    The authentication must be handled via a RADIUS server.
  - Local and RADIUS
    The authentication is possible both with the users that exist on the device (user name and password) and via a RADIUS server.
    The user is first searched for in the local database. If the user does not exist there, a RADIUS query is sent.
  - RADIUS and fallback Local
    The authentication must be handled via a RADIUS server.
    A local authentication is performed only when the RADIUS server cannot be reached in the network.

RADIUS client

The term "AAA" used in the menu stands for "Authentication, Authorization, Accounting" and is used to identify and allow network nodes, to provide them with the appropriate services and to determine the amount of use.

Authentication over an external server

The concept of RADIUS is based on an external authentication server.

Each row of the table contains access data for one server. In the search order, the primary server is queried first. If the primary server cannot be reached, secondary servers are queried in the order in which they are entered.

If no server responds, there is no authentication.

Settings

The page contains the following boxes:

- **RADIUS Authorization Mode**
  For the login authentication, the RADIUS authorization mode specifies how the rights are assigned to the user with a successful authentication (Page 1272).
  - conventional
    In this mode the user is logged in with administrator rights if the server returns the value "Administrative User" to the device for the attribute "Service Type". In all other cases the user is logged in with read rights.
  - Vendor specific
    In this mode the assignment of rights depends on whether and which group the server returns for the user and whether or not there is an entry for the user in the table "External User Accounts".

The table has the following columns:

- **Auth. Server Type**
  Select which authentication method the server will be used for.
  - Login
    The server is used only for the login authentication.
  - 802.1X
    The server is used only for the 802.1X authentication.
  - Login & 802.1X
    The server is used for both authentication procedures.
- **RADIUS Server Address**
  Enter the IPv4 address or the FQDN (Fully Qualified Domain Name) of the RADIUS server.
- **Server Port**
  Here, enter the input port on the RADIUS server. As default, input port 1812 is set.
- **Shared Secret**
  Enter your access ID.
- **Confirm Shared Secret**
  Enter your access ID again as confirmation.
- **Max. Retrans**
  Enter the maximum number of query attempts before another configured RADIUS server is queried or the login counts as having failed. As default, 3 is set.
- **Primary Server**
  Specify whether or not this server is the primary server. You can select one of the options "yes" or "no".
- **Test**
  With this button, you can test whether or not the specified RADIUS server is available. The test is performed once and not repeated cyclically.
- **Test Result**
  Shows whether or not the RADIUS server is available:
  - Failed, no test packet sent
    The IP address is not reachable.
    The IP address is reachable, the RADIUS server is, however, not running.
  - Reachable, key not accepted
    The IP address is reachable, the RADIUS server does not, however accept the shared secret.
  - Reachable, key accepted
    The IP address is reachable, the RADIUS server accepts the specified shared secret.

  The test result is not automatically updated. To delete the test result click the "Refresh" button.

802.1x-Authenticator

Setting up network access

An end device can only access the network after the device has verified the login data of the device with the authentication server. Both the end device and the authentication server must support the EAP protocol (Extensive Authentication Protocol).

Enabling authentication for individual ports

By selecting the check box, you specify whether or not network access protection according to IEEE 802.1x is enabled on this port.

Settings

- MAC Authentication
  Enable or disable MAC authentication for the device.
- Guest VLAN
  Enable or disable the "Guest VLAN" function for the device.

Table 1 has the following columns:

- 1st column
  Shows that the settings are valid for all ports of table 2.
- 802.1X Auth. Control
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- 802.1x Re-authentication
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- MAC Authentication
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- Adopt RADIUS VLAN Assignment
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- MAC Auth. Max Permitted Addresses
  Enter how many end devices are allowed to be connected to the port at the same time. If "No Change" is entered, the entry in table 2 remains unchanged
- Guest VLAN
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- Guest VLAN ID
  Enter the VLAN ID of the port. If "No Change" is entered, the entry in table 2 remains unchanged

- **Guest VLAN max. Permitted Addresses**
  Enter how many end devices are allowed in the guest VLAN at the same time.
- **Transfer to table**
  If you click the button, the settings are adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows all available ports.
- **802.1X Auth. Control**
  Specify the authentication of the port:
  - Force Unauthorized
    Data traffic via the port is blocked.
  - Force Authorized
    Data traffic via the port is allowed without any restrictions.
    Default setting
  - Auto
    End devices are authenticated on the port with the "802.1x" method.
    The data traffic via the port is permitted or blocked depending on the authentication result.
- **802.1x Re-authentication**
  Enable this option if you want reauthentication of an already authenticated end device to be repeated cyclically.
- **MAC Authentication**
  Enable this option if you want end devices to be authenticated with the "MAC Authentication" method.

  Note

  At the port level, you cannot enable "MAC Authentication" and "Guest VLAN" at the same time.

  If "Auto is configured for "802.1x Auth. Control and the " MAC Authentication is enabled, the timeout for the "802.1X procedure is 5 seconds. If manual input is necessary at a port for the authentication with the 802.1X" procedure, the 5 seconds are not adequate. To be able to run authentication using "802.1X", disable the MAC authentication on this port.
- **Adopt RADIUS VLAN Assignment**
  The RADIUS server informs the IE switch of the VLAN to which the port will belong. Enable this option if you want the information of the server to be taken into account.
  The port can only e assigned to the VLAN, if the VLAN has been created on the device. Otherwise Authentication (Page 1272) is rejected.
- **MAC Auth. Max Permitted Addresses**
  Enter how many end devices are allowed to be connected to the port at the same time.

- **Guest VLAN**
  Enable this option if you want the end device to be permitted in the guest VLAN if authentication fails.
  The port can only e assigned to the VLAN, if the VLAN has been created on the device. Otherwise Authentication (Page 1272) is rejected.
  This function is also known as "Authentication failed VLAN".

  Note

  At the port level, you cannot enable "MAC Authentication" and "Guest VLAN" at the same time.

- **Guest VLAN ID**
  Enter the VLAN ID of the port.
- **Guest VLAN max. Permitted Addresses**
  Enter how many end devices are allowed in the guest VLAN at the same time.
- **MAC Auth. Currently Permitted Addresses**
  Shows the number of currently connected end devices.
- **802.1X Auth.-Status**
  Shows the status of the authentication of the port:
  - Authorize
  - Do not authorize
- **MAC Auth. Currently Blocked Addresses**
  Shows the number of currently blocked end devices.
- **Guest VLAN Currently Permitted Addresses**
  Shows how many end devices are currently allowed in the guest VLAN.

MAC ACL

Rule configuration

On this page, you specify the access rules for the MAC-based Access Control List. Using the MAC-based ACL, you can specify whether frames of certain MAC addresses are forwarded or discarded.

Settings

- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Enter the unicast MAC address of the source.
  Destination MAC Address
  Enter the unicast MAC address of the destination.

- **Action**
  Select the action. The following is possible:
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Ingress Interfaces**
  Shows a list of all interfaces to which this rule applies.
- **Egress Interfaces**
  Shows a list of all interfaces to which this rule applies.

Note

Entering the MAC addresses

If you enter the address "00:00:00:00:00:00" for the source and/or destination MAC address, the rule created in this way applies to all source or destination MAC addresses.

Ingress Rules

On this page, you specify the ACL rule according to which incoming frames are handled by the port.

Settings

- **Interface**
  Select the required interface.
- **Add Rule**
  Select the ACL rule to be assigned to the interface. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the interface, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the interface, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Shows the unicast MAC address of the source.

- **Destination MAC Address**
  Shows the unicast MAC address of the destination.
- **Action**
  Shows the action:
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.

Egress Rules

On this page, you specify the ACL rule according to which outgoing frames are handled by the port.

Settings

- **Interface**
  Select the required interface.
- **Add Rule**
  Select the ACL rule to be assigned to the interface. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the interface, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the interface, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Shows the unicast MAC address of the source.
- **Destination MAC Address**
  Shows the unicast MAC address of the destination.
- **Action**
  Shows the action
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.

IP ACL

Rule configuration

On this page, you specify the rules for the IP-based ACL.

Settings

The table has the following columns:

- Rule Number
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- Source IP
  Enter the IPv4 address of the source.
- Source Subnet Mask
  Enter the subnet mask in which the source is located.
- Dest. IP
  Enter the IP address of the destination.
- Dest. Subnet Mask
  Enter the subnet mask in which the destination is located.
- Action
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- Ingress Interfaces
  Shows a list of all interfaces to which this rule applies.
- Egress Interfaces
  Shows a list of all interfaces to which this rule applies.

Protocol configuration

On this page, you specify the rules for protocols.

Settings

The table has the following columns:

- Rule Number
  Shows the number of the protocol rule. When you create a rule, a new row with a unique number is created.
- Protocol
  Select the protocol for which this rule is valid.

- **Protocol Number**
  Enter a protocol number to define further protocols.
  This box can only be edited if you have set "Other Protocol" for the protocol.
- **Source Port Min.**
  Enter the lowest possible port number of the source port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Source Port Max.**
  Enter the highest possible port number of the source port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Dest. Port Min.**
  Enter the lowest possible port number of the destination port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Dest. Port Max.**
  Enter the highest possible port number of the destination port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Message Type**
  Enter a message type to decide the format of the message.
  This box can only be edited if you have set "ICMP" for the protocol.
- **Message Code**
  Enter a message code to specify the function of the message.
  This box can only be edited if you have set "ICMP" for the protocol.
- **DSCP**
  Enter a value for classifying the priority.
  This box cannot be edited if you have set "ICMP" for the protocol.

Ingress Rules

On this page, you specify the ACL rule according to which incoming frames are handled by the port or VLAN.

Settings

- **Ports**
  Select the required port: a port or a VLAN interface.
  To select a VLAN interface, an IP interface must be configured.

  Note

  If you use a VLAN interface, the ACL rule applies to all ports that belong to the VLAN.

- **Add Rule**
  Select the ACL rule to be assigned to the port. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the port, click the "Add" button. The configuration is shown in the table.

- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the port, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Protocol**
  Shows the protocol for which this rule is valid.
- **Protocol Number**
  Shows the protocol number.
- **Source IP**
  Shows the IP address of the source.
- **Source Subnet Mask**
  Shows the subnet mask in which the source is located.
- **Dest. IP**
  Shows the IP address of the destination.
- **Dest. Subnet Mask**
  Shows the subnet mask of the destination.
- **Action**
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Source Port Min.**
  Shows the lowest possible port number of the source port.
- **Source Port Max.**
  Shows the highest possible port number of the source port.
- **Dest. Port Min.**
  Shows the lowest possible port number of the destination port.
- **Dest. Port Max.**
  Shows the highest possible port number of the destination port.
- **Message Type**
  Shows a message type to decide the format of the message.
- **Message Code**
  Shows a message code to specify the function of the message.
- **DSCP**
  Shows the value for classifying the priority.

Egress Rules

On this page, you specify the ACL rule according to which outgoing frames are handled by the port.

Settings

- **Ports**
  Select the required port: a port or a VLAN interface.
  To select a VLAN interface, an IP interface must be configured.

  Note

  If you use a VLAN interface, the ACL rule applies to all ports that belong to the VLAN.

- **Add Rule**
  Select the ACL rule to be assigned to the port. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the port, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the port, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Protocol**
  Shows the protocol for which this rule is valid.
- **Protocol Number**
  Shows the protocol number.
- **Source IP**
  Shows the IP address of the source.
- **Source Subnet Mask**
  Shows the subnet mask in which the source is located.
- **Dest. IP**
  Shows the IP address of the destination.
- **Dest. Subnet Mask**
  Shows the subnet mask of the source.

- **Action**
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Source Port Min.**
  Shows the lowest possible port number of the source port.
- **Source Port Max.**
  Shows the highest possible port number of the source port.
- **Dest. Port Min.**
  Shows the lowest possible port number of the destination port.
- **Dest. Port Max.**
  Shows the highest possible port number of the destination port.
- **Message Type**
  Shows a message type to decide the format of the message.
- **Message Code**
  Shows a message code to specify the function of the message.
- **DSCP**
  Shows the value for classifying the priority.

Management ACL

On this page, you can increase the security of your device. To specify which station with which IPv4 address is allowed to access your device, configure the IPv4 address or an entire address range.

You can select the protocols and the ports with which the station is allowed to access the device. You define the VLAN in which the station may be located. This ensures that only certain stations within a VLAN have access to the device.

Note

If you enable this function, note the following

A bad configuration on the "Management Access Control List" page can result in you being unable to access the device. You should therefore configure an access rule that allows access to the management before you enable the function.

Settings

- **Management ACL**
  Enable or disable the function. As default, the function is disabled.

  Note

  If the function is disabled, there is unrestricted access to the management of the IE switch. The configured access rules are only taken into account when the function is enabled.

- **IP Address**
  Enter the IPv4 address or the network address for which the rule will apply. If you use the IPv4 address 0.0.0.0, the settings apply to all IPv4 addresses.
- **Subnet Mask**
  Enter the subnet mask. The subnet mask 255.255.255.255 is for a specific IP address. If you want to allow a subnet, for example a C subnet, enter 255.255.255.0. The subnet mask 0.0.0.0 applies to all subnets.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **IP Address**
  Shows the IPv4 address.
- **Subnet Mask**
  Shows the subnet mask.
- **VLANs Allowed**
  Enter the number of the VLAN in which the device is located. The station can only access the device if it is located in this configured VLAN. If this input box remains empty, there is no restriction relating to the VLANs.
- **SNMP**
  Specify whether the station (or the IPv4 address) can access the device using the SNMP protocol.
- **TELNET**
  Specify whether the station (or the IPv4 address) can access the device using the TELNET protocol.
- **HTTP**
  Specify whether the station (or the IPv4 address) can access the device using the HTTP protocol.
- **HTTPS**
  Specify whether the station (or the IPv4 address) can access the device using the HTTPS protocol.
- **SSH**
  Specify whether the station (or the IPv4 address) can access the device using the SSH protocol.
- **Px.y**
  Specify whether the station (or the IPv4 address) can access this device via this port (slot.port).

Configuring SCALANCE W

IP address assignment

Configuration options

When shipped and after restoring to the factory settings, the device does not have an IP address.

The following options are available to assign an IP address to the device:

- DHCP (default setting)
- Primary Setup Tool
  For further information, refer to the configuration manual "Primary Setup Tool". You will find the configuration manual at Siemens Industry Automation and Drives Service & Support on the Internet under the entry ID 19440762 (http://support.automation.siemens.com/WW/view/en/19440762).
- STEP 7
- CLI via the serial interface
  For further information, refer to the configuration manuals for the Command Line Interface". You will find the configuration manuals at Siemens Industry Automation and Drives Service & Support on the Internet under the following entry IDs.
  - SCALANCE W780/W740 Command Line Interface - entry ID 62515451 (http://support.automation.siemens.com/WW/view/en/62515451)
  - SCALANCE W770/W730 Command Line Interface - entry ID 89534887 (http://support.automation.siemens.com/WW/view/en/89534887)
  - SCALANCE W760/W720 Command Line Interface - entry ID 89534699 (http://support.automation.siemens.com/WW/view/en/89534699)

Requirement

- "Set IP address on device" is enabled in the properties of the device. You will find more detailed information in "Addressing PROFINET devices".

Interfaces and system functions

SCALANCE W780 / W740

Availability of the interfaces

The following table shows the availability of the physical and logical interfaces. Note that in this table all interfaces are listed. Depending on the system function, some interfaces are not available. On the WBM pages you can only select the available interfaces.

We reserve the right to make technical changes.

	Client device **W748-1 M12** **W748-1 RJ-45**	**Access points** **W786-1 RJ-45** **W788-1 M12** **W788-1 RJ-45**	**Access points** **W786-2 RJ-45** **W786-2IA RJ-45** **W786-2 SFP** **W788-2 M12** **W788-2 M12 EEC** **W788-1 RJ-45** **W788-2 RJ-45**
Wireless interface (WLAN)	WLAN 1	WLAN 1	• WLAN 1 (in client mode only one WLAN interface is available) • WLAN 2
IP interface: LAN interface VLAN	 P1 ManagementVLAN	 P1 ManagementVLAN	 P1 ManagementV-LAN
VAP interface [1)]	-	VAP 1.Y Y = 1 ... 8	VAP X.Y X = 1 ... 2 Y = 1 ... 8
WDS interface [1)]	_	WDS 1.Y Y = 1 ... 8	WDS X.Y X = 1 ... 2 Y = 1 ... 8
VLAN	24	24	24

[1)] only in access point mode

Availability of the system functions

The following table shows the availability of the system functions on the devices. Note that all functions are described in this configuration manual and in the online help. Depending on the mode and the KEY-PLUG, some functions are not available.

We reserve the right to make technical changes.

IPv6 support

Support of IPv6

The following system functions do not support IPv6 addresses:

- Inter AP blocking
- Force roaming
- IP ACL
- Management ACL

Editing properties and parameters

Editing options

You have the following options for editing properties and parameters:

- Hardware and network editor
  Once you have inserted the network component, you can edit the properties and parameters, for example the device name. You will find more detailed information in "Hardware and network editor".
- Web Based Management (WBM)
  The parameters and properties are accessible using the supplied HTML pages (WBM pages). Each WBM page has its own help page that describes the properties and parameters. For further information, refer to the configuration manuals for Web Based Management.
  - SCALANCE W780/W740 Web Based Management - entry ID: 62382125 (http://support.automation.siemens.com/WW/view/en/62382125)
  - SCALANCE W770/W730 Web Based Management - entry ID: 89535155 (http://support.automation.siemens.com/WW/view/en/89535155)
  - SCALANCE W760/W720 Web Based Management - entry ID: 89535534 (http://support.automation.siemens.com/WW/view/en/89535534)
- Command Line Interface
  All the configuration settings for the device can be made using the CLI. The CLI provides the same options as Web Based Management (WBM). For further information, refer to the configuration manuals for the Command Line Interface.
  - SCALANCE W780/W740 Command Line Interface - entry ID: 62515451 (http://support.automation.siemens.com/WW/view/en/62515451)
  - SCALANCE W770/W730 Command Line Interface - entry ID: 89534887 (http://support.automation.siemens.com/WW/view/en/89534887)
  - SCALANCE W760/W720 Command Line Interface - entry ID: 89534699 (http://support.automation.siemens.com/WW/view/en/89534699)

Availability

The availability of the settings depends

- on the device mode
- on the configuration mode
- Device

Device mode

With SCALANCE W the following device modes are available:

- Access point mode
- Client mode

Configuration mode

The following configuration modes are available:

- Offline configuration
  You can configure a PC station the first time offline. In this mode only the settings that require no connection to the device are available.
- Online configuration mode
  If there is a connection to the device and Web Based Management has started, there are additional pages available in the work area. In the online help, these pages include the note "This page is only available if there is an online connection to the device". With some settings, the additional information "only available online" is included.
  Web Based Management can be started in the following ways:
  - Select "Management" in the navigation panel and click on "Web Based Management".
  - Start the Web browser and enter the IP address or the URL of the device in the address box.

Device

Some of the settings depend on the device. The names used in the online help have the following meaning:

SCALANCE W740	The chapter described / the section described / the setting described is only relevant for the following devices: SCALANCE W748-1 RJ-45 SCALANCE W748-1 M12
SCALANCE W780	The chapter described / the section described / the setting described is only relevant for the following devices: SCALANCE W788-1 M12 SCALANCE W788-2 M12 SCALANCE W788-2 M12 EEC SCALANCE W788-1 RJ-45 SCALANCE W788-2 RJ-45 SCALANCE W786-1 RJ-45 SCALANCE W786-2 RJ-45 SCALANCE W786-2IA RJ-45 SCALANCE W786-2 SFP

SCALANCE W770	The chapter described / the section described / the setting described is only relevant for the following devices: SCALANCE W774-1 RJ-45
SCALANCE W730	The chapter described / the section described / the setting described is only relevant for the following devices: SCALANCE W734-1 RJ-45
SCALANCE W760	The chapter described / the section described / the setting described is only relevant for the following devices: SCALANCE W761-1 RJ-45

Creating and deleting an entry

As an example, an entry will be created and deleted on the Syslog client. The procedure is valid on all pages.

Creating a new entry

1. Select the device in the network or device view.
2. Open the properties of the device in the Inspector window.
3. In the Inspector window go to System > Syslog client.
4. Enter the IP address for the Syslog server.
5. Click in the table. Select the entry "New entry" in the shortcut menu. A new entry is created in the table.

Deleting an entry

1. Select the required entry in the table.
2. Select the "Delete" entry in the shortcut menu.

Buttons you require often

- **Updating the display with "Refresh"**
  Pages that display current parameters have a "Refresh" button at the lower edge of the page. Click this button to request up-to-date information from the device for the current page.
- **Save the settings for all ports with "Transfer to table"**
  Pages on which you can configure several ports have 2 tables. In the first table, you can make the settings for all ports and transfer these to the second table. In the last column of the first table, there is the "Transfer to table" button. Click this button to save the settings you have made for all ports.

Configuration limits

SCALANCE W780 / W740

Configuration limits of the device

The following table lists the configuration limits for Web Based Management and the Command Line Interface of the device.

Depending on your device, some functions are not available.

	Configurable function	Maximum number
System	Syslog server	3
	DNS server	3
	SMTP server	2
	SNMPv1 trap recipient	10
	SNTP server	2
	NTP server	1
	DHCP pools	1
	IPv4 addresses managed by the DHCP server (dynamic + static)	100
	DHCP static assignments per DHCP pool	20
	DHCP options	20
Interfaces	Force destination addresses for roaming	10
Layer 2	Virtual LANs (port-based; including VLAN 1)	24
	Multiple Spanning Tree instances	16

	Configurable function	Maximum number
Security	IP addresses from RADIUS servers	• AAA: 4 • WLAN: 2
	Management ACLs (access rules for management)	10
	MAC ACL rule configuration	20
	Ingress and egress rules for MAC ACL (total)	40 per interface (20 ingress rules / 20 egress rules) • Client: 80 (P1, WLAN) • Access point: 680 (P1, WDS 1,Y, VAP 1,Y) • Dual access point: 1320 (P1, WDS X,Y, VAP X,Y)
	IP ACL rule configuration	20
	Ingress and egress rules for port ACL IP (total)	40 per interface (20 ingress rules / 20 egress rules) • Client: 120 (P1, WLAN, management VLAN) • Access point: 720 (P1, WDS 1,Y, VAP 1,Y, management VLAN) • Dual access point: 1360 (P1, WDS X,Y, VAP X,Y, management VLAN)
	User roles	28
	User groups	32
	Users	28

Useful information

IP addresses

IPv4 / IPv6

What are the essential differences?

	IPv4	IPv6
IP configuration	• DHCP server • Manual	• Stateless Address Autoconfiguration (SLAAC): Stateless autoconfiguration using NDP (Neighbor Discovery Protocol) – Creates a link local address for every interface that does not require a router on the link. – Checks the uniqueness of the address on the link that requires no router on the link. – Specifies whether the global addresses are obtained via a status-free mechanism, a mechanism with status or via both mechanisms. (Requires a router on the link.) • Manual • DHCPv6 (status dependent)
Available IP addresses	32-bit: 4, 29 * 10^9 addresses	128-bit: 3, 4 * 10^{38} addresses
Address format	Decimal: 192.168.1.1 with port: 192.168.1.1:20	Hexadecimal: 2a00:ad80::0123 with port: [2a00:ad80::0123]:20
Loopback	127.0.0.1	::1
IP addresses of the interface	4 IP addresses	Multiple IP addresses • LLA: A link local address (formed automatically) fe80::/128 per interface • ULA: Several unique local unicast addresses per interface • GUA: Several global unicast addresses per interface
Header	• Checksum • Variable length • Fragmentation in the header • No security	• Checking at a higher layer • Fixed size • Fragmentation in the extension header
Fragmentation	Host and router	Only endpoint of the communication
Quality of service	Type of Service (ToS) for prioritization	The prioritization is specified in the header field "Traffic Class".

	IPv4	IPv6
Types of frame	Broadcast, multicast, unicast	Multicast, unicast, anycast
Identification of DHCP clients/ server	Client ID: MAC address	DUID + IAID(s) = exactly one interface of the host DUID = DHCP unique identifier Identifies server and clients uniquely and should not change, not even when replacing network components! IAID = Identity Association Identifier At least one per interface is generated by the client and remains unchanged when the DHCP client restarts Three methods of obtaining the DUID • DUID-LLT • DUID-EN • DUID-LL
DHCP	via UDP with broadcast	via UDP with unicast RFC 3315, RFC 3363 **Stateful DHCPv6** Status-dependent configuration in which the IPv6 address and the configuration settings are transferred. Four DHVPv6 messages are exchanged between client and server: 1. SOLICIT: Sent by the DHCPv6 client to localize DHCPv6 servers. 2. ADVERTISE The available DHCPv6 servers reply to this. 3. REQUEST The DHCPv6 client requests an IPv6 address and the configuration settings from the DHCPv6 server. 4. REPLY The DHCPv6 server sends the IPv6 address and the configuration settings. If the client and server support the function "Rapid commit" the procedure is shortened to two DHCPv6 messages SOLICIT and REPLY . **Stateless autoconfiguration** In stateless DHCPv6, only the configuration settings are transferred. **Prefix delegation** The DHCPv6 server delegates the distribution of IPv6 prefixes to the DHCPv6 client. The DHCPv6 client is also known as PD router.
Resolution of IP addresses in hardware addresses	ARP (Address Resolution Protocol)	NDP (Neighbor Discovery Protocol)

IPv4 address

Structure of an IPv4 address

Address classes

IP address range	Max. number of networks	Max. number of hosts/network	Class	CIDR
1.x.x.x through 126.x.x.x	126	16777214	A	/8
128.0.x.x through 191.255.x.x	16383	65534	B	/16
192.0.0.x through 223.255.255.x	2097151	254	C	/24
224.0.0.0 - 239.255.255.255	Multicast applications		D	
240.0.0.0 - 255.255.255.255	Reserved for future applications		E	

An IP address consists of 4 bytes. Each byte is represented in decimal, with a dot separating it from the previous one. This results in the following structure, where XXX stands for a number between 0 and 255:

XXX.XXX.XXX.XXX

The IP address is made up of two parts, the network ID and the host ID. This allows different subnets to be created. Depending on the bytes of the IP address used as the network ID and those used for the host ID, the IP address can be assigned to a specific address class.

Subnet mask

The bits of the host ID can be used to create subnets. The leading bits represent the address of the subnet and the remaining bits the address of the host in the subnet.

A subnet is defined by the subnet mask. The structure of the subnet mask corresponds to that of an IP address. If a "1" is used at a bit position in the subnet mask, the bit belongs to the corresponding position in the IP address of the subnet address, otherwise to the address of the computer.

Example of a class B network:

The standard subnet address for class B networks is 255.255.0.0; in other words, the last two bytes are available for defining a subnet. If 16 subnets must be defined, the third byte of the subnet address must be set to 11110000 (binary notation). In this case, this results in the subnet mask 255.255.240.0.

To find out whether two IP addresses belong to the same subnet, the two IP addresses and the subnet mask are ANDed bit by bit. If both logic operations have the save result, both IP addresses belong to the same subnet, for example, 141.120.246.210 and 141.120.252.108.

Outside the local area network, the distinction between network ID and host ID is of no significance, in this case packets are delivered based on the entire IP address.

Note

In the bit representation of the subnet mask, the "ones" must be set left-justified; in other words, there must be no "zeros" between the "ones".

IPv6 addresses

IPv6 terms

Network node

A network node is a device that is connected to one or more networks via one or more interfaces.

Router

A network node that forwards IPv6 packets.

Host

A network node that represents an end point for IPv6 communication relations.

Link

A link is, according to IPv6 terminology, a direct layer 3 connection within an IPv6 network.

Neighbor

A network node located on the same link as the network node.

IPv6 interface

Physical or logical interface on which IPv6 is activated.

Path MTU

Maximum permitted packet size on a path from a sender to a recipient.

Path MTU discovery

Mechanism for determining the maximum permitted packet size along the entire path from a sender to a recipient.

LLA

Link local address FE80::/10

As soon as IPv6 is activated on the interface, a link local address is formed automatically. Can only be reached by accounts located on the same link.

ULA

Unique Local Address

Defined in RFC 4193. Via this address, the IPv6 interface can be reached in the LAN.

GUA

Global Unicast Address Via this address, the IPv6 interface can be reached, e.g. via the Internet.

Interface ID

The interface ID is formed with the EUI-64 method or manually.

EUI-64

Extended Unique Identifier (RFC 4291); method for forming the interface ID. In Ethernet, the interface ID is formed from the MAC address of the interface. Divides the MAC address into

the manufacturer-specific part (OUI) and the network-specific part (NIC) and inserts FFFE between the two parts.

Example:

MAC address = AA:BB:CC:DD:EE:FF

OUI = AA:BB:CC

NIC = DD:EE:FF

EUI-64 = OUI + **FFFE** + NIC = AA:BB:CC:**FF:FE**:DD:EE:FF

Scope

Defines the range of the IPv6 address.

Structure of an IPv6 address

IPv6 address format - notation

IPv6 addresses consist of 8 fields each with four-character hexadecimal numbers (128 bits in total). The fields are separated by a colon.

Example:

fd00:0000:0000:ffff:02d1:7d01:0000:8f21

Rules / simplifications:

- If one or more fields have the value 0, a shortened notation is possible.
  The address fd00:**0000:0000**:ffff:02d1:7d01:0000:8f21 can also be shortened and written as follows:
  fd00**::**ffff:02d1:7d01:0000:8f21
  To ensure uniqueness, this shortened form can only be used once within the entire address.
- Leading zeros within a field can be omitted.
  The address fd00:0000:0000:ffff:**02d1**:7d01:0000:8f21 can also be shortened and written as follows:
  fd00**::**ffff:**2d1**:7d01:0000:8f21
- Decimal notation with periods
  The last 2 fields or 4 bytes can be written in the normal decimal notation with periods.
  Example: The IPv6 address fd00::ffff.125.1.0.1 is equivalent to fd00::ffff:7d01:1

Structure of the IPv6 address

The IPv6 protocol distinguishes three types of address: Unicast , anycast and multicast. The following section describes the structure of the global unicast addresses.

IPv6 prefix		Suffix
Global prefix: n bits	Subnet ID m bits	Interface ID 128 - n - m bits
Assigned address range	Description of the location, also subnet prefix or subnet	Unique assignment of the host in the network. The ID is generated from the MAC address.

The prefix for the link local address is always fe80:0000:0000:0000. The prefix is shortened and noted as follows: fe80::

IPv6 prefix

Specified in: RFC 4291

The IPv6 prefix represents the subnet identifier.

Prefixes and IPv6 addresses are specified in the same way as with the CIDR notation (Classless Inter-Domain Routing) for IPv4.

Design

IPv6 address / prefix length

Example

IPv6 address: 2001:0db8:1234::1111/48

Prefix: 2001:0db8:1234::/48

Interface ID: ::1111

Entry and appearance

The entry of IPv6 addresses is possible in the notations described above. IPv6 addresses are always shown in the hexadecimal notation.

VLAN

VLAN tagging

Expansion of the Ethernet frames by four bytes

For CoS (Class of Service, frame priority) and VLAN (virtual network), the IEEE 802.1Q standard defined the expansion of Ethernet frames by adding the VLAN tag.

Note

The VLAN tag increases the permitted total length of the frame from 1518 to 1522 bytes. The end nodes on the networks must be checked to find out whether they can process this length / this frame type. If this is not the case, only frames of the standard length may be sent to these nodes.

The additional 4 bytes are located in the header of the Ethernet frame between the source address and the Ethernet type / length field:

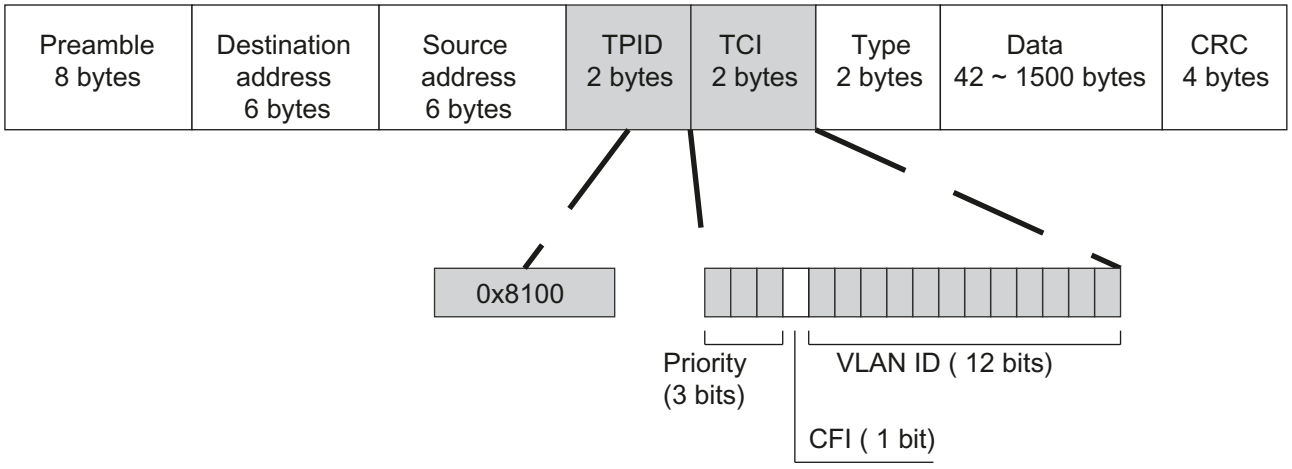

Figure 10-17 Structure of the expanded Ethernet frame

The additional bytes contain the tag protocol identifier (TPID) and the tag control information (TCI).

Tag protocol identifier (TPID)

The first 2 bytes form the Tag Protocol Identifier (TPID) and always have the value 0x8100. This value specifies that the data packet contains VLAN information or priority information.

Tag Control Information (TCI)

The 2 bytes of the Tag Control Information (TCI) contain the following information:

QoS Trust

The tagged frame has 3 bits for the priority that is also known as Class of Service (CoS), see also IEEE 802.1Q.

CoS bits	Priority	Type of the data traffic
000	0 (lowest)	Background
001	1	Best Effort
010	2	Excellent Effort
011	3	Critical Applications
100	4	Video, < 100 ms delay (latency and jitter)
101	5	Voice (language), < 10 ms delay (latency and jitter)
110	6	Internetwork Control
111	7 (highest)	Network Control

The prioritization of the data packets is possible only if there is a queue in the components in which they can buffer data packets with lower priority.

The device has multiple parallel queues in which the frames with different priorities can be processed. As default, first, the frames with the highest priority are processed. This method ensures that the frames with the highest priority are sent even if there is heavy data traffic.

Canonical Format Identifier (CFI)

The CFI is required for compatibility between Ethernet and the token Ring.
The values have the following meaning:

Value	Meaning
0	The format of the MAC address is canonical. In the canonical representation of the MAC address, the least significant bit is transferred first. Standard-setting for Ethernet switches.
1	The format of the MAC address is not canonical.

VLAN ID

In the 12-bit data field, up to 4096 VLAN IDs can be formed. The following conventions apply:

VLAN ID	Meaning
0	The frame contains only priority information (priority tagged frames) and no valid VLAN identifier.
1- 4094	Valid VLAN identifier, the frame is assigned to a VLAN and can also include priority information.
4095	Reserved

VLAN

Network definition regardless of the spatial location of the nodes

VLAN (Virtual Local Area Network) divides a physical network into several logical networks that are shielded from each other. Here, devices are grouped together to form logical groups. Only nodes of the same VLAN can address each other. Since multicast and broadcast frames are only forwarded within the particular VLAN, they are also known as broadcast domains.

The particular advantage of VLANs is the reduced network load for the nodes and network segments of other VLANs.

To identify which frame belongs to which VLAN, the frame is expanded by 4 bytes. This expansion is also known as VLAN tag and includes not only the VLAN ID but also priority information.

Note

When the device receives a doubly tagged frame, the first tag (vlan) is evaluated for the path and the second tag for the priority.

Options for the VLAN assignment

There are various options for the assignment to VLANs:

- Port-based VLAN
  Each port of a device is assigned a VLAN ID. You configure port-based VLAN in "Layer 2 > VLAN".
- Protocol-based VLAN
  Each port of a device is assigned a protocol group.
- Subnet-based VLAN
  The IP address of the device is assigned a VLAN ID.

MAC-based communication

Frames sent by the client to the access point always have the MAC address of the WLAN client as the source MAC address. In the "learning table" of the access point there is therefore only the MAC address of the WLAN client.

MAC mode "Automatic", "Manual" and "Own"

If the MAC address of a device connected to the client is adopted (Automatic) or is set manually (Manual), both the MAC-based and the IP-based frames find their destination for precisely this device. If the MAC address of the Ethernet interface of the WLAN client is used (Own), the MAC-based and IP-based frames only reach the WLAN client.

The access point checks whether the destination MAC address matches the MAC addresses of the connected clients. Since a WLAN client can only use a MAC address, communication at the MAC address level (ISO/OSI layer 2) can be to a maximum of one node downstream from the client or the client itself.

With IP Mapping, several nodes downstream from a client can be addressed based on the IP protocol. The IP packets are broken down according to an internal table and forwarded to the connected devices.

Maximum possible number of Ethernet nodes with layer 2 communication downstream from the client: 1

Notes on the "Automatic" setting:

- As long as there is no link on the Ethernet interface, the device uses the MAC address of the Ethernet interface so that it can be reached in this status. In this status, the device can be found using the Primary Setup Tool and configured with WBM or CLI.
- As soon as there is a link on the Ethernet interface, the device adopts the source MAC address of the first received frame.

Note

From the moment that the device adopts another MAC address (manually or automatically), the device no longer responds to queries of the Primary Setup Tool when the query is received over the WLAN interface. Queries of the PST over the Ethernet interface continue to be replied to.

MAC mode "Layer 2 Tunnel"

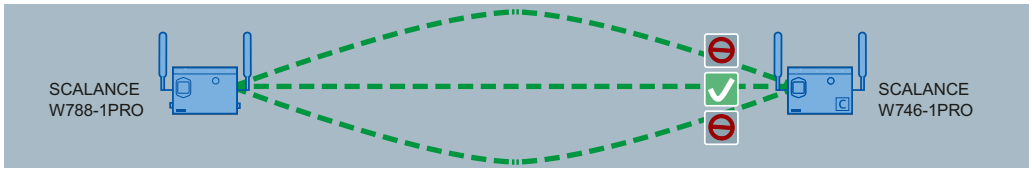
With the setting "Layer 2 Tunnel", the client provides information about the devices downstream from it when it logs in to an access point. This makes it possible to enter the MAC addresses of these devices in the "learning table" of the access point. The access point can forward MAC-based frames for the devices downstream from the client to the appropriate client.

In much the same way as with WDS, a separate port is created for the L2T client over which the Ethernet frames are sent without changing the destination MAC address.

Maximum possible number of Ethernet nodes downstream from the client: 8

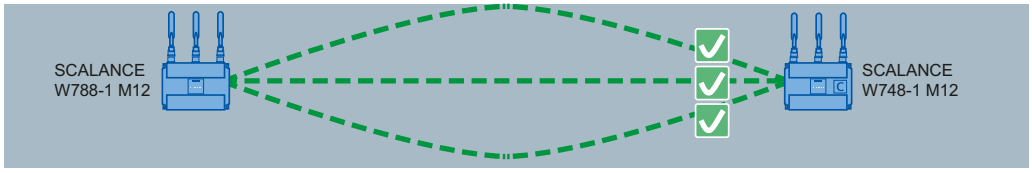
IEEE 802.11n

Overview



The standard IEEE 802.11n is an expansion of the 802.11 standard and was approved in 2009. Previous standards worked either in the 2.4 GHz frequency band (IEEE 802.11g /b) or in the 5 GHz frequency band (IEEE 802.11a). IEEE 802.11n can operate in both frequency band. In the IEEE 802.11n standard, there are mechanisms implemented in PHY and MAC layers that increase the data throughput and improve the wireless coverage.

- MIMO antenna technology
- Maximum ratio combining (MRC)
- Spatial multiplexing
- Channel bonding
- Frame aggregation
- Accelerated guard interval
- Modulation and coding scheme
- Data throughput rates up to 450 Mbps (gross)
  This is not possible on all SCALANCE W700 devices.



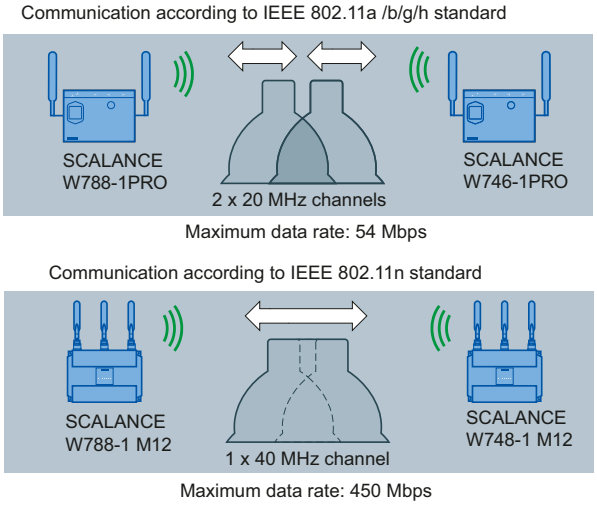
MIMO antenna technology

MIMO (Multiple Input - Multiple Output) is based on an intelligent multiple antenna system. The transmitter and the receiver have several spatially separate antennas. The spatially separate antennas transmit the data streams at the same time. Up to four data streams are possible. The data streams are transmitted over spatially separate paths and return over different paths due to diffraction, refraction, fading and reflection (multipath propagation). The multipath propagation means that at the point of reception a complex, space- and time-dependent pattern results as a total signal made up of the individual signals sent. MIMO uses this unique pattern by detecting the spatial position of characteristic signals. Here, each spatial position is different from the neighboring position. By characterizing the individual senders, the recipient is capable of separating several signals from each other.

Multipath propagation with IEEE 802.11a/b/g

Multipath propagation IEEE 802.11n (MIMO)

Maximum ratio combining (MRC)



In a multiple antenna system, the wireless signals are received by the individual antennas and combined to form one signal. The MRC method is used to combine the wireless signals. The MRC method weights the wireless signals according to their signal-to-noise ratio and combines the wireless signals to form one signal. The signal-to-noise ratio is improved and the error rate is reduced.

Spatial mutliplexing

With spatial multiplexing, different information is sent using the same frequency. The data stream is distributed over n transmitting antennas; in other words, each antenna sends only 1/n of the data stream. The division of the data stream is restricted by the number of antennas. At the receiver end, the signal is reconstructed.
Due to the spatial multiplexing, there is a higher signal-to-noise ratio and a higher data throughput.

Channel bonding

With IEEE 802.11n, data can be transferred via two directly neighboring channels. The two 20 MHz channels are put together to form one channel with 40 MHz. This allows the channel bandwidth to be doubled and the data throughput to be increased.
To be able to use channel bonding, the recipient must support 40 MHz transmissions. If the recipient does not support 40 MHz transmissions, the band is automatically reduced to 20 MHz. This means that IEEE 802.11n can also communicate with IEEE 802.11a/b/g devices.
The channel bundling is set on the "AP" WBM page with the "HT Channel Width [MHz]" parameter.

Frame aggregation

With IEEE 802.11n, it is possible to group together individual data packets to form a single larger packet; this is known as frame aggregation. There are two types of frame aggregation: Aggregated MAC Protocol Data Unit (A-MPDU) and Aggregated MAC Service Data Unit (A-MSDU).
The frame aggregation reduces the packet overheads. Frame aggregation can only be used if the individual data packets are intended for the same receiving station (client).
The SCALANCE W700 devices support both types of frame aggregation. You specify the settings for the A-MPDU data packet on the "AP 802.11n" WBM page.

Accelerated guard interval

The guard interval prevents different transmissions being mixed together. In telecommunications, this mixing is also known as intersymbol interference (ISI).
When the send time has elapsed, a send pause (guard interval) must be kept to before the next transmission begins.

The guard interval of IEEE 802.11a /b/g is 800 ns. IEEE 802.11n can use the reduced guard interval of 400 ns. You specify the guard interval on the "AP 802.11n" WBM page.

Modulation and coding schemes

The IEEE 802.11n standard supports different data rates. The data rates are based on the number of spatial streams, the modulation method and the channel coding. The various combinations are described in modulation and coding schemes.

PROFINET

PROFINET

PROFINET is an open standard (IEC 61158/61784) for industrial automation based on Industrial Ethernet. PROFINET uses existing IT standards and allows end-to-end communication from the field level to the management level as well as plant-wide engineering. PROFINET also has the following features:

- Use of TCP/IP
- Automation of applications with real-time requirements
  - Real-Time (RT) communication
  - Isochronous Real-Time (IRT) communication
- Seamless integration of fieldbus systems

You configure PROFINET in "System > PROFINET (Page 1374)".

PROFINET IO

Within the framework of PROFINET, PROFINET IO is a communications concept for implementing modular, distributed applications. PROFINET IO is implemented by the PROFINET standard for programmable controllers (IEC 61158-x-10).

EtherNet/IP

EtherNet/IP

EtherNet/IP (Ethernet/Industrial Protocol) is an open industry standard for industrial real-time Ethernet based on TCP/IP and UDP/IP. With EtherNet/IP, Ethernet is expanded by the Common Industrial Protocol (CIP) at the application layer. In EtherNet/IP, the lower layers of the OSI reference model are adopted by Ethernet with the physical, network and transport functions.

You configure EtherNet/IP in "System > EtherNet/IP (Page 1375)".

Common Industrial Protocol

The Common Industrial Protocol (CIP) is an application protocol for automation that supports transition of the field buses in Industrial Ethernet and in IP networks. This industry protocol is used by field buses/industrial networks such as DeviceNet, ControlNet and EtherNet/IP at the application layer as an interface between the deterministic fieldbus world and the automation application (controller, I/O, HMI, OPC, ...). The CIP is located above the transport layer and expands the pure transport services with communications services for automation engineering. These include services for cyclic, time-critical and event-controlled data traffic. CIP distinguishes between time-critical I/O messages (implicit messages) and individual query/ response frames for configuration and data acquisition (explicit messages). CIP is object-oriented; all data "visible" from the outside is accessible in the form of objects. CIP has a common configuration basis: EDS (Electronic Data Sheet).

Electronic Data Sheet

Electronic Data Sheet (EDS) is an electronic datasheet for describing devices.

The EDS required for EtherNet/IP operation can be found in "System > Load&Save".

NAT/NAPT

What is NAT?

With Network Address Translation (NAT), the IPv4 address in a data packet is replaced by another. NAT is normally used on a gateway between a private LAN and an external network with globally valid IPv4 addresses. A local IPv4 address of the internal LAN is changed to an external global IPv4 address by a NAT device at the gateway.

To translate the internal into the global IPv4 address, the NAT device maintains a translation list. The address assignment is automatic. You configure the address assignment in "Layer 3 > NAT > Basic".

What is NAPT?

In "Network Address Port Translation" (NAPT) or "Port Address Translation" (PAT), several internal source IPv4 addresses are translated into the same external source IPv4 address. To identify the individual source nodes, the port of the source device is also stored in the translation list of the NAT gateway and translated for the external address.

If several local clients send a query to the same external destination IPv4 address via the NAT gateway, the gateway enters its own external source IPv4 address in the header of these data packets. Since the forwarded data packets have the same global source IPv4 address, the NAT gateway assigns the data packets to the clients using different port number.

Note

NAT/NAPT is possible only on layer 3 of the ISO/OSI reference model. To use the NAT function, the networks must use the IP protocol.

When using the ISO protocol that operates at layer 2, it is not possible to use NAT.

If a client from the global network wants to use a service in the internal network, the translation list for the static address assignment needs to be configured. You configure the translation list for NAPT in "Layer 3 > NAT > NAPT".

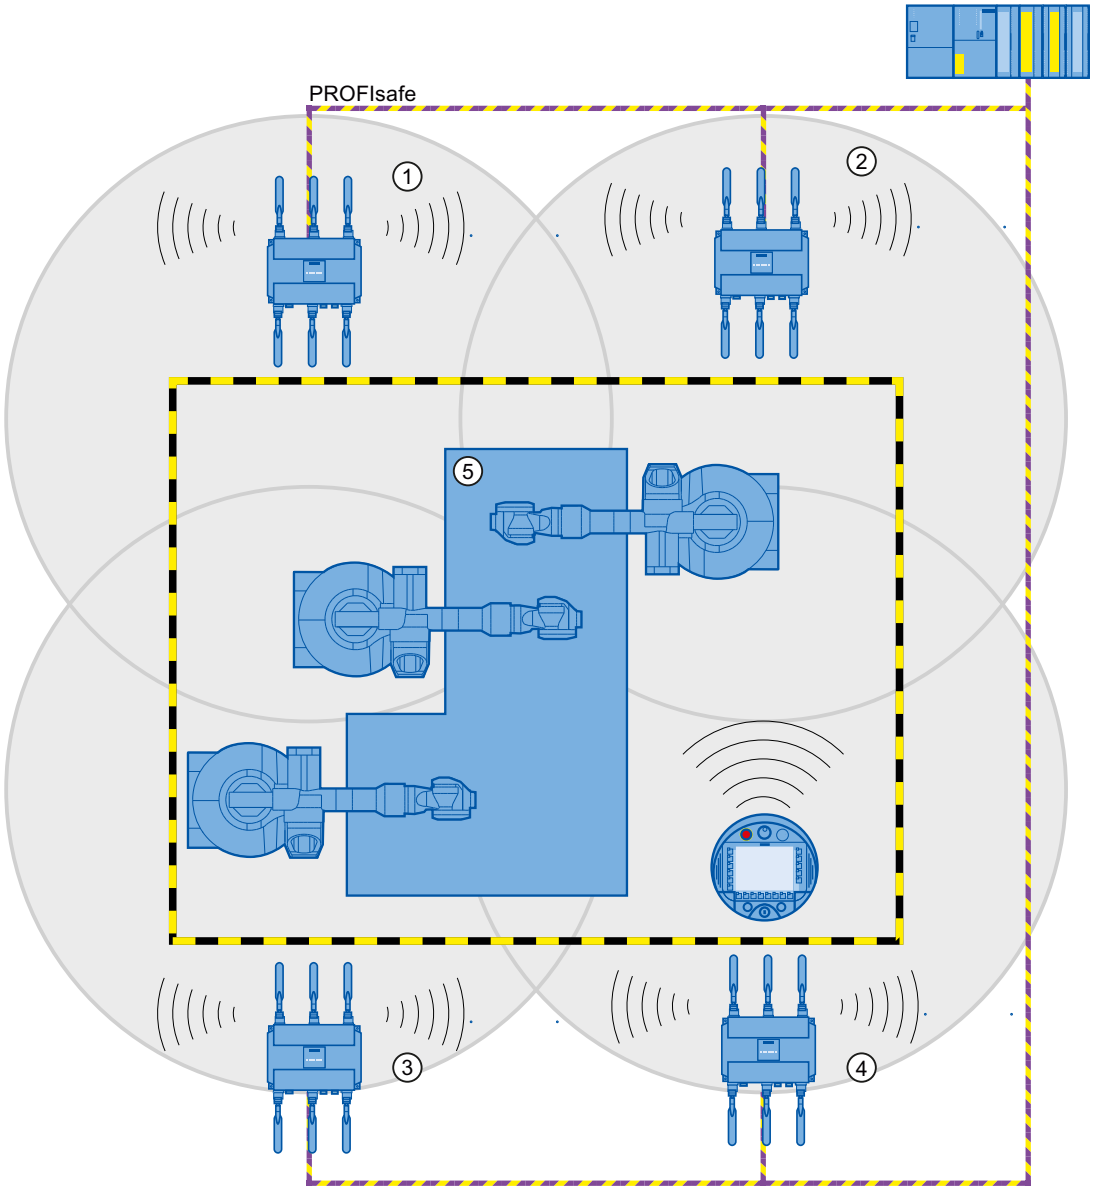
iPCF / iPCF-MC

The wireless range of an IWLAN system can be expanded by using multiple access points. If a client moves from the area covered by one access point to the area covered by another access point, the wireless link is maintained after a short interruption (roaming).

In an industrial environment, there are applications that require a deterministic response when there are large numbers of nodes and when roaming to another cell require handover times of less than 100 milliseconds.

- **iPCF** (industrial Point Coordination Function)
  iPCF ensures that the entire data traffic of a cell is ordered, controlled by the access point. Even with large numbers of nodes, collisions can also be avoided. iPCF also allows fast cell changes.
  You configure iPCF in "iFeatures > iPCF (Page 1729)".
- **iPCF-MC** (industrial Point Coordination Function - Management Channel)
  iPCF-MC was developed to make the advantages of iPCF available to fully mobile nodes that communicate without being dependent on RCoax cable or directional antennas. With iPCF-MC, the client also searches for potentially suitable access points when it receives iPCF queries from the access point and the existing connection to an access point is working problem-free. This means that if a change to a different access point is necessary, this is achieved extremely quickly. In contrast to iPCF, the handover times for iPCF-MC are not dependent on the number of wireless channels being used.
  You configure iPCF-MC in "iFeatures > iPCF-MC (Page 1731)".

iPCF / iPCF-MC - how it works



The access point checks all nodes in the wireless cell cyclically. At the same time, the scan includes the downlink traffic for this node. In the reply, the node sends the uplink data. The access point scans a new node at least every 5 ms.

The scan of a node is seen by all other nodes in the cell. This allows a client to detect the quality of the wireless link to the access point even when it is not communicating with the access point itself. If the client does not receive any frames from the access point for a certain time, it starts to search for a new access point.

In iPCF mode, both the search for a new access point and the registration with this access point have been optimized in terms of time. Handover times significantly below 50 ms are achieved.

Stable PNIO communication is only possible when a WLAN client is in a cell with more than 60 % (-65 dBm) signal strength at all times. This can be checked by activating and deactivating the various wireless cells.

This does not mean that the client needs to change when there is a signal strength < 60 % (< -65 dBm). Make sure that access points are available with adequate signal strength.

① Wireless cell of access point 1
② Wireless cell of access point 2
③ Wireless cell of access point 3
④ Wireless cell of access point 4
⑤ Plant

Figure 10-18 Configuration example of iPCF-MC

Restrictions

- iPCF and iPCF-MC are developments of Siemens AG and function only with nodes on which iPCF / iPCF-MC is implemented.
- With an access point with several WLAN interfaces, it is possible to use both iPCF as well as standard WLAN at the same time.
- Access points with a WLAN interface cannot take part in the iPCF-MC procedures, iPCF is, however, possible.

Requirements for iPCF-MC

iPCF-MC uses the two wireless interface of the access point in different ways: One interface works as the management interface and sends a beacon every five milliseconds. The other interface transfers the user data.

The following requirements must be met before you can use iPCF-MC:

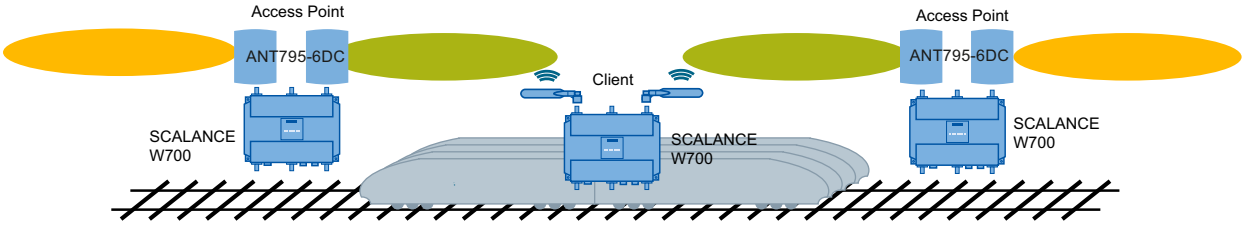
- Only SCALANCE W700 devices with two WLAN interfaces can be used as access points
- The data interface (WLAN1) and management interface (WLAN2) must be operated in the same frequency band and must match in terms of their wireless coverage. iPCF-MC will not work if the two wireless interfaces are equipped with directional antennas that cover different areas.
- The management interfaces of all access points to which a client can change must use the same channel. A client scans only this one channel to find accessible access points.
- Transmission based on IEEE 802.11h (DFS) cannot be used for the management interface. 802.11h (DFS) is possible for the data interface.
- A client must support this feature on its WLAN interface.

iREF

How it works

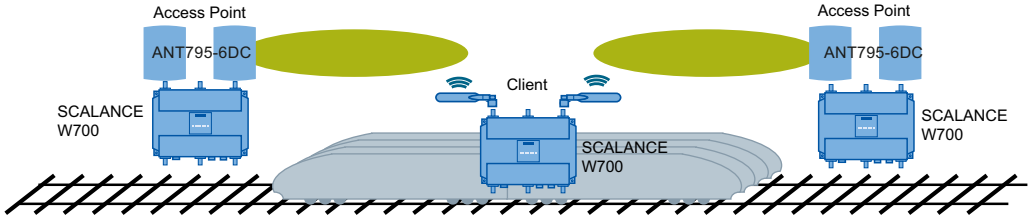
If an access point has several activated antennas, the transmit power is distributed equally on these antennas. The transmit power is subject to country-specific legal restrictions. The maximum permitted power depends on the gain of the connected antennas. If the connected antennas have different gains, the maximum antenna gain effectively restricts the permitted transmit power.

iREF (industrial Range Extension Function) ensures that the data traffic from the access point to each individual client is handled via the most suitable antenna. Which antenna is most suitable is determined by the access point based on the RSSI values of received packets.



Taking into account antenna gain and possible cable losses, packets are only sent via the antennas with which the maximum signal strength at the client end can be expected.

During this time the other antennas are inactive and the legally permitted transmit power is available for the selected antenna. The inactive antennas do not restrict the permitted transmit power.



In particular in applications in which MIMO cannot be used or brings no advantage, this allows data to be transmitted at the highest possible data transmission rate.

You configure iREF in "iFeatures > iREF"

without iREF

where iREF

Requirement

- To be able to use iREF, the SCALANCE W700 device must have at least 2 activated antennas.

Restrictions

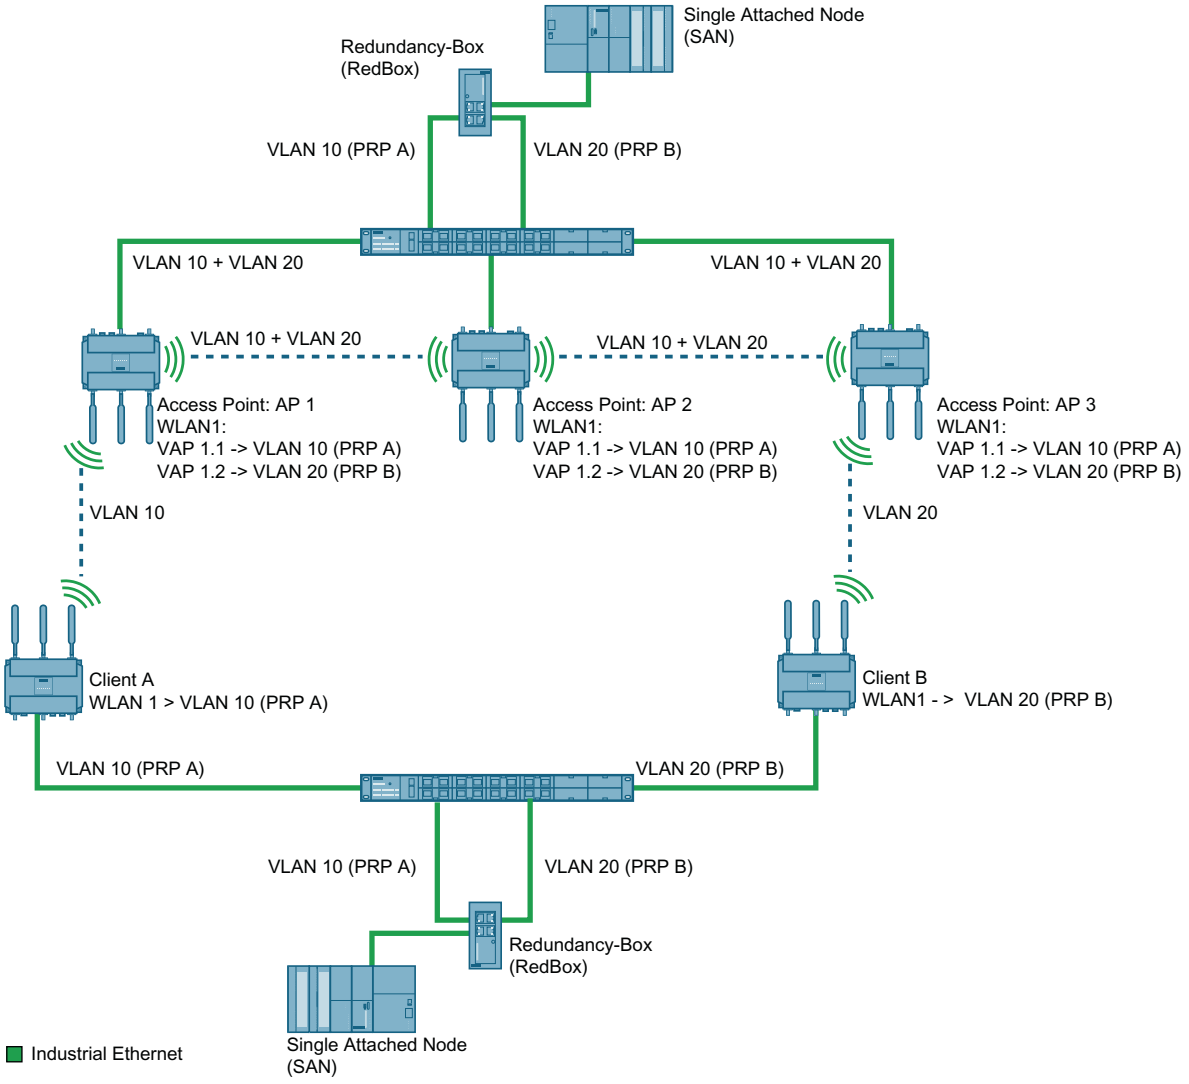
- A maximum data rate of only up to 150 Mbps (MCS 0 - 7 or 1 x spatial stream) is possible
- iREF cannot be used along with other iFeatures (for example iPCF or iPCF-MC)

Advantages

- Due to the directional data transmission and dynamic deactivation of antennas that do not radiate in the direction of the particular client, interference can be reduced.
- The signal strength is improved because the active antenna always has the maximum permitted transmit power available.

iPRP

The "Parallel Redundancy Protocol" (PRP) is a redundancy protocol for cabled networks. It is defined in Part 3 of the IEC 62439 standard.



With the "industrial Parallel Redundancy Protocol" (iPRP) the PRP technology can be used in wireless networks. iPRP improves the availability of wireless communication.

How it works

A PRP network consists of two completely independent networks. If one network is disrupted, the frames are sent without interruption/reconfiguration via the parallel redundant network. To achieve this the Ethernet frames are sent to the recipient in duplicate via both networks. Devices capable of PRP have at least two separate Ethernet interfaces that are connected to independent networks.

With devices not capable of PRP a redundancy box (RedBox) is connected upstream. This allows access for so-called Single Attached Nodes (SAN) to PRP networks. The RedBox duplicates every Ethernet frame to be sent and among other things adds the VLAN ID and a sequence number. The RedBox sends a copy of the frame at the same time on both Ethernet interfaces via both networks.

With PRP the SCALANCE W700 devices PRP can be used in wireless networks.

The access points (AP 1, AP 2 and AP 3) and the RedBox A are connected to each other via a switch. The PRP frames are sent to the access points via both networks (PRP A, PRP B). The access points receive the PRP frame.

The PRP frames are sent at the same time on two different wireless links to the recipients. The clients A and B are connected to different access points at the same time. The clients are never connected to the access point via the same interface. The clients and the RedBox B are connected via a switch.

Note

The interface of the switch and of the client must be members of the same VLAN (PRP network). For client A, VLAN 10 (PRP A) is set in the PRP network. The Ethernet interface of the switch may only be a member in VLAN 10 but not in VLAN 20 of client B.

The RedBox B forwards the first PRP frame to arrive and discards the second PRP frame.

The redundant partners (here: AP1 and AP3 or client A and client B) communicate with each other to prevent the two redundant PRP frames from arriving at the RedBox with too great a time difference.

If for example communication between AP1 and client A is not possible, the PRP frame comes to its destination via redundant client B.

You configure iPRP in "iFeatures > iPRP (Page 1732)".

Requirement

- The base bridge mode "802.1Q VLAN Bridge" is set.
- The VLANs have been created.
- The VLANs are configured on the same interface.
- Access point mode: The VAP interface is enabled.
- Client mode: In MAC mode "Layer 2 Tunnel" is set.
- Depending on the configuration the clients can communicate with every access point.

AeroScout

AeroScout tags

SCALANCE W700 devices support tags of the AeroScout company. Tags are battery-operated RFID sensors that send their data cyclically as multicast frames.

Among other things, AeroScout tags have the following features:

- **Ambient temperature**
  If a tag is fitted to a SCALANCE W700 device or material, it is possible to monitor whether a selected ambient temperature is being maintained.
- **Motion**
  Here, a tag can also supply information indicating whether it is in motion or stationary. The areas of material flow and material handling engineering represent possible applications for this function.

- **Button**
  Regardless of the frames sent cyclically, a user can also send a message by pressing a button.
- **LED**
  This provides information on the operating status of the tag.

Note

For more detailed information, please refer to the AeroScout documentation (www.aeroscout.com).

How it works

The tag sends its data as AeroScout frames. The tags and the access points communicate in the 2.4 GHz band.

If the WLAN interface of the access point receives the AeroScout frame, this is converted into a UDP datagram. The SCALANCE W700 device forwards the UDP datagram along with the information about the signal strength (RSSI) to a PC. The AeroScout Engine runs on the PC and evaluates the received information.

Note

It is **not** advisable to use PROFINET communication and AeroScout together on one wireless interface.

Accuracy of localization

To achieve optimum precision in the localization of AeroScout Tags,

- we recommend the use of antennas with omnidirectional characteristics
- if the signals should be received by at least three access points.

SNMP

Introduction

With the aid of the Simple Network Management Protocol (SNMP), you monitor and control network components from a central station, for example routers or switches. SNMP controls the communication between the monitored devices and the monitoring station.

Tasks of SNMP:

- Monitoring of network components
- Remote control and remote parameter assignment of network components
- Error detection and error notification

In versions v1 and v2c, SNMP has no security mechanisms. Each user in the network can access data and also change parameter assignments using suitable software.

For the simple control of access rights without security aspects, community strings are used.

The community string is transferred along with the query. If the community string is correct, the SNMP agent responds and sends the requested data. If the community string is not correct, the SNMP agent discards the query. Define different community strings for read and write permissions. The community strings are transferred in plain text.

Standard values of the community strings:

- public
  has only read permissions
- private
  has read and write permissions

Note

Because the SNMP community strings are used for access protection, do not use the standard values "public" or "private". Change these values following the initial commissioning.

Further simple protection mechanisms at the device level:

- Allowed Host
  The IP addresses of the monitoring systems are known to the monitored system.
- Read Only
  If you assign "Read Only" to a monitored device, monitoring stations can only read out data but cannot modify it.

SNMP data packets are not encrypted and can easily be read by others.

The central station is also known as the management station. An SNMP agent is installed on the devices to be monitored with which the management station exchanges data.

The management station sends data packets of the following type:

- GET
  Request for a data record from the SNMP agent
- GETNEXT
  Calls up the next data record.
- GETBULK (available as of SNMPv2c)
  Requests multiple data records at one time, for example several rows of a table.
- SET
  Contains parameter assignment data for the relevant device.

The SNMP agent sends data packets of the following type:

- RESPONSE
  The SNMP agent returns the data requested by the manager.
- TRAP
  If a certain event occurs, the SNMP agent itself sends traps.

SNMPv1/v2c/v3 use UDP (User Datagram Protocol) and use the UDP ports 161 and 162. The data is described in a Management Information Base (MIB).

SNMPv3

Compared with the previous versions SNMPv1 and SNMPv2c, SNMPv3 introduces an extensive security concept.

SNMPv3 supports:

- Fully encrypted user authentication
- Encryption of the entire data traffic
- Access control of the MIB objects at the user/group level

With the introduction of SNMPv3 you can no longer transfer user configurations to other devices without taking special action, e.g. by loading a configuration file or replacing the C-PLUG.

According to the standard, the SNMPv3 protocol uses a unique SNMP engine ID as an internal identifier for an SNMP agent. This ID must be unique in the network. It is used to authenticate access data of SNMPv3 users and to encrypt it.

Depending on whether you have enabled or disabled the “SNMPv3 User Migration” function, the SNMP engine ID is generated differently.

Restriction when using the function

Use the "SNMPv3 User Migration" function only to transfer configured SNMPv3 users to a substitute device when replacing a device.
Do not use the function to transfer configured SNMPv3 users to multiple devices. If you load a configuration with created SNMPv3 users on several devices, these devices use the same SNMP engine ID. If you use these devices in the same network, your configuration contradicts the SNMP standard.

Compatibility with predecessor products

You can only transfer SNMPv3 users to a different device if you have created the users as migratable users. To create a migratable user the "SNMPv3 User Migration" function must be activated when you create the user.

Spanning Tree

Avoiding loops

The Spanning Tree algorithm detects redundant physical network structures and prevents the formation of loops by disabling redundant paths. It evaluates the distance and performance of a connection or bases the decisions on settings made by the user. Data is then exchanged only over the remaining connection paths.

If the preferred data path fails, the Spanning Tree algorithm then searches for the most efficient path possible with the remaining nodes.

Root bridge and bridge priority

The identification of the most efficient connection is always related to the root bridge, a network component that can be considered as a root element of a tree-like network structure. With the "Bridge Priority" parameter, you can influence the selection of the root bridge. The computer with the lowest value set for this parameter automatically becomes the root bridge. If two computers have the same priority value, the computer with the lower MAC address becomes the root bridge.

Response to changes in the network topology

If nodes are added to a network or drop out of the network, this may affect the optimum path selection for data packets. To be able to respond to such changes, the root bridge sends configuration messages (BPDUs) at regular intervals. You can set the interval between two configuration messages with the "Hello Time" parameter.

Keeping configuration information up to date

With the "Max Age" parameter, you set the maximum age of configuration information. If a bridge has information that is older than the time set in Max Age, it discards the message and initiates recalculation of the paths.

New configuration data is not used immediately by a bridge but only after the period specified in the "Forward Delay" parameter. This ensures that operation is started with the new topology only after all the bridges have the required information.

RSTP, MSTP, CIST

Rapid Spanning Tree Protocol (RSTP)

One disadvantage of STP is that if there is a disruption or a device fails, the network needs to reconfigure itself: The devices start to negotiate new paths only when the interruption occurs. This can take up to 30 seconds. Fur this reason, STP was expanded to create the "Rapid Spanning Tree Protocol" (RSTP, IEEE 802.1w). This differs from STP essentially in that the devices are already collecting information about alternative routes during normal operation and do not need to gather this information after a disruption has occurred. This means that the reconfiguration time for an RSTP controlled network can be reduced to a few seconds.
This is achieved by using the following functions:

- Edge ports (end node port)
  Edge ports are ports connected to an end device.
  A port that is defined as an edge port is activated immediately after connection establishment. If a spanning tree BPDU is received at an edge port, the port loses its role as edge port and it takes part in (R)STP again. If no further BPDU is received after a certain time has elapsed (3 x hello time), the port returns to the edge port status.
- Point-to-point (direct communication between two neighboring devices)

  By directly linking the devices, a status change (reconfiguration of the ports) can be made without any delays.

- Alternate port (substitute for the root port)

  A substitute for the root port is configured. If the connection to the root bridge is lost, the device can establish a connection over the alternate port without any delay due to reconfiguration.

- Reaction to events

  Rapid spanning tree reacts to events, for example an aborted connection, without delay. There is no waiting for timers as in spanning tree.

- Counter for the maximum bridge hops
  The number of bridge hops a package is allowed to make before it automatically becomes invalid.

In principle, therefore with rapid spanning tree, alternatives for many parameters are preconfigured and certain properties of the network structure taken into account to reduce the reconfiguration time.

Multiple Spanning Tree Protocol (MSTP)

The Multiple Spanning Tree Protocol (MSTP) is a further development of the Rapid Spanning Tree Protocol. Among other things, it provides the option of operating several RSTP instances within different VLANs or VLAN groups and, for example, making paths available within the individual VLANs that the single Rapid Spanning Tree Protocol would globally block.

Common and Internal Spanning Tree (CIST)

CIST identifies the internal instance used by the switch that is comparable in principle with an internal RSTP instance.

Show information

Versions

This page shows the versions of the hardware and software of the device.

Note

The page is only available if there is an online connection to the device.

Displayed values

Table 1 contains the following columns:

- **Hardware**
  - Basic Device
    Shows the basic device.
  - WLAN X
    Shows the available WLAN interfaces. A device can have up to two WLAN interfaces.
- **Name**
  Shows the name of the device or module.
- **Revision**
  Shows the hardware version of the device.
- **Article number**
  Shows the article number of the device or described module. For the wireless card, only one version is then displayed if the WLAN interface is enabled.

Table 2 has the following columns:

- **Software**
  - Firmware
    Shows the current firmware version. If a new firmware file was downloaded and the device has not yet restarted, the firmware version of the downloaded firmware file is displayed here. After the next restart, the downloaded firmware is activated and used.
  - Bootloader
    Shows the version of the boot software stored on the device.
  - Firmware_Running
    Shows the firmware version currently being used on the device
- **Description**
  Shows the short description of the software.
- **Version**
  Shows the version number of the software version.
- **Date**
  Shows the date on which the software version was created.

I&M

Note

The page is only available if there is an online connection to the device.

This page contains information about device-specific vendor and maintenance data such as the article number, serial number, version number etc. You cannot configure anything on this page.

Description of the displayed values

The table has the following rows:

- **Manufacturer ID**
  Shows the manufacturer ID.
- Article number
  Shows the article number.
- **Serial number**
  Shows the serial number.
- **Hardware revision**
  Shows the hardware version.
- **Software version**
  Shows the software version.
- **Revision counter**
  Shows the revision counter: Counter for revisions since the initial commissioning
- **Revision Date**
  Date and time of the last revision
- **Function tag**
  Shows the function tag (plant designation) of the device. The plant designation (HID) is created during configuration of the device with HW Config of STEP 7.
- **Location tag**
  Shows the location tag of the device. The location identifier (LID) is created during configuration of the device with HW Config of STEP 7.
- **Date**
  Shows the date created during configuration of the device with HW Config of STEP 7.
- **Description**
  Shows the description created during configuration of the device with HW Config of STEP 7.

ARP / neighbor table

IPv6 Neighbor Table

Assignment of MAC address and IPv6 address

Via the IPv6 neighbor table, there is a unique assignment of MAC address to IPv6 address. This assignment is kept by each network node in its own separate neighbor table.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Displays the interface via which the row entry was learnt.
- **MAC Address**
  Shows the MAC address of the destination or source device.
- **IP Address**
  Shows the IPv6 address of the destination device.
- **Media Type**
  Shows the type of connection.
  - Dynamic
    The device recognized the address data automatically.
  - Static
    The addresses were entered as static addresses.

ARP table

Note

The page is only available if there is an online connection to the device.

Assignment of MAC address and IP address

With the Address Resolution Protocol (ARP), there is a unique assignment of MAC address to IPv4 addresses. This assignment is kept by each network node in its own separate ARP table. The page shows the ARP table of the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the interface via which the row entry was learnt.
- **MAC Address**
  Shows the MAC address of the destination or source device.
- **IP address**
  Shows the IP address of the target device.
- **Media Type**
  Shows the type of connection.
  - Dynamic
    The device recognized the address data automatically.
  - Static
    The addresses were entered as static addresses

Log tables

Event log

Logging events

Note

The page is only available if there is an online connection to the device.

The device allows you to log events that occur, some of which you can specify in " System > Events". This, for example, allows you to record when an authentication attempt failed or when the connection status of a port has changed. The content of the events log table is retained even when the device is turned off.

Settings

- **Severity Filter**
  You can filter the entries in the table according to severity. Select the required entries in the check boxes above the table.
  - Info
    Information
  - When this parameter is enabled, all entries of the category "Info" are displayed.
  - Warning
    Warning
    When this parameter is enabled, all entries of the category "Warning" are displayed.
  - Critical
    Critical
    When this parameter is enabled, all entries of the category "Critical" are displayed.

  The table has the following columns:

  - **Restart**
    Counts the number of restarts since you last reset to factory settings and shows the device restart after which the corresponding event occurred.
  - **System Up Time**
    Shows the time the device has been running since the last restart when the described event occurred.
  - **System Time**
    Shows the date and time when the described event occurred.
    If the system time is set, the time is also displayed at which the event occurred.
  - **Severity**
    Shows the severity of the message.
  - **Log Message**
    Displays a brief description of the event that has occurred. You will find the list of possible messages in Appendix D of the configuration manual.

Buttons

- **Delete**
  Click this button to delete the content of the event log file. All entries are deleted regardless of what you have selected under "Severity Filters".
  The display is also cleared. The restart counter is only reset after you have restored the device to the factory settings and restarted the device.

  Note

  The table can contain 400 entries for each severity. The number of entries in this table is restricted to 1200. When this number is reached, the oldest entries of the relevant severity are discarded. The table remains permanently in memory.

WLAN authentication log

Logging authentication attempts

This page shows a table with information on successful or failed authentication attempts.

Note

The page is only available if there is an online connection to the device.

Displayed values

- **Severity Filters**
  You can filter the entries in the table according to severity. To display all the entries, enable or disable all parameters.
  - Info
    Information
    When this parameter is enabled, all entries of the category "Info" are displayed.
  - Warning
    Warnings
    When this parameter is enabled, all entries of the category "Warning" are displayed.
  - Critical
    Critical
    When this parameter is enabled, all entries of the category "Critical" are displayed.

The table has the following columns:

- **Restart**
  Counts the number of restarts since you last reset to factory settings and shows the device restart after which the corresponding event occurred.
- **System Up Time**
  Shows the time the device has been running since the last restart when the described fault occurred.
- **System Time**
  Shows the time at which the described error occurred.

- **Severity**
  Shows the severity of the message.
- **Log Message**
  Displays a brief description of the event that has occurred. You will find the list of possible messages in Appendix D of the configuration manual.

If the system time is set, the time is also displayed at which the event occurred.

Buttons

- **Clear**
  Click this button to delete the content of the log file. All entries are deleted regardless of what you have selected under "Severity Filters".
  The display is also cleared. The restart counter is only reset after you have restored the device to the factory settings and restarted the device.

  Note

  The table can contain 400 entries for each severity. The number of entries in this table is restricted to 1200. When this number is reached, the oldest entries are discarded. The table remains permanently in memory.

- **Show all**
  Click this button to display all the entries on the WBM page. Note that displaying all messages can take some time.
- **Next**
  Click this button to go to the next page.
- **Prev**
  Click this button to go to the previous page.

Fault

Error status

This page displays any errors that occur. Errors of the "Cold/Warm Start" event can be deleted following confirmation. If there are no more unanswered error/fault messages, the fault LED goes off.

The time calculation always begins after the last system start. When the system is restarted, a new entry with the type of restart is created in the fault memory.

Note

The page is only available if there is an online connection to the device.

Displayed values

- **No. of Signaled Faults**
  Indicates how often the fault LED lit up and not how many faults occurred.
- **"Reset counters" button**
  The number is reset with this button.

The table contains the following columns:

- **Fault Time**
  Shows the time the device has been running since the last restart when the described fault occurred.
- **Fault Description**
  Display of the fault status for the device.
- **Clear Fault State**
  To delete files of the "Cold/warm start" event, click the "Clear Fault State" button.

Spanning Tree

Note

The page is only available if there is an online connection to the device.

The page shows the current information about the Spanning Tree and the settings of the root bridge.

- If spanning tree is turned off, only the basic information about this device is displayed.
- If Spanning Tree is turned on, the status information about the selected instance is displayed and the information about the configured ports is shown in the table. The information depends on the selected Spanning Tree mode.

Displayed values

- **Spanning Tree Mode**
  Shows the set mode. You specify the mode in "Layer 2 > MSTP > General".
  The following values are possible:
  - '-'
  - STP
  - RSTP
  - MSTP
- **Instance ID**
  Shows the number of the instance. The parameter depends on the configured mode.

- **Bridge Priority / Root Priority**
  Which device becomes the root bridge is decided based on the bridge priority. The bridge with the highest priority (in other words, with the lowest value for this parameter) becomes the root bridge. If several devices in a network have the same priority, the device whose MAC address has the lowest numeric value will become the root bridge. Both parameters, bridge priority and MAC address together form the bridge identifier. Since the root bridge manages all path changes, it should be located as centrally as possible due to the delay of the frames. The value for the bridge priority is a whole multiple of 4096 with a range of values from 0 to 32768.
- **Bridge Address / Root Address**
  The bridge address shows the MAC address of the device and the root address shows the MAC address of the root bridge.
- **Root Cost**
  Shows the path costs from the device to the root bridge.
- **Bridge Status**
  Shows the status of the bridge, e.g. whether or not the device is the root bridge
- **Regional root priority** (available only with MSTP)
  For a description, see Bridge Priority / Root Priority
- **Regional root address** (available only with MSTP)
  Shows the MAC address of the device.
- **Regional root costs** (available only with MSTP)
  Shows the path costs from the regional root bridge to the root bridge.

The table has the following columns:

- **Port**
  Shows the port via which the device communicates.
- **Role**
  Shows the status of the port. The following values are possible:
  - Disabled
    The port was removed manually from the spanning tree and will no longer be taken into account by the spanning tree.
  - Designated
    The ports leading away from the root bridge.
  - Alternate
    The port with an alternative route to a network segment
  - Backup
    If a switch has several ports to the same network segment, the "poorer" Port becomes the backup port.
  - Root
    The port that provides the best route to the root bridge.
  - Master
    This port points to a root bridge located outside the MST region.

- **Status**
  Displays the current status of the port. The values are only displayed. The parameter depends on the configured protocol. The following statuses are possible:
  - Discarding
    The port receives BPDU frames. Other incoming or outgoing frames are discarded.
  - Listening
    The port receives and sends BPDU frames. The port is involved in the spanning tree algorithm. Other outgoing and incoming frames are discarded.
  - Learning
    The port actively learns the topology; in other words, the node addresses. Other outgoing and incoming frames are discarded.
  - Forwarding
    Following the reconfiguration time, the port is active in the network. The port receives and sends data frames.
- **Oper. Version**
  Describes the type of spanning tree in which the port operates
- **Priority**
  If the path calculated by the spanning tree is possible over several ports of a device, the port with the highest priority (in other words the lowest value for this parameter) is selected. A value between 0 and 240 can be entered for the priority in steps of 16. If you enter a value that cannot be divided by 16, the value is automatically adapted.
- **Path costs**
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected. If several ports of a device have the same value, the port with the lowest port number will be selected.
  If the value "Cost Calc." is "0", the automatically calculated value is shown. Otherwise, the value of "Cost Calc." is displayed.
  The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000.

- **Edge type**
  Shows the type of the connection. The following values are possible:
  - Edge Port

    An edge port is connected to this port.
  - No Edge Port
    There is a spanning tree or rapid spanning tree device at this port.
- **P.t.P. Type**
  Shows the type of point-to-point link. The following values are possible:
  - P.t.P.
    With half duplex, a point-to-point link is assumed.
  - Shared Media

    With a full duplex connection, a point-to-point link is not assumed.

Note

Point-to-point connection means a direct connection between two devices.

A shared media connection is, for example, a connection to a hub.

Ethernet Statistics

Interface statistics

Interface statistics

The page shows the statistics from the interface table of the Management Information Base (MIB).

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **In Octet**
  Shows the number of received bytes.
- **Out Octet**
  Shows the number of sent bytes.
- **In Unicast**
  Shows the number of received unicast frames.

- **In Non Unicast**
  Shows the number of received frames that are not of the type unicast.
- **Out Unicast**
  Shows the number of sent unicast frames.
- **Out Non Unicast**
  Shows the number of sent frames that are not of the type unicast.
- **In Errors**
  Shows the number of all possible RX errors, refer to the tab "Packet Error".

Packet Size

Frames sorted by length

This page displays how many frames of which size were sent and received at each port.

Note

The page is only available if there is an online connection to the device.

The displayed values are transferred by RMON.

On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.

  Note
  Display of frame statistics

  In the statistics relating to frame lengths, note that both incoming and outgoing frames are counted.

- **Frame lengths**
  The other columns after the port number contain the absolute numbers of frames according to their frame length.
  The following frame lengths are distinguished:
  - 64 bytes
  - 65 - 127 bytes
  - 128 - 255 bytes
  - 256 - 511 bytes
  - 512 - 1023 bytes
  - 1024 - max.

Note
Data traffic on blocked ports

For technical reasons, data packets can be indicated on blocked ports.

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

Frame type

Received frames sorted by type

This page displays how many frames of the type "unicast", "multicast", and "broadcast" were received at each port.

You cannot configure anything on this page.

The displayed values are transferred by RMON. On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations. The port is made up of the module number and the port number, for example port 0.1 is module 0, port 1.
- **Unicast / Multicast / Broadcast**
  The other columns after the port number contain the absolute numbers of the incoming frames according to their frame type "unicast", "multicast" and "broadcast".

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

Packet Errors

Received bad frames

This page shows how many bad frames were received per port.

You cannot configure anything on this page.

The displayed values are transferred by RMON. On the page "Layer 2 > RMON > Statistics", you can set the ports for which values will be displayed.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Port**
  Shows the available ports and link aggregations.
- **Error types**
  The other columns after the port number contain the absolute numbers of the incoming frames according to their error type.
  In the columns of the table, a distinction is made according to the following error types:
  - CRC

    Packets whose content does not match the CRC checksum.
  - Undersize
    Packets with a length less than 64 bytes.
  - Oversize
    Frames discarded because they were too long.
  - Fragments

    Packets with a length less than 64 bytes and a bad CRC checksum.
  - Jabbers
    VLAN-tagged packets with an incorrect CRC checksum that were discarded because they were too long.
  - Collisions
    Collisions that were detected.

Button

Reset Counter

Click "Reset Counter" to reset all counters. The counters are reset by a restart.

Learning table

Address filtering

This page shows the current content of the learning table. This table lists the source addresses of unicast address frames.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **VLAN-ID**
  Shows the VLAN ID of the node.

  Note

  This column appears in the table only if a VLAN is configured.

- **MAC Address**
  Shows the MAC address of the node.
- **Status**
  Shows the status of each address entry:
  - Dynamic
    The specified address was learned by receiving a frame from this node and will be deleted when the aging time expires if no further frames are received from this node.
  - Invalid
    These values are not evaluated.
- **Port**
  Shows the port via which the node with the specified address can be reached. Frames received by the device whose destination address matches this address will be forwarded to this port.

Buttons

- **Show all**
  Click this button to display all the entries on the page. Note that displaying all messages can take some time.
- **Next**
  Click this button to go to the next page.
- **Prev**
  Click this button to go to the previous page.

Drop-down list for page change

From the drop-down list, select the page you want to go to.

IPv6 routing table

Introduction

This page shows the IPv6 routes currently being used.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Destination Network**
  Shows the destination address of this route.
- **Prefix Length**
  Shows the prefix length of this route.
- **Gateway**
  Shows the gateway for this route.
- **Interface**
  Shows the interface for this route.
- **Metric**
  Shows the metric of the route. The higher value, the longer packets require to their destination.
- **Routing Protocol**
  Shows the routing protocol from which the entry in the routing table originates. The following entries are possible:
  - connected: Connected routes
  - Static: Static routes
  - RIPng: Routes via RIPng
  - OSPFv3: Routes via OSPFv3
  - other: Other routes

DHCP Server

This page shows whether IPv4 addresses were assigned to the devices by the DHCP server.

Note

The page is only available if there is an online connection to the device.

Description

- **IP Address**
  Shows the IPv4 address assigned to the DHCP client.
- **Pool ID**
  Shows the number of the IPv4 address band.
- **Identification method**
  Shows the method according to which the DHCP client is identified.
- **Identification value**
  Shows the MAC address or he client ID of the DHCP client.
- **Remote ID**
  Shows the remote ID of the DHCP client.

- **Circuit ID**
  Shows the circuit ID of the DHCP client.
- **Assignment method**
  Shows whether the IPv4 address was assigned statically or dynamically. You configure the static entries in "System > DHCP > Static Leases".
- **Assignment status**
  Shows the status of the assignment.
  - Assigned
    The assignment is used.
  - Not used
    The assignment is not used.
  - Probing
    The assignment is being checked.
  - Unknown
    The status of the assignment is unknown.
- **Expire Time**
  Shows how long the assigned IPv4 address is still valid. Once this period has elapsed, the DHCP client must either request a new IPv4 address or extend the lease time of the existing IPv4 address.

Security

Overview

This page shows the security settings and the local and external user accounts.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the rights of the logged-on user.

Displayed values

Services

The "Services" list shows the security settings.

- **Telnet Server**
  You configure the setting in "System > Configuration".
  - Enabled: Unencrypted access to the CLI.
  - Disabled: No unencrypted access to the CLI.
- **SSH Server**
  You configure the setting in "System > Configuration".
  - Enabled: Encrypted access to the CLI.
  - Disabled: No encrypted access to the CLI.
- **Web Server**
  You configure the setting in "System > Configuration".
  - HTTP/HTTPS: Access to the WBM is possible with HTTP and HTTPS.
  - HTTPS: Access to the WBM is now only possible with HTTPS.
- **SNMP**
  You can configure setting in "System > SNMP > General".
  - "-" (SNMP disabled)
    Access to device parameters via SNMP is not possible.
  - SNMPv1/v2c/v3
    Access to device parameters is possible with SNMP versions 1, 2c or 3.
  - SNMPv3
    Access to device parameters is possible only with SNMP version 3.
- **Management ACL**
  You configure the setting in "Security > Management ACL".
  - Disabled: No access restriction
    The access control is disabled.
  - Enabled: No access restriction
    The access control is enabled but no access rules have been defined.
  - Enabled: Restricted access only
    The access control is enabled and access rules have been defined.

- **Login Authentication**
  You configure the setting in "Security > AAA > General".
  - Local
    The authentication must be made locally on the device.
  - RADIUS
    The authentication must be handled via a RADIUS server.
  - Local and RADIUS
    The authentication is possible both with the users that exist on the device (user name and password) and via a RADIUS server.
    The user is first searched for in the local database. If the user does not exist there, a RADIUS query is sent.
  - RADIUS and fallback local
    The authentication must be handled via a RADIUS server.
    A local authentication is performed only when the RADIUS server cannot be reached in the network.
- **Password Policy**
  Shows which password policy is currently being used.

Local and external user accounts

You configure local user accounts and roles in "Security > User Accounts"

When you create a local user account an external user account is generated automatically. Local user accounts involve users each with a password for logging in on the device.

In the table "External User Accounts" a user is linked to a role, for example the user "Observer" with the role "user" In this case, the user is defined on a RADIUS server. The roll is defined locally on the device. When a RADIUS server authenticates a user, the corresponding group however is unknown or does not exist, the device checks whether or not there is an entry for the user in the table "External User Accounts". If an entry exists, the user is logged in with the rights of the associated role. If the corresponding group is known on the device, both tables are evaluated. The user is assigned the role with the higher rights.

Note

The table "External User Accounts" is only evaluated if you have set "Vendor Specific" in the RADIUS Authorization Mode".

With CLI you can access external user accounts.

The table "Local User Accounts" has the following columns:

- **User Account**
  Shows the name of the local user.
- **Role**
  Shows the role of the user. You can obtain more information on the function rights of the role in "Information > Security > Roles".

The table "External User Accounts" has the following columns:

- **User Account**
  Shows the name of the user on the RADIUS server.
- **Role**
  Shows the role assigned to the user on the device. You can obtain more information on this in "Information > Security > Roles".

Supported Function Rights

The page shows the function rights available locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

- **Function Right**
  Shows the number of the function right. Different rights relating to the device parameters are assigned to the numbers.
- **Description**
  Shows the description of the function right.

Groups

This page shows which group is linked to which role. The group is defined on a RADIUS server. The roll is defined locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

The table has the following columns:

- **Group**
  Shows the name of the group. The name matches the group on the RADIUS server.
- **Role**
  Shows the role. Users who are authenticated with the linked group on the RADIUS server receive the rights of this role locally on the device.
- **Description**
  Shows a a description for the link.

Roles

The page shows the roles valid locally on the device.

Note

The page is only available if there is an online connection to the device.

The values displayed depend on the role of the logged-on user.

Displayed values

This table contains the following columns:

- **Role**
  Shows the role.
- **Function Right**
  Shows the function rights of the role:
  - 1
    Users with this role can read device parameters but cannot change them.
  - 15
    Users with this role can both read and change device parameters.
  - 0
    This is a role that the device assigns internally when the user could not be authenticated. The user is denied access to the device.
- **Description**
  Shows a description of the role.

Inter AP blocking

the page shows a list of the devices with which the clients are allowed to communicate.

Note

The page is only available

- with SCALANCE W780 / W770
- if there is an online connection to the device.
- in access point mode.
- with KEY-PLUG inserted: W780 iFeatures (MLFB 6GK5 907-8PA00) or W700 Security (MLFB 6GK5907-0PA00)

Settings

The table has the following columns:

- **Radio**
  Shows the available WLAN interfaces to which the settings relate.
- **Port**
  Shows the VAP interface to which the settings relate.
- **MAC address**
  Shows the MAC address of the device with which the client may communicate.
- **IP address**
  Shows the IP address of the device with which the client may communicate.
- **IP address resolution**
  Shows the IP address with which the permitted IP address is resolved.

WLAN

AP overview

Overview of the configuration

This page shows these settings/properties of the WLAN or the WLAN interface.

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

Displayed values

Table 1 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **WLAN Mode**
  Shows the transmission standard. If DFS is activated, the transmission standard "802.11h" is not shown additionally but only the configured transmission standard "802.11a".
- **Configured Channel**
  Shows the configured channel. If "Auto" is displayed, the access point searches for a free channel itself.

- **Alternative DFS Channel**
  If the DFS function is enabled, the configured alternative channel of the access point is displayed.
  If "Auto" is displayed, the access point searches for an alternative channel itself.
  If the DFS function is activated and the access point browses for primary users for 60 seconds before starting communication with the selected channel, the text "scanning ..." is displayed instead of the channel.
- **Operational channel**
  Shows the channel of the access point via which the access point communicates.
- **HT Channel Width**
  Shows the channel bandwidth.
  - 20
    Channel bandwidth 20 MHz
  - 40 up
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel above it are used.
  - 40 down
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel below it are used.

  Note

  Channel bandwidth 40 MHz and frequency band 2.4 GHz

  If the access point detects another access point on the configured channel or on neighboring channels, the access point changes the channel bandwidth from 40 MHz to 20 MHz. If you set a "free" channel on the access point, the access point uses the channel bandwidth 40 MHz.

- **iFeatures**
  Shows which iFeatures are used.
  - -
    iFeatures are not used.
  - iPCF
  - iPCF-MC
  - iREF
- **Status**
  Shows the status of the WLAN interface.
  - enabled
    The WLAN interface is enabled.
  - disabled
    The WLAN interface is disabled.

Table 2 has the following columns:

- **Radio**
  Shows the available WLAN interfaces in this column.
- **Port**
  Shows the port of the virtual access point.
- **MAC Address**
  Shows the MAC address of the virtual access point.
- **SSID**
  Shows the SSID.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.
- **Status**
  Shows the status of the WLAN interface.
  - enabled
    The WLAN interface is enabled.
  - disabled
    The WLAN interface is disabled.

Client list

Logged-on clients

The page the clients logged on with the access point as well as additional information, for example status, signal strength, MAC address.

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

Displayed values

- **Logged-on Clients**
  Shows the number of clients logged on to the access point.

The table has the following columns:

- **AID** (Associated ID)
  Shows the connection ID of the client. If the client connects to the access point via the VAP interface, the client is assigned a connection ID. The connection ID is unique within a VAP interface. If two clients log on at different VAP interfaces, both clients can receive the same ID.
- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the VAP interface.
- **Type**
  Shows the client type, for example "Sta" stands for IEEE 802.11 standard client.
- **MAC Address**
  Shows the MAC address of the client.
- **System Name**
  Shows the system name of the client if the client communicates this to the access point. Not all clients support this parameter.
- **Channel**
  Shows the channel over which the client communicates with the access point.
- **Signal Strength [dBm]**
  Shows the signal strength of the connected client in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the connected client as a percentage.
- **Age [s]**
  Shows the time that has elapsed since the last client activity.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.
- **WLAN Mode**
  Shows the transmission standard. If DFS is activated, the transmission standard "802.11h" is not shown additionally but only the configured transmission standard "802.11a".
- **Maximum Data Rate [Mbps]**
  Shows the maximum data rate in megabits per second.
- **Status**
  Shows the current status of the connection, for example connected means that the client is connected to the AP and is ready to communicate with the AP.

WDS list

Communication between access points

In normal operation, the access point is used as an interface to a network and communicates with clients. There are, however, situations in which several access points need to communicate with each other, for example to extend wireless coverage or to set up a wireless backbone. This mode is possible with WDS (Wireless Distributed System).

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

This page shows information about the WDS connections of the access point.

Displayed values

The table has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the port.
- **BSSID**
  Shows the MAC address of the WDS partner.
- **WDS ID**
  Shows the name of the WDS partner.
- **Channel**
  Shows the channel over which the access point communicates with the WDS partner.
- **Signal Strength [dBm]**
  Shows the signal strength of the connected access point in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the connected access point as a percentage.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.
- **Max. Data Rate [Mbps]**
  Shows the maximum data rate in megabits per second.
- **Status**
  Shows the current status of the WDS connection.

AP overlap

Overlapping channels

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

For optimum data throughput, it is important that the set wireless channel is not used by other access points. In the 2.4 GHz band (802.11b or 802.11g), there is overlapping of the channels so that an access point occupies not only the set channel but also the two or three adjacent channels. You should therefore make sure that there is adequate channel spacing to neighboring access points.

This page shows all access points that are visible on the set or adjacent channels (at 2.4 GHz). If entries exist here, the maximum data throughput of the access point and the availability of the communication link to the access point is potentially impaired.

Displayed values

Table 1 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Aging Time [min]**
  Specify the life time of the entries in the list. If an access point is inactive for longer than the set time, it is removed from the list.

  Note

  Changing the aging time

  The aging time is a WLAN setting. For this reason, if a change is made, the WLAN connection is briefly interrupted to accept the new value.

The table has the following columns:

- **Radio**
  Shows the available WLAN interfaces in this column.
- **Type**
  Shows the mode of the WLAN interface.
- **SSID**
  Shows the SSID of the access point.
- **BSSID**
  Shows the MAC address of the access point.
- **System Name**
  Shows the system name of the device. The entry depends on the access point. Not all access points support this parameter.

- **Channel**
  Shows the channel over which the client communicates with the access point.
- **Signal Strength [dBm]**
  Shows the signal strength of the client in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the client as a percentage.
- **Age [s]**
  Shows the time that has elapsed since the last access point activity.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.
- **WLAN Mode**
  Shows the transmission standard. If DFS is activated, the transmission standard "802.11h" is not shown additionally but only the configured transmission standard "802.11a" or "802.11n".

Client overview

Overview of the configuration

The page shows an overview of the existing clients and their configuration.

Note

The page is only available

- if there is an online connection to the device.
- for clients or access points in client mode.

Displayed values

- **Radio**
  Shows the available WLAN interfaces in this column.
- **WLAN Mode**
  Shows the transmission standard.

- **MAC Mode**
  Shows how the MAC address is assigned to the interface.
  - Automatic
    The client automatically adopts the source MAC address of the first frame that it receives over the Ethernet interface.
  - Manual
    The address was entered manually
  - Own
    The client uses the MAC address of the Ethernet interface for the WLAN interface.
  - Layer 2 Tunnel
    The client uses the MAC address of the Ethernet interface for the WLAN interface. The network is also informed of the MAC addresses connected to the Ethernet interface of the client. Up to eight MAC addresses can be used.
- **MAC Address**
  Shows the MAC address of the WLAN interface.
- **Operational channel**
  Shows the channel of the access point with which the client is connected.
- **HT Channel Width [MHz]**
  Shows the channel bandwidth.
  - 20
    Channel bandwidth 20 MHz
  - 40 up
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel above it are used.
  - 40 down
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel below it are used.

  Note

  Channel bandwidth 40 MHz and frequency band 2.4 GHz

  If the access point detects another access point on the configured channel or on neighboring channels, the access point changes the channel bandwidth from 40 MHz to 20 MHz. If you set a "free" channel on the access point, the access point uses the channel bandwidth 40 MHz.
- **Connected BSSID**
  This box shows the MAC address of the access point with which the client is connected.
- **Connected SSID**
  This box shows the SSID of the access point with which the client is connected.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.

- **iFeatures**
  Shows which iFeatures are used.
  - -
    iFeatures are not used.
  - iPCF
  - iPCF-MC
- **Status**
  Shows the status of the WLAN interface.
  - enabled
    The WLAN interface is enabled.
  - disabled
    The WLAN interface is disabled.

Available APs

Available access points

Note

The page is only available

- if there is an online connection to the device.
- for clients or access points in client mode.

This page shows all the access points visible to the client. The list also includes the access points to which the client cannot connect due to its configuration.

Note

Display when iPCF mode is activated

If the iPCF mode is active, the display is different. Since the client does not run a background scan in this case, only the access point with which the client is currently connected is displayed.

Displayed values

The table has the following columns:

- **Radio**
  Shows the WLAN interface visible to the access point.
- **SSID**
  Shows the SSID of the access point.
- **BSSID**
  Shows the MAC address of the access point.

- **System Name**
  Shows the system name of the access point. The entry depends on the access point. Not all access points support this parameter.
- **Channel**
  Shows the channel on which the access point transmits or communicates.
- **Signal Strength [dBm]**
  Shows the signal strength of the access point in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the access point as a percentage.
- **Type**
  Shows the mode of the WLAN interface.
- **Security**
  Shows which authentication method is used.
  If the authentication method "Open System + Encryption" or "Shared Key" is used, the "Encrypted (WEP/AES)" authentication method is displayed for both.
- **WLAN Mode**
  Shows the transmission standard. If DFS is activated, the transmission standard "802.11h" is not shown additionally but only the configured transmission standard "802.11a" or "802.11n".
- **Status**
  Shows the status of the access point, for example whether or not the access point is available.

Force Roaming

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

The device monitors the connection to IP addresses cyclically. To achieve this, the device sends echo messages (pings) to the configured destination IP address at regular intervals.

This WBM page shows the current status of the connection. It also shows whether there is roaming.

Displayed values

The table has the following columns:

- **Port**
  Shows the available VAP interfaces.
- **Destination Address / State**
  Shows which destination address is monitored and the status of the connection. You configure the destination address in "Interfaces > WLAN > Force Roaming".
  - not configured: No destination address is configured.
  - idle: The configuration is incomplete.
  - up:The destination address is reachable.
  - down: The destination address is unreachable.
- **Force Roaming on IP down**
  Indicates whether roaming is currently being performed.
  - inactive: No roaming is being performed.
  - active: Roaming is being performed. None of the destination addresses is reachable.

IP mapping table

WLAN access for several devices via a client

Note

The page is only available

- if there is an online connection to the device.
- for clients or access points in client mode.

You can make WLAN access available for several devices with one client if you use IP mapping. This means that you do not need to equip every device with its own WLAN client. This is possible only if the connected devices are addressed only by IP frames. Communication at MAC address level (ISO/OSI layer 2) can

- be established with one component whose MAC address is configured on the client,
- be established with a maximum of eight components if the "Layer 2 Tunnel" MAC mode is selected.

The "Layer 2 Tunnel" setting meets the requirements of industrial applications in which MAC address-based communication takes place with several devices downstream from the client. Clients with this setting cannot connect to standard Wi-Fi devices and access points with firmware V3.0 or older.

The client maintains a table with the assignment of MAC address and IP address to be able to send incoming IP frames to the correct MAC address. The page shows the IP mapping table of the device.

Note

Display of the IP mapping table

If "Layer 2 Tunnel" is configured on the device for the MAC mode, the IP mapping table is not displayed.

Displayed values

- **MAC address**
  The MAC address of a device located downstream from the WLAN client from the perspective of the access point.
- **IP address**
  The IP address managed for this device by the WLAN client.
- **Type**
  There are two options for the type:
  - system
    The information relates to the WLAN client itself.
  - learned
    The information relates to a device downstream from the WLAN client.

MAC mode

Frames sent by the client to the access point always have the MAC address of the WLAN client as the source MAC address. In the "learning table" of the access point there is therefore only the MAC address of the WLAN client.

If there are further SCALANCE W700 devices downstream from the client, the "Automatic" option should not be enabled. In this case, the MAC address would be assigned indiscriminately to the first SCALANCE W700 device that signals over Ethernet. If there is only IP communication between the access point and the client, the default setting "Own" can be retained. If MAC address-based frames are also to be sent by SCALANCE W700 devices downstream from the client, you need to select the settings "Automatic", "Manual" or "Layer 2 Tunnel".

Background noise

The page displays the background noise of the channel.

Note

The page is only available if there is an online connection to the device.

Description

- **Connector**
  Shows the name of the relevant antenna connector.
- **Channel [dBm]**
  Shows the background noise of the set channel.
- **Extended Channel [dBm]**
  Shows the background noise of the extended channel (HT-40).

WLAN statistics

Fault

The page show how many bad frames were received or sent per WLAN interface. If an increased number of errors occurs, you should check the settings for the WLAN interface(s), the setup of the devices and the connection quality.

Note

The page is only available if there is an online connection to the device.

Displayed values

The Transmission Errors table has the following columns:

- **Interface**
  Shows the WLAN interface to which the entries apply.
- **Error types**
  The other columns after the WLAN interface contain the absolute numbers of the frames sent according to their error type.
  The columns of the table distinguish the following error types:
  - Transmission errors
    Shows the number and percentage of bad frames that were sent.
  - Discarded frames
    Shows the number and percentage of frames that were discarded. Despite all the retries, the frame could not be successfully sent.
    The frame has not yet been sent and the recipient has logged off in the meantime.
  - Retries
    Shows the number and percentage of frames sent successfully that required one or more retries.

The "Received Errors" table has the following columns:

- **Interface**
  Shows the WLAN interface to which the entries apply.
- **Error types**
  The other columns after the WLAN interface contain the absolute numbers of the frames received according to their error type.
  The columns of the table distinguish the following error types:
  - Received errors
    Shows the number and percentage of bad frames that were received.
  - Duplicate frames
    Shows the number and percentage of frames that were received twice.
  - Encryption errors
    Shows the number and percentage of incorrectly encrypted frames.
  - FCS errors
    Shows the number and percentage of frames in which the checksum was incorrect.

Sent management frames

The page shows how many frames in response to logging on or logging off were counted per VAP interface.

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

Displayed values

The table has the following columns:

- Interface
  Shows the VAP interface to which the entries apply.
- Frames
  - Management Frames
    Shows the number of management frames
  - Association Requests
    Shows the number of requesting association frames relevant for a logon.
  - Association Responses
    Shows the number of responding association frames relevant for a logon.
  - Disassociation Requests
    Shows the number of requesting disassociation frames relevant for a logoff.
  - Authentication Requests
    Shows the number of requesting Authentication frames relevant for a logon.
  - Authentication Responses
    Shows the number of responding authentication frames relevant for a logon.
  - Deauthentication Requests
    Shows the number of requesting deauthentication frames relevant for a logon.

Management Frames Received

The page shows how many frames in response to logging on or logging off were counted per VAP interface.

Note

The page is only available

- if there is an online connection to the device.
- in access point mode.

Displayed values

The table has the following columns:

- **Interface**
  Shows the VAP interface to which the entries apply.
- **Frame**
  - Management Frames
    Shows the number of management frames
  - Association Requests
    Shows the number of requesting association frames relevant for a logon.
  - Association Responses
    Shows the number of responding association frames relevant for a logon.
  - Disassociation Requests
    Shows the number of requesting disassociation frames relevant for a logoff.
  - Authentication Requests
    Shows the number of requesting Authentication frames relevant for a logon.
  - Authentication Responses
    Shows the number of responding authentication frames relevant for a logon.
  - Deauthentication Requests
    Shows the number of requesting deauthentication frames relevant for a logon.

Sent data frames

The page shows how many frames were sent per VAP interface.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the VAP interface to which the entries apply.
- **Frame types**
  The other columns after the VAP interface contain the absolute numbers of the sent frames according to the frame types.
  In the columns of the table, a distinction is made according to the following frame types:
  - Data Frames
    Shows the number of sent data frames.
  - Multicast/Broadcast Frames
    Shows the number of sent multicast and broadcast frames.
  - Unicast Frames
    Shows the number of unicast frames sent.
  - Average Data Rate
    Shows average data rate of the last data frames sent.

Received data frames

The page shows how many frames were received per VAP interface.

Note

The page is only available if there is an online connection to the device.

Displayed values

The table has the following columns:

- **Interface**
  Shows the VAP interface to which the entries apply.
- **Frame types**
  The other columns after the VAP interface contain the absolute numbers of the received frames according to the frame types.
  In the columns of the table, a distinction is made according to the following frame types:
  - Data Frames
    Number of received data frames.
  - Multicast/Broadcast Frames
    Shows the number of received multicast and broadcast frames.
  - Unicast Frames
    Shows the number of received unicast frames.
  - Average Data Rate
    Shows average data rate of the last data frames received.

WLAN iFeatures

iREF Client List

The page shows the antenna connector via which the clients logged on to the access point communicate. Other information such as the signal strength and the MAC address of the WLAN interface is also shown.

Note

The page is only available

- for SCALANCE W780
- for SCALANCE W780
- if there is an online connection to the device.
- in access point mode.
- with KEY-PLUG inserted: W780 iFeatures (MLFB 6GK5 907-8PA00)

Displayed values

- **Associates Stations**
  Shows the number of clients logged in to the access point.

The table has the following columns:

- **AID** (Associated ID)
  Shows the connection ID of the client. If the client connects to the access point via the VAP interface, the client is assigned a connection ID. The connection ID is unique within a VAP interface. If two clients log on at different VAP interfaces, both clients can receive the same ID.
- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the VAP interface.
- **MAC Address**
  Shows the MAC address of the client.
- **System Name**
  Shows the system name of the client if the client communicates this to the access point. Not all clients support this parameter.
- **TX Chain**
  Shows the antenna connector over which the client communicates with the access point.
- **Signal Strength [dBm]**
  Shows the signal strength of the connected client in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the connected client as a percentage.
- **Age [s]**
  Shows the age of the listed client.

iREF WDS List

The page shows the access points logged on to the access point via a WDS link. Information such as the antenna used and the signal strength of the WLAN interface is shown.

Note

The page is only available

- SCALANCE W780
- SCALANCE W770
- if there is an online connection to the device.
- in access point mode.
- with KEY-PLUG inserted: Access point W780 iFeatures (MLFB 6GK5 907-8PA00)

Displayed values

- **Connected WDS partners**
  Shows the number of access points logged in to the access point

The table has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the WDS interface.
- **BSSID**
  Shows the MAC address of the WDS partner.
- **WDS ID**
  Shows the name of the WDS partner.
- **TX Chain"**
  Shows the antenna connector over which the two access points communicate with each other.
- **Signal Strength [dBm]**
  Shows the signal strength of the connected access point in bBm.
- **Signal Strength [%]**
  Shows the signal strength of the connected access point as a percentage.

AeroScout

Note

The page is only available

- for SCALANCE W780 and SCALANCE W774-1 RJ-45
- if there is an online connection to the device.
- in access point mode.
- with KEY-PLUG inserted: Access points W780 iFeatures (MLFB 6GK5 907-8PA00)

Note

AeroScout and iPCF mode

The AeroScout function cannot be combined with other iFeatures (iPCF, iPCF-MC iREF). AeroScout can only be used in the 2.4 GHz band according to IEEE 802.11g, IEEE 802.11n and IEEE 802.11n-only.
For more detailed information, please refer to the AeroScout documentation of (www.aeroscout.com).

Displayed values

- **Tag Information forwarding**
  Shows the setting of the management program.
  In the management program that evaluates the AeroScout frames, you can specify whether or not an IWLAN device will forward frames.

  Note

  No evaluation or processing

  With a suitable configuration, the SCALANCE W device forwards AeroScout frames but does not process or evaluate them itself. This is done only in the "AeroScout System Manager" program.

- **AeroScout Status**
  Shows whether or not AeroScout is activated. You can set this for each WLAN interface of the device in "iFeatures > AeroScout". If you have enabled forwarding, "active" is displayed here, otherwise "inactive"
- **Engine Port**
  Shows the port at which the device expects UDP datagrams from the AeroScout Engine.
- **Response Port**
  Shows the port via which the device forwards the received AeroScout frames.
- **Response IP**
  Shows the IP address of the PC on which the AeroScout Engine for evaluation of the AeroScout frames is running.
- **Multicast Address**
  Shows the multicast address that the tag uses. The multicast address is configured in the AeroScout Engine.

- **Acknowledgments Sent**
  Shows the number of acknowledgments sent by the device. The number reflects the received UDP datagrams.
- **Messages Dropped**
  Shows the number of AeroScout frames that were discarded by the device. If, for example, an AeroScout tag is configured so that it sends on channel 1, the device does not forward a frame received on channel 6.

Configuring system functions

Configuration

Specify the services that access the device. With some services, there are further configuration pages on which more detailed settings can be made.

Settings

The page contains the configuration overview of the access options of the device.

- **Telnet Server**
  Enable or disable the "Telnet Server" service for unencrypted access to the CLI.
- **SSH server**
  Enable or disable the "SSH Server" service for encrypted access to the CLI.
- **HTTPS Server only**
  Enable or disable access using HTTP.
- **DNS client**
  Enable or disable the DNS client. You can configure other settings in "System > DNS Client".
- **SMTP Client**
  Enable or disable the SMTP client. You can configure other settings in "System > SMTP Client".
- **Syslog Client**
  Enable or disable the system event client. You can configure other settings in "System > Syslog Client".
- **DCP Server**
  Specify whether or not the device can be accessed with DCP (Discovery and Configuration Protocol):
  - "-" (disabled)
    DCP is disabled. Device parameters can neither be read nor modified.
  - Read/write access
    With DCP, device parameters can be both read and modified.
  - Read-Only
    With DCP, device parameters can be read but cannot be modified.

- **Time**
  Select the required setting. The following settings are possible:
  - Manual
    The system time is set manually.
  - SIMATIC Time
    The system time is set using a SIMATIC time transmitter. You can configure other settings in "System > System Time > SIMATIC Time Client".
  - SNTP Client
    The system time is set via an SNTP server. You can configure other settings in "System > System time > SNTP client".
  - NTP Client
    The system time is set via an NTP server. You can configure other settings in "System > System Time > NTP Client".
- **SNMP**
  Select the required protocol. The following settings are possible:
  - "-" (SNMP disabled)
    Access to device parameters using SNMP is not possible.
  - SNMPv1/v2c/v3
    Access to device parameters is possible with SNMP versions 1, 2c or 3. You can configure other settings in "System > SNMP > General".
  - SNMPv3
    Access to device parameters is possible with SNMP version 3. You can configure other settings in "System > SNMP > General".
- **SNMPv1/v2 Read-Only**
  Enable or disable write access to SNMP variables with SNMPv1/v2c.
- **SNMPv1 Traps**
  Enable or disable the sending of SNMP traps (alarm frames). You can configure other settings in "System > SNMP > Traps".
- **DHCP Client**
  Enable or disable the DHCP client. You can configure other settings in "System > DHCP client".
- **DHCPv6 Client**
  Enable or disable the DHCPv6 client.

- **SINEMA configuration interface**
  If the SINEMA configuration interface is enabled, you can download configurations to the device via the TIA Portal.
- **Configuration Mode**
  Select the required mode. The following modes are possible:
  - Automatic Save
    Automatic backup mode. Approximately 1 minute after the last parameter change or when you restart the device, the configuration is automatically saved. In addition to this, the following message appears in the display area "Changes will be saved automatically in x seconds. Press 'Write Startup Config' to save immediately".

    Note

    Interrupting the save

    Saving starts only after the timer in the message has elapsed. How long saving takes depends on the device.

    During the save, the message "Saving configuration data in progress. Please do not switch off the device" is displayed.

    - Do not switch off the device immediately after the timer has elapsed.
  - Trial
    Trial mode. In Trial mode, although changes are adopted, they are not saved in the configuration file (startup configuration).
    To save changes in the configuration file, use the "Write Startup Config" button. The "Write Startup Config" button is displayed when you set trial mode. In addition to this after every parameter change the following message is displayed in the display area: "Trial Mode Active – Press "Write Startup Config" button to make your settings persistent" as soon as there are unsaved modifications. This message can be seen on every WBM page until the changes made have either been saved or the device has been restarted.

General

Device

This page contains the general device information.

Settings

- **Current System Time**(Only available online)
  Shows the current system time. The system time is either set by the user or by a time-of-day frame: either SINEC H1 time-of-day frame, NTP or SNTP. (readonly)
- **System Up Time**(only available online)
  Shows the operating time of the device since the last restart. (readonly)
- **Device Type**(only available online)
  Shows the type designation of the device. (readonly)

- **System Name**
  You can enter the name of the device. The entered name is displayed in the selection area. A maximum of 255 characters are possible. The system name is also displayed in the CLI input prompt. The number of characters in the CLI input prompt is limited. The system name is truncated after 16 characters.
- **System Contact**
  You can enter the name of a contact person responsible for managing the device.
- **Location**
  You can enter the location of the device. The entered installation location is displayed in the selection area.

Note

The ASCII characters 0x20 to 0x7e are used in the input boxes.

At the start and end of the input boxes"System name", "System Contact" and "System Location", the characters "<", ">" and "space" are not permitted.

Coordinates

On this page, you configure the geographic coordinates (latitude, longitude and the height above the ellipsoid according to WGS84). These boxes are purely for information with a maximum length of 32 characters.

Getting the coordinates

Use suitable maps for obtaining the geographic coordinates of the device.

The geographic coordinates can also be obtained using a GPS receiver. The geographic coordinates of these devices are normally displayed directly and only need to be entered in the input boxes of this page.

Settings

- **Latitude**
  Enter the north or south latitude for the location of the device.
  For example, +49° 1´ 31.67" means that the device is located at 49 degrees, 1 arc minute and 31.67 arc seconds north latitude.
  A south latitude is shown by a preceding minus character.
  You can also append the letters N (north latitude) or S (south latitude) to the numeric information (49° 1´ 31.67" N).
- **Longitude**
  Enter the value of the eastern or western longitude of the location of the device.
  For example, +8° 20´ 58.73" means that the device is located at 8 degrees, 20 minutes and 58.73 seconds east.
  A western longitude is indicated by a preceding minus sign.
  You can also add the letter E (eastern longitude) or W (western longitude) to the numeric information (8° 20´ 58.73" E).
- **Height**
  Enter the value of the height above sea level in meters.
  For example, 158 m means that the device is located at a height of 158 m above sea level.
  Heights below sea level (for example the Dead Sea) are indicated by a preceding minus sign.

Agent IPv4

Configuration of the IP addresses

On this page, you configure the IPv4 address for the device.

Settings

- **IP Assign Method**
  Shows how the IPv4 address is assigned.
  - Static
    The IPv4 address is static. You enter the IP settings in "IP Address" and "Subnet Mask".
  - Dynamic (DHCP)
    The device obtains a dynamic IPv4 address from a DHCP server.
- **IP Address**
  Enter the IP address of the device. If you change the IPv4 address, the Web browser should automatically set itself to the new address. If this does not happen, enter the new address in the Web browser manually.
- **Subnet Mask**
  Enter the subnet mask of the device.
- **Default gateway**
  Enter the IPv4 address of the default gateway to be able to communicate with devices in another subnet, for example diagnostics stations, e-mail server.

- **Agent VLAN ID**
  Select the VLAN ID from the drop-down list. The drop-down list is only available if "802.1 Q VLAN Bridge" is set for the "Base Bridge Mode" parameter. You configure the parameter in "Layer 2 > VLAN > General". You can only select VLANs that have already been configured.

  Note
  Changing the agent VLAN ID

  If the configuration PC is connected directly to the device via Ethernet and you change the agent VLAN ID, the device is no longer reachable via Ethernet following the change.

- **MAC Address** (only available online)
  Shows the MAC address of the device. The MAC address is linked to the hardware and cannot be modified.

Agent IPv6

Agent IPv6

Configuration of the IP addresses

On this page, enable IPv6 on the management VAN. This VLAN interface is also called an IPv6 interface. An IPv6 interface can have several IPv6 addresses.

Description

The page contains the following:

- **Interface**
  Shows the VLAN interface on which IPv6 will be enabled.
- **IPv6 Enable**
  Enable or disable IPv6 on the interface. When you enable the setting and accept it, the link local address is created automatically.
- **IPv6 Address**
  Enter the IPv6 address. The entry depends on the selected address type.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix
- **IPv6 Address Type**
  Select the address type:
  - Unicast
  - Link Local: IPv6 address is only valid on the link.

- **Address Configuration**
  Specify the mechanism for the address configuration:
  - Automatic (default)
    The IPv6 address is created using a stateless mechanism or a stateful mechanism.
  - DHCPv6
    Stateful: Obtains the IPv6 address and the configuration file from the DHCPv6 server.
  - SLAAC (Stateless Address Auto Configuration)
    Stateless autoconfiguration using NDP (Neighbor Discovery Protocol)
  - Static
    Enter a static IPv6 address.
- **Rapid Commit**
  When enabled the procedure for the IPv6 address assignment is shortened. Instead of 4 DHCPv6 messages (SOLICIT, ADVERTISE , REQUEST, REPLY) only 2 DHCPv6 messages (SOLICIT, REPLY) are used. You will find further information on the messages in RFC 3315.

The table has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Interface Name**
  Shows the name of the VLAN interface.
- **IPv6 Address**
  Shows the IPv6 address.
- **Prefix Length**
  Shows the prefix length.
- **IPv6 Address Type**
  Displays the address type. The following values are possible:
  - Unicast
  - Link Local

IPv6 default routes

On this page, you configure the default IPv6 routes.

Description

The page contains the following:

- **Destination Network**
  Enter the network address of the destination that can be reached via this route.
- **Prefix Length**
  Enter the number of left-hand bits belonging to the prefix
- **Gateway**
  Enter the IPv4 address of the gateway via which this network address is reachable.

- **Metric**
  Enter the metric for the route. The metric corresponds to the quality of a connection, based for example on speed or costs. If there are several equal routes, the route with the lowest metric value is used.
  Range of values: 1 - 254
- **Interface**
  Specify the interface via which the network address of the destination is reached.

This table contains the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Destination Network**
  Shows the network address of the destination.
- **Prefix Length**
  Shows the prefix length.
- **Gateway**
  Shows the IPv6 address of the next gateway.
- **Interface**
  Shows the Interface of the route.
- **Metric**
  Enter the metric for the route. When creating the route, "not used" is entered automatically. The metric corresponds to the quality of a connection, based for example on speed or costs. If there are several equal routes, the route with the lowest metric value is used.
  Range of values: 1 - 254
- **Status**
  Shows whether or not the route is active.

DNS client

The DNS server (Domain Name System) assigns a domain name to an IP address so that a device can be uniquely identified.

If this setting is enabled, the device can communicate with a DNS server as a DNS client.

Note

Only resource records (RR) of type A (IPv4 address of a host) are supported.

Settings

- **DNS client**
  Enable or disable depending on whether the device should operate as a DNS client.
- **DNS server used**
  - learned only
    The device uses only the DNS servers assigned by DHCP.
  - manual only
    The device uses only the manually configured DNS servers. The DNS servers must be connected to the Internet.
  - all
    The device uses all available DNS servers.
- **DNS Server Address**
  Enter the IP address of the DNS server.

The table has the following columns:

- **DNS Server Address**
  Shows the IP address of the DNS server.
- **Origin**
  This shows whether the DNS server was configured manually or was assigned by DHCP.

Restart

On this page, there is a button with which you can restart the device and various options for resetting to the device defaults.

Note

The page is only available if there is an online connection to the device.

Note

Note the following points about restarting a device:

- You can only restart the device with administrator privileges.
- A device should only be restarted with the buttons of this page or with the appropriate CLI commands and not by a power cycle on the device.
- Any modifications you have made only become active on the device after clicking the "Set Values" button on the relevant page. If the device is in "Trial Mode", configuration modifications must be saved manually before a restart. In "Automatic Save" mode, the last changes are saved automatically before a restart.

Settings

The following options are available for restarting:

- **Restart**
  Click this button to restart the system. You must confirm the restart in a dialog box. During a restart, the device is reinitialized, the internal firmware is reloaded, and the device runs a self-test. The learned entries in the address table are deleted. You can leave the browser window open while the device restarts. You then need to log in again.
- **Restore Memory Defaults and Restart**
  Click on this button to restore the factory configuration settings with the exception of the following parameters and to restart:
  - IP addresses
  - Subnet mask
  - IP address of the default gateway
  - DHCP client ID
  - DHCP
  - System name
  - System location
  - System contact
  - Mode of the device
- **Restore Factory Defaults and Restart**
  Click on this button to restore the factory configuration settings. The protected defaults are also reset.
  An automatic restart is triggered.

Note

By resetting all the defaults to the factory configuration settings, the IP address is also lost. Following this, the device can only be accessed using the Primary Setup Tool or using DHCP.

With the appropriate attachment, a previously correctly configured device can cause circulating frames and therefore the failure of the data traffic.

Commit Control

Description

Note

The page is only available if there is an online connection to the device.

On this page, you specify when the WLAN settings become effective on the device.
If you change a WLAN setting and confirm the change, this change is adopted and takes effect

immediately. To do this, the WLAN connection is briefly interrupted. This means that you can lose the WLAN connection to your device before it is fully configured.

With the "Manual Commit" setting, you have the opportunity of first fully configuring the device. The changes are accepted, but are not active immediately. The changes only take effect when you confirm the changes with the "Set Values" button.

Note

If you configure the device via the WLAN interface, we recommend that you use the "Manual Commit" setting. Check the parameters again before you confirm the changes with the "Set Values" button.

Settings

- **Commit Mode**
  Select the required setting.
  - Automatic Commit
    Each change in the WLAN settings is adopted and is immediately effective when you click the "Set Values" button. With its default setting, the SCALANCE W700 device is set to "Automatic Commit".
  - Manual Commit
    The changes are accepted, but do not take effect immediately. The changes only take effect when you click the "Set Values" button. The "Commit Changes" button is displayed when you set "Manual Commit". In addition to this the message “Manual Commit Mode active - Click the "Commit Changes" button to to provide current configuration to driver” appears as soon as there are WLAN changes. This message can be seen on every WBM page until the changes made have either taken effect or the device has been restarted.

    Note

    When the changes take effect, the WLAN connection to all WLAN interfaces will be interrupted for a short time. The WLAN driver is started with the new settings.

Load & save

Overview of the file types

Table 10-106 HTTP

File type	Description	Down-load	Save	Delete
Config	Start configuration	X	X	--
ConfigPack	Detailed configuration information. for example, start configuration, users, certificates, firmware of the device (if saved as well). For more detailed information on creating and using the ConfigPack incl. firmware, refer to the section "Maintenance".	X	X	--
CountryList	The zip file contains the country list as a csv and as a pdf file.	--	X	--
Debug	This file contains information for Siemens Support.	--	X	X
EDS	Electronic Data Sheet (EDS) Electronic data sheets for describing devices in the EtherNet/IP mode	--	X	--
Firmware	Loading firmware updates	X	X	--
GSDML	Information on the device properties (PROFINET)	--	X	--
HTTPS Cert	HTTPS certificate Maximum file size: 8192 bits	X	X	X
LogFile	File with entries from the event log table	--	X	--
MIB	Private MSPS MIB file "Scalance_w_msps.mib"	--	X	--
RunningCLI	This file contains an overview of the current configuration in the form of CLI commands. You can download the text file. The file is not intended to be uploaded again unchanged.	--	X	--
Script	CLI script file	X	--	--
StartupInfo	Startup log file	--	X	--
Users	File with user names and passwords	X	X	--
WLANAuth-log	File with entries from the WLAN Authentication Log (information on successful or failed authentication attempts)	--	X	--
WLANCert (in client mode only)	User certificate. You can specify a password for the user certificate on the WBM page "Load&Save > Password". Maximum file size: 8192 bits	X	X	X
WLANServ-Cert (in client mode only)	Server certificate Maximum file size: 8192 bits	X	X	X

File type	Description	Down-load	Save	Delete
WLANSi-gRec (in client mode only)	The zip file contains the following: • csv file with the measured values of the signal recorder • pdf file with the measured values and an additional graphic representation of the measured values. You will find information about the measured values and their graphic representation in the section "AU-TOHOTSPOT".	--	X	X
WLANSpec-trumAnalyz-er (Only in ac-cess point mode)	The Zip file contains a csv file with the measured values of the spectrum analyzer. You will find information about the measured values and their graphic representation in the section "AU-TOHOTSPOT".	--	X	X

Table 10-107 TFTP

File type	Description	Save	Down-load
Config	Start configuration	X	X
ConfigPack	Detailed configuration information. for example, start configuration, users, certificates, firmware of the de-vice (if saved as well). For more detailed information on creating and using the ConfigPack incl. firmware, refer to the section "Maintenance".	X	X
CountryList	The zip file contains the country list as a csv and as a pdf file.	X	--
Debug	This file contains information for Siemens Support.	X	--
EDS	Electronic Data Sheet (EDS) Electronic data sheets for describing devices in the EtherNet/IP mode	X	--
Firmware	Loading firmware updates	X	X
GSDML	Information on the device properties (PROFINET)	X	--
HTTPS Cert	HTTPS certificate Maximum file size: 8192 bits	X	X
LogFile	File with entries from the event log table	X	--
MIB	Private MSPS MIB file "Scalance_w_msps.mib"	X	--
RunningCLI	This file contains an overview of the current configura-tion in the form of CLI commands. You can download the text file. The file is not intended to be uploaded again unchanged.	X	--
Script	CLI script file	--	X
StartupInfo	Startup log file	X	--
Users	File with user names and passwords	X	X

File type	Description	Save	Down-load
WLANAuthlog	File with entries from the WLAN Authentication Log (information on successful or failed authentication attempts)	X	--
WLANCert (in client mode only)	User certificate. You can specify a password for the user certificate on the WBM page "Load&Save > Password". Maximum file size: 8192 bits	X	X
WLANServerCert (in client mode only)	Server certificate Maximum file size: 8192 bits	X	X
WLANSigRec (in client mode only)	The zip file contains the following: • csv file with the measured values of the signal recorder • pdf file with the measured values and an additional graphic representation of the measured values. You will find information about the measured values and their graphic representation in the section "AUTOHOTSPOT".	X	--
WLANSpectrumAnalyzer (Only in access point mode)	The Zip file contains a csv file with the measured values of the spectrum analyzer. You will find information about the measured values and their graphic representation in the section "AUTOHOTSPOT".	X	--

Uploading and saving using HTTP

Loading and saving data via HTTP

This page allows you to store device data in an external file on your client PC or to load such data from an external file from the client PC to the devices.
This means, for example, that you can also load new firmware from a file located on your client PC.

Note

The page is only available if there is an online connection to the device.
This page is available both for connections using HTTP and for connections using HTTPS.

Firmware

The firmware is signed and encrypted. This ensures that only firmware created by Siemens can be downloaded to the device.

Note

Incompatibility with predecessor versions

During the installation of a previous version, the configuration data and log files can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

Incompatibility with previous firmware versions with/without PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

In this situation, if a PLUG is inserted in the device, following the restart, this has the status "Not Accepted" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data. If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using the WBM page "System > PLUG".

Configuration files

Note

Configuration files and trial mode/automatic save mode

In "Automatic Save" mode, the data is saved automatically before the configuration files (ConfigPack and Config) are transferred.
In trial mode, although the changes are adopted, they are not saved in the configuration files (ConfigPack and Config). Use the "Write Startup Config" button on the "System > Configuration" WBM page to save changes in the configuration file.

CLI script file

You can download existing CLI configurations (RunningCLI) and upload your own CLI scripts (Script).

Note

The downloadable CLI script is not intended to be uploaded again unchanged.

Settings

The table has the following columns:

- **Type**
  Shows the designation of the file.
- **Description**
  Shows the short description of the file type.

- **Load**
  With this button, you can upload files to the device. The button can be enabled, if this function is supported by the file type.
- **Save**
  With this button, you can save files from the device. The button can only be enabled if this function is supported by the file type and the file exists on the device.
- **Delete**
  With this button, you can delete files from the device. The button can only be enabled if this function is supported by the file type and the file exists on the device.

Note

Following a firmware update, delete the cache of your Internet browser.

Uploading and saving using TFTP

Loading and saving data via a TFTP server

On this page, you can configure the TFTP server and the file names. You can also store device data in an external file on a TFTP server or load such data from an external file from the TFTP server to the devices. This means, for example, that you can also load new firmware from a file located on a TFTP server.

Firmware

The firmware is signed and encrypted. This ensures that only firmware created by Siemens can be downloaded to the device.

Note

Incompatibility with predecessor versions

During the installation of a previous version, the configuration data and log files can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

Incompatibility with previous firmware versions with/without PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed.

In this situation, if a PLUG is inserted in the device, following the restart, this has the status "Not Accepted" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data. If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using the WBM page "System > PLUG".

Configuration files

Note

Configuration files and Trial mode/Automatic Save

In "Automatic Save" configuration mode, the data is saved automatically before the configuration files (ConfigPack and Config) are transferred.
In trial mode , although the changes are adopted, they are not saved in the configuration files (ConfigPack and Config). Use the "Write Startup Config" button on the "System > Configuration" WBM page to save changes in the configuration files.

CLI script file

You can download existing CLI configurations (RunningCLI) and upload your own CLI scripts (Script).

Note

The downloadable CLI script is not intended to be uploaded again unchanged.

Settings

- **TFTP Server IP Address**
  Enter the IP address or the FQDN of the TFTP server with which you exchange data.
- **TFTP Server Port**
  Here, enter the port of the TFTP server via which data exchange will be handled. If necessary, you can change the default value 69 to your own requirements.

The table has the following columns:

- **File type**
  Shows the designation of the file.
- **Description**
  Shows the short description of the file type.

- **File name**
  A file name is preset here for every file type.

  Note
  Changing the file name

  You can change the file name preset in this column. After clicking the "Set Values" button, the changed name is stored on the device and can also be used with the Command Line Interface.

- **Select action** (only available online)
  Select the required action. The selection depends on the selected file type, for example you can only save the log file.
  The following actions are possible:
  - Save file
    With this selection, you save a file on the TFTP server.
  - Load file
    With this selection, you load a file from the TFTP server.

Passwords

Password for certificates

There are files to which access is password protected. For example to use the HTTPS certificate, you need to specify the corresponding password on this WBM page.

Settings

- **Type**
  Shows the file type
- **Description**
  Shows the short description of the file type.
- **Enabled**
  When selected, the file is used. Can only be enabled if the password is configured.
- **Password**
  Enter the password for the file.

- **Password Confirmation**
  Confirm the new password.
- **Status**
  Shows whether the password for the file match the device.
  - Valid
    The "Enabled" check box is selected and the password matches the file.
  - Invalid
    The "Enabled" check box is selected but the password does not match the file or no file has been loaded yet.
  - '-'
    The password cannot be evaluated or is not yet being used. The "Enabled" check box is not selected.

Events

Configuration

On this page, you specify how the device reacts to system events. By enabling the appropriate options, you specify how the device reacts to events. To enable or disable the options, click the relevant settings of the columns.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all events of table 2.
- **E-mail / Trap / Log Table / Syslog / Faults**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Event**
  The column contains the following values:
  - **Cold/Warm Restart**
    The device was turned on or restarted by the user.
  - **Link Change**
    This event occurs only when the port status is monitored and has changed, see "System > Fault Monitoring > Link Change".
  - Authentication error
    This event occurs when attempting access with a bad password.
  - Power Change
    This event occurs when power supply lines 1 and 2 are monitored. It indicates that there was a change to line 1 or line 2. The event occurs when the PoE power supply has failed, see "System > Fault Monitoring > Power Supply".
  - Spanning Tree Change
    The STP or RSTP or MSTP topology has changed.
  - Fault State Change
    The fault status has changed. The fault state can relate to the activated port monitoring, the response of the signaling contact or the power supply monitoring.
  - Overlap AP Detection (only in access point mode)
    This event is triggered when there is an entry in the Overlap AP list.
  - WDS (Only in access point mode)
    The connection status of a WDS link has changed.
  - DFS (Only in access point mode)
    This event occurs if a radar signal was received or the DFS scan was started or stopped.
  - WLAN General (Only in access point mode)
    This event occurs if a the channel bandwidth has changed.
  - WLAN Authentication Log
    Forwarding of the entries from the WLAN authentication log to the system protocol server.
  - WLAN De/Authentication (Only in client mode)
    With successful or failed WLAN authentication attempts.
  - iPCF Cycle Time (Only in access point mode)
    Only available when the KEY-PLUG is inserted.
    This event occurs if too many clients are logged on for the set iPCF cycle time or if some clients were not reached in one cycle.
  - iPCF Poll Size
    Only available when the KEY-PLUG is inserted.
    This event occurs if the PROFINET data size is too large for transfer.
- **E-mail**
  The device sends an e-mail. This is only possible if the SMTP server is set up and the "SMTP client" function is enabled.

- **Trap**
  The device sends an SNMP trap. This is only possible if "SNMPv1 Traps" is enabled in "System > Configuration".
- **Log Table**
  The device writes an entry in the event log table.
- **Syslog**
  The device writes an entry to the system log server. This is only possible if the system log server is set up and the "Syslog client" function is enabled.
- **Faults**
  The device triggers an error. The error LED lights up.
- **E-mail**
  The device sends an e-mail. This is only possible if the SMTP server is set up and the "SMTP client" function is enabled.
- **Trap**
  The device sends an SNMP trap. This is only possible if "SNMPv1 traps" is enabled in "System > Configuration".
- **Log table**
  The device writes an entry in the log table.
- **Syslog**
  The device writes an entry to the system log server. This is only possible if the system log server is set up and the "Syslog client" function is enabled.
- **Fault**
  The device triggers a fault. The error LED lights up

Severity filter

On this page, set the threshold levels for sending system event notifications.

Settings

The table has the following columns:

- **Client Type**
  Select the client type for which you want to make settings:
  - E-mail
    Sending system event messages by e-mail
  - Log table
    Entry of system events in the log table.
  - Syslog
    Entering system events in the Syslog file
  - WLAN Authentication Log
    Forwarding of the entries from the WLAN Authentication Log to the system protocol server.
    Can only be configured with SCALANCE W770 and SCALANCE W780
- **Severity**
  Select the required level. The following settings are possible:
  - Info
    System events are processed as of the severity level "Info".
  - Warning
    System events are processed as of the severity level "Warning".
  - Critical
    System events are processed as of the severity level "Critical".

SMTP client

The device provides the option of automatically sending an e-mail if an alarm event occurs (for example to the network administrator). The e-mail contains the identification of the sending device, a description of the cause of the alarm in plain language, and a time stamp. This allows centralized network monitoring to be set up for networks with few nodes based on an E-mail system. When an e-mail error message is received, the WBM can be started by the Internet browser using the identification of the sender to read out further diagnostics information.

On this page, you can configure up to three SMTP servers and the corresponding e-mail addresses.

Settings

- **SMTP Client**
  Enable or disable the SMTP client.
- **Sender Email Address**
  Enter the name of the sender to be included in the e-mail, for example the device name. This setting applies to all configured SMTP servers.
- **Send Test Mail**
  Send a test e-mail to check your configuration.

- **SMTP Port**
  Enter the port via which your SMTP server can be reached.
  Factory settings: 25
  This setting applies to all configured SMTP servers.
- **SMTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the SMTP server.

This table contains the following columns:

- **SMTP Server Address**
  Shows the IP address or the FQDN (Fully Qualified Domain Name) of the SMTP server.
- **Email address of the recipient**
  Enter the e-mail address to which the device sends an e-mail if a fault occurs.

Syntax of email addresses

The following conditions apply to e-mail addresses:

- Alphanumeric characters are permitted.
- The following special characters are permitted:
  - @
  - _ (underscore)
  - - (hyphen)
  - . (period)
- A @ character must be included.
- Only one @ may be used.
- The characters "@" and "." must not be the first or last character.

DHCPv4

DHCP client

If the device is configured as a DHCP client, it starts a DHCP query. As the reply to the query the device receives an IPv4 address from the DHCP server. The server manages an address range from which it assigns IPv4 addresses. It is also possible to configure the server so that the client always receives the same IPv4 address in response to its request.

Settings

- **DHCP client configuration file request (opt 66, 67)**
  Select this option if you want the DHCP client to use options 66 and 67 to download and then enable a configuration file.
- **DHCP Mode**
  Select the DHCP mode. The following modes are possible:
  - via MAC Address
    Identification is based on the MAC address.
  - via DHCP Client ID
    Identification is based on a freely defined DHCP client ID.
  - Via System Name
    Identification is based on the system name. If the device name is 255 characters long, the last character is not used for identification.
  - via PROFINET Name of Station
    Identification is based on the PROFINET name of the station.

This table contains the following columns:

- **Interface**
  Interface to which the setting relates.
- **DHCP**
  Enable or disable the DHCP client for the relevant interface.

DHCP server

Note

The page is only available for

- SCALANCE W780 / W770 / W740 / W730, W761-1 RJ-45 and W722-1 RJ-45

You can operate the device as a DHCP server. This allows IPv4 addresses to be assigned automatically to the connected devices. The IPv4 addresses are either distributed dynamically from an IPv4 address band you have specified or a specific IPv4 address (static) can be assigned to a particular device.

On this page, specify the IPv4 address band from which the device receives any IPv4 address. You configure the static assignment of the IPv4 addresses in "Static IP addresses".

Requirement

- In access point mode
  - The connected devices are configured so that they obtain the IPv4 address from a DHCP server.
- In client mode
  - The connected devices are configured so that they obtain the IPv4 address from a DHCP server.
  - NAT is enabled. You enable NAT in "Layer 3 > NAT".

Settings

- **DHCP server**
  Enable or disable the DHCP server on the device.

  Note

  To avoid conflicts with IPv4 addresses, only one device may be configured as a DHCP server in the network.

  Note

  Access point

  With an access point, the "DHCP Server" function is only possible on the VLAN assigned to the management (agent VLAN ID).

- **Prior to offering, check the address with ICMP echo**
  When selected, the DHCP server checks whether or not the IPv4 address has already been assigned. To do this the DHCP server sends ICMP echo messages (ping) to the IPv4 address. If no reply is received, the DHCP server can assign the IPv4 address.

  Note

  If there are devices in your network on which the echo service is disabled as default, there may be conflicts with the IPv4 addresses. To avoid this, assign these devices an IPv4 address outside the IPv4 address band.

The table has the following columns:

- **Pool ID**
  Shows the number of the IPv4 address band.

  Note

  Only one pool ID (ID = 1) can be created.

- **Enable**
  Specify whether or not this IPv4 address band will be used.

  Note

  If the IPv4 address band is enabled, neither DHCP options nor static PPv4 addresses can be configured.

- **Interface**
  Specify the interface via which the IPv4 addresses are dynamically assigned.
  The requirement for the assignment is that the IPv4 address of the interface is located within the IPv4 address band. If this is not the case, the interface does not assign any IPv4 addresses.
- **Subnet**
  Enter the network address range that will be assigned to the devices. Use the CIDR notation.
- **Lower IP address**
  Enter the IPv4 address that specifies the start of the dynamic IPv4 address band. The IPv4 address must be within the network address range you configured for "Subnet".
- **Upper IP address**
  Enter the IPv4 address that specifies the end of the dynamic IPv4 address band. The IPv4 address must be within the network address range you configured for "Subnet".
- **Lease Time [sec]**
  Specify for how many seconds the assigned IPv4 address remains valid. Once this period has elapsed, the device must either request a new IPv4 address or extend the lease time of the existing IPv4 address.

DHCP options

Note

The page is only available for

- SCALANCE W780 / W770 / W740 / W730, W761-1 RJ-45 and W722-1 RJ-45

On this page you specify which DHCP options the DHCP server supports. The various DHCP options are defined in RFC 2132.

Settings

- **Pool ID**
  Select the required IPv4 address band.
- **Option Code**
  Enter the number of the required DHCP option. The various DHCP options are defined in RFC 2132. The DHCP options 1, 3, 6, 66 and 67
  are created automatically when the IPv4 address band is created. With the exception of option 1, the options can be deleted.
  With the DHCP option 3, the internal IPv4 address of the device is automatically set as a DHCP parameter.

  Note

  Not supported DHCP servers

  The DHCP options 50 - 60 and 255 are not supported.

The table has the following columns:

- **Pool ID**
  Shows the number of the IPv4 address band.
- **Option Code**
  Shows the number of the DHCP option.
- **Use Interface IP**
  Specify whether or not the internal IPv4 address of the device will be used.
- **Value**
  Enter the DHCP parameter that is transferred to the DHCP client. The content depends on the DHCP option.
  - DHCP option 67 (boot file name)
    Enter the name of the boot file in the string format.
  - DHCP options 3 (Router) and 6 (DNS):
    Enter the DHCP parameter as an IPv4 address, e.g. 192.168.100.2. With DHCP option 6, you can specify several IPv4 addresses separated by commas.
  - DHCP option 66 (TFTP Server):
    Enter the DHCP parameter as an IPv4 address, e.g. 192.168.100.2 or the FQDN name.
  - All other DHCP options
    Enter the DHCP parameter in hexadecimal, e.g. the IPv4 address 192.168.100.2 corresponds to "C0A86402".

Static IP addresses

Note

The page is only available for

- SCALANCE W780 / W770 / W740 / W730, W761-1 RJ-45 and W722-1 RJ-45

On this page you specify that devices with a certain MAC address are assigned to the selected IPv4 address.

Settings

- **Pool ID**
  Select the required IPv4 address band.
- **Client Identification Method**
  Select the method according to which a client is identified.
  - Ethernet MAC
    The client is identified by its MAC address.
  - Client ID
    The client is identified by a freely defined DHCP client ID.
- **Value**
  Enter the MAC address.

The table has the following columns:

- **Pool ID**
  Shows the number of the IPv4 address band.

  Note

  Only Pool ID = 1 is supported.

- **Identification Method**
  Shows whether the client is identified by its MAC address or the client ID.
- **Value**
  Shows the MAC address to which the IPv4 address is assigned.
- **IP Address**
  Specify the IPv4 address. The IPv4 address must match the subnet of the IPv4 address band.

SNMP

General

On this page, you make the basic settings for SNMP. Enable the options according to the function you want to use.

Settings

- **SNMP**
  Select the SNMP protocol. The following settings are possible:
  - "-" (disabled)
    SNMP is disabled.
  - SNMPv1/v2c/v3
    SNMPv1/v2c/v3 is supported.
  - SNMPv3
    Only SNMPv3 is supported.
- **SNMPv1/v2 Read-Only**
  If you enable this option, SNMPv1/v2c can only read the SNMP variables.

  Note

  Community String

  For security reasons, do not use the standard values "public" or "private". Change the community strings following the initial installation.

- **SNMPv1/v2c Read Community String**
  Enter the community string for access of the SNMP protocol.
- **SNMPv1/v2c Read/Write Community String**
  Enter the community string for read and write access of the SNMP protocol.

- **SNMPv1 Traps**
  Enable or disable the sending of SNMP traps (alarm frames). On the "Trap" tab, specify the IP addresses of the devices to which SNMP traps will be sent.
- **SNMPv1/v2c Trap Community String**
  Enter the community string for sending SNMPv1/v2 messages.
- **SNMPv3 User Migration**
  - **Enabled**
    If the function is enabled, an SNMP engine ID is generated that can be migrated. You can transfer configured SNMPv3 users to a different device.
    If you enable this function and load the configuration of the device on another device, configured SNMPv3 users are retained.
  - **Disabled**
    If the function is disabled, a device-specific SNMP engine ID is generated. To generate the ID, the agent MAC address of the device is used. You cannot transfer this SNMP user configuration to other devices.
    If you load the configuration of the device on another device, all configured SNMPv3 users are deleted.
- **SNMP Engine ID**
  Shows the SNMP engine ID.

Traps

If an alarm event occurs, a device can send SNMP traps (alarm frames) to up to ten different management stations at the same time. Traps are only sent if the events specified in "Events" occur.

Note

SNMP traps are sent only when the "SNMPv1 Traps" setting was selected in "SNMP > General".

Settings

- **Trap Receiver Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the station to which the device sends SNMP traps. You can specify up to ten different recipients.

The table has the following columns:

- **Trap Receiver Address**
  If necessary, change the IP addresses or the FQDN of the stations.
- **Trap**
  Enable or disable the sending of SNMP traps. Stations that are entered but not selected do not receive SNMP traps.

v3 Groups

Security settings and assigning permissions

SNMP version 3 allows permissions to be assigned, authentication, and encryption at protocol level. The security levels and read/write permissions are assigned according to groups. The settings automatically apply to every member of a group.

Settings

- **Group Name**
  Enter the name of the group. The maximum length is 32 characters.
- **Security Level**
  Select the security level (authentication, encryption) valid for the selected group. You have the following options for the security levels:
  - no Auth/no Priv
    No authentication enabled / no encryption enabled.
  - Auth/no Priv
    Authentication enabled / no encryption enabled.
  - Auth/Priv
    Authentication enabled / encryption enabled.

The table has the following columns:

- **Group Name**
  Shows the defined group names.

  Note

  Once a group name and the security level have been specified, they can no longer be modified after the group is created. If you want to change the group name or the security level , you will need to delete the group and recreate it and reconfigure it with the new name.

- **Security Level**
  Shows the configured security level.
- **Read**
  Enable or disable read access for the required group.

- **Write**
  Enable or disable write access for the required group.

  Note

  For write access to work, you also need to enable read access.

- **Persistence**
  Shows whether or not the group is assigned to an SNMPv3 user. If the group is not assigned to an SNMPv3 user, no automatic saving is triggered and the configured group is deleted after restarting the device.
  - Yes
    The group is assigned to an SNMPV3 user.
  - No
    The group is not assigned to an SNMPV3 user.

v3 users

User-specific security settings

On the WBM page, you can create new SNMPv3 users and modify or delete existing users. The user-based security model works with the concept of the user name; in other words, a user ID is added to every frame. This user name and the applicable security settings are checked by both the sender and recipient.

Settings

- **User name**
  Enter a freely selectable user name. After you have entered the data, you can no longer modify the name.

The table has the following columns:

- **User name**
  Shows the created users.
- **Group Name**
  Select the group to which the user will be assigned.
- **Authentication Protocol**
  Specify the authentication protocol for which a password will be stored.
  The following settings are available:
  - None
  - MD5
  - SHA
- **Encryption Protocol**
  Specify whether or not a password should be stored for encryption with the DES algorithm. Can only be enabled when an authentication protocol has been selected.

- **Authentication Password**
  Enter the authentication password. This password must have at least 6 characters, the maximum length is 32 characters.
- **Confirm authentication password**
  Confirm the password by repeating the entry.
- **Encryption Password**
  Enter your encryption password. This password must have at least 6 characters, the maximum length is 32 characters.
- **Confirm Encryption Password**
  Confirm the encryption password by repeating the entry.
- **Persistence**
  Shows whether or not the user is assigned to an SNMPv3 group. If the user is not assigned to an SNMPv3 group, no automatic saving is triggered and the configured user is deleted after restarting the device.
  - Yes
    The user is assigned to an SNMPv3 group.
  - No
    The user is not assigned to an SNMPv3 group.

System time

Manual time setting

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

On this page, you set the date and time of the system. For this setting to be used, enable "Manual time setting".

Note

The page is only available if there is an online connection to the device.

Settings

- **Time Manually**
  Enable or disable the manual time setting. If you enable the option, the "System Time" input box can be edited.
- **System Time**
  Enter the date and time in the format "MM/DD/YYYY HH:MM:SS".
- **Use PC Time**
  Click the button to use the time setting of the PC.

- **Last Synchronization Time**
  Shows when the last time-of-day synchronization took place.
  If no time-of-day synchronization was possible, the box displays "Date/time not set".
- **Last Synchronization Mechanism**
  This box displays how the last time-of-day synchronization was performed.
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame.
  - PTP
    Automatic time-of-day synchronization with PTP

DST overview

On this page, you can create new entries for the daylight saving time changeover.

The table provides an overview of the existing entries.

Settings

- **DST No.**
  Shows the number of the entry.
  If you create a new entry, a new line with a unique number is created.
- **Name**
  Shows the name of the entry.
- **Year**
  Shows the year for which the entry was created.
- **Start Date**
  Shows the month, day and time for the start of daylight saving time.
- **End Date**
  Shows the month, day and time for the end of daylight saving time.
- **Recurring Date**
  With an entry of the type "Rule", the period in which daylight saving time is active is displayed consisting of week, day, month and time of day. With an entry of the type "Date" a "-" is displayed.

- **State**
  Shows the status of the entry:
  - enabled
    The entry was created correctly.
  - invalid
    The entry was created new and the start and end date are identical.
- **Type**
  Shows how the daylight saving time changeover is made:
  - Date
    A fixed date is entered for the daylight saving time changeover.
  - Recurring
    A rule was defined for the daylight saving time changeover.

DST configuration

On this page, you can configure the entries for the daylight saving time changeover. As result of the changeover to daylight saving or standard time, the system time for the local time zone is correctly set.

You can define a rule for the daylight saving time changeover or specify a fixed date.

Settings

Note

The content of this page depends on the selection in the "Type" box.

The boxes "DST No.", "Type" and "Name" are always shown.

- **DST No.**
  Select the type of the entry.
- **Type**
  Select how the daylight saving time changeover is made:
  - Date
    You can set a fixed date for the daylight saving time changeover.
    This setting is suitable for regions in which the daylight saving time changeover is not governed by rules.
  - Recurring
    You can define a rule for the daylight saving time changeover.
    This setting is suitable for regions in which the daylight saving time always begins or ends on a certain weekday.
- **Name**
  Enter a name for the entry.

Settings with "Date" selected

You can set a fixed date for the start and end of daylight saving time.

- **Year**
  Enter the year for the daylight saving time changeover.
- **Start Date**
  Enter the following values for the start of daylight saving time:
  - Day
    Specify the day.
  - Hour
    Specify the hour.
  - Month
    Specify the month.
- **End Date**
  Enter the following values for the end of daylight saving time:
  - Day
    Specify the day.
  - Hour
    Specify the hour.
  - Month
    Specify the month.

Settings with "Recurring" selected

You can create a rule for the daylight saving time changeover.

- **Start Date**
  Enter the following values for the start of daylight saving time:
  - Hour
    Specify the hour.
  - Month
    Specify the month.
  - Week
    Specify the week.
    You can select the 1st to 4th or the last week of the month.
  - Weekday
    Specify the weekday.
- **End Date**
  Enter the following values for the end of daylight saving time:
  - Hour
    Specify the hour.
  - Month
    Specify the month.
  - Week
    Specify the week.
    You can select the 1st to 4th or the last week of the month.
  - Weekday
    Specify the weekday.

SNTP client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

SNTP (Simple Network Time Protocol) is used for synchronizing the time in the network. The appropriate frames are sent by an SNTP server in the network.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **SNTP Client**
  Enable or disable automatic time-of-day synchronization using SNTP.
- **Current System Time** (only available online)
  Shows the current date and current normal time received by the IE switch. If you specify a time zone, the time information is adapted accordingly.

- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.
- **Last Synchronization Mechanism** (only available online)
  Shows how the last time-of-day synchronization was performed. The following methods are possible:
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP
- **Time Zone**
  Enter the time zone you are using in the format "+/- HH:MM". The time zone relates to UTC standard world time.
  The time in the "Current System Time" box is adapted accordingly.
- **Daylight Saving Time**
  Shows whether the daylight saving time changeover is active.
  - active (offset +1 h)
    The system time was changed to daylight saving time; in other words an hour was added. The normal time including the time zone continues to be displayed in the "Current System Time" box.
    The normal time including the time zone continues to be displayed in the "Current System Time" box.
  - inactive (offset +0 h)
    The current system time is not changed.
- **SNTP Mode**
  Select the synchronization mode. The following types of synchronization are possible:
  - Poll
    If you select this protocol type, the input boxes "SNTP Server Address", "SNTP Server Port" and "Poll Interval[s]" are displayed to allow further configuration. With this type of synchronization, the device is active and sends a time query to the SNTP server.
  - Listen
    With this type of synchronization, the device is passive and "listens" for SNTP frames that deliver the time of day.
- **Poll Interval[s]**
  Here, enter the interval between two-time queries. In this box, you enter the query interval in seconds. Possible values are 16 to 16284 seconds.

- **SNTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the SNTP server.
- **SNTP Server Port**
  Enter the port of the SNTP server.
  The following ports are possible:
  - 123 (standard port)
  - 1025 to 36564
- **Primary**
  The check mark is set for the SNTP server that you create first. If several SNTP servers have been created, the primary server is queried first.

NTP client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

If you require time-of-day synchronization using NTP, you can make the relevant settings here.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **NTP Client**
  Enable or disable automatic time-of-day synchronization using NTP.
- **Current System Time** (only available online)
  Shows the current date and current normal time received by the IE switch. If you specify a time zone, the time information is adapted accordingly.
- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.

- **Last Synchronization Mechanism** (only available online)
  This box displays how the last time-of-day synchronization was performed. The following methods are possible:
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP
- **Time Zone**
  Enter the time zone you are using in the format "+/- HH:MM". The time zone relates to UTC standard world time.
  The time in the "Current System Time" box is adapted accordingly.
- **Daylight Saving Time**
  Shows whether the daylight saving time changeover is active.
  - active (offset +1 h)
    The system time was changed to daylight saving time; in other words an hour was added. The normal time including the time zone continues to be displayed in the "Current System Time" box.
  - inactive (offset +0 h)
    The current system time is not changed.
- **NTP Server Index**
  Select the index of the NTP server. The server with the lowest index is queried first.
- **NTP Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the NTP server.
- **NTP Server Port**
  Enter the port of the NTP server.
  The following ports are possible:
  - 123 (standard port)
  - 1025 to 36564
- **Poll Interval[s]**
  Here, enter the interval between two time queries. In this box, you enter the poll interval in seconds. Possible values are 64 to 1024 seconds.

SIMATIC Time Client

There are different methods that can be used to set the system time of the device. Only one method can be active at any one time. If one method is activated, the previously activated method is automatically deactivated.

On this page, you configure time synchronization with the SIMATIC Time Client.

Note

To avoid time jumps, make sure that there is only one time server in the network.

Settings

- **SIMATIC Time Client**
  Enable or disable the SIMATIC time client.
- **Current System Time** (only available online)
  Shows the current system time.
- **Last Synchronization Time**(only available online)
  Shows when the last time-of-day synchronization took place.
- **Last Synchronization Mechanism** (only available online)
  This box displays how the last time-of-day synchronization was performed.
  - Not set
    The time was not set.
  - Manual
    Manual time setting
  - SNTP
    Automatic time-of-day synchronization using SNTP
  - NTP
    Automatic time-of-day synchronization using NTP
  - SIMATIC
    Automatic time-of-day synchronization using the SIMATIC time frame
  - PTP
    Automatic time-of-day synchronization with PTP

Auto logout

On this page, set the times after which there is an automatic logout from WBM or the CLI following user in activity.

Note

No automatic logout from the CLI

If the connection is not terminated after the set time, check the setting of the "keepalive" mechanism on the Telnet client.

If the interval is shorter than the configured time, the connection is kept alive although no user data is transferred. Example: you selected 300 seconds for the automatic logout and 120 seconds is set for the keepalive function. In this case, a packet is sent every 120 seconds that keeps the connection up.

- Disable the keepalive mechanism (interval time = 0)
  or
- Set the interval high enough so that the underlying connection is terminated when there is inactivity.

Settings

- **Web Based Management [s]**
  Enter the time in seconds for the automatic logout from WBM. If you enter the value 0, the automatic logout is disabled.
- **CLI (TELNET, SSH) [s]**
  Enter the time in seconds for the automatic logout from the CLI. If you enter the value 0, the automatic logout is disabled.

Syslog client

Syslog according to RFC 3164 is used for transferring short, unencrypted text messages over UDP in the IP network. This requires a system log server.

Requirements for sending log entries:

- The Syslog function is enabled on the device.
- The Syslog function is enabled for the relevant event.
- There is a Syslog server in your network that receives the log entries. Since this is a UDP connection, there is no acknowledgment to the sender.
- The IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server is entered in the device.

Settings

- **Syslog Client**
  Enable or disable the Syslog function.
- **Syslog Server Address**
  Enter the IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server.

The table contains the following columns:

- **Syslog Server Address**
  Shows the IP address or the FQDN (Fully Qualified Domain Name) of the Syslog server.
- **Server Port**
  Enter the port of the Syslog server being used.

Fault Monitoring

Power supply

Note

This page is not available on the SCALANCE W786-2 SFP.

Configure whether or not the power supply should be monitored by the messaging system. Depending on the hardware variant, there are one or two power connectors (Supply 1 / Supply 2). With a redundant power supply, configure the monitoring separately for each individual feed-in line.

If there is no power on one of the monitored lines (Supply 1 or Supply 2) or when the voltage is too low, a fault is signaled by the signaling system.

Note

You will find the permitted operating voltage limits in the operating instructions of the device.

An error causes the fault LED to light up on the device. Depending on the configuration, the error may trigger a trap, an e-mail or an entry in the event log table.

Settings

- **Line 1**
  Enable or disable the monitoring of power connector 1.
- **Line 2** (not available with W760/W720)
  Enable or disable the monitoring of power connector 2.

- **PoE** (not available with W760/W720)
  Enable or disable the monitoring of the power supply via Ethernet.
- **PROFINET redundancy** (not available with W760/W720)
  With the following devices, you can also configure which power supply will be monitored by PROFINET:
  - SCALANCE W788-x RJ-45 variants
  - SCALANCE W748-1 RJ-45
  - SCALANCE W774-1 (RJ-45 and M12 variant)
  - SCALANCE W734-1 RJ-45

Link Change

On this page, you configure whether or not an error message is triggered if there is a status change on a network connection.

If connection monitoring is enabled, an error is signaled

- when there should be a link on a port and this is missing.
- or when there should not be a link on a port and a link is detected.

An error causes the signaling contact to trigger and the fault LED to light up on the device. Depending on the configuration, the error may trigger a trap, an e-mail or an entry in the event log table.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports.
- **Setting**
  Select the required setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns

- **Port**
  Shows the available ports.
- **Setting**
  Select the setting. You have the following options:
  - Up
    Error handling is triggered when the port changes to the active status.
    (From "Link down" to "Link up")
  - Down
    Error handling is triggered when the port changes to the inactive status.
    (From "Link up" to "Link down")
  - "-" (disabled)
    The error handling is not triggered.

EtherNet/IP

EtherNet/IP

On this page, you configure the mode of EtherNet/IP.

Note

Devices with two Ethernet interfaces

On devices with two Ethernet interfaces only one of the interfaces (P1 or P2) may be used for the EtherNet/IP configuration.

This applies to the following devices:

- SCALANCE W786-2 SFP .
- SCALANCE W774-1 RJ-45
- SCALANCE W774-1 M12 EEC
- SCALANCE W734-1 RJ-45.

Description of the displayed boxes

The page contains the following boxes:

- **EtherNet/IP Device Diagnostics**
  Shows whether EtherNet/IP is enabled ("On") or disabled ("Off").
- **EtherNet/IP Device Diagnostics for next boot**
  Set whether EtherNet/IP will be enabled ("On") or disabled ("Off") after the next device restart.

Note

EtherNet/IP and PROFINET

When EtherNet/IP is turned on, PROFINET is turned off. The switchover from EtherNet/IP and PROFINET has no effect on DCP.

Note

PROFINET AR Status

If a PROFINET connection is established; in other words the PROFINET AR status is "Online", you cannot enable EtherNet/IP.

PROFINET

Settings for PROFINET

This page shows the PROFINET AR status and the device name.

Description of the displayed boxes

The page contains the following boxes:

- **PROFINET Mode**
  Shows whether PROFINET is enabled ("On") or disabled ("Off").
- **PROFINET Mode for next boot**
  Set whether PROFINET will be enabled ("On") or disabled ("Off") after the next device restart.

Note

PROFINET and EtherNet/IP

When PROFINET is turned on, EtherNet/IP is turned off. The switchover from PROFINET and EtherNet/IP has no effect on DCP.

Note

PROFINET AR Status

If a PROFINET connection is established; in other words the PROFINET AR status is "Online", you cannot disable PROFINET.

- **PROFINET AR Status**
  This box shows the status of the PROFINET connection; in other words whether the device is connected to a PROFINET controller "Online " or "Offline".
  Here, online means that a connection to a PROFINET controller exists, that this has downloaded its configuration data to the device and that the device can send status data to the PROFINET controller. In this status known as "in data exchange", the parameters set via the PROFINET controller cannot be configured.
- **PROFINET Name of Station**
  This box displays the PROFINET device name according to the configuration in HW Config of STEP 7.

Note

Devices with two Ethernet interfaces

With devices that have two Ethernet interfaces, only interface P1 should be used for the PROFINET configuration because LLPD frames can only be sent and received via interface P1. They are blocked at interface P2 and are also not forwarded between the interfaces.

This applies to the following devices:

- SCALANCE W786-2 SFP
- SCALANCE W774-1 RJ-45
- SCALANCE W774-1 M12 EEC
- SCALANCE W734-1 RJ-45

SCALANCE W700 and STEP 7

The Ethernet interface can be configured in STEP 7 if the following requirements are met:

- STEP 7 V13 Update 3 with HSP0107 or
- STEP7 version 5.5.4 with GSDML version 2.31

The diagnostics functions can also be used. The WLAN interface cannot be configured with STEP 7.

PROFINET for client devices

If a client is to be used as a PROFINET device, the MAC address of the client must be specified as follows (MAC Mode):

- **Own**
  In the network beyond the device, only IP communication and no PROFINET is possible.
- **Layer 2 Tunnel**
  The client and the devices downstream from it can be used as PROFINET devices.

  Note

  If "Automatic" or "Manual" is configured as the MAC mode for a client, this device cannot be used as a PROFINET device.

PLUG

Configuration

Note

The page is only available if there is an online connection to the device.

This page is only available for SCALANCE W780 / W 770 / W740 / W730.

NOTICE

Do not remove or insert a C-PLUG / KEY-PLUG during operation!

A PLUG may only be removed or inserted when the device is turned off.

The device checks whether or not a PLUG is inserted at one second intervals. If it is detected that the PLUG was removed, there is a restart. If a valid KEY-PLUG was inserted in the device, the device changes to a defined error state following the restart. With SCALANCE W, the available wireless interfaces are deactivated in this case.

If the device was configured at some time with a PLUG, the device can no longer be used without this PLUG. To be able to use the device again, reset the device to the factory settings.

Information about the configuration of the C-PLUG / KEY-PLUG

This page provides detailed information about the configuration stored on the C-PLUG or KEY-PLUG. It is also possible to reset the PLUG to factory defaults or to load it with new contents.

Note

The action is only executed after you click the "Set Values" button.

The action cannot be undone.

If you decide against executing the function after making your selection, click the "Refresh" button. As a result the data of this page is read from the device again and the selection is canceled.

Note

Incompatibility with previous versions with PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed. In this situation, if a PLUG is inserted in the device, following the restart, this has the status "NOT ACCEPTED" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data.

If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using "System > PLUG".

Settings

The table has the following rows:

- **Status**
  Shows the status of the PLUG. The following are possible:
  - ACCEPTED
    There is a PLUG with a valid and suitable configuration in the device.
  - NOT ACCEPTED
    Invalid or incompatible configuration on the inserted PLUG.
  - NOT PRESENT
    There is no C-PLUG or KEY-PLUG inserted in the device.
  - FACTORY
    PLUG is inserted and does not contain a configuration. This status is also displayed when the PLUG was formatted during operation.
  - MISSING
    There is no PLUG inserted. Functions are configured on the device for which a license is required.
- **Device Group**
  Shows the SIMATIC NET product line that used the C-PLUG or KEY-PLUG previously.
- **Device Type**
  Shows the device type within the product line that used the C-PLUG or KEY-PLUG previously.
- **Configuration Revision**
  The version of the configuration structure. This information relates to the configuration options supported by the device and has nothing to do with the concrete hardware configuration. This revision information does not therefore change if you add or remove additional components (modules or extenders), it can, however, change if you update the firmware.
- **File System**
  Displays the type of file system on the PLUG.

NOTICE
New file system UBI As of firmware version 2.0, UBI is the standard file system for the C-PLUG or KEY-PLUG. If a C-PLUG with the previous file system IECP is detected in such a device, this C-PLUG will be formatted for the UBI file system and the data will be rewritten to the C-PLUG. This change in the file system also occurs following a firmware update to V2.0. A downgrade to the previous version of the firmware then presents a problem. The firmware can neither read nor write the C-PLUG or KEY-PLUG and it is not even possible to "Erase PLUG to factory default".

- **File System Size [bytes]**
  Shows the maximum storage capacity of the file system on the C-PLUG.
- **File System Usage**
  Displays the storage space in use in the file system of the C-PLUG.

- **Firmware on PLUG**
  When enabled, the firmware will be stored on the PLUG. This means that automatic firmware updates/downgrades can be made with the PLUG.
- **Info String**
  Shows additional information about the device that used the PLUG previously, for example, article number, type designation, and the versions of the hardware and software. The displayed software version corresponds to the version in which the configuration was last changed. With the "NOT ACCEPTED" status, further information on the cause of the problem is displayed.
  If a PLUG was configured as a PRESET PLUG this is shown here as additional information in the first row. For more detailed information on creating and using a PRESET PLUG refer to the section "Maintenance (page 363)".
- **Modify PLUG**
  Select the required setting. You have the following options for changing the configuration on the C-PLUG or KEY-PLUG:
  - Write current configuration to PLUG
    This option is available only if the status of the PLUG is "NOT ACCEPTED" or FACTORY. The configuration in the internal flash memory of the device is copied to the PLUG.
  - Erase PLUG to factory default
    Deletes all data from the C-PLUG and triggers low-level formatting.

License

NOTICE
Do not remove or insert a C-PLUG / KEY-PLUG during operation! A PLUG may only be removed or inserted when the device is turned off. The device checks whether or not a PLUG is present at one second intervals. If it is detected that the PLUG was removed, there is a restart. If a valid KEY-PLUG was inserted in the device, the device changes to a defined error state following the restart. With SCALANCE W, the available wireless interfaces are deactivated in this case. If the device was configured at some time with a PLUG, the device can no longer be used without this PLUG. To be able to use the device again, reset the device to the factory settings.

Note

Incompatibility with previous versions with PLUG inserted

During the installation of a previous version, the configuration data can be lost. In this case, the device starts up with the factory settings after the firmware has been installed. In this situation, if a PLUG is inserted in the device, following the restart, this has the status "NOT ACCEPTED" since the PLUG still has the configuration data of the previous more up-to-date firmware. This allows you to return to the previous, more up-to-date firmware without any loss of configuration data.

If the original configuration on the PLUG is no longer required, the PLUG can be deleted or rewritten manually using "System > PLUG".

Information about the license of the KEY-PLUG

A C-PLUG can only store the configuration of a device. In addition to the configuration, a KEY-PLUG also contains a license that enables certain functions of your SIMATIC NET device.

Note

Information only available online

You can only view the information on this page if there is an online connection to the device.

This page is only available for SCALANCE W780 / W 770 / W740 / W730.

Displayed values

- **Status**
  Shows the status of the KEY-PLUG. The following are possible:
  - ACCEPTED
    The KEY-PLUG in the device contains a suitable and valid license.
  - NOT ACCEPTED
    The license of the inserted KEY-PLUG is not valid.
  - NOT PRESENT
    No KEY-PLUG is inserted in the device.
  - MISSING
    There is no KEY-PLUG or a C-PLUG with the status "FACTORY" inserted in the device. Functions are configured on the device for which a license is required.
  - WRONG
    The inserted KEY-PLUG is not suitable for the device.
  - UNKNOWN
    Unknown content of the KEY-PLUG.
  - DEFECTIVE
    The content of the KEY-PLUG contains errors.
- **Article number**
  Shows the article number of the KEY-PLUG. The KEY-PLUG is available for various functional enhancements and for various target systems.
- **Serial Number**
  Shows the serial number of the KEY-PLUG.
- **Info String**
  Shows additional information about the device that used the KEY-PLUG previously, for example, article number, type designation, and the versions of the hardware and software. The displayed software version corresponds to the version in which the configuration was last changed. With the "NOT ACCEPTED" status, further information on the cause of the problem is displayed.

Note

When you save the configuration, the information about whether or not a KEY-PLUG was inserted in the device at the time is also saved. This configuration can then only work if a KEY-PLUG with the same order number / license is inserted. This applies regardless of whether or not iFeatures are configured.

Ping

Reachability of an address in an IP network

Note

The page is only available if there is an online connection to the device.

With the ping function, you can check whether a certain IPv4 address is reachable in the network.

Settings

- **IP Address**
  Enter the IPv4 address of the device.
- **Repeat**
  Enter the number of ping requests.
- **Ping**
  Click this button to start the ping function.
- **Ping Output**
  This box shows the output of the ping function.
- **Delete**
  Click this button to delete the ping output.

Configuring interfaces

Ethernet

Overview

The page shows the configuration for the data transfer for all ports of the device.

Settings

- **Port**
  Shows the configurable ports.
- **Port name**
  Shows the name of the port.
- **Status**
  Shows whether the port is on or off. Data traffic is possible only over an enabled port.
- **OperState**
  Displays the current operational status. The operational status depends on the configured "Status" and the "Link".
  The available options are as follows:
  - up
    You have configured the status "enabled" for the port and the port has a valid connection to the network.
  - down
    You have configured the status "disabled" or "Link down" for the port or the port has no connection.
- **Link** (only available online)
  Shows the connection status to the network. With the connection status, the following is possible:
  - up
    The port has a valid link to the network, a link integrity signal is being received.
  - down
    The link is down, for example because the connected device is turned off.
- **Mode** (only available online)
  Shows the transfer parameters of the port
- **MTU**
  Shows the maximum packet size.
- **Negotiation**
  Shows whether the automatic configuration is enabled or disabled.
- **MAC Address** (only available online)
  Shows the MAC address of the port.

Configuration

On this page, you configure the Ethernet ports of the device.

Note

SCALANCE W786-2 SFP

The two SFP ports of the SCALANCE W786-2 SFP cannot be assigned parameters or diagnosed individually.

Settings

- **Port**
  Select the port to be configured.
- **Status**
  Specify whether the port is enabled or disabled.
  - enabled
    The port is enabled. Data traffic is possible only over an enabled port.
  - disabled
    The port is disabled but the connection remains.
  - Link down
    The port is disabled and the connection to the partner device is terminated.
- **Port name**
  Enter a name for the port.
- **MAC Address** (only available online)
  Shows the MAC address of the port.
- **Mode Type**

  Note

  This parameter cannot be configured for:
  - SCALANCE W786-2 SFP
  - SCALANCE W770
  - SCALANCE W760
  - SCALANCE W730
  - SCALANCE W720

  The value is permanently set to “Auto negotiation“.

  Shows the transmission speed and the transmission method of the port. You make the settings for "Autonegotiation" and "Transmission rate" in the port options.

  Note

  Before the port and partner port can communicate with each other, the settings must match at both ends.

- **Mode** (only available online)
  Shows which transmission speed and which transmission mode is currently being used.
- **Negotiation**
  Shows whether the automatic configuration of the connection to the partner port is enabled or disabled.
- MTU ((Maximial Transmission Unit)
  Enter the packet size above which packets are fragmented.

- **OperState**
  Displays the current operational status. The operational status depends on the configured "Status" and the "Link".
  The available options are as follows:
  - up
    You have configured the status "enabled" for the port and the port has a valid connection to the network.
  - down
    You have configured the status "disabled" or "Link down" for the port or the port has no connection.
- **Link** (only available online)
  Shows the connection status to the network. With the connection status, the following is possible:
  - Up
    The port has a valid link to the network, a link integrity signal is being received.
  - Down
    The link is down, for example because the connected device is turned off.

Changing the port configuration

Note

Optical ports only work with the full duplex mode and at maximum transmission rate. As a result, the following settings cannot be made for optical ports:

- Automatic configuration
- Transmission speed
- Transmission technique

Note

With various automatic functions, the device prevents or reduces the effect on other ports and priority classes (Class of Service) if a port is overloaded. This can mean that frames are discarded even when flow control is enabled.

Port overload occurs when the device receives more frames than it can send, for example as the result of different transmission speeds.

WLAN

Basic

Note

To configure the WLAN interface, you must always specify the country code first. Some parameters are dependent on the country setting, for example the transmission standard.

Settings

- **Country Code**
  Specify the country in which the device will be used.
  You do not need to know the data for the specific country, the channel division and output power are set by the device according to the country you select.

  Note

  Locale setting

  The correct country setting is mandatory for operation complying with the approvals. Selecting a country different from the country of use can lead to legal prosecution.

- **Device Mode**
  Mode of the device. The mode can only be changed for access points.
  The following modes are possible:
  - AP: Access point mode
  - Client: Client mode

  Note

  After changing the mode, a message is displayed. If you confirm the message with "Yes", the configuration settings are updated in the changed mode.

- **Radio**
  Shows the available WLAN interfaces.
- **Enabled**
  Status of the WLAN interface. To enable the WLAN interface, enable the setting.

  Note

  Enabling the WLAN interface

  The WLAN interfaces are disabled when the device is supplied. The WLAN interfaces are can be enabled once the country and the antenna settings are configured.

- **Radio Mode**
  Shows the mode of the WLAN interface.

- **Frequency Band**
  Specify the frequency band. In client mode, dual-frequency operation is also possible.
  - 2.4 GHz
  - 5 GHz
  - 2.4 GHz + 5 GHz (only in client mode)

Note

Configuring WLAN interfaces of the W786-2IA RJ-45 for different frequency bands

If both WLAN interfaces are configured for the same frequency band on this device, there may be mutual influence or interference. This applies in particular when there is a high data throughput.

- **WLAN Mode 2.4 GHz/WLAN Mode 5 GHz**
  Select the required transmission standard for the configured frequency band.
  The selection depends on the country setting.
  - Auto (in client mode only)
    The transmission standard is determined automatically (2.4 GHz + 5 GHz).
  - 802.11a
    The transmission standard IEEE 802.11a (5 GHz) is set.
  - 802.11g
    The transmission standard IEEE 802.11g (2.4 GHz) is set. This transmission standard is downwards compatible with IEEE 802.11b
  - 802.11n
    The transmission standard IEEE 802.11n (2.4 GHz and 5 GHz) is set. This transmission standard is downwards compatible with IEEE 802.11a and IEEE 802.11g.
  - 802.11n only
    The transmission standard IEEE 802.11n (2.4 GHz and 5 GHz) is set. This transmission standard is downwards compatible with IEEE 802.11a and IEEE 802.11g.

Note

Fragmentation length

If you select the transmission standard "802.11n", "802.11n only" or "Auto" (only in client mode), you cannot set the threshold value of the fragmentation length see "Fragmentation Length Threshold" in "Interfaces > WLAN > Advanced".

- **DFS (802.11h)**
  Enables or disables the "Dynamic Frequency Selection (DFS)" function.
  - Enabled
    If you have enabled this function, additional DFS channels from the 5 GHz band are available to you. These channels are country-specific and are subject to certain DFS regulations.
    If the access point discovers a disturbance on the current channel, it changes automatically to an alternative channel and the current channel is blocked for 30 minutes. The disturbance can originate from a primary user or radar interference.
    Before the access point starts the communication on a channel it searches 60 seconds for primary users on the channel. During this time the access point does not send beacons. If signals are found on the channel, the access point changes channel and repeats the check. Only when no signals from primary users are detected after 60 seconds does the access point send on a channel. The access point also searches for primary users during operation.
  - Disabled
    The DFS function is not used.
- **Outdoor Mode**
  - Enabled
    If you have enabled the outdoor mode, you only have the channels available that are permitted for outdoor operation.
  - Disabled
    If you have disabled the outdoor mode, you only have the channels available that are permitted for operation in a building.

- **Maximum Tx Power**
  Specify the transmit power of the device. If the transmit power is set too high the received signal at the client may be overmodulated. Check the received signal strength at the client (dBm). It may be necessary to reduce the transmit power depending on the antennas being used to avoid exceeding the maximum legal transmit power. Reducing the transmit power effectively reduces cell size.

  Note

  The maximum possible transmit power varies depending on the channel and data rate. For more detailed information on transmit power, refer to the documentation "Characteristics radio interface".

  Note

  If both interfaces of access points with two WLAN interfaces are operated in the same frequency range, this may cause wireless interference on one or both interfaces at a transmit power higher than 15 dBm.

- **Tx power check (only available online)**
  Indicates whether the settings that have been made will violate the permitted transmit power restrictions of the selected country. The following parameters influence this calculation: max. Maximum Tx Power, Antenna Gain, Additional Attenuation.
  The following displays can appear:
  - Allowed
    The channels can be used with the current settings.
  - Not Allowed (Some Channels)
    Among the channels, there are some on which the current transmit power exceeds the maximum permitted transmit power.
  - Not Allowed (All Channels)
    No permitted operation is possible. The transmit power is too high.
  - Controlled automatically by iREF.
    Controlled by the iREF function.

Advanced

You only need to adapt the settings on this page if the device cannot be used as it is intended with the default settings.

Settings

- **Radio**
  Shows the available WLAN interfaces.
- **Beacon Interval [ms]** (Only in access point mode)
  Specify the interval (40 - 1000 ms) at which the access point sends beacons. Beacons are packets that are sent cyclically by an access point to inform clients of its existence.

- **DTIM**(Only in access point mode)
  The DTIM interval (1-15) specifies the number of beacons to be sent before the access point sends the collected packets (broadcast, unicast, multicast) to the client.
  - If you enter a "1", the access point transmits broadcast, unicast and multicast packets directly after each beacon (recommended setting for normal network environments).
  - If you entered a "5", this would mean that the access point collects the packets and sends them after every fifth beacon.

  Increasing this value allows a longer sleep mode for the clients but means a greater delay for packets.
- **RTS/CTS Threshold [Bytes]**
  RTS/CTS (Request To Send/Clear To Send) is a method for avoiding collisions. The method is based on the exchange of status information prior to sending the actual data (Hidden node problem). To minimize the network load due to additional protocol traffic, this method is used only as of a certain packet size. You specify the packet size with the RTS/CTS Threshold parameter.
- **Fragmentation Length Threshold [Bytes]**
  Specify the maximum packet size transferred on the wireless link. Large packets are divided up into small packets prior to transmission and then reassembled into the original size after they have been received. This can be beneficial if the transmission quality is poor because larger packets are more difficult to transmit. However fragmentation into smaller packets means a poorer throughput.

  Note

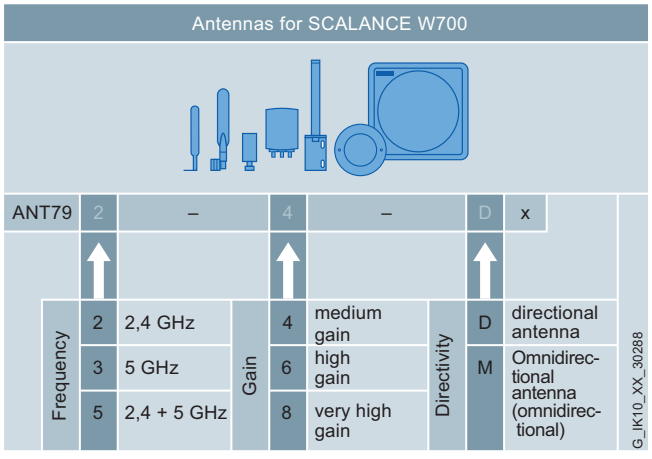
  You can only edit this value if the you have set the transmission standard "802.11g" (2.4 GHz) or "802.11 a" (5 GHz), see "WLAN Mode" in "Interfaces > WLAN > Basic".

- **HW Retries**
  Specify the number of hardware retries. The hardware repetition is performed by the WLAN chip itself when it tries to repeat an unacknowledged packet immediately.
  If all hardware repetitions were unsuccessful, the packet is deleted.

  Note

  If you have enabled iPCF or iPCF-MC, you can set up to 16 hardware retries.

- **Multi Radar Detection** (only in access point mode)
  - Enabled
    This function is only available if you have enabled the "DFS" function on the "Basic" page. This function is suitable for systems with several access points connected via an Ethernet network and that send on the same channel. When an access point detects a radar signal it distributes this information to all connected access points. If at least one further access point verifies the radar signal within 40 ms, all connected access points are informed. All the devices sending on this channel change to a different channel. The channel is blocked for 30 minutes for the access points in the network. If you have configured "Auto" for the channel on the "Interfaces > WLAN > AP" page, the function cannot be used reliably. In this case the verification of the radar signals is only possible when at least two connected access points happen to transmit on the same channel. If only one access point detects a signal on a channel, it treats this as a valid radar signal.
  - Disabled
    The function is not used. When an access point detects a radar signal it changes to another channel.. The configured channel is no longer taken into account.
- **Prefer Configured DFS Channel** (only in access point mode)
  - Enabled
    This function is only available if you have enabled the "DFS" function on the "Basic" page. If the configured channel of a WLAN interface was blocked due to radar detection and is released again after 30 minutes the access point changes automatically to the configured channel. Before the access point starts the communication on the configured channel it searches 60 seconds for primary users on the channel. During this time the access point does not send beacons. If signals are found on the channel, the access point changes channel and repeats the check. Only when no signals from primary users are detected after 60 seconds does the access point send on the channel. If you have configured "Auto" for the channel on the "Interfaces > WLAN > AP" page, the device does not have a configured channel to which it can return.
  - Disabled
    The function is not used.



Antennas

Overview

Overview of IWLAN antennas:

Antennas only for SCALANCE W700 to IEEE 802.11n						Antennas for SCALANCE W700 to IEEE 802.11n and IEEE 802.11a/b/g		Antennas only for SCALANCE W700 to IEEE 802.11a/b/g	
with 1 connector		with 2 connectors (dual)		with 3 connectors (MIMO)		with 1 connector		with 1 connector	
	ANT795-4MA		ANT793-6DG		ANT795-6MT		ANT792-4DN		ANT795-4MR
	ANT795-4MC		ANT793-8DJ		ANT793-6DT		ANT793-4MN		ANT795-4MS
	ANT795-4MD		ANT793-8DK		ANT896-6MM		ANT792-6MN		ANT795-6DN
	ANT795-6DC		ANT793-8DL				ANT793-6MN		ANT793-8DN
	ANT793-8DP						ANT792-8DN		
	ANT795-4MX						ANT795-6MN		
	ANT795-MP						RCoax leaky feeder		

The antenna name provides information about the properties of the antennas listed in the IWLAN antenna overview:

Antennas

On this page, you configure the settings for the connected external antennas.

Note

Transmission disruptions without an antenna connected

A WLAN interface can have up to three antenna connectors. A the first connector, there must be always be an antenna connected as soon as the associated WLAN Interface is turned on.

Connectors that are not used must have a 50 Ω terminating resistor fitted.

If no antenna is connected, the relevant WLAN interface must also be disabled for Rx and Tx. Otherwise, there may be transmission disruptions.

Settings

- **Connector**
  Shows the name of the relevant antenna connection.
- **Antenna Type**
  Select the type of external antenna connected to the device. If the type of your external antenna is not available, select the entry "User defined".
  If you terminate an antenna connection using a 50 Ω terminating resistor, select the entry "Not used (Connect 50 Ohm Termination)".
- **Antenna Gain**
  If you select the "User defined" entry for the "Antenna Type", enter the antenna gain manually in the "dBi" unit.
  - **Antenna Gain 2.4 GHz [dBi]**
    Here, enter the antenna gain the antenna has in the 2.4 GHz frequency band.
  - **Antenna Gain 5 GHz [dBi]**
    Here, enter the antenna gain the antenna has in the 5 GHz frequency band.
- **Cable Length [m]**
  Enter the length of the flexible antenna connecting cable between the device and the external antenna in meters.

- **Additional Attenuation [dB]**
  Here, specify the additional attenuation caused, for example by an additional splitter.
- **Antenna Mode**
  Specify the use of the antenna. For antenna connector 1 (R1 A1 and R2 A1), the entry cannot be changed.
  - TX
    For sending only
  - RX
    For receiving only
  - RX\TX
    For receiving and sending

  The following table shows which combinations are possible:

R1 A1 / R2 A1	R1 A2 / R2 A2	R1 A3 / R2 A3
RX\TX	RX\TX	RX\TX
RX\TX	RX\TX	RX
RX\TX	RX	RX
RX\TX	RX\TX	TX
RX\TX	TX	TX
RX\TX	RX\TX	-- 1)
RX\TX	TX	-- 1)
RX\TX	RX	-- 1)
RX\TX	-- 1)	-- 1)

1) Antenna type "50 Ω termination"

Permitted channels

For communication, a specific channel within a frequency band is used. You can either set this channel specifically or configure so that the channel is selected automatically.

Settings

Table 1 contains the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Use Allowed Channels only**
  If you enable the setting, you restrict the selection of channels via which the AP or the client is allowed to establish the connection.
  In the following tables, you define the
  - channels that the AP can use to establish a wireless cell when the "Auto" channel setting is enabled.
  - the channels on which the client searches for an AP.

  The tables are divided up according to frequency bands.
  When disabled, the channels available based on the settings (country code, antennas, transmit power etc.) are used.

Above the tables for the frequency bands, you will find the following setting:

- **Select / Deselect all**
  - Enabled
    All channels are activated.
  - Disabled
    The first valid channel of the frequency band remains enabled. Enable the required channel.

The tables of the frequency bands have the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Radio Mode**
  Shows the mode.
- **Channel number**
  To specify the valid channels for the required frequency band, select the appropriate check box for the channel number.
  The table displays the permitted channels of the country. Only the valid channels can be enabled. Invalid channels are grayed out and cannot be enabled.

Note

To specify the channels, the setting "Use Allowed Channels only" must be enabled.

802.11n

Properties of 802.11n

With the IEEE 802.11n standard, it is possible to put together individual data packets in one larger data packet, the A-MPDU and A-MSDU data packets. This achieves a higher data throughput.
On this page, you make the settings for the A-MPDU and A-MSDU data packets. Some of the settings depend on the set transmission standard and the selected channel width.

Settings

The table has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **A-MPDU**
  Enables or disables the sending of A-MPDU data packets. If this setting is disabled, only A-MPDU data packets are received.
- **A-MPDU Limit [frames]**
  Specify the number of individual subframes grouped together in one A-MPDU data frame.
- **A-MPDU Limit [Bytes]**
  Specify the maximum size of the A-MPDU frame.
- **A-MSDU**
  Aggregated MAC Service Data Unit (A-MSDU)Enables or disables that several MSDUs with the same destination address are bundled into an A-MSDU and are sent together. This reduces the network load. Due to their shorter maximum length A-MSDUs are more suitable for the bundling of several shorter frames. If this check box is disabled, A-MSDU data packets are received but not sent.
- **A-MSDUPacket Size [bytes]**
  Specify the maximum size of the A-MSDU data packet.
  Range of values: 50 - 200 bytes
  Default: 100 bytes
- **Guard Interval [ns](only in access point mode)**
  Select the send pause that must be kept to between two transmitted OFDM symbols. The following settings are possible. The selection depends on the selected transmission standard.
  - 400 (short)/800 (long): The setting 400 ns is optional. Depending on the signal quality, packets can be sent with a send pause of 400 ns or 800 ns.
  - 800 (long): The send pause is 800 ns.

Access point

Note

The page is available only in access point mode.

Settings

Table 1 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Channel**
  Specify the main channel.
  If you want the access point to search for a free channel itself, use "Auto". The selection of channels used by an access point when establishing a wireless cell can be restricted. For "Channel selection", enable the setting "Use Allowed Channels only". If you want to use a fixed channel, select the required channel from the drop-down list.

  Note

  SCALANCE W780/W740: Channel spacing with WLAN interfaces

  If you use a second WLAN interface, make sure that you have adequate channel spacing.

- **Alternative DFS Channel (802.11h)**
  If you have enabled the "DFS" function on the "Basic" page, specify the alternative channel here. If you want the access point to search for a free channel itself, use "Auto".
  If a primary user was detected both on the main and alternative channel, the access point automatically searches for a free channel.
  If you want to use a fixed channel, select the required channel from the drop-down list.
- **HT Channel Width [MHz]**
  You can specify the channel bandwidth only with the IEEE 802.11n transmission standard. The following settings are possible.
  - 20
    Channel bandwidth 20 MHz
  - 40 up
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel above it are used.
  - 40 down
    Channel bandwidth 40 MHz. The configured channel and the neighboring channel below it are used.

    Note

    Channel bandwidth 40 MHz and frequency band 2.4 GHz

    If the access point detects another access point on the configured channel or on neighboring channels, the access point changes the channel bandwidth from 40 MHz to 20 MHz. If you set a "free" channel on the access point, the access point uses the channel bandwidth 40 MHz.

Table 2 has the following columns:

- **Radio**
  Shows the available WLAN interfaces in this column.
- **Available Channels**
  Shows the permitted channels. The display depends on the wireless approvals of the currently selected country and the settings for "Channel selection".

Table 3 has the following columns:

- **Radio**
  Shows the WLAN interface.
- **Port**
  Shows the VAP interface.
- **Enabled**
  To use the required VAP interface, select this check box.
- **SSID**
  Enter the SSID of the WLAN. The length of the character string for SSID it is 1 to 32 characters.
  The ASCII characters 0x20 to 0x7e are used for the SSID.
- **Broadcast SSID**
  - deactived
    The SSID is no longer sent in the beacon frame of the access point. This means that the SSID is not visible for other devices. Only clients that know the SSID of the access point and that are configured with it can connect to the access point. The "Any SSID" option must be disabled on these clients.
  - activated
    The SSID is sent in the Beacon frame of the access point and is visible for other devices. This means that clients on which the "Any SSID" setting is enabled can also connect to the access point.

  Note

  Since no encryption is used for the SSID transfer, this function can only provide basic protection against unauthorized access. The use of an authentication method (for example WPA2 (RADIUS) or WPA2-PSK if this is not possible) provides higher security. You must also expect that certain end devices may have problems with access to a hidden SSID.

- **WDS only**
  If you enable this setting, the access point only supports communication via WDS. In WDS mode, all access points must use the same channel.
- **WDS ID**
  Enter the WDS ID. The WDS ID can be a maximum of 32 characters long.
  To establish a WDS connection, enter this WDS ID for the WDS partner.
  ASCII characters 0x20 to 0x7e are used for the WDS ID.

AP WDS

In normal operation, the access point is used as an interface to a network and communicates with clients. There are, however, situations in which several access points need to communicate with each other, for example to extend wireless coverage or to set up a wireless backbone. This mode is possible with WDS (Wireless Distributed System).

Note

This tab is available only in access point mode.

Settings

- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the port.
- **Port enabled**
  Enables the WDS interface.
- **Connection over**
  Specify the VAP interface via which the WDS connection is established. Both the MAC address of the VAP as well as security settings (for example WPA2) are used.
- **Partner ID Type**
  Specify the type of WDS communication.
  - MAC Address
    The MAC address is used. The "Partner WDS ID" input box is grayed out. For "Partner MAC", enter the MAC address of the WDS partner.
  - WDS ID
    The WDS ID is used. The "Partner MAC" input box is grayed out. Enter the WDS ID of the WDS partner in "Partner WDS ID". Use this option if you want to replace the access point later using the C-PLUG or KEY-PLUG.
- **Partner MAC**
  Enter the MAC address of the WDS partner. Can only be edited if "MAC Address" is set for the "Partner ID Type".
- **Partner WDS ID**
  Enter the WDS ID of the WDS partner. Can only be edited if "WDS ID" is set for the "Partner ID Type". For the WDS ID, the ASCII characters 0x20 to 0x7e are permitted.

Note

Matching security settings in WDS mode

In WDS mode, make sure that the security settings match up for all devices involved. If settings are incorrect or not compatible on the individual devices, no data exchange is possible due to incorrect authentication. Avoid the "Auto" setting in the security settings of the Basic Wizard, because with this setting, synchronization of the security settings between the access points is not possible.

Note

In WDS operation, the following restrictions apply to all access points involved:

- All access points that will communicate with each other must use the same channel, the same transmission procedure and the same data rate.
- You can select either WEP or WPA(2)-PSK as the encryption method.
  You configure the security settings in the assigned VAP interface: "Security > WLAN > Basic"
  You cannot use authentication with a RADIUS server for a WDS connection.
- In the IEEE 802.11h transmission mode, it is not practical to select the WDS mode. In WDS mode, all access points must use the same channel. If a signal from a primary user is detected by an access point, the channel is changed automatically and the existing connection is then terminated.

AP 802.11a/b/g Rates

Note

The page is only

- available in access point mode.
- Can be configured if "802.11a", "802.11g" or "802.11n" is set for the WLAN mode.

The page shows the available data transmission speeds for the WLAN mode 802.11a/b/g. If necessary, you can change the data transmission speeds. Otherwise, we recommend that you retain the default setting for data transmission speeds. The access point will then use only the selected data transmission speeds for communication with the clients.

Settings

Table 1 has the following columns:

- **Radio**
  Specifies the WLAN interface to which the information relates.
- **Use selected data rates only**
  If you select this setting, you can specify the data transmission speeds for the required WLAN interface.
  If this setting is disabled, the default values are used.

Radio
Select the WLAN interfaces displayed in Table 3 (Data rate).

Table 2 has the following columns:

- **All data rate settings**
  Shows that the setting is valid for all entries in Table 3.
- **Enabled / Basic settings**
  Select the required setting. If "No Change" is selected, the entry in table 3 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 3

Table 3 (Data Rate) has the following columns:

- **Radio**
  Specifies the WLAN interface to which the information relates.
- **Data Rate [Mbps]**
  Shows the supported data transmission speeds in megabits per second.

- **Enabled**
  Enable the setting to assign the required data transmission speed to the WLAN interface.

  Note

  You need to enable at least one data transmission speed.

- **Basic**
  Enable the option to declare the required data transmission speed as "Basic". The setting specifies that a client must be capable of the required speed to be able to connect to the access point. The setting can only be enabled if an available data rate has been selected.

  Note

  At least one data transmission speed needs to be specified as "Initial Setup".

Default Values
The "Default Values" button sets the selection of values to conform with the standard.

AP 802.11n data rates

Note

The page is only

- available in access point mode.
- Can be configured if "802.11n only" or "802.11n" is set for the WLAN mode.

The page shows the available data transmission speeds (MCS = Modulation and Coding Schemes) for the WLAN mode 802.11n. You can select any combination of these data transmission speeds. The access point will then use only the selected data transmission speeds for communication with the clients.

Settings

Table 1 has the following columns:

- **Radio**
  Specifies the WLAN interface to which the information relates.
- **Use selected data rates only**
  If you select this setting, you can specify the data transmission speeds for the required WLAN interface.
  If this setting is disabled, the default values are used. As default, the setting is disabled.

Radio
Select the WLAN interfaces displayed in Table 3 (MCS Index).

Table 2 has the following columns:

- **All data rate settings**
  Shows that the setting is valid for all entries in Table 3.
- **Enabled**
  Select the required setting. If "No Change" is selected, the entry in table 3 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 3.

Table 3 (MCS Index) consists of the following columns:

- **Radio**
  Specifies the WLAN interface to which the information relates.
- **MCS Index**
  Shows the supported MCS indexes. The displayed MCS indexes depend on the settings "Antenna Type" and "Antenna Mode". You will find the settings in "Interfaces > WLAN > Antennas". If, for example, you only use one antenna, only the MCS 0 to 7 are displayed.
- **Streams**
  Shows the maximum possible number of parallel data streams that can be transmitted with the selected MCS index.
- **Data Rate [Mbps]**
  Shows the supported data transmission speeds in megabits per second. The displayed data transmission speeds depend on the settings "Guard Interval" and "HT Channel Width". The "HT Channel Width" setting can be found in "Interfaces > WLAN > Access Point". The "Guard Interval" setting can be found in "Interfaces > WLAN > 802.11n"
- **Enabled**
  Enable the setting to assign the required data transmission speed to the WLAN interface.

Note

You need to enable at least one MCS index.

Default Values
The "Default Values" button sets the selection of values to conform with the standard.

Client

Connecting to a network

On this page, you can specify how the device connects to a network as client.

Note

This page is only available for clients or access points in client mode.

Settings

Table 1 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.

  Note
  WLAN interface disabled

  The WLAN interface will be disabled unless at least one SSID is configured or the setting "Any SSID" is enabled.

- **MAC Mode**
  Specify how the MAC address is assigned to the client. The following are possible:
  - Automatic
    The client automatically adopts the source MAC address of the first frame that it receives over the Ethernet interface.
  - Manual
    If you select Manual, enter the MAC address in the "MAC Address" column.
  - Own
    The client uses the MAC address of the Ethernet interface for the WLAN interface.
  - Layer 2 Tunnel
    The client uses the MAC address of the Ethernet interface for the WLAN interface. The network is also informed of the MAC addresses connected to the Ethernet interface of the client. Up to eight MAC addresses can be used.
- **MAC Address**
  If you have selected "Manual" for "MAC Mode", enter the MAC address of the client.
- **Any SSID**
  - Enabled
    In client mode the SCALANCE W700 device attempts to connect to the access point that corresponds to the security settings of security context 1. The clients can only connect to the access point on which the "Broadcast SSID" option is enabled.
  - Disabled
    The client attempts to connect to the access point from the SSID list whose security settings match one of the defined security contexts.
- **DHCP Renew After Roaming**
  - Enabled
    After changing to a different access point, a check is made to find out whether the IPv4 address of the client is still valid. If he IPv4 address is invalid, a new IPv4 address is requested from the DHCP server.
  - Disabled
    If the client changes to a different access point the IPv4 address is not checked.

- **Roaming Threshold**
  Specify the threshold after which the client roams to the new access point.
  - High
    Changes only at a significantly higher field strength to the AP with the stronger signal.
  - Medium
    Changes at a moderately higher field strength to the AP with the stronger signal.
  - Low
    Changes at a slightly higher field strength to the AP with the stronger signal.
- **Background Scan Mode**
  While the client is connected to an access point, it scans for other access points in the background with which it can connect when necessary. Specify the mode for the scan. The following options are available:
  - always
    If the background scan threshold is undershot, the client searches continuously for access points.
  - idle
    If there is no data transfer for a certain time, a scan is started for further access points.
  - disabled
    As long as the client is connected, there is no scan for further access points.
- **Background Scan Interval [ms]**
  Specify the interval at which further access points are scanned.
- **Background Scan Threshold [dBm]**
  Specify the threshold. If the threshold is undershot, the client searches for further access points.

Table 2 has the following columns:

- **Radio**
  Shows the WLAN interface.
- **Scan Channels**
  Shows the channels on which the client searches for an access point. The display depends on the wireless approvals of the selected country and the settings for "Channel selection".

Table 3 has the following columns:

- **Enabled**
  Enables or disables the relevant SSID.
- **Radio**
  Shows the WLAN interface.

- **SSID**
  Enter the SSID of the access point with which the client will connect.
  For the SSID, ASCII code 0x20 to 0x7e is used.
- **Security**
  Select a security context. You create and configure a security context in "Security > WLAN > Basic".
  Default setting: Context 1

Note

iPCF or iPCF-MC mode activated

If the iPCF or iPCF-MC mode is enabled, you can only select security context 1.

Force Roaming

Note

The page is only available

- in access point mode
- if there is an online connection to the device.

The WLAN interface of the device must be enabled, otherwise the frequency ranges cannot be scanned.

If the interface is no longer available (cable break, network component faild, connector removed), a client connected over the wireless network is not aware of this. The access point can force the logged-on clients to roam by deactivating the relevant interface.

On this page you specify when roaming is performed.

- On connection abort
  If the wired Ethernet interface is no longer available the WLAN interface is turned off. The clients roam and then connect to a different access point. As soon as the first access point reaches the server again it switches its WLAN interfaces active again.
- When the destination address is unreachable.
  Roaming depends on destination addresses. To monitor the device sends pings to the configured destination addresses at regular intervals.
  - VAP interface monitored using a destination address
    If no ping response is received from this destination address, the access point turns the relevant VAP interface off.
  - VAP interface monitored using several destination addresses
    Only when no ping response is received from any of these destination addresses does the access point turn the relevant VAP interface off. As long as at least one destination address is reachable, the VAP interface remains active.

  The access point sends a disassociation frame to the WAN clients connected via this VAP interface. The WLAN clients roam and connect to a different VAP interface. If the address becomes reachable again, the connection can be established again via this VAP interface.

Settings

Table 1 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Force roaming on link down**
  When enabled if there is a connection abort via the Ethernet interface, the WLAN interface is turned off.

The table "Force Roaming on IP down"has the following columns:

- **Select**
  Select the check box in the row to be deleted.
- **Destination Address**
  Enter the IPv4 address or the FQDN (Fully Qualified Domain Name) of the destination whose reachability will be checked.

  Note

  Destination address not in the agent IP subnet

  If the destination address is not in the agent IP subnet, a gateway must be entered for "Layer 2 > Agent IP".

  The Base Bridge mode "802.1Q VLAN Bridge"

  If you have configured the "Base Bridge Mode" "802.1Q VLAN Bridge" in "Layer 2 > VLAN", echo messages (ping packets) are sent into the management VLAN.

- **Interval [ms]**
  Specify the interval at which echo messages (pings) are sent.
- **Max. Lost Packets**
  Specify the maximum number of consecutive lost ping responses. When this number is reached for a destination address, this destination address counts as being unreachable (down).
- **VAP X.Y**
  Specify the VAP interface via which the address is monitored.

Signal recorder

Recording the effective user signal

The signal recorder is used to record the effective user signal between access point and client. Using this data, you can locate areas with an inadequate user signal. The signal recorder can be particularly useful when the client moves along a fixed path.

Note

The page is only available

- for clients or access points in client mode
- if there is an online connection to the device.

The WLAN interface of the device is enabled, otherwise no recording will be made.

Description

The display is divided into two areas.

- Client
  Displays the measurement on the client.
- Access point
  Displays the measurement of the access point with which the client is currently connected. This requires that the setting "Bidirectional Recording" is enabled and that a firmware version > 6.1 is installed on the access point. The access point sends its data to a maximum of 3 clients on which signal recorders are running. The access point data is not displayed on other clients.

Both areas each contain two graphics.

The first graphic contains the following elements:

- Scroll bar
  With the scroll bar, you can look through the entire measurement. To do this you can use the "<<" and ">>" buttons or the arrow keys on the keyboard.
- Bar (left)
  In the bar on the left-hand side the user signal of the client / access point is displayed in real time according to the color scheme. The gray line shows the background noise.
  If the client has an iPCF-MC connection, the user signal of the management channel is shown with a black line.
- Color scheme
  The range > -35 dBm (blue) is the overmodulation range, in other words the WLAN signal is too strong and is received overmodulated. As of approximately -60 dBm (yellow) the WLAN signal is weaker.

- x axis
  The x axis shows the course of the measurement in random samples and seconds.
- Measurement data
  - Client
    The measurement data shows the value of the effective user signal according to the color scheme shown. The gray line shows the background noise.
    If the client changes access points during a measurement (roaming) or reconnects, this is displayed by a vertical black line. On the line the previous AP system name and the BSSID are shown.
    If during a measurement the client has no connection to an access point, no user signal is displayed. To make it clear that there is no connection to an access point, the BSSID is set to 00:00:00:00:00:00 and shown in red.
    If the client has an iPCF-MC connection, the user signal of the management channel is shown with an additional black line.
  - Access point
    The measurement data shows the value of the effective user signal according to the color scheme shown. The gray line shows the background noise.
    If the client changes access points during a measurement (roaming) or reconnects, this is displayed by a vertical black line.
    If the access point does not support the setting "Bidirectional Recording" no user signal is displayed.

The second graphic contains the following elements:

- Bar (left)
  In the bar on the left-hand side the transfer attempts and the data rate of the client / access point are displayed according to the color scheme.
- Color scheme
  The range > -35 dBm (blue) is the overmodulation range, in other words the WLAN signal is too strong and is received overmodulated. As of approximately -60 dBm (yellow) the WLAN signal is weaker. The individual colors are described again under the graphic.
- x axis
  The x axis shows the course of the measurement in random samples and seconds.
- Measurement data
  - Client
    The measurement data shows the transfer attempts according to the color scheme shown. The transfer attempts are shown as a bar. The data rate of the sent data packets is represented as a line. If the client changes access points during a measurement (roaming) or reconnects, this is displayed by a vertical black line.
  - Access point
    The measurement data shows the transfer attempts according to the color scheme shown. The transfer attempts are shown as a bar. The data rate of the sent data packets is represented as a line.
    If the client changes access points during a measurement (roaming) or reconnects, this is displayed by a vertical black line. If the access point does not support the setting "Bidirectional Recording" no data is displayed

Beside the graphics the following values are displayed:

- Current Sample
  The number of the current measurement
- CL Signal [dBm] / AP Signal [dBm]
  The effective user signal of the client / access point in dBm
- CL Noise Floor [dBm] / AP Noise Floor [dBm]
  The background noise of the client / access point in dBm
- CL Retries [%] / AP Retries [%]
  The transfer repetitions of the client / access point as a percentage.
- CL RSSI / AP RSSI
  The raw value of the RSSI (Received Signal Strength Indication) of the client / access point
- CL TX Rate [Mbps] / AP TX Rate [Mbps]
  The average data rate of the sent data packets during the current random test
- AP System Name
  The system name of the access point
- Client Count
  Number of clients connected to the access point.
- BSSID
  The BSSID (Basic Service Set Identification)
- Operative Channel
  The current channel or the channel on which the client is connected to the access point
- Roaming Counter
  The roaming counter shows how often the client has changed access points. After 99999 changes the counter is reset.

Settings

This table contains the following columns:

- **Radio**
  Shows the available WLAN interfaces. Since a client has a WLAN interface, there is only ever one row for "WLAN 1" in this table.
- **Interval [ms]**
  Specify the time interval between acquiring two measured values in milliseconds.
- **Samples**
  Specify how many measurements should be made.
- **Endless**
  If you enable the option checkmark, the number of measurements is unlimited The "Samples" box is grayed out . The signal recorder runs until it is stopped manually or the device is reconfigured.
  You can only select this option starting at a time interval ≥ 10 milliseconds.
- **Bidirectional Recording**
  If you enable the setting the values of the access point are recorded as of a time interval of ≥ 10 milliseconds.

- **Start**
  Click the button in this column to start recording the user signal.

  Note
  - If you start a new recording, the previous recording will be overwritten.
  - If the recording has lasted less than 10 minutes and has not yet been completed (e.g. due to a restart or power down), the measured values are deleted.

  The signal recorder saves the recorded data automatically every 10 minutes. Following a restart, the recording contains all the values up to the last save action.
- **Stop**
  Click the button in this column to stop recording the user signal prematurely. If the specified number of measurements has been made, recording of the user data signal stops automatically.
- **Displayed samples**
  Select how many measured values will be shown in the graphic.

Notes on usage

Note the following tips that will help you to obtain useful measurements with the signal recorder:

- Set a fixed data rate on the access point.
- If you have activated iPCF, set as low a cycle time on the access point as possible for the measurements.
- Make sure that there is enough data communication during the measurement because the statistics functions evaluate incoming data frames.
- The measurement path should be traveled 2 to 3 times with the same parameters to find out whether losses of signal strength always occur at the same position.
- Selective measurements at a fixed position should be made over a longer period of time.

Note
- If you start a new recording, the previous recording will be overwritten.
- When the device restarts, the measured values are deleted.

Change to one of the following menu items to call up the result of the recording:

- System > Load&Save > HTTP
  Click the "Save" button in the "WLANSigRec" table row to save the file "signal_recorder_SCALANCE_W700.zip" in the file system of the connected PC.
- System > Load&Save > TFTP
  If necessary, change the file name "signal_recorder_SCALANCE_W700.zip" in the "WLANSigRec" table row. In the table row "WLANSigRec", select the "Save file" entry from the drop-down list of the last column and click the "Save Values" button.

The downloaded ZIP file contains two files with the results of the recording:

- A PDF file
- A CSV file

Spectrum Analyzer

Note

The page is only available

- in access point mode
- if there is an online connection to the device.

The WLAN interface of the device must be enabled, otherwise the frequency ranges cannot be scanned.

Technical information

The frequency range depends on the configuration.

Parameters		Value
Amplitude accuracy	In 2.4 GHz	3 dBm
	In 5 GHz	7 dBm
Resolution bandwidth		330 KHz
Min. signal strength		-100 dBm
Max. signal strength		0 dBm
Analysis time	At 40 MHz	120 ms
	At 20 MHz	95 ms
Update time		1 s.

Representing signals of the frequency range

Which the spectrum analyzer you can recognize and represent the electromagnetic signals of a frequency range. You can measure the strength of all signals located in the environment of the access point.

Note

When the spectrum analyzer is started, all WLAN connections are terminated on both WLAN interfaces. The access point then also does not send any beacons.

Note

Do not enable the spectrum analyzer if the device is operating productively. This can influence the performance of the device.

Note

The functionality of the spectrum analyzer does not replace a dedicated spectrum analyzer.

Description

The page contains the following graphics:

In all graphics, the lower x axis shows the channels around the selected center frequency for which the measurements are made. The upper x axis shows the frequency range. The display of the y axis depends on the selected graphic.

- Realtime
  The y axis shows the signal strength in dBm.
  The graphic shows the strength of all signals that the access point receives in its environment in the configured frequency range.
  The red line shows the maximum values since the start of the measurement. The white line shows the current values. The green line shows the average values.
- Spectrogram
  The y axis shows the course of the measured values over time from current (0 s) to the values received before 500 s.
  The graphic shows the strength of all signals that the access point receives in its environment in the configured frequency range.
  The color depends on the setting for "Color Scheme".
- Density Chart
  The y axis shows the signal strength in dBm.
  The graphic shows how often signals occur with a certain strength in the configured frequency range.
  The color goes from the lowest value (0%) in black to the highest value (100%) in red.

The page contains the following buttons:

- Expand 
  With this icon you only show one graphic type in large format on the page.
- Reduce 
  With this icon you return to the view with all three graphic types.
- Color Scheme 
  With this icon, you change the colours scheme for the graphic type "Spectrogram":
  - The color goes from the lowest value (-100 dBm) in black to the highest value (0 dBm) in red.
  - The color goes from the lowest value (-100 dBm) in red to the highest value (0 dBm) in black.
- Reset 
  With this icon you reset the maximum and average values of the graphic type "Realtime".

This table contains the following columns:

- Radio
  Shows the WLAN interface to which the information applies.
- State
  Shows the status of the measurement. The following values are possible:
  - Stopped
    The measurement was stopped.
  - Started
    The measurement is running.
- Frequency Band
  Specify the frequency band.

- Center Frequency
  Select the center frequency.
  How many channels are displayed depends on the setting for the "HT Channel Width", refer to the page "Interfaces > WLAN > AP".
- Start
  Click the button in this column to start the measurement.

  Note

  If you start a new measurement, the previous measurement will be overwritten.

- Stop
  Click the button in this column to end the measurement.

You can save the measurement result as a CSV file with the menu “System > Load&Save > WLANSpectrumAnalyzer”.

Measurement results

CSV file

The CSV file contains information on the configuration of the device and detailed information on all individual measurements and is divided into two areas. The first area contains the configured settings:

- System Name
  The system name of the access point
- Device IP
  The IP address of the device
- Device MAC
  The MAC address of the device
- Recording Interval
  The interval between acquisition of two measured values

The second area is a table. The table contains the following for each measured value:

- Sample
  The consecutive number of the measurement
- Timestamp
  The time stamp
- The following columns show all frequencies of the selected frequency band. The cells are only filled for the frequencies for which a value was measured. The measured values show the signal strength in dBm.

Configuring layer 2 functions

VLAN

General

On this page you specify whether or not the device forwards frames with VLAN tags transparently (IEEE 802.1D/VLAN-unaware mode) or takes VLAN information into account (IEEE 802.1Q/VLAN-aware mode). If the device is in the "802.1Q VLAN Bridge" mode, you can define VLANs and specify the use of the ports .

Note

Changing the agent VLAN ID

If the configuration PC is connected directly to the device via Ethernet and you change the agent VLAN ID, the device is no longer reachable via Ethernet following the change.

Settings

The page contains the following boxes:

- **Base Bridge-Mode**
  Select the required mode from the drop-down list. The following modes are possible:

  Note

  Changing Base bridge mode

  Note the section "Changing Base bridge mode". This section describes how a change affects the existing configuration.

  – 802.1 D Transparent Bridge
    Sets the mode "VLAN-unaware" for the device. In this mode, VLAN tags are not taken into account or changed but are forwarded transparently. In this mode, you cannot create any VLANs.
  – 802.1Q VLAN Bridge
    Sets the mode "VLAN-unaware" for the device. In this mode, VLAN tags are not taken into account or changed but are forwarded transparently. In this mode, you cannot create any VLANs.
    Only a management VLAN is available: VLAN 1.

- **VLAN ID**
  Enter the VLAN-ID (a number between 1 and 4094).
  You can create up to 2 (SCALANCE W760), 8 (SCALANCE W770) or 24 (SCALANCE W780) VLANS.

The table has the following columns:

- VLAN ID
  Shows the VLAN ID. The VLAN ID (a number between 1 and 4094) can only be assigned once when creating a new data record and can then no longer be changed. To make a change, the entire data record must be deleted and created again.
- Name
  Enter a name for the VLAN. The name only provides information and has no effect on the configuration.
- Status
  Shows the status type of the entry in the internal port filter table. Here, static means that the address was entered as a static address by the user. The entry GVRP means that the configuration was registered by a GVRP frame. This is, however, only possible if GVRP was enabled for the device.
- List of ports
  Specify the use of the port. The following options are available:
  - "-"
  - The port is not a member of the specified VLAN.
    With a new definition, all ports have the identifier "-".
  - M
    The port is a member of the VLAN. Frames sent in this VLAN are forwarded with the corresponding VLAN tag.
  - R
    The port is a member of the VLAN. A GVRP frame is used for the registration.
  - U (upper case)
    The port is an untagged member of the VLAN. Frames sent in this VLAN are forwarded without the VLAN tag. Frames without a VLAN tag are sent from this port.
  - u (lower case)
    The port is an untagged member of the VLAN, but the VLAN is not configured as a port VLAN. Frames sent in this VLAN are forwarded without the VLAN tag.
  - F
    The port is not a member of the specified VLAN and it is not possible for the VLAN to be registered dynamically at this port using GVRP. You can configure other settings in "Layer 2 > VLAN > Port-based VLAN".

Changing Base bridge mode

VLAN-unaware (802.1D transparent bridge) → VLAN-aware (802.1Q VLAN bridge)

If you change the Base Bridge mode from VLAN-unaware to VLAN aware, this has the following effects

- All static and dynamic unicast entries are deleted.

VLAN-aware (802.1Q VLAN bridge) → VLAN-unaware (802.1D transparent bridge)

If you change the Base Bridge mode from VLAN-aware to VLAN-unaware, this has the following effects:

- All VLAN configurations are deleted.
- A management VLAN is created: VLAN 1.
- All static and dynamic unicast entries are deleted.

802.1Q VLAN Bridge: Important rules for VLANs

Make sure you keep to the following rules when configuring and operating your VLANs:

- Frames with the VLAN ID "0" are handled as untagged frames but retain their priority value.
- As default, all ports on the device send frames without a VLAN tag to ensure that the end node can receive these frames.
- With SCALANCE W devices, the VLAN ID "1" is the default on all ports.
- If an end node is connected to a port, outgoing frames should be sent without a tag (static access port). If, however, there is a further switch at this port, the frame should have a tag added (trunk port).

Port-based VLAN

Processing received frames

On this page, you specify the configuration of the port properties for receiving frames.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the settings are valid for all ports.
- **Priority / Port VID / Acceptable Frames / Ingress Filtering**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Port**
  Shows the available ports and link aggregations.
- **Priority**
  Select the priority assigned to untagged frames.
  The CoS priority (Class of Service) used in the VLAN tag. If a frame is received without a tag, it will be assigned this priority. This priority specifies how the frame is further processed compared with other frames.
  There are a total of eight priorities with values 0 to 7, where 7 represents the highest priority (IEEE 802.1p Port Priority).

- **Port VID**
  Select the VLAN ID. Only VLAN IDs defined on the "VLAN > General" page can be selected. If a received frame does not have a VLAN tag, it has a tag with the VLAN ID specified here added to it and is sent according to the rules at the port.
- **Acceptable Frames**
  Specify which types of frames will be accepted. The following alternatives are possible:
  - Tagged Frames Only
    The device discards all untagged frames. Otherwise, the forwarding rules apply according to the configuration.
  - All
    The device forwards all frames
- **Ingress Filtering**
  Specify whether the VID of received frames is evaluated.
  The following options are available:
  - Enabled
    The VLAN ID of received frames decides whether they are forwarded: To forward a VLAN tagged frame, the receiving port must be a member in the same VLAN. Frames from unknown VLANs are discarded at the receiving port.
  - Disabled
    All frames are forwarded.

Dynamic MAC aging

The device automatically learns the source addresses of the connected nodes.

This information is used to forward data frames to the nodes specifically involved. The network load for the other nodes is reduced.
If a device does not receive a frame whose source address matches a learnt address within a certain time, the learnt address is deleted. This mechanism is known as aging. Aging prevents frames being forwarded incorrectly, for example when an end device (for example a programming device) is connected to a different port. If the check box is not enabled, a device does not delete learned addresses automatically.

Settings

- **Dynamic MAC Aging**
  Enable or disable the function for automatic aging of learned MAC addresses:
- **Aging Time [s]**
  Enter the time in seconds. After this time, a learned address is deleted if the device does not receive any further frames from this sender address.

Spanning Tree

General

General settings of MSTP

This is the basic page for spanning tree. Select the compatibility mode from the drop-down list. As default, Multiple Spanning Tree is enabled.

On the configuration pages of these functions, you can make detailed settings.

Note

Client device not as root bridge

Using the configuration of priorities and path costs, make sure that a client device can never become the root bridge. If a client device becomes the root bridge the Rapid Spanning Tree function no longer works.

Depending on the compatibility mode, you can configure the corresponding function on the relevant configuration page.

Settings

- **Spanning Tree**
  Enable or disable Spanning Tree.

  Note

  Clients or access points in client mode

  If "Automatic" is set for "MAC Mode", spanning tree is not supported.

- **Protocol Compatibility**
  Select the compatibility mode of Spanning Tree. If, for example, you select RSTP, Spanning Tree behaves like RSTP.
  The following settings are available:
  - STP
  - RSTP
  - MSTP

  Note

  If iPCF mode is enabled, only the compatibility modes STP and RSTP are supported.

CIST general

The page consists of the following parts:

- The left-hand side of the page shows the configuration of the device.
- The central part shows the configuration of the root bridge that can be derived from the spanning tree frames received by a device.
- The right-hand side shows the configuration of the regional root bridge that can be derived from the MSTP frames received by a device. The displayed data is only visible if you have enabled "Spanning Tree" on the "General" page and if "MSTP" is set for "Protocol Compatibility". This also applies to the "Bridge Max Hop Count" parameter. If the device is a root bridge, the information on the left and right matches.

Settings

- **Bridge Priority / Root Priority** (only available online)
  Which device becomes the root bridge is decided based on the bridge priority. The bridge with the highest priority becomes the root bridge. The lower the value, the higher the priority. If several devices in a network have the same priority, the device whose MAC address has the lowest numeric value will become the root bridge. Both parameters, bridge priority and MAC address together form the bridge identifier. Since the root bridge manages all path changes, it should be located as centrally as possible due to the delay of the frames.
- **Bridge Address** / **Root Address**(only available online)
  The bridge address shows the MAC address of the device and the root address shows the MAC address of the root bridge.
- **Root Port** (only available online)
  Shows the port via which the switch communicates with the root bridge.
- **Root Cost** (only available online)
  The path costs from this device to the root bridge.
- **Topology Changes** / **Last Topology Change** (only available online)
  The entry for the device shows the number of reconfigurations due to the spanning tree mechanism since the last startup. For the root bridge, the time since the last reconfiguration is displayed as follows:
  - Seconds: "Sec" unit after the number
  - Minutes: "Min" unit after the number
  - Hour: "Hr" unit after the number
- **Bridge Hello Time / Root Hello Time** (only available online)
  Each bridge regularly sends configuration frames (BPDUs). The interval between two such frames is the Hello time. The default for this parameter is 2 seconds.
- **Bridge Forward Delay [s] / Root Forward Delay [s]**
  New configuration data is not used immediately by a bridge but only after the period specified in the parameter. This ensures that operation is only started with the new topology after all the bridges have the required information.
- **Bridge Max Age / Root Max Age** (only available online)
  Bridge Max Age defines the maximum "age" of a received BPDU for it to be accepted as valid by the switch.

The following values are available only in access point mode:

- **Regional root priority** (only available online)
  For a description, see Bridge Priority / Root Priority
- **Regional root address** (only available online)
  The MAC address of the device.
- **Regional root costs** (only available online)
  The path costs from this device to the root bridge.
- **Bridge Max Hop Count**
  This parameter specifies how many MSTP nodes a BPDU may pass through. If an MSTP BPDU is received and has a "Bridge Max Hop Count" that exceeds the value configured here, it is discarded.
- **Region Name**
  Enter the name of the MSTP region to which this device belongs. As default, the MAC address of the device is entered here. This value must be the same on all devices that belong to the same MSTP region.
- **Region Version**
  Enter the version number of the MSTP region in which the device is located. This value must be the same on all devices that belong to the same MSTP region.
- **Layer-2 Tunnel Admin Edge Port** (only available in access point mode)
  Enable this setting if there can be an end device on a layer 2 tunnel port. Otherwise a reconfiguration of the network will be triggered whenever a link to this port is modified. The L2T clients should be interconnected.
- **Layer-2 Tunnel Auto Edge Port**(Only available in access point mode)
  Enable this setting if you want to detect automatically at all layer 2 tunnel ports whether or not an end device is connected.

To reset the counters on this page the following button is available:

- **Reset Counters** (only available online)
  The values are reset with this button.

CIST port

MSTP-CIST port configuration

When the page is called, the table displays the current status of the configuration of the port parameters.

To configure them, click the relevant cells in the port table.

Settings

Table 1 has the following columns:

- **1st column**
  Shows that the setting is valid for all ports of table 2.
- **Spanning Tree Status**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.

Table 2 has the following columns:

- **Port**
  Shows the available ports and interfaces.
  - Port X
  - WLAN X
  - VAP X.Y
  - WDS X.Y
- **Spanning Tree Status**
  Specify whether or not the port is integrated in the spanning tree.

  Note

  If you disable the "Spanning Tree Status" setting for a port, this may cause the formation of loops. The topology must be kept in mind.

- **Priority**
  Enter the priority of the port. The priority is only evaluated when the path costs are the same. The value must be divisible by 16. If the value that cannot be divided by 16, the value is automatically adapted.
- **Cost Calc.**
  Enter the path cost calculation. If you enter the value "0" here, the automatically calculated value is displayed in the "Path Costs" box.

- **Path Costs** (only available online)
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected as the path. If several ports of a device have the same value for the path costs, the port with the lowest port number is selected.
  If The "Cost Calc." is "0", the automatically calculated value is shown. Otherwise, the value of the "Cost Calc." box is displayed. The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000

  The values can, however, also be set individually.
- **Status** (only available online)
  Displays the current status of the port. The values are only displayed and cannot be configured. The "Status" parameter depends on the configured protocol. The following is possible for status:
  - Disabled

    The port only receives and is not involved in STP, MSTP and RSTP.
  - Discarding
    In the "Discarding" mode, BPDU frames are received. Other incoming or outgoing frames are discarded.
  - Listening

    In this status, BPDUs are both received and sent. The port is involved in the spanning tree algorithm.
  - Learning

    Stage prior to the forwarding status, the port is actively learning the topology (in other words, the node addresses).
  - Forwarding

    Following the reconfiguration time, the port is active in the network; it receives and forwards data frames.

- **Fwd. Trans** (only available online)
  Specifies the number of changes from the "Discarding" status to the "Forwarding" status
- **Edge type**
  Specify the type of edge port. You have the following options:
  - "-"
    Edge port is disabled. The port is treated as a "no edge port".
  - Admin
    Select this option when there is always an end device on this port. Otherwise a reconfiguration of the network will be triggered each time a connection is changed.
  - Auto
    Select this option if you want a connected end device to be detected automatically at this port. When the connection is established the first time, the port is treated as a "no Edge Port".
  - Admin/Auto
    Select these options if you operate a combination of both on this port. When the connection is established the first time, the port is treated as an Edge Port.
- **Edge** (only available online)
  Shows the status of the port.
  - Enabled

    An edge port is connected to this port.
  - Disabled
    There is a spanning tree or rapid spanning tree device at this port.

  With an end device, a switch can change over the port faster without taking into account spanning tree frames. If a spanning tree frame is received despite this setting, the port automatically changes to the "Disabled" setting for switches.
- **P.t.P. Type**
  Select the required option. The selection depends on the port that is set.
  - "-"
    Point to point is calculated automatically. If the port is set to half duplex, a point-to-point link is not assumed.
  - P.t.P.

    Even with half duplex, a point-to-point link is assumed.
  - Shared Media

    Even with a full duplex connection, a point-to-point link is not assumed.

  Note

  Point-to-point connection means a direct connection between two devices. A shared media connection is, for example, a connection to a hub.

- **P.t.P.**
  - Enabled
    Shows that a point-to-point link exists.
  - Disabled
    Shows that no point-to-point link exists.
- **Hello Time**
  Enter the interval after which the bridge sends configuration BPDUs

Note

The port-specific setting of the Hello time is only possible in MSTP compatible mode.

MST General

Multiple Spanning Tree configuration

With MSTP, in addition to RSTP, several VLANs can be managed in a LAN with separate RSTP trees.

Settings

- **MSTP Instance ID**
  Enter the number of the MSTP instance.

The table has the following columns:

- **Select**
  Select the line to be deleted.
- **MSTP Instance ID**
  Shows the number of the MSTP instance.
- **Root Address**
  Shows the MAC address of the root bridge
- **Root Priority**
  Shows the priority of the root bridge.
- **Bridge Priority**
  Enter the bridge priority. The value for the bridge priority is a whole multiple of 4096.
- **VLAN ID**
  Enter the VLAN ID. Here, you can also specify ranges with Start ID, "-", End ID. Several ranges or IDs are separated by ",".

MST port

Configuration of the Multiple Spanning Tree port parameters

On this page, you set the parameters for the ports of the configured multiple spanning tree instances.

Settings

- **MSTP Instance ID**
  Select the ID of the MSTP instance.

Table 1 has the following columns

- **1st column**
  Shows that the setting is valid for all ports.
- **MSTP Status**
  Select the setting. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2

Table 2 has the following columns:

- **Port**
  Shows all available ports and link aggregations.
- **MSTP Instance ID**
  ID of the MSTP instance.
- **MSTP Status**
  Enable or disable MSTP for this port.
- **Priority**
  Enter the priority of the port. The priority is only evaluated when the path costs are the same. The value must be divisible by 16. If the value that cannot be divided by 16, the value is automatically adapted.
- **Cost Calc.**
  Enter the path cost calculation in the input box. If you enter the value "0" here, the automatically calculated value is displayed in the next box "Path Costs".
- **Path Costs** (only available online)
  This parameter is used to calculate the path that will be selected. The path with the lowest value is selected as the path. If several ports of a device have the same value for the path costs, the port with the lowest port number is selected.
  If the value for the Cost Calc is "0" the automatically determined value is displayed. Otherwise, the value of the "Cost Calc box is displayed. The calculation of the path costs is largely based on the transmission speed. The higher the achievable transmission speed is, the lower the value of the path costs.
  Typical values for path costs with rapid spanning tree:
  - 10,000 Mbps = 2,000
  - 1000 Mbps = 20,000
  - 100 Mbps = 200,000
  - 10 Mbps = 2,000,000

  The values can, however, also be set individually.

- **Status** (only available online)
  Displays the current status of the port. The values are only displayed and cannot be configured. The following is possible for status:
  - Discarding
    The port exchanges MSTP information but is not involved in the data traffic.
  - Blocked
    In the blocking mode, BPDU frames are received.
  - Forwarding
    The port receives and sends data frames.
- **Fwd. Trans**(only available online)
  Specifies the number of status changes Discarding - Forwarding or Forwarding - Discarding for a port.

DCP forwarding

Applications

The DCP protocol is used by STEP 7 and the PST Tool for configuration and diagnostics. When shipped, DCP is enabled on all ports; in other words, DCP frames are forwarded at all ports. With this option, you can disable the sending of these frames for individual ports, for example to prevent individual parts of the network from being configured with the PST Tool or to divide the full network into smaller parts for configuration and diagnostics.

Note

Empty table

If you have enabled NAT on the device, the table is empty or will be emptied:

Settings

- **Port**
  Shows the available ports.
- **Setting**
  Specify whether the port should block or forward outgoing DCP frames. The following options are available:
  - block
    No outgoing DCP frames are forwarded via this port. It is nevertheless still possible to receive via this port.
  - forward
    DCP frames are forwarded via this port.

LLDP

Identifying the network topology

LLDP (Link Layer Discovery Protocol) is defined in the IEEE 802.AB standard.

LLDP is a method used to discover the network topology. Network components exchange information with their neighbor devices using LLDP.

Network components that support LLDP have an LLDP agent. The LLDP agent sends information about itself and receives information from connected devices at periodic intervals. The received information is stored in the MIB.

Applications

PROFINET uses the LLDP protocol for topology diagnostics. In the default setting, LLDP is enabled for all ports; in other words, LLDP frames are sent and received on all ports. With this function, you have the option of enabling or disabling sending and/or receiving per port.

Settings

The table has the following columns:

- Port
  Shows the port.
- Setting
  Specify the LLDP functionality. The following options are available:
  - Tx
    This port can only send LLDP frames.
  - Rx
    This port can only receive LLDP frames.
  - Rx & Tx
    This port can receive and send LLDP frames.
  - "-" (disabled)
    This port can neither receive nor send LLDP frames.

Configuring layer 3 functions for IPv4

NAT

Basic

Note

The page is only available

- SCALANCE W740, SCALANCE W730 and SCALANCE W722-1 RJ45
- clients or access points in client mode.

On this page, you specify the basic settings for NAT.

Settings

- **Interface**
  Select the required interface.
- **Enable NAT**
  Enable or disable NAT for the Ethernet interface. Cannot be enabled if Layer 2 Tunnel is set for MAC Mode on the client.
- **TCP Idle Timeout [s]**
  Enter the required time in seconds. If no data exchange takes place, the TCP connection is deleted from the translation table when this time has elapsed.
  The range of values is 1 to 4294967295. Default setting: 86400 seconds
- **UDP Idle Timeout [s]**
  Enter the required time in seconds. If no data exchange takes place, the UDP connection is deleted from the translation table when this time has elapsed.
  The range of values is 1 to 4294967295. Default setting: 300 seconds
- **Local Interface IP address**
  Enter the local IP address of the Ethernet interface. This IP address is the gateway address of the local device.
- **Local Interface Subnet Mask**
  Enter the subnet mask for the local Ethernet.
- **IPv6 Transparent Mode**
  When enabled, the transparent mode is activated. IPv6 frames are forwarded unchanged between Ethernet and WLAN. This assumes that "Own" is not set for MAC mode and IPv6 is turned off.

NAPT

Note

The page is only available

- SCALANCE W740, SCALANCE W730 and SCALANCE W722-1 RJ45
- clients or access points in client mode.

On this page, you define the translation list for communication from the global to the local network.

Settings

- **Interface**
  Interface to which the settings relate. Can only be selected if the device has several interfaces.
- **Traffic Type**
  Specify the protocol for which the address assignment is valid.
- **Global Port**
  Enter the global port. Incoming frames with this port as the destination port are forwarded.

  Note

  If the port is already occupied by a local service, for example Telnet, a warning is displayed. In this case, avoid using TCP port 23 (Telnet), port 22 (SSH), ports 80/443 (http/https: reachability of the client with the WBM) and UDP port 161 (SNMP) as global port.
- **Local IP address**
  Enter the IP address of the node in the local network. The frame is forwarded to this IP address.
- **Local Port**
  Enter the number of the port. This is the new destination port to which the incoming frame will be forwarded. You can enter the same port in the local area network for more than one node.

The table has the following columns:

- **Select**
  Select the lines to be deleted.
- **Interface**
  Shows the interface to which the settings relate.
- **Activate**
  When enabled, the entry for the address assignment is used.
- **Traffic Type**
  Shows the protocol for which the address assignment applies.
- **Dynamic Global IP Address**
  Shows whether or not dynamic address translation is used.
- **Global IP Address**
  Shows the global IP address to which the local IP address will be translated.

- **Global Port**
  Shows the global port.
- **Local IP address**
  Shows the IP address of the node in the local network.
- **Local Port**
  Shows the number of the local port.

Configuring security functions

Passwords

Passwords

Note

The page is only available if there is an online connection to the device.

On this page, you can change passwords. If you are logged on with the "admin" role, you can change the passwords for all user accounts. If you are logged on with the "user" role, you can only change your own password.

Note

If you log on the first time or log on after a "Reset to factory defaults and restart", you will be prompted to change the password.

Note

If you are logged in via a RADIUS server, you cannot change any local device passwords.

Note

Changing the password in "Trial" configuration mode

Even if you change the password in "Trial" configuration mode, this change is saved immediately.

Note

The factory settings for the passwords when the devices ship are as follows:

- admin: admin

When you log in for the first time or following a "Restore Factory Defaults and Restart", with the preset user "admin" you will be prompted to change the password.

Settings

- **Current User**
  Shows the user that is currently logged in.
- **Current User Password**
  Enter the password for the currently logged in user.
- **User Account**
  Select the user whose password you want to change.
- **Password Policy**
  Shows which password policy is being used when assigning new passwords.
  - High
    Password length: at least 8 characters, maximum 128 characters
    at least 1 uppercase letter
    at least 1 special character
    at least 1 number
  - Low
    Password length: at least 6 characters, maximum 128 characters
- **New Password**
  Enter the new password again to confirm it.
- **Password Confirmation**
  Enter the new password again to confirm it.

Options

On this page you specify which password policy will be used when assigning new passwords.

Description

- **Password Policy**
  Shows which password policy is currently being used
- **New Password Policy**
  Select the required setting from the drop-down list.
  - High
    Password length: at least 8 characters, maximum 128 characters
    at least 1 uppercase letter
    at least 1 special character
    at least 1 number
  - Low
    Password length: at least 6 characters, maximum 128 characters

Users

Local users

Note

The page is only available if there is an online connection to the device.

Local users

On this page, you create local users with the corresponding rights.

When you create or delete a local user this change is also made automatically in the table "External User Accounts". If you want to make change explicitly for the internal or external user table, use the CLI commands.

Note

The values displayed depend on the rights of the logged-in user.

Description

The page contains the following:

- **User Account**
  Enter the name for the user. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 250 characters long.
  - The following characters must not be included: § ? " ; : < =

  Note
  User name cannot be changed
  After creating a user, the user name can no longer be modified.
  If a user name needs to be changed, the user must be deleted and a new user created.

  Note
  Default user "user" set in the factory
  As of firmware version 6.0 the default user set in the factory "user" is no longer available when the product ships.
  If you update a device to the firmware V6.0 the default user set in the factory "user" is initially still available. If you reset the device to the factory settings ("Restore Factory Defaults and Restart") the default user set in the factory "user" is deleted.
  You can create new users with the role "user".

- **Password Policy**
  Shows which password policy is being used. You configure the password policy, see the Security > Passwords > Options page
- **Password**
  Enter the password. The strength of the password depends on the set password policy:

  Note
  Password Policy: Low
  - Password length: at least 6 characters, maximum 128 characters

  Password Policy: High
  The password must meet the following conditions:
  - Password length: at least 8 characters, maximum 128 characters
  - At least 1 uppercase letter
  - At least 1 special character
  - At least 1 number

- **Password Confirmation**
  Enter the password again to confirm it.
- **Role**
  Select a role.
  You can choose between default and self-defined roles, refer to the page "Security > Users > Roles.".

The table contains the following columns:

- **Select**
  Select the check box in the row to be deleted.

  Note

  The preset users as well as logged in users cannot be deleted or changed.

- **User Account**
  Shows the user name.
- **Role**
  Shows the role of the user.
- **Description**
  Displays a description of the user account. The description text can be up to 100 characters long.

Roles

Note

The page is only available if there is an online connection to the device.

Roles

On this page, you create roles that are valid locally on the device.

Note

The values displayed depend on the rights of the logged-in user.

Settings

- **Role Name**
  Enter the name for the role. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 64 characters long.

  Note
  Role name cannot be changed

  After creating a role, the name of the role can no longer be changed.

  If a name of a role needs to be changed, the role must be deleted and a new role created.

  Deleting roles

  Predefined roles and assigned roles cannot be deleted or modified.

The table contains the following columns:

- **Role**
  Shows the name of the role.
- **Function Right**
  Select the function rights of the role.
  - 1
    Users with this role can read device parameters but cannot change them.
  - 15
    Users with this role can both read and change device parameters.

  Note
  Function right cannot be changed

  If you have assigned a role, you can no longer change the function right of the role.

  If you want to change the function right of a role, follow the steps outlined below:
  1. Delete all assigned users.
  2. Change the function right of the role:
  3. Assign the role again.

- **Description**
  Enter a description for the role. With predefined roles a description is displayed. The description text can be up to 100 characters long.

Groups

Note

The page is only available if there is an online connection to the device.

User Groups

On this page you link a group with a role.

In this example the group "Administrators" is linked to the "admin"role: The group is defined on a RADIUS server. The role is defined locally on the device. When a RADIUS server authenticates a user and assigns the user to the "Administrators" group, this user is given rights of the "admin" role.

Settings

- Group Name
  Enter the name of the group. The name must match the group on the RADIUS server. The name must meet the following conditions:
  - It must be unique.
  - It must be between 1 and 64 characters long.

The table contains the following columns:

- Group
  Shows the name of the group.
- Role
  Select a role. Users who are authenticated with the linked group on the RADIUS server receive the rights of this role locally on the device.
  You can choose between system-defined and self-defined roles, refer to the page "Security > Users > Roles.".
- Description
  Enter a description for the link of the group.to a role.

AAA

User management

Overview of user management

Access to the device is managed by configurable user settings. Set up users with a password for authentication. Assign a role with suitable rights to the users.

The authentication of users can either be performed locally by the device or by an external RADIUS server. You configure how the authentication is handled on the "Security > AAA > General" page.

Local logon

The local logging on of users by the device runs as follows:

1. The user logs on with user name and password on the device.
2. The device checks whether an entry exists for the user.
   → If an entry exists, the user is logged in with the rights of the associated role.
   → If no corresponding entry exists, the user is denied access.

Login via an external RADIUS server

RADIUS (Remote Authentication Dial-In User Service) is a protocol for authenticating and authorizing users by servers on which user data can be stored centrally.

Depending on the RADIUS authorization mode you have selected on the "Security > AAA > RADIUS Client" page, the device evaluates different information of the RADIUS server.

RADIUS authorization mode "Standard"

If you have set the authorization mode "conventional", the authentication of users via a RADIUS server runs as follows:

1. The user logs on with user name and password on the device.
2. The device sends an authentication request with the login data to the RADIUS server.
3. The RADIUS server runs a check and signals the result back to the device.
   - The RADIUS server reports a successful authentication and returns the value "Administrative User" to the device for the attribute "Service Type".
     → The user is logged in with administrator rights.
   - The RADIUS server reports a successful authentication and returns a different or even no value to the device for the attribute "Service Type".
     → The user is logged in with read rights.
   - The RADIUS server reports a failed authentication to the device:
     → The user is denied access.

RADIUS authorization mode "SiemensVSA"

Requirement

For the RADIUS authorization mode "Siemens VSA" the following needs to be set on the RADIUS server:

- Manufacturer code: 4196
- Attribute number: 1
- Attribute format: Character string (group name)

Procedure

If you have set the authorization mode "SiemensVSA", the authentication of users via a RADIUS server runs as follows:

1. The user logs on with user name and password on the device.
2. The device sends an authentication request with the login data to the RADIUS server.
3. The RADIUS server runs a check and signals the result back to the device.
   Case A: The RADIUS server reports a successful authentication and returns the group assigned to the user to the device.
   - The group is known on the device and the user is not entered in the table "External User Accounts"
     → The user is logged in with the rights of the assigned group.
   - The group is known on the device and the user is entered in the table "External User Accounts"
     → The user is assigned the role with the higher rights and logged in with these rights.
   - The group is not known on the device and the user is entered in the table "External User Accounts"
     → The user is logged in with the rights of the role linked to the user account.
   - The group is not known on the device and the user is not entered in the table "External User Accounts"
     → The user is logged in with the rights of the role "Default".

   Case B: The RADIUS server reports a successful authentication but does not return a group to the device.
   - The user is entered in the table "External User Accounts":
     → The user is logged in with the rights of the linked role "".
   - The user is not entered in the table "External User Accounts":
     → The user is logged in with the rights of the role "Default".

   Case C: The RADIUS server reports a failed authentication to the device:
   - The user is denied access.

General

The term "AAA" used in the menu stands for "Authentication, Authorization, Accounting" and is used to identify and allow network nodes, to provide them with the appropriate services and to determine the amount of use.

On this page, you configure the login.

Settings

Note

To be able to use the login authentication "RADIUS", "Local and RADIUS" or "RADIUS and fallback Local" a RADIUS server must be stored and configured for user authentication.

- **Login Authentication**
  Specify how the login is made:
  - Local
    The authentication must be made locally on the device.
  - RADIUS
    The authentication must be handled via a RADIUS server.
  - Local and RADIUS
    The authentication is possible both with the users that exist on the device (user name and password) and via a RADIUS server.
    The user is first searched for in the local database. If the user does not exist there, a RADIUS query is sent.
  - RADIUS and fallback Local
    The authentication must be handled via a RADIUS server.
    A local authentication is performed only when the RADIUS server cannot be reached in the network.

RADIUS client

The term "AAA" used in the menu stands for "Authentication, Authorization, Accounting" and is used to identify and allow network nodes, to provide them with the appropriate services and to determine the amount of use.

Authentication over an external server

The concept of RADIUS is based on an external authentication server.

Each row of the table contains access data for one server. In the search order, the primary server is queried first. If the primary server cannot be reached, secondary servers are queried in the order in which they are entered.

If no server responds, there is no authentication.

Settings

The page contains the following boxes:

- **RADIUS Authorization Mode**
  For the login authentication, the RADIUS authorization mode specifies how the rights are assigned to the user with a successful authentication.
  - conventional
    In this mode the user is logged in with administrator rights if the server returns the value "Administrative User" to the device for the attribute "Service Type". In all other cases the user is logged in with read rights.
  - Vendor specific
    In this mode the assignment of rights depends on whether and which group the server returns for the user and whether or not there is an entry for the user in the table "External User Accounts".

The table has the following columns:

- **Auth. Server Type**
  Select which authentication method the server will be used for.
  - Login
    The server is used only for the login authentication.
  - 802.1X
    The server is used only for the 802.1X authentication.
  - Login & 802.1X
    The server is used for both authentication procedures.
- **RADIUS Server Address**
  Enter the IPv4 address or the FQDN (Fully Qualified Domain Name) of the RADIUS server.
- **Server Port**
  Here, enter the input port on the RADIUS server. As default, input port 1812 is set.
- **Shared Secret**
  Enter your access ID.
- **Confirm Shared Secret**
  Enter your access ID again as confirmation.
- **Max. Retrans**
  Enter the maximum number of query attempts before another configured RADIUS server is queried or the login counts as having failed. As default, 3 is set.
- **Primary Server**
  Specify whether or not this server is the primary server. You can select one of the options "yes" or "no".
- **Test**
  With this button, you can test whether or not the specified RADIUS server is available. The test is performed once and not repeated cyclically.
- **Test Result**
  Shows whether or not the RADIUS server is available:
  - Failed, no test packet sent
    The IP address is not reachable.
    The IP address is reachable, the RADIUS server is, however, not running.
  - Reachable, key not accepted
    The IP address is reachable, the RADIUS server does not, however accept the shared secret.
  - Reachable, key accepted
    The IP address is reachable, the RADIUS server accepts the specified shared secret.

  The test result is not automatically updated. To delete the test result click the "Refresh" button.

MAC ACL

Rule configuration

On this page, you specify the access rules for the MAC-based Access Control List. Using the MAC-based ACL, you can specify whether frames of certain MAC addresses are forwarded or discarded.

Settings

- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Enter the unicast MAC address of the source.
  Destination MAC Address
  Enter the unicast MAC address of the destination.
- **Action**
  Select the action. The following is possible:
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Ingress Interfaces**
  Shows a list of all interfaces to which this rule applies.
- **Egress Interfaces**
  Shows a list of all interfaces to which this rule applies.

Note

Entering the MAC addresses

If you enter the address "00:00:00:00:00:00" for the source and/or destination MAC address, the rule created in this way applies to all source or destination MAC addresses.

Ingress Rules

On this page, you specify the ACL rule according to which incoming frames are handled by the port.

Settings

- **Interface**
  Select the required interface.
- **Add Rule**
  Select the ACL rule to be assigned to the interface. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the interface, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the interface, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Shows the unicast MAC address of the source.
- **Destination MAC Address**
  Shows the unicast MAC address of the destination.
- **Action**
  Shows the action:
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.

Egress Rules

On this page, you specify the ACL rule according to which outgoing frames are handled by the port.

Settings

- **Interface**
  Select the required interface.
- **Add Rule**
  Select the ACL rule to be assigned to the interface. You specify the ACL rule on the "Rules Configuration" page.

- **Add**
  To permanently assign the ACL rule to the interface, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the interface, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source MAC**
  Shows the unicast MAC address of the source.
- **Destination MAC Address**
  Shows the unicast MAC address of the destination.
- **Action**
  Shows the action
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.

IP ACL

Rule configuration

On this page, you specify the rules for the IP-based ACL.

Settings

The table has the following columns:

- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Source IP**
  Enter the IPv4 address of the source.
- **Source Subnet Mask**
  Enter the subnet mask in which the source is located.
- **Dest. IP**
  Enter the IP address of the destination.

- **Dest. Subnet Mask**
  Enter the subnet mask in which the destination is located.
- **Action**
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Ingress Interfaces**
  Shows a list of all interfaces to which this rule applies.
- **Egress Interfaces**
  Shows a list of all interfaces to which this rule applies.

Protocol configuration

On this page, you specify the rules for protocols.

Settings

The table has the following columns:

- **Rule Number**
  Shows the number of the protocol rule. When you create a rule, a new row with a unique number is created.
- **Protocol**
  Select the protocol for which this rule is valid.
- **Protocol Number**
  Enter a protocol number to define further protocols.
  This box can only be edited if you have set "Other Protocol" for the protocol.
- **Source Port Min.**
  Enter the lowest possible port number of the source port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Source Port Max.**
  Enter the highest possible port number of the source port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Dest. Port Min.**
  Enter the lowest possible port number of the destination port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Dest. Port Max.**
  Enter the highest possible port number of the destination port.
  This box can only be edited if you have set "TCP" or "UDP" for the protocol.
- **Message Type**
  Enter a message type to decide the format of the message.
  This box can only be edited if you have set "ICMP" for the protocol.

- **Message Code**
  Enter a message code to specify the function of the message.
  This box can only be edited if you have set "ICMP" for the protocol.
- **DSCP**
  Enter a value for classifying the priority.
  This box cannot be edited if you have set "ICMP" for the protocol.

Ingress Rules

On this page, you specify the ACL rule according to which incoming frames are handled by the port or VLAN.

Settings

- **Ports**
  Select the required port: a port or a VLAN interface.
  To select a VLAN interface, an IP interface must be configured.

  Note

  If you use a VLAN interface, the ACL rule applies to all ports that belong to the VLAN.

- **Add Rule**
  Select the ACL rule to be assigned to the port. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the port, click the "Add" button. The configuration is shown in the table.
- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the port, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Protocol**
  Shows the protocol for which this rule is valid.
- **Protocol Number**
  Shows the protocol number.
- **Source IP**
  Shows the IP address of the source.
- **Source Subnet Mask**
  Shows the subnet mask in which the source is located.

- **Dest. IP**
  Shows the IP address of the destination.
- **Dest. Subnet Mask**
  Shows the subnet mask of the destination.
- **Action**
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Source Port Min.**
  Shows the lowest possible port number of the source port.
- **Source Port Max.**
  Shows the highest possible port number of the source port.
- **Dest. Port Min.**
  Shows the lowest possible port number of the destination port.
- **Dest. Port Max.**
  Shows the highest possible port number of the destination port.
- **Message Type**
  Shows a message type to decide the format of the message.
- **Message Code**
  Shows a message code to specify the function of the message.
- **DSCP**
  Shows the value for classifying the priority.

Egress Rules

On this page, you specify the ACL rule according to which outgoing frames are handled by the port.

Settings

- **Ports**
  Select the required port: a port or a VLAN interface.
  To select a VLAN interface, an IP interface must be configured.

  Note

  If you use a VLAN interface, the ACL rule applies to all ports that belong to the VLAN.

- **Add Rule**
  Select the ACL rule to be assigned to the port. You specify the ACL rule on the "Rules Configuration" page.
- **Add**
  To permanently assign the ACL rule to the port, click the "Add" button. The configuration is shown in the table.

- **Remove Rule**
  Select the ACL rule to be deleted.
- **Remove**
  To remove the ACL rule from the port, click the "Remove" button.

The table has the following columns:

- **Rule Order**
  Shows the order of the ACL rules.
- **Rule Number**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **Protocol**
  Shows the protocol for which this rule is valid.
- **Protocol Number**
  Shows the protocol number.
- **Source IP**
  Shows the IP address of the source.
- **Source Subnet Mask**
  Shows the subnet mask in which the source is located.
- **Dest. IP**
  Shows the IP address of the destination.
- **Dest. Subnet Mask**
  Shows the subnet mask of the source.
- **Action**
  Select whether the frame is forwarded or rejected when it corresponds to the ACL rule.
  - Forward
    If the frame complies with the ACL rule, the frame is forwarded.
  - Discard
    If the frame complies with the ACL rule, the frame is not forwarded.
- **Source Port Min.**
  Shows the lowest possible port number of the source port.
- **Source Port Max.**
  Shows the highest possible port number of the source port.
- **Dest. Port Min.**
  Shows the lowest possible port number of the destination port.
- **Dest. Port Max.**
  Shows the highest possible port number of the destination port.
- **Message Type**
  Shows a message type to decide the format of the message.
- **Message Code**
  Shows a message code to specify the function of the message.
- **DSCP**
  Shows the value for classifying the priority.

WLAN

Basic (Access Point)

Safety levels

To make the network secure, authentication and encryption are used. On this page, you specify the security settings.

Note

Transmission standard IEEE 802.11 n

The transmission standard IEEE 802.11 n with the setting "802.11n" or "802.11 n only" supports only WPA2/ WPA2-PSK with AES in the security settings.

iPCF or iPCF-MC

If iPCF or iPCF-MC is enabled, only "Open System" with the encryption methods WEP or AES is supported in the security settings.

Settings

The table has the following columns:

- **Interface**
  Shows the available interfaces.
- **Authentication Type**
  Select the type of authentication. The selection depends on the operating mode and the transmission standard.
  - **Open System**
    There is no authentication. Encryption with a fixed (unchanging) WEP key can be selected as an option. To use the key, enable "Encryption". You define the WEP key on the "Keys" page.
    If iPCF mode is enabled, the encryption method AES with 128 bit key length is also supported.
  - **Shared Key**
    With this authentication, a fixed key is stored on the client and access point. This WEP key is then used for authentication and encryption. You define the WEP key on the "Keys" page.

    Note

    If you use "Open System" with "Encryption" or "Shared Key", Key 1 must always be set on the "Keys" page.

  - **WPA (RADIUS)**
    Wi-Fi Protected Access is a method specified by the Wi-Fi Alliance to close security gaps in WEP. Authentication using a server is stipulated (802.1x). The dynamic exchange of keys at each data frame introduces further security.
  - **WPA-PSK**
    WPA Pre Shared Key (WPA-PSK) is a weakened form of WPA. In this method, authentication is not established by a server but is based on a password. This password is configured manually on the client and server.
  - **WPA2 (RADIUS)**
    WPA2 (Wi-Fi Protected Access 2) is a further development of WPA and implements the functions of the IEEE 802.11i security standard. WPA authentication works, however, without the RADIUS server.
  - **WPA2-PSK**
    WPA2-PSK is based on the 802.11i standard. WPA authentication works, however, without a RADIUS server. Instead of this, a WPA(2) key (WPA(2) pass phrase) is stored on each client and access point. The WPA(2) pass phrase is used for authentication and further encryption.
  - **WPA/WPA2-Auto-PSK**
    Setting with which an access point can process both the "WPA-PSK" as well as the "WPA2-PSK" type of authentication. This is necessary when the access point communicates with different clients, some using "WPA-PSK" and others "WPA2-PSK". The same encryption method is set on the clients.

  - **WPA/WPA2-Auto**
    Setting with which an access point can process both the "WPA" as well as the "WPA2" type of authentication. This is necessary when the access point communicates with different clients, some using "WPA" and others "WPA2". The same encryption method is set on the clients

- **Encryption**
  Encryption protects the transferred data from eavesdropping and corruption. You can only disable encryption if you have selected "Open System" for authentication. All other security methods include both authentication and encryption.

- **Cipher**
  Select the encryption method. The selection depends on the transmission standard.

  - **AUTO**
    AES or TKIP is used depending on the capability of the other station.

  - **WEP**
    WEP (Wired Equivalent Privacy)
    A symmetrical stream encryption method with only 40- or 104-bit long keys based on the RC4 algorithm (Ron's Code 4).

  - **TKIP (Temporal Key Integrity Protocol)**
    A symmetrical encryption method with the RC4 algorithm (Ron's Code 4). In contrast to the weak WEP encryption, TKIP uses changing keys derived from a main key. TKIP can also recognize corrupted data frames.

  - **AES (Advanced Encryption Standard)**

    Strong symmetrical block encryption method based on the Rijndael algorithm that further improves the functions of TKIP.

    Note

    To provide better protection of your data against attacks, use WPA2/ WPA2-PSK with AES.

- **WPA(2) Pass Phrase**
  Enter a WPA(2) pass phrase here. This WPA(2) key must be known both at the client end and on the access point and is entered by the user at both ends.
  ASCII code 0x20 to 0x7e is used for the WPA(2) key.

- **WPA(2) Pass Phrase Confirmation**
  Confirm the entered WPA(2) key.

- **Default Key**
  Specify the WEP key used to encrypt the data. You define the WEP key on the "Keys" page.

Options

Which settings are possible depends on the "Authentication Type" you have selected.

Authentication type	Encryption	Cipher	Encryption key source
Open System	disabled	--	--
Open System	Enabled	WEP	Default Key
Open System	Enabled	AES[1)]	Default Key (128-bit)

Authentication type	Encryption	Cipher	Encryption key source
Shared Key	Enabled	WEP	Default Key
WPA (RADIUS)	Enabled	Auto/TKIP/AES	RADIUS Server
WPA-PSK	Enabled	Auto/TKIP/AES	WPA(2) Pass Phrase
WPA2 (RADIUS)	Enabled	Auto/TKIP/AES	RADIUS Server
WPA2-PSK	Enabled	Auto/TKIP/AES	WPA(2) Pass Phrase
WPA/WPA2-AutoPSK	Enabled	Auto/TKIP/AES	WPA(2) Pass Phrase
WPA/WPA2-Auto (RADIUS)	Enabled	Auto/TKIP/AES	RADIUS Server

[1] available only with iPCF or iPCF-MC

Basic (Client)

Safety levels

To make the network secure, authentication and encryption are used. On this page, you specify the security settings.

Note

Transmission standard IEEE 802.11 n

The transmission standard IEEE 802.11 n with the setting "802.11n" or "802.11 n only" supports only WPA2/ WPA2-PSK with AES in the security settings.

iPCF or iPCF-MC mode activated

If iPCF or iPCF-MC mode is enabled, only "Open System" with the encryption method AES is supported in the security settings with Security Context 1.

Settings

The table has the following columns:

- Security context
  Shows the number of the entry. If you create a new entry, a new row with a unique number is created.
  You can create up to 8 security contexts. The security context 1 cannot be deleted.
- Authentication Type
  Select the type of authentication. The selection depends on the operating mode and the transmission standard.
  - Open System
    There is no authentication. Encryption with a fixed (unchanging) WEP key can be selected as an option. To use the key, enable "Encryption". You define the WEP key on the "Keys" page.
    If iPCF or iPCF-MC mode is enabled, only the encryption method AES with 128 bit key length is supported.
  - Shared Key
    In Shared Key authentication, a fixed key is stored on the client and access point. This WEP key is then used for authentication and encryption. You define the WEP key on the "Keys" page.
  - WPA (RADIUS)
    Wi-Fi Protected Access is a method specified by the Wi-Fi Alliance to close security gaps in WEP. Authentication using a server is stipulated (802.1x). The dynamic exchange of keys at each data frame introduces further security.

    Note

    Make the relevant RADIUS settings initially on the page "Security > WLAN > Basic".

  - WPA-PSK
    WPA Pre Shared Key (WPA-PSK) is a weakened form of WPA. In this method, authentication is not established by a server but is based on a password. This password is configured manually on the client and server.
  - WPA2 (RADIUS)
    WPA2 (Wi-Fi Protected Access 2) is a further development of WPA and implements the functions of the IEEE 802.11i security standard. WPA authentication works, however, without the RADIUS server.

    Note

    Make the relevant RADIUS settings initially on the page "Security > WLAN > Client Radius Supplicant".

  - WPA2-PSK
    WPA2-PSK is based on the 802.11i standard. WPA authentication works, however, without a RADIUS server. Instead of this, a WPA(2) key (WPA(2) pass phrase) is stored on each client and access point. The WPA(2) pass phrase is used for authentication and further encryption.

  - **WPA/WPA2-Auto-PSK**
    Setting with which an access point can process both the "WPA-PSK" as well as the "WPA2-PSK" type of authentication. This is necessary when the access point communicates with different clients, some using "WPA-PSK" and others "WPA2-PSK". The same encryption method is set on the clients.
  - **WPA/WPA2-Auto**
    Setting with which an access point can process both the "WPA" as well as the "WPA2" type of authentication. This is necessary when the access point communicates with different clients, some using "WPA" and others "WPA2". The same encryption method is set on the clients

- **Encryption**
  Encryption protects the transferred data from eavesdropping and corruption. You can only disable encryption if you have selected "Open System" for authentication. All other security methods include both authentication and encryption.
- **Cipher**
  Select the encryption method. The selection depends on the transmission standard.
  - **AUTO**
    AES or TKIP is used depending on the capability of the other station.
  - **WEP**
    WEP (Wired Equivalent Privacy)
    A symmetrical stream encryption method with only 40- or 104-bit long keys based on the RC4 algorithm (Ron's Code 4).
  - **TKIP (Temporal Key Integrity Protocol)**
    A symmetrical encryption method with the RC4 algorithm (Ron's Code 4). In contrast to the weak WEP encryption, TKIP uses changing keys derived from a main key. TKIP can also recognize corrupted data frames.
  - **AES (Advanced Encryption Standard)**

    Strong symmetrical block encryption method based on the Rijndael algorithm that further improves the functions of TKIP.

    Note

    To provide better protection of your data against attacks, use WPA2/ WPA2-PSK with AES.

- **WPA(2) Pass Phrase**
  Enter a WPA(2) pass phrase here. This WPA(2) key must be known on both the client and the access point and is entered by the user at both ends.
  For a key with 8 to 63 characters, you can only use the following readable ASCII characters: 0x20 - 0x7e.
  For a key with precisely 64 characters, you can use the following ASCII characters: 0 - 9, a - f and A - F.
- **WPA(2) Pass Phrase Confirmation**
  Confirm the entered WPA(2) key.
- **Default Key**
  Specify the WEP key used to encrypt the data. You define the WEP key on the "Keys" page.

AP communication

Communications options

On this page, you specify the type of communication allowed by the access point.

Note

The page is available only in access point mode.

Settings

Table 1 has the following columns:

- **Port**
  Shows that the settings are valid for all ports of Table 2.
- **within own VAP / with other VAPs / with Ethernet**
  Select the setting you require. If "No Change" is selected, the entry in table 2 remains unchanged.
- **Transfer to table**
  If you click the button, the setting is adopted for all ports of table 2.

Table 2 has the following columns:

- **Radio**
  Shows the available WLAN interfaces.
- **Port**
  Shows the VAP interface.
- **within own VAP**
  - Enabled
    Clients logged on to the same VAP interface of an access point can communicate with each other.
  - Disabled
    Option is disabled.

- **with other VAPs**
  Only available if the device has at least 2 VAP interfaces.
  - Enabled
    Clients logged on to different VAP interfaces of an access point can communicate with each other.
  - Disabled
    Option is disabled.

  Note

  For an access point, "with other VAPs" must be enabled on all WLAN interfaces or on all VAPs to allow communication between clients logged on at different VAP interfaces of the access point.

- **with Ethernet**
  - Enabled
    Clients can communicate via the Ethernet interface of the access point.
  - Disabled
    Option is disabled.

Client RADIUS Supplicant

Client Supplicant

On this page, you configure the settings for the RADIUS authorization of the client.

Note

This page is only available for clients or access points in client mode.

Settings

The table has the following columns:

- **Security context**
  Shows the security context.
- **Dot1x User Name**
  Enter the user name with which the client will log on with the RADIUS server.
- **Dot1x User Password**
  Enter the password for the user name specified above. The client logs on with the RADIUS server using this combination.
  For password assignment, ASCII characters 0x20 to 0x7e are used.
- **Confirm Dot1x user password**
  Confirm the password.

- **Dot1x Check Server Certificate**
  Specify whether or not the RADIUS server identifies itself to the client using a certificate.
- **Dot1x EAP Types**
  Specify the authentication method. The following methods are available:
  - Auto
    EAP-TLS, EAP-TTLS or PEAP is used depending on the capability of the other station.
  - EAP-TLS
    Client logs on using a certificate.
  - EAP-TTLS
    The client logs on with the RADIUS server using the user name and password
  - PEAP
    The client logs on with the RADIUS server using the user name and password.

AP RADIUS Authenticator

Configuration of the RADIUS server

On this page, you define the RADIUS servers and the RADIUS authentication of the access point. You can enter data for two RADIUS servers.

Note

The page is available only in access point mode.

Settings

- **Reauthentication Mode**
  Specify who sets the time after which the clients are forced to reauthenticate.
  - '-' Disabled
    Reauthentication mode is disabled.
  - Server
    Enables time management on the server.
  - Local
    Enables local time management. In "Reauthentication Interval", specify the time of validity.
- **Reauthentication Interval [s]**
  If time management is local, enter the period of validity of the authentication in seconds. The minimum time is 1 minute (enter 60), the maximum time is 12 hours (enter 43200). The default is one hour (3,600 seconds).

The table has the following columns:

- **Server IP Address**
  Here, enter the IP address of the RADIUS server.
- **Server Port**
  Here, enter the input port on the RADIUS server.
- **Shared Secret**
  Enter the password of the RADIUS server.
  For the password, ASCII code 0x20 to 0x7e is used.
- **Confirm Shared Secret**
  Confirm the password.
- **Max. Retransmissions**
  Enter the maximum number of connection attempts.
- **Primary Server**
  Specify whether or not this server is the primary server.
  - yes: Primary server
  - no: Backup server.
- **Status**
  With this setting, you can enable or disable the RADIUS server

Key

Specifying the WEP key

To allow you to enable the encryption for the "Open System" and "Shared Key" authentication methods, you must first enter at least one key in the key table.

Settings

The table has the following columns:

- **Key 1 - 4**
  Enter the WEP or AES key. For the WEP key, characters of the ASCII code from 0x20 to 0x7E or hexadecimal characters from 0x00 to 0xFF are permitted.
  If iPCF or iPCF-MC mode is enabled, only the encryption method AES with 128-bit key length is supported.
  You can choose between the following key lengths:
  - 5 or 13 ASCII or 10 or 26 hexadecimal characters (40/104 bits)
  - 16 ASCII or 32 hexadecimal characters (128 bits)

  Note

  The hexadecimal characters are entered without being preceded by "0x". One hexadecimal character codes four bits. The entries "ABCDE" (ASCII characters) and "4142434445" (hexadecimal characters) are therefore the same because the ASCII character "A" has hexadecimal code "0x41".

- **Key 1 - 4 Confirmation**
  Confirm the WEP key.

Management ACL

On this page, you can increase the security of your device. To specify which station with which IP address is allowed to access your device, configure the IP address or an entire address range.

You can select the protocols and the ports with which the station is allowed to access the device. You define the VLAN in which the station may be located. This ensures that only certain stations within a VLAN have access to the device.

Note

Note that a bad configuration may mean that you can no longer access the device.

Settings

- **Management ACL**
  Enable or disable the function.
- **IP Address**
  Enter the IP address or the network address to which the rule will apply. If you use the IP address 0.0.0.0, the settings apply to all IP addresses.
- **Subnet Mask**
  Enter the subnet mask. The subnet mask 255.255.255.255 is for a specific IP address. If you want to allow a subnet, for example a C subnet, enter 255.255.255.0. The subnet mask 0.0.0.0 applies to all subnets.

The table has the following columns:

- **Select**
  Select the lines to be deleted.
- **Rule Order**
  Shows the number of the ACL rule. When you create a rule, a new row with a unique number is created.
- **IP Address**
  Shows the IP address.
- **Subnet Mask**
  Shows the subnet mask.
- **VLANs Allowed**
  Enter the number of the VLAN in which the device is located. The station can only access the device if it is located in this configured VLAN. If this input box remains empty, there is no restriction.
- **SNMP**
  Specify whether the station or the IP address accesses the device using the SNMP protocol.
- **TELNET**
  Specify whether the station or the IP address accesses the device using the TELNET protocol.
- **HTTP**
  Specify whether the station or the IP address accesses the device using the HTTP protocol.
- **HTTPS**
  Specify whether the station or the IP address accesses the device using the HTTPS protocol.
- **SSH**
  Specify whether the station or the IP address accesses the device using the SSH protocol.
- **Px**
  Specify whether the station or the IP address accesses the device via this port.
- **WLAN1** (In client mode only)
  Specify whether the station or the IP address accesses the device via the WLAN interface.
- **VAPX.Y** (only in access point mode)
  Specify whether the station or the IP address accesses the device via the VAP interface.
- **WDSX.Y** (only in access point mode)
  Specify whether the station or the IP address accesses the device via the WDS interface.

Inter AP blocking

Basic

Note

- This tab is only available.
  - SCALANCE W780 / W770
  - in access point mode
- This WBM page can only be configured with the following KEY-PLUGs:
  - W780 iFeatures (MLFB 6GK5 907-8PA00)
  - W700 Security (MLFB 6GK5907-0PA00)

When should Inter AP blocking be used?

The clients connected to an access point can normally communicate with all devices of the layer 2 network.

With inter AP blocking, the communication of the clients connected to the access point can be restricted. Only the devices whose IP addresses are configured in "Allowed Addresses" on the access point are accessible to the clients. Communication with other nodes in the network is therefore prevented.

Settings

- **Refresh Interval [s]**
  Enter the refresh interval for the ARP table.

The table has the following columns:

- **Radio**
  Specifies the WLAN interface to which the settings relate.
- **Port**
  Specifies the VAP interface to which the settings relate.
- **SSID**
  Specifies the SSID to which the settings relate.
- **Enabled**
  When selected, the access restriction is used. You configure the devices that are accessible for the clients in "Security > Inter AP Blocking > Allow IP Addresses".
- **Block Gratuitous ARP Requests**
  When enabled, gratuitous ARP packets are not forwarded.
- **Block Non-IP Frames**
  When enabled, there is no exchange of non-IP packets, for example layer 2 packets between the client and the devices configured on the access point as permitted communications partners.

Allowed Addresses

On this page you specify which devices are accessible to the clients.

Note

- This tab is only available.
  - SCALANCE W780 / W770
  - in access point mode
- This WBM page can only be configured with the following KEY-PLUGs:
  - W780 iFeatures (MLFB 6GK5 907-8PA00)
  - W700 Security (MLFB 6GK5907-0PA00)

Settings

- **Port**
  Select the required port.
- **IP address**
  Enter the IP address of the devices accessible to the client.

The table has the following columns:

- **Select**
  Select the lines to be deleted.
- **Radio**
  Specifies the WLAN interface to which the settings relate
- **Port**
  Specifies the VAP interface to which the settings relate
- **IP address**
  IP Address of the devices accessible to the client. If necessary, you can change the IP address.
- **Resolver IP Address**
  The IP address with which the allowed IP address is resolved. The entry is necessary if the management IP address is located in a different subnet. If the IP address "0.0.0.0" is configured for "IP address resolution", the management IP address is used for the resolution.

Configuring iFeatures

iPCF

Note

iPCF for clients or access points in client mode

- SCALANCE W740, SCALANCE W734-1 RJ-45 and SCALANCE W722-1 RJ-45
- The setting can only be configured with the following KEY-PLUG:
  - Client: W740 iFeatures (MLFB 6GK5 907-4PA00)

iPCF in access point mode

- SCALANCE W780 and SCALANCE W774-1 RJ-45
- The setting can only be configured with the following KEY-PLUG:
  - Access point: W780 iFeatures (MLFB 6GK5 907-8PA00)

When should iPCF be used?

The use of iPCF is advisable particularly if you have a large number of nodes and want to implement highly deterministic operation. This is necessary, for example with PROFINET or other cyclic protocols.

Note

iPCF, iPCF-MC and iPRP are not compatible with each other and cannot be used at the same time on a device.

Settings

In both modes, the table has the following columns:

- **Radio**
  Specifies the WLAN interface to which the settings relate.
- **Enable iPCF**
  Enable or disable iPCF mode. For PROFINET communication, we recommend that you enable the iPCF mode. By enabling iPCF, the data rates provided by the access point are adapted. We strongly recommend that you retain the default setting for the data rates (802.11 a/b/g = 12 Mbps and 802.11n = MCS 2).

In access point mode, the table has the following additional columns:

- **Protocol Support**
  Specify which protocol is handled with priority by the WLAN interface.
  - PROFINET
    if you set PROFINET, there must be no PROFINET controller downstream from the client.
  - EtherNet/IP
    If you set Ethernet/IP, there must be no scanner downstream from the client.
  - Disabled
    The function is disabled.
- **iPCF Cycle Time [ms]**
  Select the required cycle time from the drop-down list.
  The following points need to be taken into account when setting the cycle time. Otherwise it may not be possible to establish stable communication.
  - There is only one access point in the system; in other words, the clients move only in one wireless cell. In this case, update times >= 16 ms are supported.
  - There are several access points in the system that communicate over different channels. The clients roam between the access points. In this case, select update times >= 32 ms.

  In addition to the guide values shown above, remember that the shortest cycle time to be set is calculated according to the formula "2 ms * max. number of nodes".
- **Scanning Mode**
  The selected setting affects the scanning of the logged-on clients.
  The following settings are available:
  - All Channels
    The client scans all permitted channels and selects the access point with the best signal strength and connects to it.
  - Next Channel
    The client scans the next channel from its permitted channel list. If an access point is there, it connects to it. If it does not find an access point on this channel, it scans the next channel.
- **Signal Quality Threshold**
  Can only be configured if "Next Channel" is set for "Scanning Mode". The client is given a minimum signal strength with which the access point must be seen during the scan so that a connection can be established to it.
  The following threshold values exist for the signal strength:

Level	Signal quality in RSSI	Signal quality in %
1	20	40
2	25	50
3	30	60
4	35	70
5	40	80

iPCF-MC

Requirements to be able to use iPCF-MC:

- The access point has at least two WLAN interfaces (dual AP).
- Access point mode: Only dual APs with KEY-PLUG W780 iFeatures (MLFB 6GK5 907-8PA00)
- Client mode: Client with KEY-PLUG W740 iFeatures (MLFB 6GK5 907-4PA00)
- The management interface and data interface must be operated in the same frequency band and mode and must match in terms of their wireless coverage. iPCF-MC will not work if both wireless interfaces are equipped with directional antennas that cover different areas.
- The management interfaces of all access points to which a client can change must use the same channel. A client scans only this one channel to find accessible access points.
- Transmission based on IEEE801.11h (DFS) cannot be used for the management interface. 801.11h (DFS) is possible for the data interface.
- The client cannot be operated with "Use Allowed Channels only".
- "Force Roaming on link down" is automatically mirrored on the second interface.
- The following applies to clients: All configured and active SSIDs must be assigned to security context 1. An SSID is active when the corresponding check box "Enabled" is selected on the page "Interfaces > WLAN > Client".
- In Japan, iPCF-MC cannot be enabled if the data or management interface uses a frequency of the 4920 MHz - 5080 MH frequency band.

When should iPCF-MC be used?

iPCF was developed to achieve short handover times when roaming between cells. The iPCF-MC technique allows short handover times even for freely mobile clients and when a lot of cells are involved or a large number of channels is being used.

Note

- iPCF, iPCF-MC and iPRP are not compatible with each other and cannot be used at the same time on a device.
- With 11n devices, remember that the assignment of the WLAN interfaces is fixed for iPCF-MC.
  - WLAN1: Data interface
  - WLAN2: Management interface

Settings

The following setting exists in both modes

- **Enable iPCF-MC**
  Enable or disable the iPCF-MC mode of the device.
  For PROFINET communication, we recommend enabling the iPCF-MC mode. By enabling iPCF-MC, the data rates provided by the access point are adapted.
  We strongly recommend that you retain the default setting for the data rates (802.11 a/b/g = 12 Mbps and 802.11n = MCS 2).

The following setting exists only in access point mode

- **iPCF Cycle Time**
  Select the update time configured for the network to which the access point is connected. The lowest value for the update time is 32 ms.

The following setting exists only in client mode

- **Management Scan Period**
  This parameter specifies the time between two client background scans (specified in iPCF cycles). If, for example, you select two, the client runs a background scan only in every second iPCF cycle.
  A lower value for the background scan interval provides the basis for fast roaming, however this means that no high data throughput can be achieved. A higher value should be selected for a high data throughput.

Protocol Support (only in access point mode)

Specify which protocol is handled with priority.

- PROFINET
  if you set PROFINET, there must be no PROFINET controller downstream from the client.
- EtherNet/IP
  If you set Ethernet/IP, there must be no scanner downstream from the client.

iPRP

Note

- SCALANCE W770/W740, SCALANCE W770/W730 and SCALANCE W722-1 RJ45

The following KEY-PLUGs are inserted:

- Access point: W780 iFeatures (MLFB 6GK5 907-8PA00)
- Client: W740 iFeatures (MLFB 6GK5 907-4PA00)

When should iPRP be used?

Note

Use of iPRP with other iFeatures

IPRP and other iFeatures (e.g. iPCF. iPCF-MC,) are not compatible with each other and cannot be used at the same time on a device.

iPRP with oversize frames (jumbo frames)

To be able to use oversize frames, oversize frames (jumbo frames) must be configured on all devices in the network.

With the "industrial Parallel Redundancy Protocol" (iPRP) the PRP technology can be used in a wireless network. With IPRP the PRP frames are transferred parallel via two wireless links. The parallel transfer allows disruptions of the transfer on one wireless link to be compensated on the other.

Requirement

- The Base Bridge mode "802.1Q VLAN Bridge" is set.
- The VLANs have been created.
- Access point mode: The VAP interface is enabled.
- Client mode: For "MAC Mode", Layer 2 Tunnel is set.

Settings

The page contains the following:

- **PRP A**
  Select the VLAN assignment for PRP from the drop-down list.
- **PRP B**
  Select the VLAN assignment for PRP B from the drop-down list.

This table contains the following columns:

- **Interface**
  Shows the available interfaces.

  Note

  Access point

  On the access point the iPRP function is only supported on a VAP interface.

- **Enable iPRP**
  Enable or disable iPRP for the required interface.
- **PRP Network**
  Specify the PRP network in which the interface is a member.

iREF

Note

- The page is available only in access point mode.
- The function is supported by SCALANCE W780 / W770.
- The setting can only be configured with the following KEY-PLUG:
  - Access point: W780 iFeatures (MLFB 6GK5 907-8PA00)

When should iREF be used?

With iREF, the data can be sent with the highest possible transmit power. This applies in particular to use cases in which MIMO cannot be used, is of no advantage or when using sector antennas.

Note

Use of iREF with other iFeatures

iREF and other iFeatures (e.g. iPCF) are not compatible with each other and cannot be used at the same time on a device.

Settings

The table has the following columns:

- **Radio**
  Specifies the WLAN interface to which the settings relate.
- **Enable iREF**
  Enable or disable iREF for the required WLAN interface. The result is shown in "Information > WLAN >iFeatures".

  Note

  To be able to use iREF, there must be at least two antennas.

  The antennas are automatically switched to antenna mode RX/TX as soon as iREF is enabled.

AeroScout

Note

- The page is only available
  - SCALANCE W780 / W770
  - in access point mode
- The setting can only be configured with the following KEY-PLUG:
  - Access point: W780 iFeatures (MLFB 6GK5 907-8PA00)

Note

The AeroScout function cannot be combined with other iFeatures (iPCF,iPCF-MC, iREF).

AeroScout can only be used in the 2.4 GHz band according to IEEE 802.11g, IEEE 802.11n and IEEE 802.11n-only.

For more detailed information, please refer to the AeroScout documentation (www.aeroscout.com).

Settings

The table has the following columns:

- **Radio**
  Specifies the WLAN interface to which the settings relate.
- **Enable AeroScout**
  Enable or disable AeroScout support for the required WLAN interface. The result is shown in "Information > WLAN iFeatures". This page is only available in the WBM.

10.1.4.6 Configuring PROFIBUS DP (S7-1200)

The basics of configuring a DP master system (S7-1200)

Distributed I/O

DP master systems that consist of a DP master and DP slaves which are connected via a bus and communicate with one another via the PROFIBUS DP protocol are referred to as distributed I/O.

Firmware version of the S7-1200 CPU

Use of the PROFIBUS functions with the S7-1200, requires CPUs with firmware version 2.0 or higher.

Configuring distributed I/O

Since DP masters and DP slaves are different devices, these instructions only provide a basic configuration procedure. However, the process for configuring distributed I/O is practically identical to that of non-distributed configuration.

Creating the DP master system in the network view

After you have used dragged a DP master and a DP slave (for example, a CM 1243-5 and a CM 1243-5) from the hardware catalog to the network view, connect them both to a PROFIBUS subnet.

Additional information

Observe additional information on the scope of functions in the manuals of the respective device.

DP slaves within the hardware catalog (S7-1200)

DP slaves within the hardware catalog

You will find the DP slaves in the "Distributed I/O" folder of the hardware catalog. Compact and modular DP slaves are located there:

- Compact DP slaves
  Modules with integrated digital/analog inputs and outputs, for example, ET 200L
- Modular DP slaves
  (Interface modules with S7 modules assigned, for example, ET 200M

The available DP master and the desired functionality will determine which DP slaves can be used.

I slaves within the hardware catalog

The CM 1242-5 is, for example, an DP slave that can be configured as intelligent DP slave. You can find it in the hardware catalog at:

- CM 1242-5
  "PLC > SIMATIC S7 1200 > Communication module > PROFIBUS"

DP/DP coupler in the hardware catalog (S7-1200)

Introduction

A DP/DP coupler connects two PROFIBUS DP networks as a gateway so that the DP master from one network can transfer data to the DP master of the other network.

The maximum amount of data that can be transferred is 244 bytes input data and 244 bytes output data.

DP/DP coupler in the hardware catalog

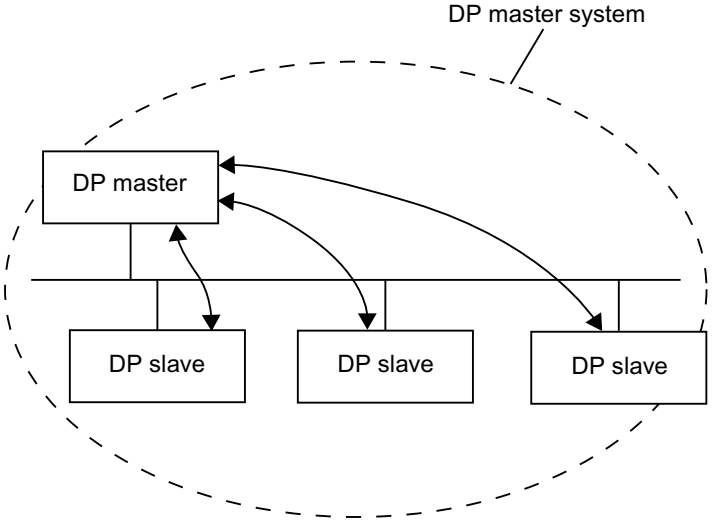
Details of a DP/DP coupler as gateway between two DM master systems are contained in the hardware catalog in the folder "Other field devices > PROFIBUS-DP > Gateways".

Configuring the DP/DP coupler

DP/DP couplers are configured in both PROFIBUS networks, each in their own master systems.

The input and output areas of both networks must thereby be matched to one another. The output data from one end of the DP/DP coupler are accepted as input data at the other respective end and vice versa.

Configurations involving PROFIBUS DP (S7-1200)



Configurations involving basic DP slaves (S7-1200)

Communication between DP master and DP slave

In the case of a configuration involving simple DP slaves, data is exchanged between the DP master and simple DP slaves, i.e. with I/O modules via the DP master. The DP master sequentially polls each DP slave configured within the DP master system and contained in its polling list. In doing so, it transfers the output data to the slaves and receives their input data in return.

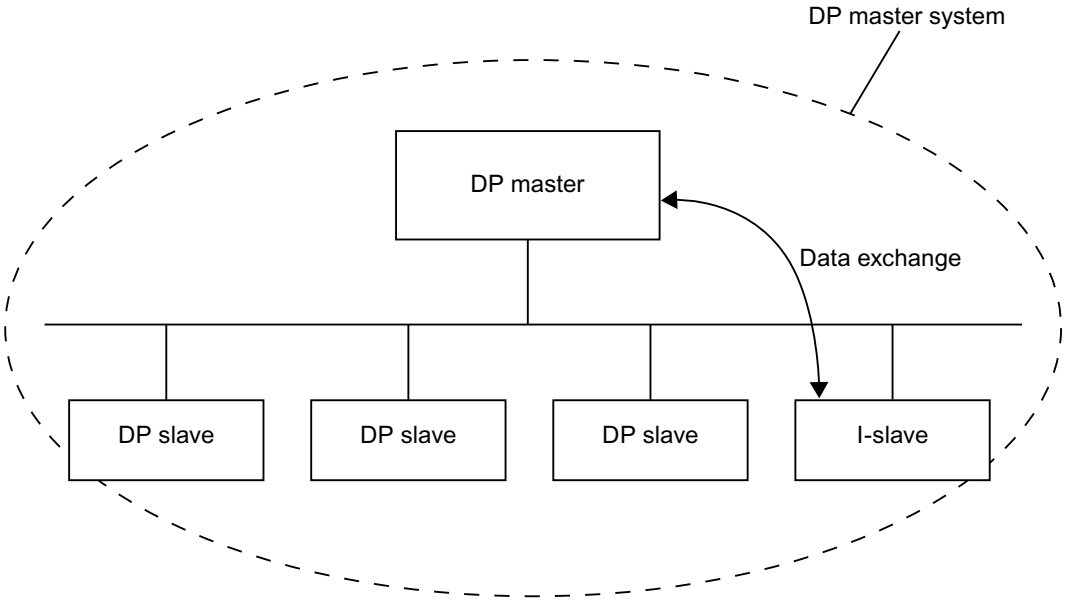
Mono-master system

The configuration with only one DP master is also described as mono-master system. A single DP master with its associated DP slaves is connected to a physical PROFIBUS DP subnet.

Configurations involving intelligent DP slaves (S7-1200)

Definition

DP slaves that feature their own preprocessing program are referred to as intelligent DP slaves (I-slaves).



CM 1242-5 is an intelligent DP slave.

I-slave <> DP master data exchange

A higher-level automation system processes the automation task, which is broken down into sub-tasks. The sub-tasks are processed in the lower-level automation systems. The necessary control tasks are processed separately and efficiently in the CPUs as preprocessing programs.

In the case of configurations involving intelligent DP slaves, the DP master only accesses the operand area of the I-slave's CPU, and not the I/O modules of the intelligent DP slave. The operand area must not be assigned to any actual I/O modules in the I-slave. The assignment must be made during I-slave configuration.

The addresses of the data to be exchanged between the master and slave are configured in the transfer area of the I-slave.

Configuring distributed I/O systems (S7-1200)

Creating a DP master system (S7-1200)

Introduction

To create a PROFIBUS DP master system, you need to have one DP master and at least one DP slave. As soon as you connect a DP master to a DP slave via their PROFIBUS DP interfaces, a master-slave link is established.

DP master and DP slave

The DP master must have a PROFIBUS DP interface. When using an S7-1200 CPU with PROFINET interface, you require the communications module CM 1243-5 with PROFIBUS DP interface for use as the DP master.

As DP slave, you can use head modules of the distributed I/O with PROFIBUS DP interface or CPUs as intelligent DP slaves. When using an S7-1200 CPU with PROFINET interface, you require the communications module CM 1242-5 with PROFIBUS DP interface to use the CPU as an intelligent DP slave.

Requirement

- You are in the network view.
- The hardware catalog is open.

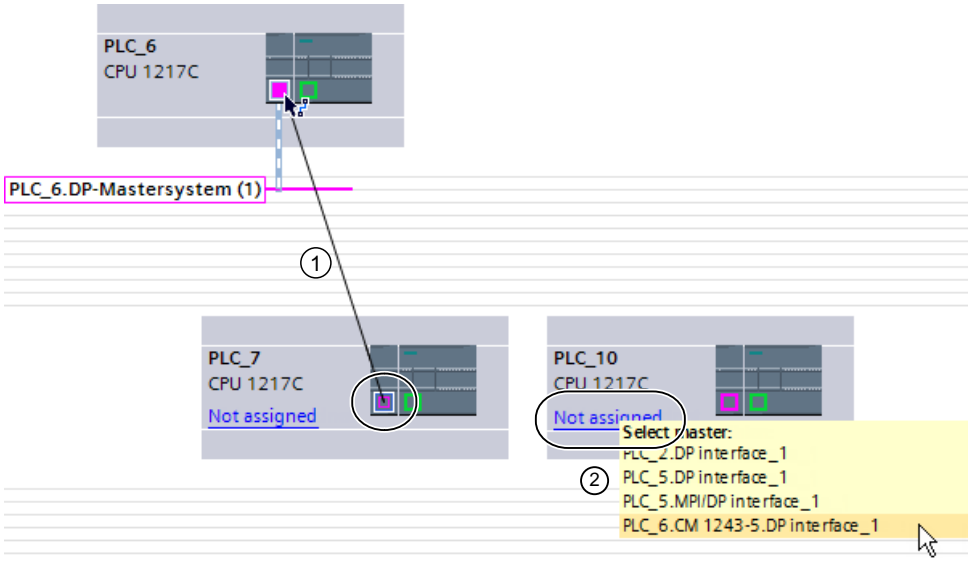
Procedure

To create a DP master system, for example with a CPU 1217C , follow these steps:

1. Select a CPU 1217C from the hardware catalog as a potential DP master.
2. Drag the CPU onto the free area within the network view.
3. Select the communications module CM 1243-5 from the hardware catalog.
4. Drag the communications module to the CPU in the network view.
5. Right-click on the DP interface of the communications module.
6. Select "Create master system" from the shortcut menu.

A DP master system with a CPU 1217C is created as the only node via the CM 1243-5 as DP master.

If you connect the DP interface of a DP slave to the DP interface of the DP master, the DP slave will be added automatically to the DP master system. If there is not yet a subnet between the DP master and DP slave, a new subnet is created between the DP master and DP slave.



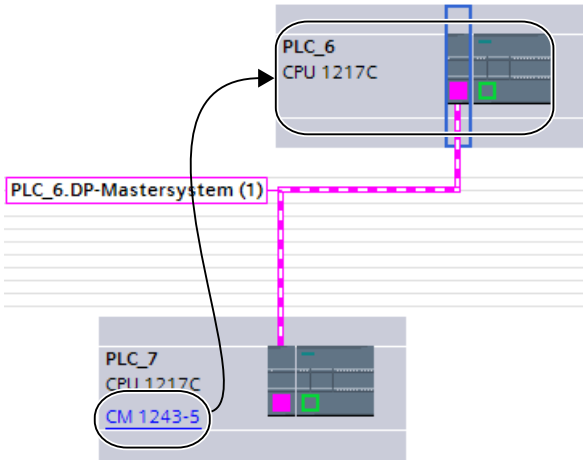
To include, for example, a CPU 1217C with communications module CM 1242-5 as an intelligent DP slave in the DP master system, follow the steps below:

1. Click on the DP interface of the DP master (interface of the CM 1243-5) or DP slave (interface of the CM 1242-5).
2. Hold down the mouse button and draw a connecting line between this DP interface and that of the desired communication partner.

or

1. Click on the hyperlink of the DP slave CPU 1217C with CM 1242-5.
2. Select the required DP master from the list of possible DP masters displayed.

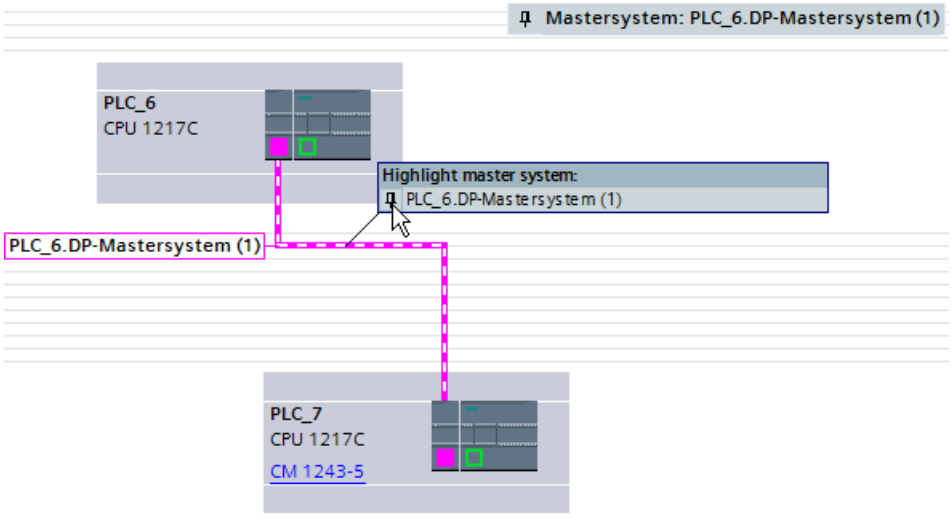
The intelligent DP slave CPU 1217C with CM 1242-5 is included in the DP master system as DP master with CPU 1217C and CM 1243-5 .



① Drag between the DP interfaces of DP slave to DP master.

② Click on the link of an unassigned DP slave, and a selection of possible DP masters opens.

If necessary, adapt the properties of the PROFIBUS subnet or of the DP master (e.g. PROFIBUS address) in the Inspector window under "Properties".



DP master display on the DP slave

When a DP slave is connected to a DP master, the name of the DP master is displayed on the DP slave as a hyperlink. Click the hyperlink to select the associated DP master.

Highlighting applied to the DP master system

When you create a new DP master system, highlighting will be applied to it. This enables you to identify quickly which devices belong to the DP master system. You can also highlight a DP master system yourself by moving the mouse pointer over a subnet. This will result in the names of the available DP master systems being displayed. Click the required DP master system to highlight it.

There are various ways of removing the highlighting from a DP master system:

- Highlight a different DP master system.
- Click on the pin with the name of the DP master system in the top right-hand corner of the network view.

Editing DP master systems and interfaces (S7-1200)

Introduction

Once you have created a DP master system, you also have the option of disconnecting the DP master system from its components. This can result in subnets with DP slaves but without DP master.

Generally, there is no need to edit the interfaces of a DP master.

You can change the name and number on the DP master system.

Disconnection of master or slaves from the DP master system

If you have configured a PROFIBUS CP as a DP master with master system, you can then disconnect the DP master system from the DP master. After this, the device will no longer be connected to the DP master system.

Disconnecting the subnet from a DP master effectively eliminates the master system in the sense that it is no longer assigned to a DP master. However, the individual DP slaves are still interconnected via the subnet.

If you delete the DP slaves or disconnect them from the master system, the master system is then retained on the DP master.

Requirement

- You must be in the network view.
- There has to be a DP master system with one DP master and at least one DP slave.

Disconnecting the DP master from the DP master system

To disconnect the DP master system, proceed as follows:

1. Right-click on the DP master's DP interface.
2. Select "Disconnect from master system" from the shortcut menu.

The selected DP master will be disconnected from the DP master system. A subnet with the DP slaves will be retained.

Adding a DP master to the DP master system

To reassign a DP master to a subnet, proceed as follows:

1. Right-click on the DP master's DP interface.
2. Select "Create master system" from the shortcut menu.
3. Draw connecting lines between the new DP master system and the DP interfaces of the DP slaves.

The DP master combines with the DP slaves to recreate a DP master system.

Editing the properties of a DP master system

To edit the properties of a DP master system, proceed as follows:

1. Move the mouse pointer over a subnet with a DP master system.
2. A message will appear displaying the available DP master systems. Click the one you want to edit. The DP master system will now be color-highlighted.
3. Click on the highlighted DP master system.
4. In the inspector window, edit the DP master system attributes under "Properties > General".

Note

If you click a subnet when no DP master system is highlighted, you will be able to edit the properties of the entire subnet under "Properties" in the inspector window.

Adding DP slaves to the master system and configuring them (S7-1200)

In the network view, you can add various DP slaves from the hardware catalog directly by using the drag-and-drop function or by double-clicking.

Types of DP slaves

For configuration purposes, DP slaves are broken down into the following categories:

- Compact DP slaves
  (Modules with integrated digital/analog inputs and outputs, for example, ET 200L)
- Modular DP slaves
  (interface modules with S5 or S7 modules assigned, for example ET 200M)
- Intelligent DP slaves (I-slaves)
  (SIMATIC S7-300 with, for example, CP 342-5, CPU 315-2 DP, or ET 200S with IM 151-7 CPU)

Slot rules

- Your DP master system should only contain one DP master, but it may contain one or or more DP slaves.
- You may only configure as many DP slaves in a DP master system as are permitted for the specific DP master.

Note

When configuring the DP master system, remember to observe the DP master technical data (max. number of nodes, max. number of slots, max. quantity of user data). User data restrictions may possibly prevent you from being able to use the maximum number of nodes that is theoretically possible.

Requirements

- You are in the network view.
- A DP master system must have been created.

Adding a DP slave to the DP master system

To add a DP slave from the hardware catalog to the DP master system, follow these steps:

1. Select a DP slave from the hardware catalog.
2. Drag-and-drop the DP slave from the hardware catalog into the network view.
3. Draw a connecting line between the DP master's DP interface or a highlighted DP master system and the DP interface of the new DP slave.

A DP master system will be created and the DP slave will be connected to the DP master automatically.

Note

When a DP master system is highlighted, you can double-click the required DP slave in the hardware catalog. This will result in the DP slave being added to the highlighted DP master system automatically.

Disconnecting a DP slave from the DP master system

To disconnect a DP slave from the DP master system, follow these steps:

1. In the network view, right-click on the DP slave's DP interface.
2. From the shortcut menu, select the method for disconnecting from the DP master system:
   - "Disconnect from subnet": The PROFIBUS connection is broken and the device is no longer connected to the DP master system or a subnet.
   - "Disconnect from master system": The DP slave remains connected to the subnet, but is no longer assigned to the DP master system as a DP slave.

The selected DP slave will be disconnected from the DP master system.

You can also disconnect directly using the shortcut menu of the DP slave:

1. In the network view, right-click on the DP slave.
2. Select "Disconnect from DP master/IO system" from the shortcut menu.

The DP slave remains connected to the subnet, but is no longer assigned to the DP master system as a DP slave.

Assigning a DP slave to a new DP master system

To assign an existing DP slave to a new DP master system, follow these steps:

1. Right-click on the DP slave's DP interface.
2. From the shortcut menu, select "Assign to new master".
   It does not matter whether the DP slave concerned is already assigned to another DP master system.
3. From the selection list, select the DP master with the DP master system to which you want to connect the DP slave.
   The selected DP slave is now assigned to a new DP master system.

The "Assign to new subnet" function works in a similar way in that it allows you to connect a DP slave to a new subnet. However, in this case, the DP slave will not be connected to an existing DP master system.

You can also make the assignment directly using the shortcut menu of the DP slave:

1. Right-click the DP slave.
2. From the shortcut menu, select "Assign new DP master/IO system".
3. Select the DP master from the list of available DP masters.

The selected DP slave has now been assigned to a new DP master system.

Note

If there is only one DP master on a subnet, you only have to connect the interface of the DP slave to the subnet of this DP master with drag-and-drop. The DP slave is then connected to the subnet of the DP master immediately, and the DP slave is assigned to this DP master.

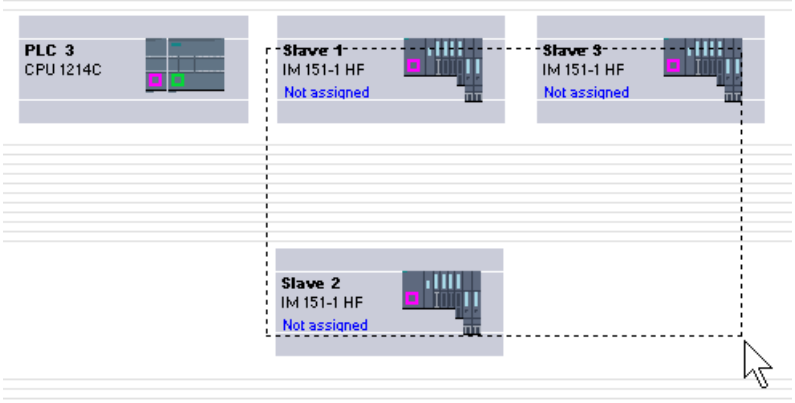
Configuring a DP slave

To configure a DP slave, follow these steps:

1. Switch to the DP slave's device view.
2. Select the module you want.
3. Configure the DP slave in the Inspector window.

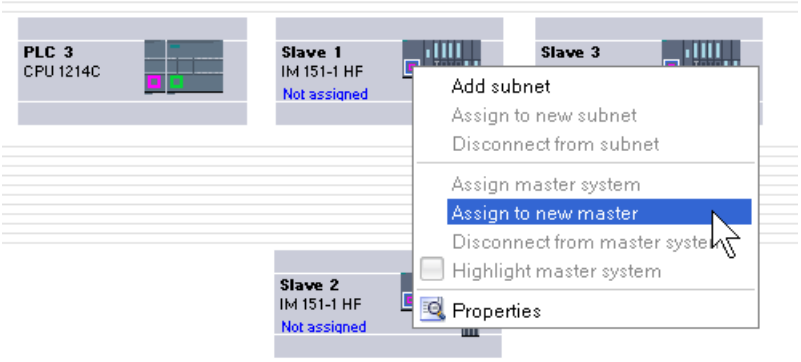
Hint: Quick configuration of master systems (S7-1200)

If the DP master system has several DP slaves, use drag-and-drop operation to assign to the master in one step all DP slaves that were placed.



Requirements

DP master and DP slaves are placed in the network view.



Assigning DP slaves to a DP master system

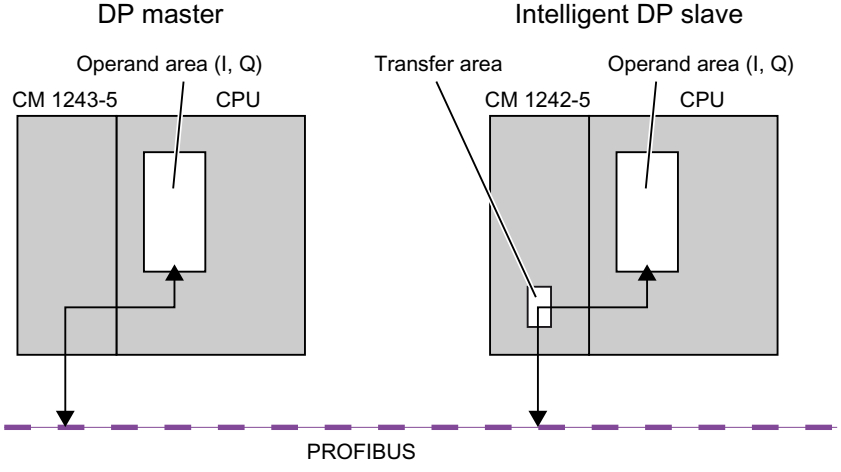
To do this, follow these steps:

1. Select an appropriate zoom factor so that you can see as many DP slaves as possible in the network view.
2. Arrange the DP slaves in a maximum of two rows.
3. Select all DP interfaces with the mouse cursor (not all devices!). This only works if you begin to drag the mouse cursor outside of the first DP slave and release the mouse button at the last DP slave (selection with the lasso).

4. Select the shortcut menu "Assign to new master" and select the corresponding DP interface for the DP master in the subsequent dialog.

5. The DP slaves are automatically networked with the DP master and combine with it to form a DP master system.

Note



When a DP master system is highlighted, you can double-click on a DP slave in the hardware catalog and thereby quickly add additional DP slaves. This will result in the DP slave being added to the highlighted DP master system automatically.

Configuring intelligent DP slaves (S7-1200)

Adding an I-slave to a DP master system (S7-1200)

Introduction

One of the characteristics of an intelligent DP slave (I-slave) is that the DP master is not provided with I/O data directly by a real I/O, but by a preprocessing CPU. Together with the CP, this preprocessing CPU forms the I-slave.

Difference: DP slave v. intelligent DP slave

In the case of a DP slave, the DP master accesses the distributed I/O directly.

In the case of an intelligent DP slave, the DP master actually accesses a transfer area in the I/O address space of the preprocessing CPU instead of accessing the connected I/O of the intelligent DP slave. The user program running on the preprocessing CPU is responsible for ensuring data exchange between the address area and I/O.

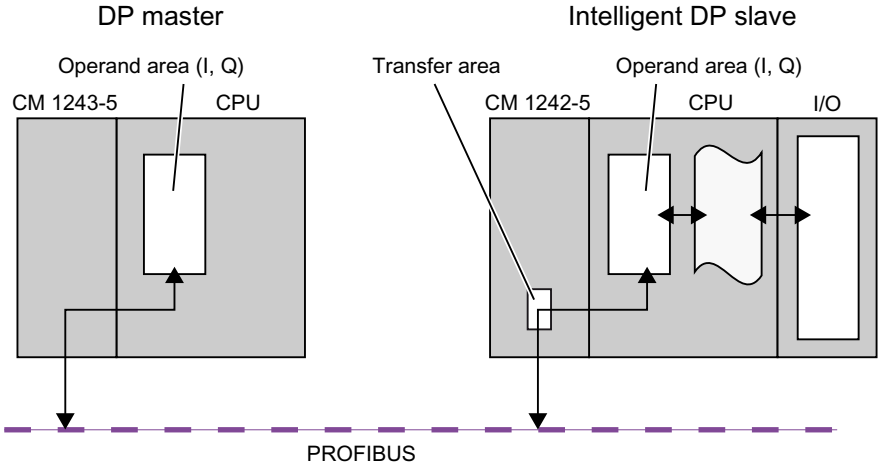
Note

The I/O areas configured for data exchange between the DP master and DP slaves must not be used by I/O modules.

Applications

Configurations involving intelligent DP slaves: I-slave <> DP master data exchange

Procedure



To add an I-slave to a DP master system, follow these steps:

1. In the network view, drag from the hardware catalog to a station one CM 1242-5 as an I-slave and one CM 1243-5 as a DP master.
2. Draw a connecting line between the DP interfaces of both devices.
   This way you connect the I-slave with a DP master in a DP master system.
   Result: You have now set up a DP master system with one DP master and one I-slave.

Configuring access to I slave data (S7-1200)

Data access

The following applies to the CP 1242-5 in its function as I-slave: The addresses for the data transfer area and the address for the I/O modules in the I-slave differ. This means that the start address occupied by an I/O module can no longer be used for the transfer memory. If the higher-level DP master is to access the data of an I/O module in the I-slave, you must configure this data exchange between the I/O module and transfer area in the I-slave user program.

Configuration of the transfer area for the CM 1242-5 (transfer area)

With CM 1242-5, the transfer area for the cyclic PROFIBUS data exchange is configured as transfer area in the parameter group "PROFIBUS interface > Mode > I Slave Communication".

Direct data access from CPU to CPU

Direct data access from CPU to CPU via PROFIBUS is supported by the S7-1200 PROFIBUS CMs only via the PUT/GET services.

Configuring DP slaves as distributed I/O devices (S7-1200)

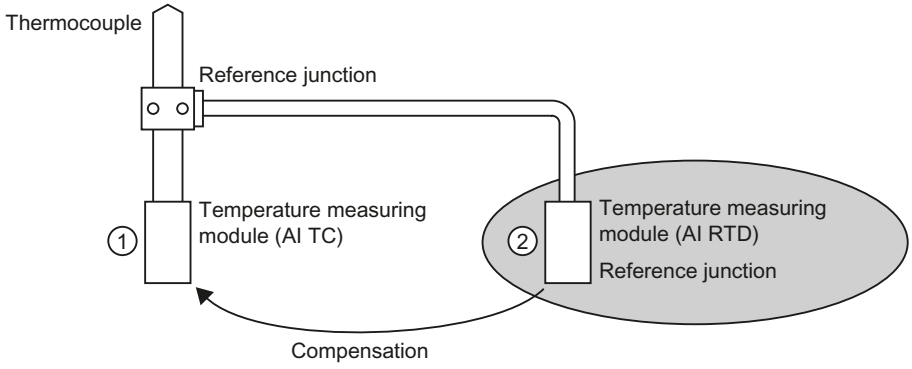
Configuring an ET 200S (S7-1200)

Slot rules for configuring an ET 200S

The following rules apply when configuring an ET 200S:

- Do not leave any gaps when inserting the ET 200S modules.
- Slot 1: only for PM-E or PM-D Power Modules.
- To the left of an Electronics Module (EM): an EM or a Power Module (PM-E or PM-D) only.

- To the left of Motor Starter (MS): an MS, a PM-D, PM-D Fx (1..x..4) Power Module or a PM-X Power Module only.
- To the left of a PM-X: a motor starter or a PM-D only
- Up to 63 modules and one IM Interface Module are permitted



Note

Remember to ensure that the correct PM-E and EM voltage ranges are assigned.

Configuring reference junctions

A reference junction is the connection of a thermocouple to a supply line (generally in the terminal box). The voltage that occurs due to the effects of temperature falsifies the temperature value measured by the module.

On the ET 200S, one channel of the AI RTD module can be programmed as a reference junction. Other AI TC modules can correct their measured values using the temperature at the reference junction as measured by this module.

① Configuring the AI TC:
→ Selection of the reference junction used

② Configuring of the AI RTD:
→ Activation of the reference junction
→ Specifying the slot and channel of the AI RTD

Special characteristics to be noted when assigning parameters for reference junctions

The process of assigning parameters for reference junctions will be explained based on the example of a resistance thermometer with a Pt 100 climatic range that is used for measuring the reference junction temperature.

To assign parameters for the reference junction, follow these steps:

1. In the ET 200S device view, insert an analog electronics module, for example a 2AI RTD HF.
2. Select the module on the rack.

3. Under "Properties > Inputs" in the inspector window, set a channel for the reference junctions function to the "RTD-4L Pt 100 climatic range" measuring range.
4. Select the ET 200S.
5. Under "Properties > Module parameters > Reference junctions" in the inspector window, select the "Reference junction" check box and specify the slot and channel number of the relevant RTD module.
6. Insert the analog electronics module for measuring the temperature using a thermocouple (TC module) and parameterize it with the reference junction number of the RTD module.

Additional information

For additional information on the various types and uses of ET 200S modules, please refer to the operating instructions and the manual titled "ET 200S Distributed I/O System".

For additional information on analog value processing, please see the documentation for the ET 200S distributed I/O system.

Packing addresses (S7-1200)

Introduction

DP slaves and I/O devices from the ET 200S family are configured in the same way as other modular DP slaves and I/O devices. As well as supporting all the standard modular DP slave and I/O device functions, the ET 200S also offers the "Pack addresses" function:

When digital electronics modules requiring an address space of 2 or 4 bits are inserted into the device view, they will initially be spread over a total area of 1 byte. However, the address area actually occupied can be compressed after configuration using the "Pack addresses" function.

	Initial state	After "Pack addresses"
Module	I address	I address
2DI (2-bit)	Byte 10	10.0...10.1
4DI (4-bit)	Byte 11	10.2...10.5

Requirements

- You are in the device view.
- An ET 200S, for example an IM 151-1, must be present.
- A pair of digital electronics modules, for example 2DI AC120V ST, must be inserted into the slots.

Packing addresses

To pack addressed, follow these steps:

1. Select the electronics modules whose addresses are to be packed. The following options are available for selecting multiple electronics modules:
   - Press and hold down <Shift> or <Ctrl> while clicking the relevant electronics modules.
   - Click off the rack and select the required electronics modules by drawing round them with the mouse.
2. Click "Pack addresses" in the shortcut menu for the selected electronics modules.

The address areas for inputs, outputs and motor starters are packed separately. The packed addresses will be displayed in the I address and Q address columns of the device overview.

How packed addresses are generated and structured

If you make use of the "Pack addresses" function, the addresses of the selected electronics modules will be packed in accordance with the following rules:

- The start of the address area is determined by the lowest address of the selected electronics modules: X.0
- If the bit address is not "0", then the next (free) byte address as of which the selected area can be compacted will be selected automatically: (X+n).0
- If no coherent area exists, the addresses will be automatically packed into any available address gaps.

Electronics modules with packed addresses and the same byte address form a packing group.

Unpacking addresses

To unpack addressed, follow these steps:

1. Select one or more electronics modules with packed addresses.
2. Click "Unpack addresses" in the shortcut menu for the selected electronics modules.

The packing groups of the selected electronics modules will be disbanded and the packed addresses for the relevant electronics modules unpacked.

The packing group will also be disbanded and the packed addresses unpacked in the following cases: if you delete electronics modules from a packing group, move electronics modules out of a packing group or insert electronics modules on a free slot within a packing group.

The start addresses of the unpacked electronics modules will be assigned to the next available byte addresses in each case.

Special characteristics of electronics modules with packed addresses

The following special characteristics apply to electronics modules with packed addresses:

- As far as the CPU is concerned, there is no way of assigning a slot for the electronics module. Consequently, the instruction GADR_LGC (SFC 5) outputs error information W#16#8099 "Slot not configured" for the actual slot of the electronic module.
- The instruction LGC_GADR (SFC 49) and SZL-ID W#16#xy91 "module status information" cannot be evaluated for an electronics module.
- The electronics module receives an additional diagnostics address via the DPV1 function, because otherwise the packed addresses would prevent interrupts from being assigned as far as the CPU is concerned.
- The "Insert/remove interrupt" is not possible. This is because the "Pack addresses" and "Insert/remove interrupt" functions are mutually exclusive.

Configuring option handling with standby modules (S7-1200)

You can use the option handling function to prepare the ET 200S with PROFIBUS interface for future expansions (options). This section describes option handling with standby modules.

You do this by assembling, wiring, configuring, and programming the maximum configuration envisaged for the ET 200S and by using cost-effective standby modules (138-4AA00 or 138-4AA10) during assembly until it becomes time to replace them with the necessary electronics modules.

Note

The ET 200S can be completely factory-wired with the master cabling, as no connection exists between a standby module and the terminals of the terminal module (and, in turn, to the process).

Requirement

- ET 200S interface module
  - IM 151-1 STANDARD (6ES7 151-1AA03-0AB0 or higher)
  - IM 151-1 FO STANDARD (6ES7 151-1AB02-0AB0 or higher)
- Power module with option handling
  - PM-E DC24..48V
  - PM-E DC24..48V/AC24..230V

Procedure

To activate option handling, follow these steps:

1. Select the IM 151-1 in the device view and enable it in "Option handling" check box under "Properties > General > Option handling" in the inspector window.
2. Select the numbered check boxes for the slots that are initially to accommodate the standby modules prior to the future electronics modules.
3. Select the power module in the device view and enable it in the "Option handling" check box under "Properties > Addresses" in the inspector window. Reserve the necessary address space for the control and check-back interface in the process image output (PIQ) and process image input (PII).

The assembled standby modules can be replaced with the configured modules at a later date without having to modify the configuration.

Note

The addresses for these interfaces are reserved as soon as you activate option handling on the power module. The "Option handling" function must also be activated on the DP slave (IM 151-1 STANDARD Interface Module). If it is not activated, the addresses reserved for the control and check-back interface will be released again.

Note that activating and deactivating the option handling function repeatedly can change the address of the control and check-back interface.

Option handling may be activated for one PM-E DC24..48V or one PM-E DC24..48V/ AC24..230V Power Module only.

Additional information

For additional information on the assignment and significance of bytes within the process image, option handling with PROFIBUS and the use of standby modules, please refer to the documentation for the ET 200S distributed I/O system.

How option handling works during startup

If "Startup when expected/actual config. differ" is not available, the ET 200S will still start up if a standby module is inserted instead of the configured electronics module and option handling has been activated for the slot concerned.

How option handling works during operation

During operation, the option handling mode varies in accordance with the following:

- Option handling enabled for a slot:
  Either the standby module (option) or the configured electronics module can be plugged into this slot. If any other kind of module is present on this slot, diagnostics will be signaled (no module/incorrect module).
- Option handling disabled for a slot:
  Only the configured electronics module can be plugged into this slot. If any other kind of module is present, diagnostics will be signaled (no module/incorrect module).

Standby module substitute values

- Substitute value for digital inputs: 0
- Substitute value for analog inputs: 0x7FFF

Control and evaluation in the user program

The ET 200S is equipped with a control and feedback interface for the "Option handling" function.

The control interface is located in the process image output (PIQ). Each bit in this address area controls one of the slots from 2 to 63:

- Bit value = 0: Option handling parameterized. Standby modules are permitted.
- Bit value = 1: Option handling canceled. Standby modules are not permitted on this slot.

The check-back interface is located in the process image input (PII). Each bit in this address area provides information about the modules that are actually plugged into slots 1 to 63:

- Bit value = 0: This slot has the standby module, an incorrect module or no module plugged into it.
- Bit value = 1: The configured module is plugged into this slot.

See also

Which modules support option handling? (http://support.automation.siemens.com/WW/view/en/22564754)

Configuring option handling without standby modules (S7-1200)

You can use the option handling function to prepare the ET 200S for future expansions (options) without installing standby modules. This section describes option handling without standby modules.

Note

ET 200S with PROFINET interface

This description refers to the ET 200S with PROFIBUS interface. In principle, option handling for ET 200S with PROFINET interface functions as described here without standby modules. PN interface modules are to be used instead of the DP interface modules listed here. You can find additional information about option handling for ET 200S with PROFINET interface in the corresponding manuals.

Requirement

- ET 200S interface module
  - IM 151-1 HIGH FEATURE (6ES7151-1BA02 or higher)
  - IM 151-1 STANDARD (6ES7 151-1AA05-0AB0 or higher)
- Power module with option handling
  - PM-E DC24..48V
  - PM-E DC24..48V/AC24..230V

Procedure

To activate option handling, follow these steps:

1. Select the IM 151-1 in the device view and enable it in "Option handling" check box under "Properties > General > Option handling" in the inspector window.
2. Select the power module in the device view and enable it in the "Option handling" check box under "Properties > Addresses" in the inspector window. Reserve the necessary address space for the control and check-back interface in the process image output (PIQ) and process image input (PII).
3. Configure the slave's maximum configuration. The selection/clearing of options is controlled via the user program.

   Note

   The addresses for these interfaces are reserved as soon as you activate option handling on the power module. The "Option handling" function must also be activated on the DP slave (IM 151-1 interface module). If it is not activated, the addresses reserved for the control and check-back interface will be released again.

   Note that activating and deactivating the option handling function repeatedly can change the address of the control and check-back interface.

   Option handling may be activated for one PM-E DC24..48V or one PM-E DC24..48V/ AC24..230V Power Module only.

Additional information

For additional information on the assignment and significance of bytes within the process image, option handling with PROFIBUS and the use of standby modules, please refer to the documentation for the ET 200S distributed I/O system.

Control and evaluation in the user program

The ET 200S is equipped with a control and feedback interface for the "Option handling" function.

The control interface is located in the process image output (PIQ). Each bit in this address area controls one of the slots from 1 to 63:

- Bit value = 0: Slot is not available in the actual configuration.
- Bit value = 1: Slot is available in the actual configuration.

The check-back interface is located in the process image input (PII). Each bit in this address area provides information about the modules that are actually plugged into slots 1 to 63:

- Bit value = 0: Slot belongs to an option that is not available or module status is faulty.
- Bit value = 1: The configured module is plugged into this slot.

Sample applications for ET 200S, option handling without standby module (http://support.automation.siemens.com/WW/view/en/29430270)

Configuring the ET 200S in DPV1 mode (S7-1200)

PROFIBUS DPV1 enables you to access extended PROFIBUS functions.

Requirement

- You must be in network view.
- A DP master with DPV1 functionality must be available.
- A master-slave connection must be established with PROFIBUS.

Procedure

To switch the DP slave over to DPV1, follow these steps:

1. Select the DP slave.
2. Under "Properties > Module parameters" in the Inspector window, select "DPV1" mode from the "DP interrupt mode" drop-down list.

or

1. Select the DP master.
2. In the I/O communications table, select the row with the connection between the DP master and the desired DP slave.
3. Under "Properties > Module parameters" in the Inspector window, select "DPV1" mode from the "DP interrupt mode" drop-down list.

Special characteristics

The parameters are subject to interdependencies, which are outlined below:

Parameter	DPV0 mode	DPV1 mode
Operation when target configuration does not match actual configuration	Fully available	Fully available
Diagnostics interrupt (OB 82)	Not available, not set	Fully available
Hardware interrupt (OB 40 to 47)	Not available, not set	Fully available
Insert/remove interrupt (OB 83)	Not available, not set	Only available when addresses are not packed. "Startup when target configuration does not match actual configuration" is activated automatically along with an insert/remove interrupt.

Interrupts in the case of modules with packed addresses

If the module is capable of triggering interrupts and the bit address is not equal to 0 because of packed addresses, you will need to assign a diagnostics address in the ET 200S address dialog.

The diagnostics address is required for the purpose of assigning a DPV1 interrupt to the module as an interrupt trigger. The CPU will only be able to assign an interrupt correctly and store information on the interrupt in the interrupt OB start information/in the diagnostics buffer if the module concerned has this "unpacked" address. In this context, the CPU cannot make use of "packed" addresses.

From the point of view of interrupt processing (interrupt OB), this means the module will have the assigned diagnostics address, but from the point of view of processing the input and output data in the user program, the module will have the packed addresses.

Note

When the module addresses are packed, the insert/remove interrupt for the ET 200S is unavailable.

Using GSD files (S7-1200)

GSD revisions (S7-1200)

What you need to know about GSD revisions

The properties of DP slaves are made available to configuration tools by means of GSD files. Functional enhancements in the area of the distributed I/O will have an effect on the GSD specification, for example, they will require the definition of new keywords. This results in the versioning of the specification. In the case of GSD files, the version of the specification on which a GSD file is based is called a "GSD revision". From GSD revision 1, the GSD revision must be included as a keyword "GSD_revision" in GSD files. GSD files without this keyword will therefore be interpreted by configuration tools as GSD revision "0".

GSD files can be interpreted up to GSD revision 5. This means that DP slaves that support the following functions, for example, will be supported:

- Diagnostic alarms for interrupt blocks
- Isochronous mode and constant bus cycle time
- SYNC/FREEZE
- Clock synchronization for DP slaves

Installing the GSD file (S7-1200)

Introduction

A GSD file (generic station description file) contains all the DP slave properties. If you want to configure a DP slave that does not appear in the hardware catalog, you must install the GSD file provided by the manufacturer. DP slaves installed via GSD files are displayed in the hardware catalog and can then be selected and configured.

Requirement

- The hardware and network editor is closed.
- You have access to the required GSD files in a directory on the hard disk.

Procedure

To install a GSD file, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. In the "Installed GSDs" tab, select the directory in which the GSD files are stored.
3. Choose one or more files from the list of displayed GSD files.
4. Click on the "Install" button. The selected GSD files are now being installed.

5. To create a log file for the installation, click on the "Save log file" button.
   Any problems during the installation can be tracked down using the log file.
6. Click "Close". You will be notified that the DP slaves from the installed GSD files are entered into the hardware catalog. This process can take a few seconds.

By installing a GSD file you have added the DP slave described in the file to the hardware catalog.

Result

You will find the new DP slaves installed by means of GSD files in the hardware catalog under "Additional field devices > PROFIBUS DP".

GSD files are always saved together with the project, which means all information relevant for display of the device (including symbols) is also available in the saved project.

See also

Overview of hardware and network editor (Page 525)

Deleting GSD file (S7-1200)

Introduction

You can delete installed DP slaves using GSD files. These DP slaves are then no longer displayed in the hardware catalog.

Requirement

- The hardware and network editor is closed.
- The hardware catalog contains DP slaves installed using GSD files.

Procedure

To delete a GSD file, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. In the "Installed GSDs" tab, select the directory in which the GSD file is stored.
3. Select the file that is to be deleted from the list of displayed GSD files.
4. Click the "Delete" button.

The selected GSD file was deleted and the DP slave is no longer located in the hardware catalog.

Finding unused GSD files (S7-1200)

Introduction

When you add a GSD-based hardware component to your hardware configuration, different GSD files are added to the project data. If the GSD-based hardware component is once again deleted from the configuration, the GSD files remain in the data inventory of the project. The GSD files are no longer needed in the project if the corresponding GSD-based hardware component is not used in the hardware configuration again. You can find files that are no longer needed in the project with a search function and delete them.

Requirement

- A project must be open.
- The project must not be online.
- The project must not be write-protected.

Procedure

To find and delete unused GSD files, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. Click on the "Find unused GSDs" button in the "GSDs in the project" tab.

   Note

   Unused GSD files are only available if at least one GSD-based hardware component was added to the configuration and then removed from the configuration. Unused GSD files in the project libraries are included in the search. GSD-based hardware components that are still being used in the configuration are not considered to be unused.

   Installed GSD-based hardware components that are included in the hardware catalog but have not been used in the hardware configuration of the project yet, could not have stored unused GSD data in the project.

3. If GSD files that are no longer needed were found in the project data, you can now delete them. To do so, click the "Delete" button.

GSD files that are no longer needed are deleted from the project data. The GSD-based hardware component is still available in the hardware catalog and, if necessary, can be added to the configuration once again. The necessary GSD data are once again copied to the project data in this case.

Note

If you delete a GSD-based hardware component with "Options > Manage general station description files (GSD) > Installed GSDs", it is deleted from the hardware catalog. However, unused GSD files of this hardware component can still be a part of the project data and can be deleted with the function for finding the unused GSD files.

NOTICE
Actions that cannot be undone When you delete GSD files that are not being used as an action, the action stack for actions that can be undone is deleted. This means the action of deleting unused GSD files as well as all previous actions can no longer be undone.

Basics of undoing and redoing actions (Page 316)

Configuring GSD-based DP slave (S7-1200)

DP slaves that you have inserted through installation of a GSD file can be selected as usual via the hardware catalog and inserted in the network view. If you want to insert the modules of the GSD-based DP slaves, you must take into account some particular details.

Requirement

- You have installed a DP slave using a GSD file.
- You have inserted the head module in the network view in the usual manner.
- The device overview opens in the device view.
- The hardware catalog is open.

Procedure

To add the modules of a GSD-based DP slave, proceed as follows:

1. In the hardware catalog, navigate to the modules of the GSD-based DP slave.
   GSD-based DP slaves, also referred to as DP standard slaves, can be found in the "Other field devices" folder of the hardware catalog.
2. Select the desired module.
3. Use drag-and-drop to move the module to a free space in the device overview.
4. Select the module in the device overview to edit parameters.

You have now inserted the module in a free slot of the GSD-based DP slave and can edit its parameters.

Note

You can see only the GSD-based DP slave in the graphic area of the device view. The added modules of GSD-based DP slaves are only found in the device overview.

Preset configuration

For modules with an adjustable preset configuration, you can change this configuration in the inspector window under "Properties > Preset configuration".

10.1.4.7 Configuring PROFINET IO

What you need to know about PROFINET IO

What is PROFINET IO?

PROFINET IO

PROFINET is an Ethernet-based automation standard of PROFIBUS Nutzerorganisation e.V. (PNO) which defines a manufacturer-neutral communication, automation and engineering model.

Objective

The objective of PROFINET is:

- Integrated communication via field bus and Ethernet
- Open, distributed automation
- Use of open standards

Architecture

The PROFIBUS User Organisation e.V. (PNO) has designated the following aspects for PROFINET architecture:

- Communication between controllers as components within distributed systems.
- Communication between field devices, such as I/O devices and drives.

Implementation by Siemens

The demand for "Communication between controllers as components within distributed systems" is implemented by "Component Based Automation" (CBA). Component Based Automation is used to create a distributed automation solution based on prefabricated components and partial solutions.

The demand for "Communication between field devices" is implemented by Siemens with "PROFINET IO". Just as with PROFIBUS DP, the complete configuration and programming of the components involved is possible using the Totally Integrated Automation Portal.

The following sections deal with the configuration of communication between field devices using PROFINET IO.

Overview of RT classes

RT classes in PROFINET IO

PROFINET IO is a scalable, real-time communication system based on Ethernet technology. The scalable approach is reflected in several real-time classes:

- **RT:** Transmission of data in prioritized, non-isochronous Ethernet frames. The required bandwidth is within the free bandwidth area for TCP/IP communication.
- **IRT:** Isochronous transmission of data with high stability for time-critical applications (for example, motion control). The required bandwidth is from the area of bandwidth reserved for cyclic data.

Depending on the device, not all real-time classes are supported.

Which IO controllers and IO devices support which PROFINET functions?

Additional information and overviews

In the following Siemens Industry Online Support article (http://support.automation.siemens.com/WW/view/en/44383954), you will find an overview of the PROFINET IO controllers and IO devices that support the following PROFINET functions:

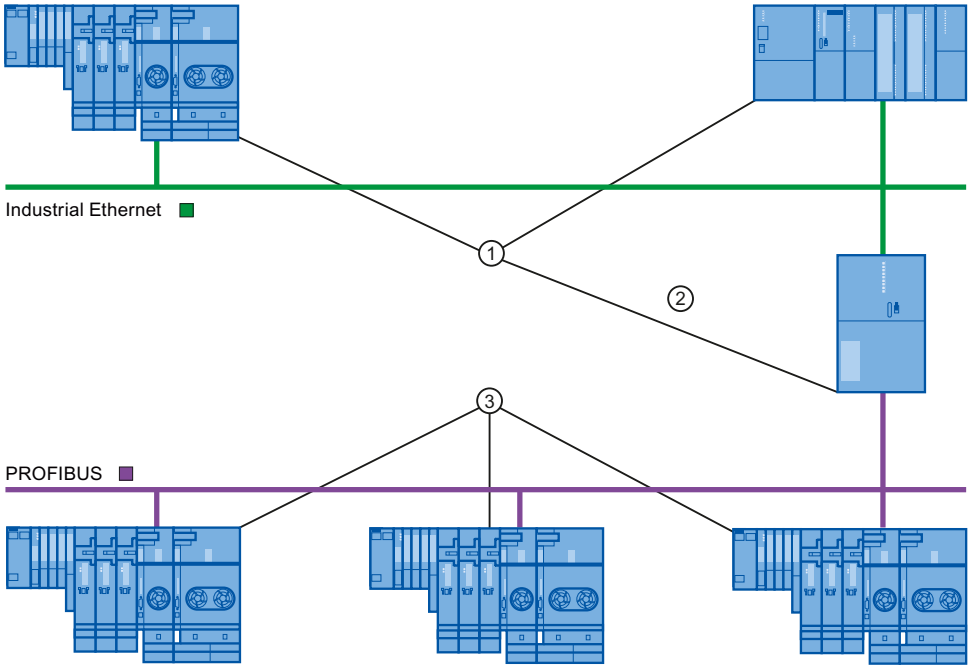
- Isochronous real-time communication (IRT)
- Prioritized startup
- Media redundancy (MRP)
- PROFIenergy
- Shared device
- I-device
- Isochronous mode of process data

The functions are explained in the following sections, but without naming the respective hardware that supports these functions.

In the hardware catalog, you can also find an overview of the supported functions in the description below the selected components.

You can also find a description of PROFINET in the respective current STEP 7 version here (http://support.automation.siemens.com/WW/view/en/49948856).

Connecting existing bus systems



Connection of PROFINET and PROFIBUS

PROFINET IO and PROFIBUS DP can be connected with each other as follows:

- via Industrial Ethernet:
  To connect the two network types, Industrial Ethernet (plant control level) and PROFIBUS (cell level/field level), use the IE/PB link, for example.
- via Industrial Wireless LAN:
  PROFIBUS devices, for example, can be connected to PROFINET IO via a wireless LAN/PB link. This allows existing PROFIBUS configurations to be integrated into PROFINET.

AS interface devices can be connected by an IE/AS-i link PN IO to the interface of a PROFINET device. This allows the existing AS-i network to be integrated into PROFINET.

The following figure shows the connection of a PROFIBUS subnet via a PROFINET device with proxy functions.

① PROFINET devices
② PROFINET device with proxy functions (for example, IE/PB link)
③ PROFIBUS devices

PROFINET device with proxy functions used as proxy for a PROFIBUS device

The PROFINET device with proxy functions is the proxy for a PROFIBUS device on the Ethernet. The proxy functionality enables a PROFIBUS device to communicate with all devices on the PROFINET and not just with its master.

Existing PROFIBUS systems can easily be integrated into PROFINET communication using the proxy functions.

If, for instance, you connect a PROFIBUS device via an IE/PB link to PROFINET, the IE/PB link acts as a proxy for the PROFIBUS components for communicating via PROFINET.

Configuration using IE/PB link PN IO

Configuration using IE/PB Link PN IO

You can use the IE/PB Link PN IO to connect PROFIBUS DP configurations to PROFINET IO.

From the CPU perspective, the PROFIBUS DP slaves are connected to the same network as the IE/PB Link PN IO. These slaves have the same device name and IP address as the IE/PB Link PN IO, but different device numbers. Furthermore, each also has a specific PROFIBUS address.

In the properties of the IE/PB link, the PROFIBUS addresses of the connected DP slaves are displayed in addition to the PROFINET device numbers, as this device has two addressing schemes.

Handling device numbers and PROFIBUS addresses on the master system

During placement, the same number is assigned for the PROFINET device number and the PROFIBUS address.

In the Inspector window under "General Properties > PROFINET device number", you can find an overview of the device numbers used and the PROFIBUS addresses of an IE/PB link. The device number can also be changed here. You can also set that the device number and the PROFIBUS address should or should not always be identical. If the "PROFINET device number=PROFIBUS address" option is activated, you do not have to update the device number when the PROFIBUS address changes.

The PROFIBUS address can be changed in the properties of the PROFIBUS device.

Restrictions

The following restrictions apply to DP slaves configured as described above on the PROFIBUS subnet of an IE/PB link:

- No pluggable IE/PB link
- No pluggable DP/PA link
- No pluggable Y link
- Not CiR-compliant
- No pluggable redundant slaves
- No isochronous transmission / constant bus cycle time can be configured
- SYNC/FREEZE instructions ("DPSYC_FR") of a CPU on the the Ethernet subnet for DP slaves behind the IE/PB-Link are not supported.

See also

Connect the DP slave via the IE/PB Link to a PROFINET IO system (Page 1800)

Configuration using IWLAN/PN link

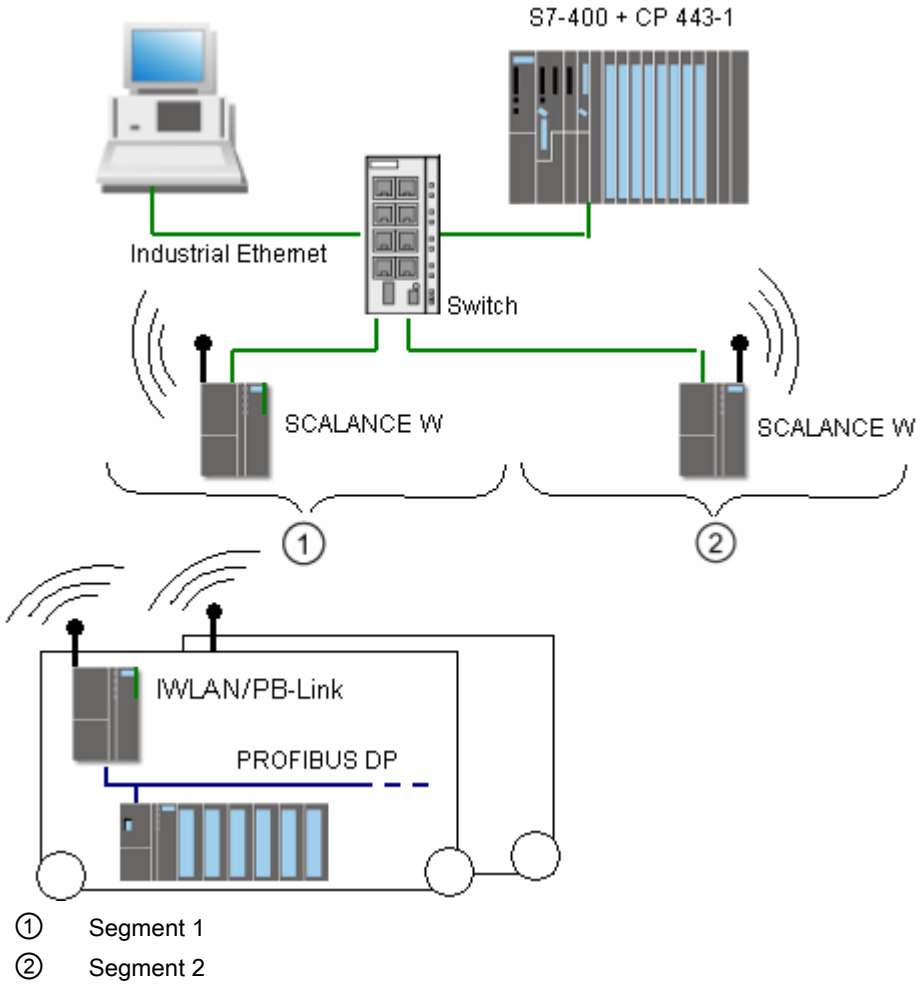
Maximum number of devices in a IWLAN segment

If an Ethernet subnet is set up as wireless network (IWLAN = Industrial Wireless LAN), cyclic data exchange between IO controllers and IO devices is possible via a wireless route.

On one side of the wireless route there are fixed installed access points (for example, SCALANCE W 788) and on the other side mobile stations (with, for example IWLAN/PB links with PROFIBUS devices).

If the action radius of the mobile stations is large, it may be necessary to install several access points (SCALANCE W 788). Since each access point forms a segment with its wireless range, the IWLAN is made up of a series of segments.

The mobile devices "on the one side" of the wireless link with their IWLAN/PB links can move along the segments.



Special feature

If several IWLAN/PB links are located within a segment, they have to share the bandwidth that is available for wireless transmission. This leads to a lengthening of the update time for these devices.

Example

In the following example there are two IO devices (IWLAN/PB link) with a segment.

If no more than a maximum of two IWLAN/PB links are present in a IWLAN segment at the same time, enter a "2".

① Segment 1
② Segment 2

Configure PROFINET IO

Addressing PROFINET devices

Assigning addresses and names to PROFINET devices

In this chapter you will learn which address and naming conventions are valid for the PROFINET devices.

IP addresses

All PROFINET devices work with the TCP/IP protocol and therefore require an IP address for Ethernet operation.

You can set the IP addresses in the module properties. If the network is part of an existing company Ethernet network, ask your network administrator for this data.

The IP addresses of the IO devices are assigned automatically, usually at CPU startup. The IP addresses of the IO devices always have the same subnet mask as the IO controller and are assigned in ascending order, starting at the IP address of the IO controller.

Device names

Before an IO device can be addressed by an IO controller, it must have a device name. This procedure was chosen for PROFINET because names are easier to administer than complex IP addresses.

Both the IO controller as well as IO devices have a device name. When the "Generate PROFINET device name automatically" option is activated, the device name is automatically derived from the name configured for the device (CPU, CP or IM):

- The PROFINET device name is made up of the name of the device (for example, the CPU), the name of the interface (only with multiple PROFINET interfaces) and optionally the name of the IO system:
  <CPU name>.<Name of the interface>.<IO system name>
  You cannot change this name directly. You change the PROFINET device name indirectly, by changing the name of the affected CPU, CP or IM in the general properties of the module. This PROFINET device name is also displayed, for example, in the list of accessible devices. If you want to set the PROFINET device name independently of the module name, you have to deactivate the "Generate PROFINET device name automatically" option.
- A "converted name" is generated from the PROFINET device name. This is the device name that is actually loaded into the device.
  The PROFINET device name is only converted if it does not comply to the rules of IEC 61158-6-10. You cannot change this name directly either.

Rules for the converted name

The rules for the converted name are listed in the following section. If the converted name is **not** different from the name of the module, the name of the module must comply with this rule.

- The name consists of one or more labels , which are separated by a dot [.].
- Restricted to a total of 240 characters (lower case letters, numbers, dash, or dot)
- A name component within the device name, which means a character string between two dots, must not exceed 63 characters.
- A name component consists of the characters [a-z, 0-9].
- The device name must not begin or end with the "-" character.
- The device name must not begin with a number.
- The device name form n.n.n.n (n = 0, ... 999) is not permitted.
- The device name must not begin with the string "port-xyz" or "port-xyz-abcde" (a, b, c, d, e, x, y, z = 0, ... 9).

Example of device names

```
device-1.machine-1.plant-1.vendor
```

If you assign this name to a CPU, for example, STEP 7 will not convert it since it conforms to the rules described above.

Device number

In addition to the device name, a device number is also automatically assigned when an IO device is plugged in. You can change this number.

Devices in the PROFINET subnet

In a PROFINET subnet the maximum allowable number of devices is monitored during configuration.

See also

Assigning the device name and IP address (Page 1769)

Retentivity of IP address parameters and device names (Page 1779)

Assigning the device name and IP address

Assigning an IP address and subnet mask for an IO controller the first time

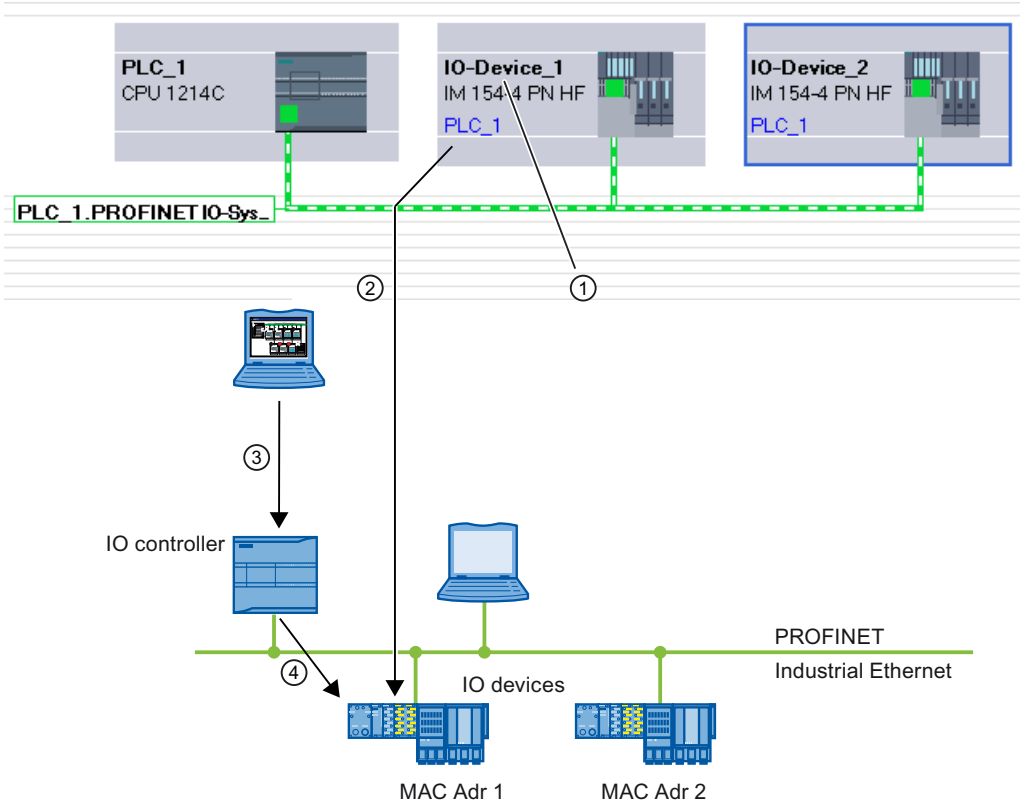
There are various options for this.

During parameter assignment of the PROFINET interface you must specify if the IP address is set in the project (which means in the hardware configuration) or if the IP address is to be set on the device.

Assignment of an IP address	Comments
Option "IP address is set in the project": The IO controller receives the IP address by loading the hardware configuration, for example, via one of the PROFINET interfaces, by means of the PROFIBUS interface or via the MPI interface.	When the hardware configuration is loaded to the IO controller (e.g. CPU), the IP address and the device name, if set, are also loaded. Example PROFINET interface: 1. Connect your programming device/PC to the same network as the relevant PROFINET device. The interface of the PG/PC must be set to TCP/IP (Auto) mode. 2. Have a list of accessible devices displayed. 3. Select the target device by using its MAC address and load the hardware configuration including the configured IP address (IP address is then saved retentively). If your PROFINET device has an MPI or PROFIBUS DP interface, connect your programming device/PC directly to the PROFINET device via the MPI or PROFIBUS DP interface. The configured IP address is applied when the hardware configuration is loaded.
Option "IP address is set directly at the device": • Assign online • Assignment by user program (instruction IP_CONFIG for S7-300/400, T_CONFIG for S7-1200/1500) • Assign via CPU display (S7-1500) • Higher-level IO controller makes assignment (only with I-devices)	If you have selected this option in the properties of the PROFINET interface, the IP address can be assigned by the online and diagnostics editor, by the primary setup tool, or by the user program ("IP_CONFIG" instruction). This option is set automatically if the option "Multiple use IO system" has been enabled in the properties of the PROFINET IO system (standard machine project). In case of an S7-1200-CPU, make sure that access to the CPU is not protected by a password. If the CPU is write-protected, no IP address and no device name can be assigned directly on the device.

Commissioning a PROFINET interface

Further details of how to commission a PROFINET interface can also be found in the operating instructions for the PROFINET devices of the SIMATIC family.



Assignment of device name for IO devices when the "Support device replacement without exchangeable medium" option is selected

For IO controllers with the "Support device replacement without exchangeable medium" option selected, you do not have to assign device names to the IO devices locally, for example in the event of device replacement. Another application is automatic commissioning, in which the CPU automatically assigns the device name and IP address parameters to the IO devices during startup.

Requirement: The ports of the devices are interconnected, and the devices involved support LLDP. The devices have been put into the delivery state or – for S7-1500 CPUs version V1.5 and higher – the "Permit overwriting of device names of all assigned IO devices" option is selected for the IO controller ("Advanced options > Interface options" area of the properties of the PROFINET interface).

Assignment of device name and address for an IO device

The following graphic illustrates the process for assigning the device name and address. This process does not apply when the "Support device replacement without exchangeable medium" option is selected.

① Each device receives a name; STEP 7 automatically assigns an IP address.

② From the name, STEP 7 generates a PROFINET device name that you assign to an IO device online (MAC address) and that is written to the device.

③ You load the configuration to the IO controller.

④ The IO controller assigns the appropriate IP address to the IO device with the assigned PROFINET device name during startup.

Changing the device name and IP address

You can change the name and IP address manually. The device name must first be changed in the configuration in order to subsequently assign it to the IO device via the memory card or online with programming device/PC.

Offline with memory card:

1. Place the configured data (device name: for example, turbo-3) for the IO device on the MMC in the PG/PC. Use the command "SIMATIC Card Reader > Save Device Name to Memory Card" in the "Project" menu for this.
2. Then insert the MMC into the IO device. The IO device automatically adopts the configured device name.

Online with programming device/PC:

1. Connect the programming device/PC directly to the Ethernet subnetwork via the PROFINET interface.
2. In the network view, select the subnet or I/O device, and click the "Assign device name" command:
   - Either in the shortcut menu of the selected subnet / I/O device or
   - in the menu bar of the graphic view on the corresponding button.
3. In the "Assign PROFINET device name" dialog box, select the suitable PG/PC interface to connect to the Ethernet subnet. All configured PROFINET device names are in the top drop-down list. Select a PROFINET device name from it and select the IO device to receive this device name from the table at the bottom. You can filter the display of devices in the table according to various criteria.
4. You can easily identify the device using the "Flash LED" button.
5. Click "Assign name".

The IO controller recognizes the IO device by its device name and automatically assigns the configured IP address to it.

IP address assignment for special IO devices

Special IO devices, for example, SCALANCE X, S7-300 CPs, support the option of assigning the IP addresses not from the IO controller during startup. In this case, the IP address is assigned in a different way. The option is called "IP address is set directly at the device". For additional information, refer to the manual of the respective PROFINET device of the SIMATIC device family.

Another special case is the option "IP address is set directly at the device" in the "IP protocol" area of the Ethernet address properties of an IO device. This option is set automatically when the option "Multiple use IO system" is selected for a standard machine project in the associated PROFINET IO system. In this case, an adapted IP address is not assigned by the IO controller until the IO controller itself has received a local IP address.

Requirement for additional procedures when assigning IP address and device name

If the IO device, as described above, should not obtain the IP address or device name from the IO controller, proceed as follows:

1. Select device or network view.
2. Open the properties of the respective PROFINET device and select the area "PROFINET interface [X1]" > "Ethernet addresses".
3. Select the option "IP address is set directly at the device" under "IP protocol" or the option "PROFINET device name is set directly at the device" under "PROFINET".

Rules

If the "IP address/device name is set directly at the device" option is used for a PROFINET device, note the following:

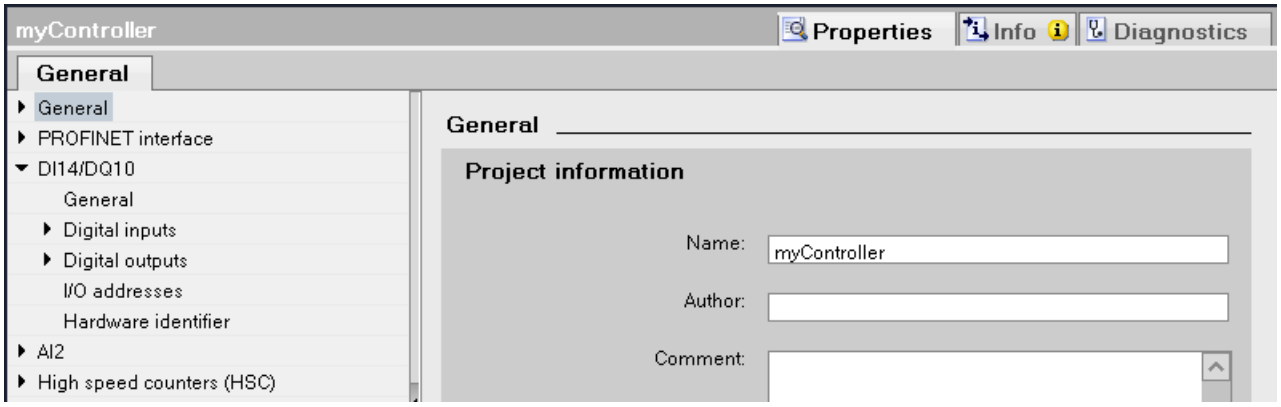
- The subnet part of the IP address of the IO device must match the subnet part of the IP address of the IO controller.
- The corresponding PROFINET device cannot be used as a gateway.

See also

Enabling device replacement without exchangeable medium (Page 1798)

Example of the assignment of the device name

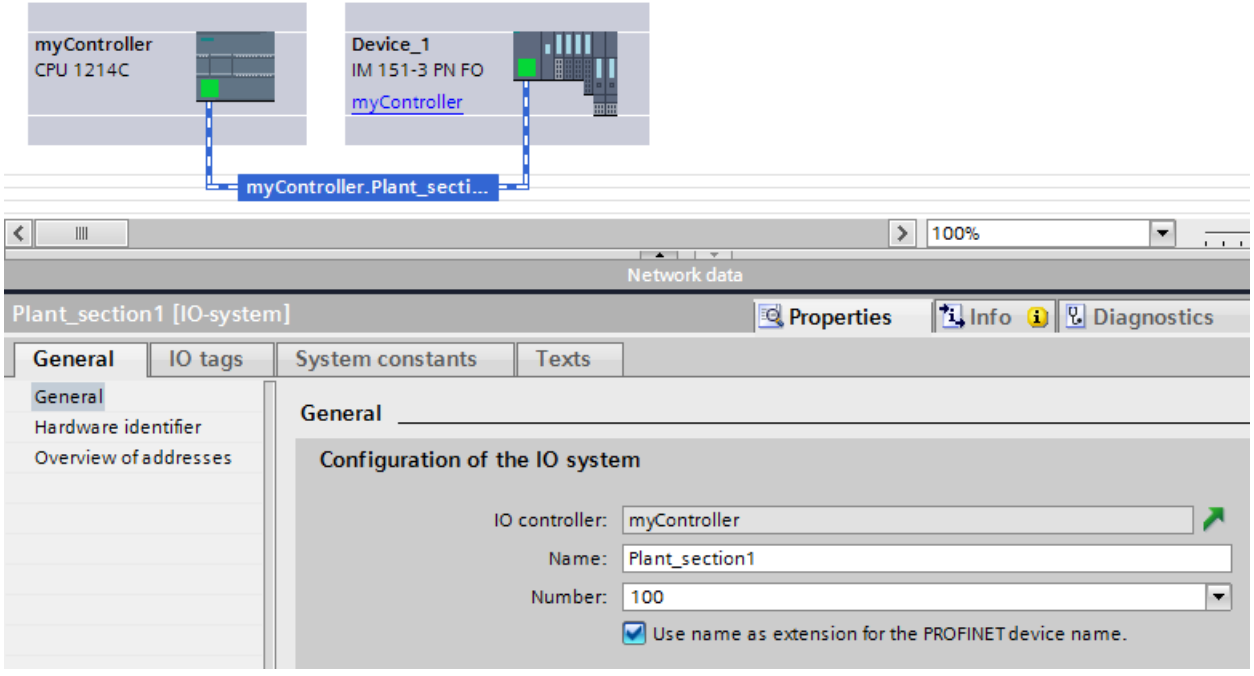
In this example you assign device names to a PROFINET IO controller and a PROFINET IO device. To make assignment easier, the device names should also contain the names of the PROFINET IO system.



Requirement

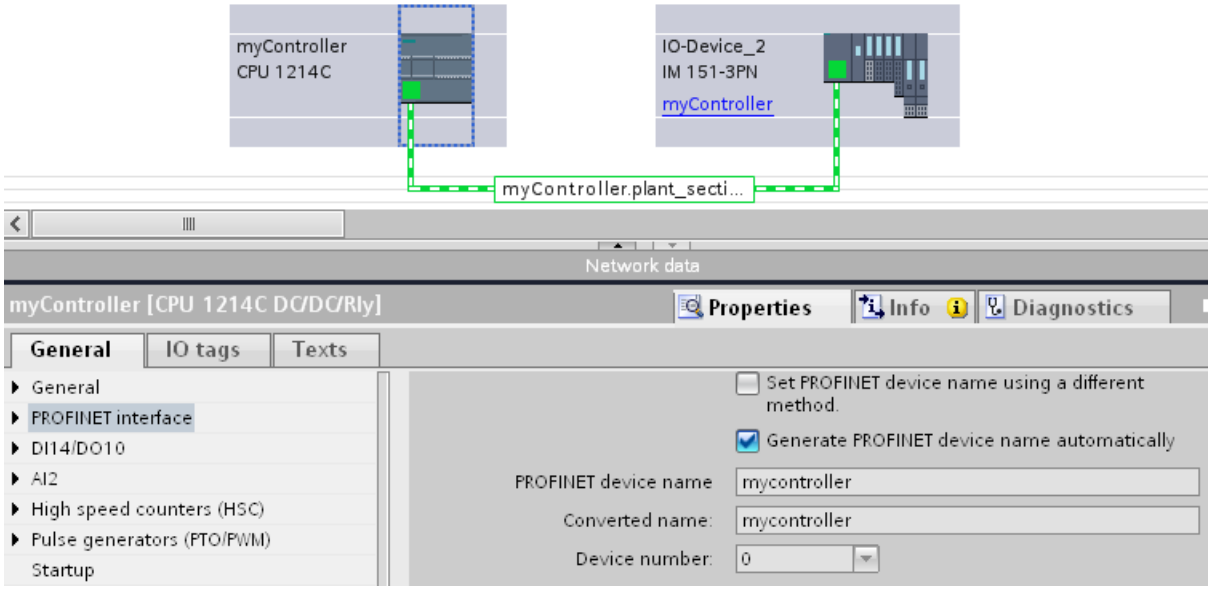
- You must be in the network view.
- A CPU 1214C (V2.0 or higher) must be available in the network view.
- An interface module IM 151-3PN exists.
- The PROFINET interfaces of both modules are networked.

Procedure



To assign the names, follow these steps:

1. Select the CPU.
   Make sure that you have selected only the CPU and not the complete device!
2. Assign the name "myController" in the Inspector window, under "General".



3. Select the interface module.
   Ensure that you have selected only the interface module and not the complete ET 200S device.
4. Assign the name "Device_1" in the Inspector window, under "General".
5. Right-click on the PROFINET IO system and select the "Properties" command.

6. Assign the name "Plant_section1" to the IO system and select the check box "Use name as extension for PROFINET device names".

7. You can find the automatically generated PROFINET device names at the selected device in the Inspector window, at "PROFINET interface".

The PROFINET device name corresponds to the name of the module (with the name of the IO system as extension) with the difference that only lower case text is used. Background: No distinction is made between upper and lower case ("case insensitive") for the storing of the name.

If you want to specify the device name independently of the module name, you have to deactivate the "Generate PROFINET device name automatically" option. The PROFINET device name can be edited in this case.
The converted name is displayed below. This is the name that is automatically generated from the PROFINET device name and satisfies the DNS conventions. If you work with STEP 7, you do not require this name. This name is displayed here as a check and corresponds to the name that is stored in the device. If you work with other tools that are able to record the data exchange and read the actual device names, then you find the converted names.

Other special features

For PROFINET devices with multiple PROFINET interfaces, the name of the interface is attached to the name of the module, separated by a dot.

Example:

- Name of the module: myController
- Name of the interface: Interface_1
- PROFINET device name: mycontroller.interface_1

Assign device name via communication table

Introduction

You can assign the device names of PROFINET IO devices configured offline to the devices online. You can do this in the table area of the network view in the table "I/O communication". You can also assign the device names to several devices at the same time.

"Online assignment" tab

In the I/O communication table, you will find the tabs "Offline configuration" and "Online assignment". In the "Online assignment" tab, you can assign the PROFINET device names that were assigned offline to the corresponding IO devices online. To do this, use the buttons "Check devices" and "Assign now".

The objects displayed in the table of the "Online assignment" tab depend on the setting of the filter function. If only selected objects should be displayed, only objects of the corresponding context are displayed depending on the selection in the network view.

- PROFINET subnet: All connected devices and their PROFINET interfaces
- IO system All devices involved and their PROFINET interfaces
- Sync domain: All devices involved and their PROFINET interfaces
- Devices: The device and any existing PROFINET interfaces
- Other subnets or interfaces such as MPI or PROFIBUS are not displayed

If the display is set for all devices using the filter function, all devices are displayed that have a PROFINET interface, regardless of whether they are connected via a PROFINET subnet or are part of an IO system. Devices without a PROFINET interface, for example only with a DP or MPI interface, are not displayed.

General procedure

To assign PROFINET device names, you must first detect the IO devices available online. With this procedure, it matters whether the MAC addresses are known or unknown. This results in a general procedure in two steps:

1. Detecting the IO devices available online
2. Assigning configured PROFINET device names to the IO devices available online

Requirements

- You are in the network view.
- There is an online connection to the devices.

Procedure (step 1)

To detect IO devices available online from the I/O communication table, follow these steps:

1. Optional: Entered known MAC addresses in the "MAC address" column. After every valid entry, the check box under "Assign device" is selected for the relevant row.

   Note

   You can enter, insert or import the MAC address in different formats. The correct format is automatically entered in the cell. The following entries are supported and then converted to the required format:

   - "08:00:06:BA:1F:20"
   - "08 00 06 BA 1F 20"
   - "080006BA1F20"

   The formats used in the example are automatically converted to "08-00-06-BA-1F-20".

2. Click "Check devices" to start the check of the IO devices available online.
3. Set the PG/PC interface in the dialog window and click "Start".

Intermediate result

After the check, the result is displayed for every device in the table. Online data found is automatically entered in the table and the check box "Assign device" is set to "checked" in the rows in which a MAC address was entered or found online. The result of the check is shown as an icon in the "Status" column.

Status	Meaning
	Agreement: Matching device and compatible type. The PROFINET device name and the device type of the device found online matches the device in the project. No action is required.
	Ready for assignment: The device type of the device found online matches the device in the project. With a known MAC address the device is ready for the assignment of the PROFINET device name.
	Different device type: A matching device was found online, but the device type does not match the device type in the project. Please select a device with a matching device type online.

Status	Meaning
	Different device: No device could be found online that uniquely matches the device in the project. Please select a matching device manually.
	Device cannot be accessed: With a known MAC address the device cannot be accessed online. Please check the connection to the device.

Note

The icon "Ready for assignment" appears when a MAC address exists and matching device data was found, but no PROFINET device name was found online.

You can update the data of the detected devices again via their MAC addresses at any time. To do this, you specify the MAC address and the status of the device is displayed immediately without having to re-detect the device.

Procedure (step 2)

All PROFINET device names configured offline will be assigned to the devices available online in a bulk operation.

1. Click the "Assign now" button.

   Note

   The bulk operation cannot be reversed. A message to this effect appears in a dialog window.

2. Click "Start" in the dialog window to start the assignment of the PROFINET device names.

Result

The PROFINET device names configured offline will be assigned to the devices available online. This relates to devices in whose row the check box under "Assign device" is selected, that have a MAC address and have the status "Ready for assignment".

Importing and exporting data

Using the import and export button, you can import or export the data of the I/O communication table for the online assignment:

- When you export, the currently displayed data of the table is exported to a CSV file. Using the filter function of the table, you can select which data will be exported.
- When you import, the data of the CSV file is written to the table. If there are conflicts with values already existing in the table, you can decide whether the data should be overwritten or whether the import needs to be stopped.

Assign device name via memory card

Introduction

You can configure the device names of PROFINET IO devices offline. To do this, store a configured device name on a memory card and then insert the card into the appropriate IO device.

If an IO device has to be completely replaced due to a device defect, the IO controller automatically reconfigures the new device. Using the memory card, a device can be replaced without a programming device.

Requirements

- The programming device has a card reader for memory cards.
- The IO device must support the assignment of the device name via memory card.
- The station and its PROFINET IO system is configured.

Procedure

To store a device name on a memory card, follow these steps:

1. Insert the memory card into the card reader.
2. Select the IO device whose device name is to be assigned by the memory card.
3. Select the "Card reader > Save Device Name to Memory Card" command in the "Project" menu.
   If the memory card is not empty, a message will be issued informing you of this and you will have the option to delete the card.

Retentivity of IP address parameters and device names

The retentivity of IP address parameters (IP address, subnet mask, router setting) and device name depends on how the address is assigned.

The non-retentive, temporary assignment means:

- IP address parameters and device name remain valid for the following time period:
  - Until the next POWER OFF
  - Until the next memory reset
  - Until termination of the online connection (for example, after loading the program)
    After POWER OFF / POWER ON or a memory reset, the CPU can only be accessed via the MAC address.

If the IP address parameters are not retentive, communication based on the IP protocol can no longer take place after the above described events (for example, after POWER OFF/ POWER ON).

The assignment of a temporary IP address also deletes retentively saved IP address parameters.

Assigning IP address parameters and device name non-retentively

IP address parameters and device name are not retentive in the following cases:

- A temporary IP address that is not retentive is implicitly assigned with the "Accessible devices" function, if the device (e.g. CPU) does not yet have an IP address.
- The device is a "normal" IO controller (i.e., not an I-device), and it is specified in the user program ("IP_Conf" instruction) that the IP address parameters/device name are not to be retentive.

Assigning IP address parameters and device name retentively

IP address parameters and device name are retentive in the following cases:

- In the properties of the PROFINET interface, it is specified that the IP address parameters are set in the project ("Set IP address in the project" option).
- In the properties of the PROFINET interface, it is specified that the IP address is to be set on the device.
  - Once the configuration is loaded, the IP address parameters and the device name are assigned via STEP 7 or a setup tool such as PST (STEP 7: online and diagnostic function "Assign IP address"). The assigned IP address parameters are retentive.
  - The device is a "normal" IO controller (i.e., not an I-device), and it is specified in the user program ("IP_Conf" instruction) that the IP address parameters/device name are to be retentive.

Special features of the I-device

In the properties of the PROFINET interface of the I-device, it is specified that the IP address parameters are to be set on the device. The IP address parameters for the I-device are assigned by the higher-level IO controller.

- If prioritized startup is set, the IP address parameters are retentive.
- If no prioritized startup is set, the IP address parameters are not retentive.

Recommendation

If possible, use the "Set IP address in project" option and specify an appropriate IP address. In this case, the IP address is assigned retentively.

Resetting of retentive IP address parameters and device names

Retentive IP address parameters and device names are reset via the online and diagnostic function "Reset to factory settings".

Note

Consequences of reassignment of IP address parameters on top of existing IP parameters

- The temporary assignment of IP address parameters/device names results in a reset of any retentively saved IP address parameters/device names.
- With a fixed assignment of IP address parameters/device names, previously retentively-saved parameters are replaced by the newly assigned parameters.

Note

Reuse of devices

Execute the "Reset to factory settings" before you install a device with retentive IP address parameters and device name in another subnet or system or before you place it in storage.

Creating a PROFINET IO system

Introduction

To create a PROFINET IO system, you need to have a PROFINET IO controller and at least one PROFINET IO device. As soon as you connect an IO controller to an IO device via their PROFINET interfaces, a controller-device link is established.

IO controller and IO device

As IO controller, you can use the following devices with a PROFINET interface:

- CPU with a permanently integrated or plug-in PROFINET interface
- CP in conjunction with a CPU
- Interface module assigned to a CPU/FM
- Interface module with a PROFINET interface

As IO device, you can use head modules of the distributed I/O with PROFINET interface or CPUs as intelligent IO devices.

With some devices, you can switch between modes (such as "IO controller" and "IO device") under "Mode" in the Inspector window of the PROFINET interface. Select the option button with the required mode.

Requirements

- You are in the network view.
- The hardware catalog is open.

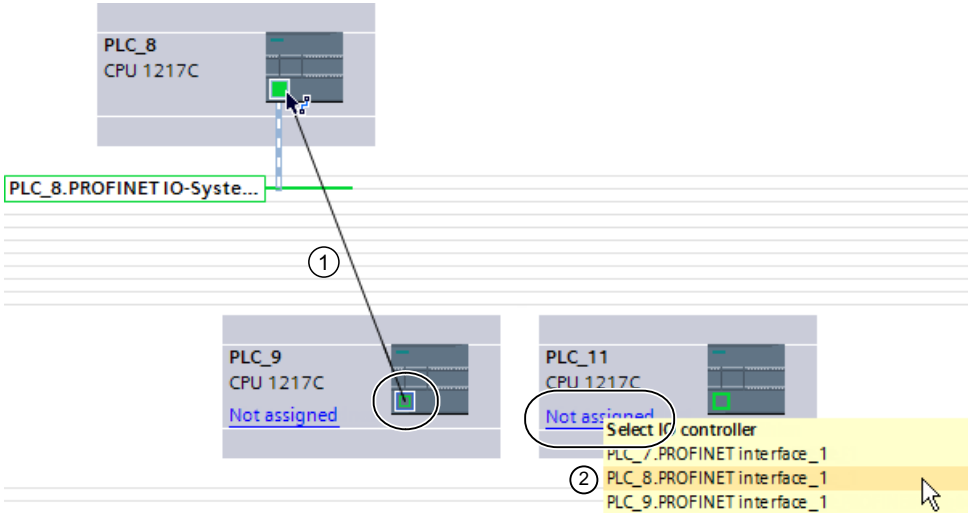
Procedure

To create a PROFINET IO system, for example with a CPU 1217C , follow these steps:

1. Select a CPU 1217C as a potential IO controller from the hardware catalog.
2. Drag the CPU onto the free area within the network view.
3. Right-click on the PROFINET interface of the CPU.
4. Select "Create IO system" from the shortcut menu.

A PROFINET IO system with a CPU 1217C as IO controller will be created as the only node.

If you connect the PROFINET interface of an IO device to the PROFINET interface of the IO controller, the IO slave will be added automatically to the IO system. If there is not yet a subnet between the IO controller and IO device, a new subnet is created between the IO controller and IO device.



To include a CPU 1217C as an intelligent IO device in the DP master system, for example, follow the steps below:

1. Click on the PROFINET interface of the IO controller or IO device.
2. Hold down the mouse button and drag a connection from the selected PROFINET interface to the PROFINET interface of the desired communications partner.

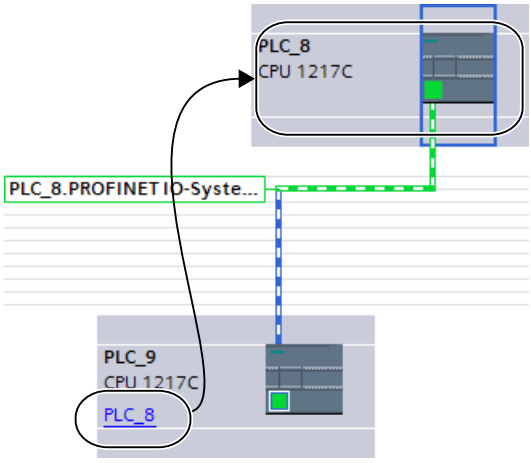
or

1. Click on the hyperlink of the IO device CPU 1217C.
2. Select the required IO controller from the displayed list of possible IO controllers.

The intelligent IO device CPU 1217C is included in the PROFINET IO system with the CPU 1217C as IO controller.

① Drag between the PROFINET interfaces of IO device to IO controller.

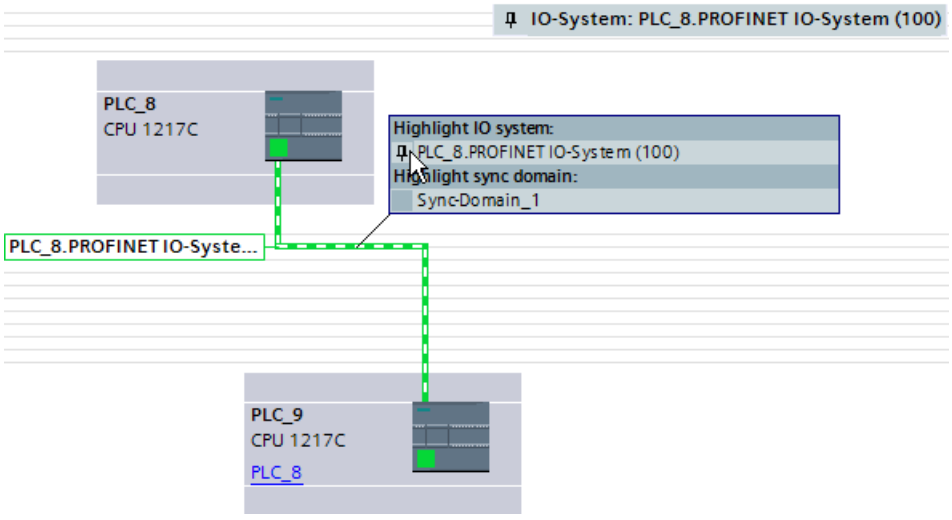
② Click on the link of an unassigned IO device, and a selection of possible IO controller opens.



If required, adapt the properties of the Ethernet subnet or the IO controller (for example, IP address) under "Properties" in the inspector window.

Note

If there is only one IO controller on a subnet, you only have to connect the interface of the IO device to the subnet of this IO controller with drag-and-drop. The IO device is then connected to the subnet of the IO controller immediately, and the IO device is assigned to this IO controller.



Display of the IO controller in the IO device

When an IO device is connected to an IO controller, the name of the IO controller is displayed on the IO device as a hyperlink. Click the hyperlink to select the assigned IO controller.

Highlighting the PROFINET IO system

When you have created a new PROFINET IO system, the PROFINET IO system will be highlighted. This enables you to identify quickly which devices belong to the PROFINET IO system. You can also highlight a PROFINET IO system yourself by moving the mouse pointer over a subnet. This will result in the names of the available PROFINET IO systems being displayed. If you click on one of the displayed PROFINET IO systems with the mouse, the corresponding PROFINET IO system is highlighted.

There are various ways of removing the highlighting from a PROFINET IO system:

- Highlight a different PROFINET IO system.
- Click on the pin with the name of the PROFINET IO system in the top right-hand corner of the network view.

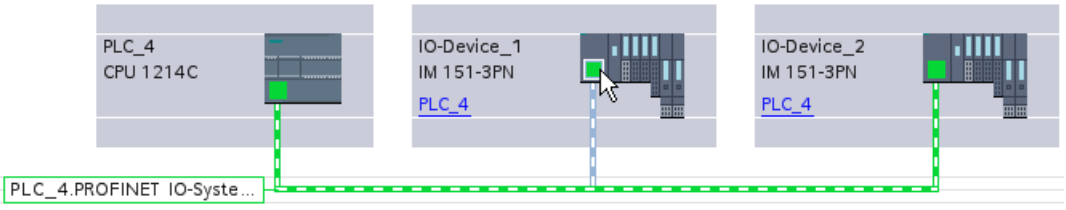
Handling PROFINET IO systems

Using shortcut menu commands, you can delete PROFINET IO systems, create new ones or even connect the interface to another subnet from within the network view.

An existing PROFINET configuration can thereby be corrected in the network view.

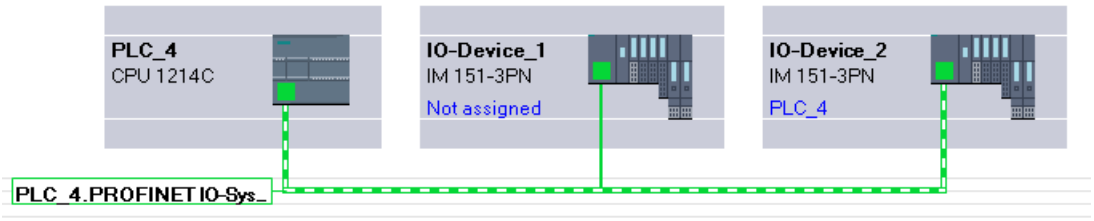
Create new PROFINET IO system for IO controller

To create a new PROFINET IO for an IO controller, proceed as follows:



1. Make sure that no IO system is already assigned to the IO controller. If an IO system is already assigned to the IO controller, the "Assign IO system" shortcut menu command is disabled.
2. Select the PROFINET interface and then select the "Assign IO system" shortcut menu command.

A new PROFINET IO system is created at the IO controller and you can assign IO devices to this IO system.



Disconnecting PROFINET IO devices from PROFINET IO system

To disconnect an already networked PROFINET IO device from its PROFINET IO system, follow these steps:

1. Click on the PROFINET interface of an IO device.

2. Select the "Disconnect from IO system" shortcut menu command.
   The IO device that was assigned to this IO system is then no longer assigned to it.

You can create a new IO systems and can assign each of the non-assigned IO devices to an IO controller.

Assign PROFINET IO devices to other IO controllers

Existing PROFINET IO systems can be easily reconfigured in the network view by selecting the IO device or its interface and the required command from the shortcut menu:

When selecting the interface:

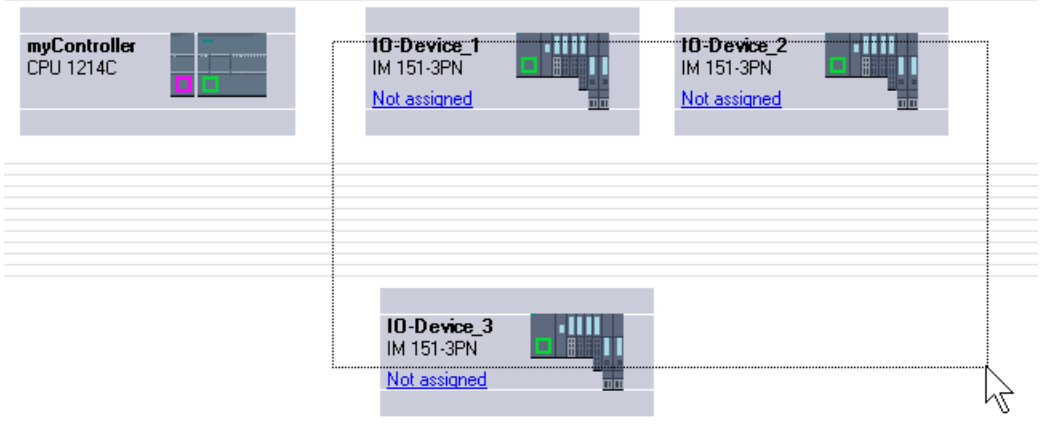
1. Select the interface of an IO device and then select the shortcut menu. You have the following options here:
   - Assign a new subnet to the IO device or disconnect it from the existing subnet
   - Assign the IO device to a new IO controller
   - Assign a new IO system to the IO device or disconnect it from the existing subnet
2. To assign another IO controller to the IO device, select the "Assign to new IO controller" shortcut menu command.
   If there is no connection, a subnet is automatically created and the IO device is assigned to the IO system of the new IO controller.

When selecting the entire device:

1. Select the IO device and select the shortcut menu. You have the following options here:
   – Assign the IO device to a new IO controller
   – Disconnect the IO device from the existing subnet
2. To assign the IO device to another IO controller, select the "Assign new DP master/IO controller" shortcut menu command.
   If there is no connection, a subnet is automatically created and the IO device is assigned to the IO system of the new IO controller.

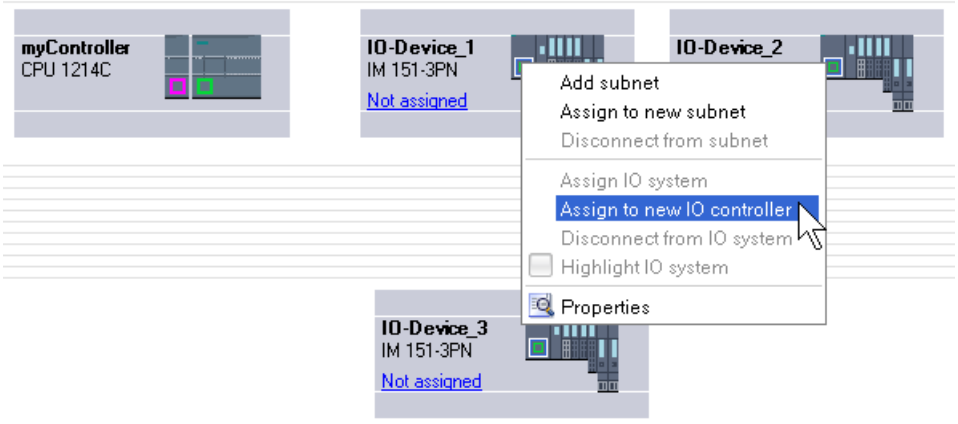
Tip: Quick configuration of IO systems

If the IO system has a lot of IO devices, assign all IO devices placed by drag-and-drop operation to an IO controller on one step.



Requirements

IO controller and IO devices are placed in the network view.



Assign IO devices to an IO system

To do this, follow these steps:

1. Select an appropriate zoom factor so that you can see as many IO devices as possible in the network view.
2. Arrange the IO devices in not more than of two rows.
3. Select all IO interfaces (not all devices) with the mouse cursor. This only works if you begin to drag the mouse cursor outside of the first IO device and release the mouse button at the last IO device (selection with the lasso).

4. Select the shortcut menu "Assign new IO controller" and select the corresponding IO interface of the IO controller in the subsequent dialog.

5. The IO devices are automatically networked with the IO controller and combine with it to form an IO system.

Note

When an IO system is highlighted, you can double-click on an IO device in the hardware catalog and thereby quickly add additional IO devices. Result: The IO device is automatically added to the highlighted IO system.

Interconnecting ports

If an IO device is assigned to an IO controller, this does not yet specify how the ports are connected to each other.

Although a port interconnection is not required to make use of the Ethernet/PROFINET functions, it does offer the following advantages:

- A target topology is specified with the port interconnection. Based on an online-offline comparison, it is possible to conduct a target-actual comparison with all devices that support this function.
- Only with IRT communication: If a port interconnection is configured, STEP 7 can determine the required bandwidth more precisely. As a rule, this leads to a higher performance.

Make sure that no invalid ring structures occur through the interconnection of ports.

Port interconnection is only advisable for devices that support the topology configuration.

Interconnecting ports in the Inspector window

To interconnect ports, follow these steps:

1. Select the Ethernet/PROFINET device or the Ethernet/PROFINET interface.
2. Navigate to the port property "Port interconnection".
   When the Ethernet/PROFINET interface is selected, you can find this setting in the Inspector window as follows: Properties > General > Advanced Options > Port [...] > Port Interconnection.
3. In the "Local port" section, you can find the settings at the local port. In the case of fiber-optic cable you can, for example, set the cable names here.
   In the "Partner port" section, click on the black triangle in the "Partner port" box to display and select the available partner ports.
4. If the port interconnection is a port interconnection with copper as medium and the devices support IRT communication, you can also set cable length and signal transit time.

If the Ethernet/PROFINET interface was disconnected, it is automatically networked by this action. In the properties of the subnet you can set whether this subnet should or should not be used for the networking.

Note

Interconnecting an electric with an optical port

If you want to interconnect an electrical and an optical port, you have to distinguish between RT and IRT communication:

- With RT communication, it is not necessary to configure a media converter.
- With IRT communication, you have to make the interconnection via a media converter.

Information on monitoring the partner port

After you have interconnected the two ports, you receive information on the monitoring of the partner port in a text field. The following displays are possible:

- Monitoring of the partner port is not possible.
- Partner port is being monitored.

It is not possible to monitor the partner port if you, for example, select a deactivated port as partner port. In this case it is not possible to monitor the target topology and the signal propagation time. A device replacement is then only possible with a Micro Memory Card.

Overview (Page 712)

Setting the send clock

Requirements to change the send clock at the PROFINET device

The PROFINET device must be an IO controller as sync master or IRT (Isochronous Realtime) must not be configured in the IO system.

If the PROFINET device is not an IO controller as sync master, the following requirements must be met for the setting of the send clock:

- No device must be configured at the IO system as a sync slave or sync master.
- All devices at the IO system must be unsynchronized.

When IRT is configured with an IO controller as sync master, the send clock can be set at the device or in the sync domain.

Procedure

To set the send clock on the PROFINET device, follow these steps:

1. Select the PROFINET IO controller in the device or network view.
2. Change the value for the shortest possible update interval in the properties of the PROFINET interface under "PROFINET Interface > Advanced options > Real-time settings > IO communication > Send clock".

The send clock is valid for all PROFINET devices at the IO system. If the synchronization role is set to a value other than "Unsynchronized", you can also set the send clock in the sync domain, in other words, centrally at the PROFINET IO system.

1. Select the IO system using the PROFINET subnet.
2. Change the value for the send clock in the properties of the sync domain under "Domain management > Sync domains > Sync_domain_1 > Send clock".

Setting the update time

Update time

An IO device / IO controller in the PROFINET IO system is supplied with new data from the IO controller / IO device within this time period. The update time can be separately configured for each IO device and determines the time interval in which data is transmitted from the IO controller to the IO device (outputs) as well as data from the IO device to the IO controller (inputs).

STEP 7 calculates the update time automatically in the default setting for each IO device of the PROFINET IO system, taking into account the volume of data to be exchanged as well as the set send clock.

Setting the update time

If you do not want to have the update time calculated automatically, you can change the setting.

To change the update time in the Inspector window, proceed as follows:

1. Select the PROFINET interface of the IO device in the network or device view.
2. Specify the update time in the interface properties under "Advanced options > Real time settings > IO cycle". You can specify the update time in two ways:
   - Automatic calculation of the optimal update time.
   - Update time you can set yourself by selecting different values from a drop-down list.
3. If you want to keep the relationship between the send clock and the update time constant, enable the "Adapt update time when send clock changes" option.
   This option ensures that the update time is not set to less than the send clock.

You can also carry out this setting directly in the I/O communication table via the drop-down list in the "Update time mode" column.

Manual setting of the send clock may result in errors if the available bandwidth is not adequate or when other limits/configuration limits are exceeded (for example, too many nodes are configured).

Note

When you change the update time mode from "Can be set" to "Automatic", a manually entered update time is overwritten by the automatically calculated value.

No update time can be calculated

STEP 7 determines the sequence of the cyclic data exchange based on the configuration information (IO controller properties, IO device properties, number and type of the IO devices, consistency of the cyclic user data...). The cyclic data is packed in frames and sent/received successively at calculated time intervals.

The maximum number/size of the frames and the maximum number of intervals available must be sufficient to "accommodate" all the data. The resulting send/receive interval must also be supported by every PROFINET device.

If the limits relating to the amount of cyclic user data/number of frames or relating to the intervals available are exceeded, STEP 7 cannot calculate an update time.

If there is no common basis for the send/receive interval, calculating the update time is also not possible.

If there is a reason preventing the calculation of the update time, STEP 7 reports the cause when compiling the hardware configuration.

How to eliminate the problem:

- Reduce the number of IO devices
- Reduce the number of modules within the IO devices
- If you are using an IE/PB link: Reduce the number of DP slaves downstream from the IE/PB link
- Use a more powerful IO controller or IE/PB link

- Increase the send clock
  - With RT: in the properties of the IO controller
  - With IRT: in the properties of the sync domain
- Check the device properties of the IO devices ('MinDeviceInterval' and the possible scan rates) due to the common basis for the send/receive interval. Replace unsuitable IO devices. This device properties are stored in the GSD file of the IO device.
- With IRT configuration:
  - Check whether the ports of the sync master and sync slaves are interconnected.
  - Check the order of the IO devices: There can be **no** unsynchronized device connected between the sync master and sync slave
    (Example of bad configuration: Sync master --- unsynchronized device --- sync slave).
  - Check whether you have configured more than one sync master.
  - Check the bandwidth remaining for RT data. The bandwidth for RT data available for the transfer can be restricted by IRT communication on the same Ethernet subnet.
- When using I-devices:
  It may not be possible to use the set send clock together with the existing I-device configuration.
  - Configure the I-device without lower-level IO devices and activate the setting "Parameter assignment of PN interface by higher-level IO controller".
  - Change the send clock of the IO controller to an even value (... 0.250, 0.500, 1.000, ...).

Identification of the IO devices involved:

You can identify the IO devices involved for which no update time can be calculated in the "I/O communication" table of the PROFINET IO system in the network view. No entry is made in the "Update time" column for the IO device involved (entry "-").

Setting the watchdog time

Watchdog time

You can configure the watchdog time for PROFINET IO devices.

If the IO device is not supplied with input or output data (IO data) by the IO controller within the watchdog time, it switches to the safe state.

Do not enter the watchdog time directly, but as "Accepted number of update cycles when IO data is missing". This makes setting easier because the update time can be shorter or longer, depending on the power of the IO device or the setting.

The resulting watchdog time is automatically calculated from the "Accepted number of update cycles when IO data is missing".

Configuring the watchdog time

To specify the watchdog time, follow these steps:

1. Select the PROFINET interface of the IO device in the network or device view.
2. In the properties of the interface, navigate to "Advanced options > Realtime settings > IO cycle".
3. Select the required number of cycles from the drop-down list "Trigger watchdog after # cycles with missing IO data".

The watchdog time is subsequently calculated automatically based on the preset factor. It must not be more than 1.92 seconds.

Note

The default setting should only be changed in exceptional cases, for example, during the commissioning phase.

Calculated bandwidth for cyclic IO data

Calculated bandwidth for cyclic IO data

Adherence to the maximum available bandwidth for cyclic IO data is monitored by the system. The maximum bandwidth depends on the send clock cycle. If the send clock cycle is greater than or equal to 1 ms, the maximum bandwidth is 0.5 ms. If the send clock cycle is shorter, the maximum available bandwidth is also reduced.

The bandwidth actually required for cyclic IO data is determined by the system based on the number of configured IO devices and IO modules. Furthermore, the required bandwidth depends on the update time that is used.

In general, the calculated bandwidth increases in the following cases:

- There is a greater number of IO devices
- There is a greater number of IO modules
- The update times are shorter.

Maximum bandwidth for cyclic IO data depending on the send clock

The following table shows how the maximum available bandwidth for cyclic IO data reacts based on the send clock:

Send clock cycle	Maximum bandwidth for cyclic IO data
250 µs – 468.75 µs	<< 125 µs
500 µs – 968.75 µs	= send clock / 2
1 – 4 ms	= 500 µs

Setting port options

Setting the port options

Changing connection settings for the PROFINET IO port

By default, the settings for ports of a PROFINET interface are specified in such a way that problem-free data exchange is ensured in normal situations.

If necessary, you can change the settings. The setting options are described below.

Possible settings for transmission rate/duplex

Depending on the selected device, you can make the following settings for "Transmission rate/ duplex":

- Automatic setting
  Recommended default setting of the port. The transmission settings are automatically "negotiated" with the partner port. The "Enable autonegotiation" option is automatically selected by default.
- TP/ITP at x Mbps full duplex (half duplex)
  Setting of the transmission rate and the full duplex/half duplex mode. The effectiveness depends on the "Enable autonegotiation" setting:
  - Autonegotiation enabled
    You can use both cross cable and patch cable. The port is monitored with this setting.
  - Autonegotiation disabled
    Make sure that you use the correct cables (patch or cross cables). The port is also monitored with this setting.
- Deactivated
  Depending on the device type, the drop-down list box can contain the "Deactivated" option. With this option, you can prevent access via an unused port for security reasons, for example. With this setting, diagnostic events are not generated.

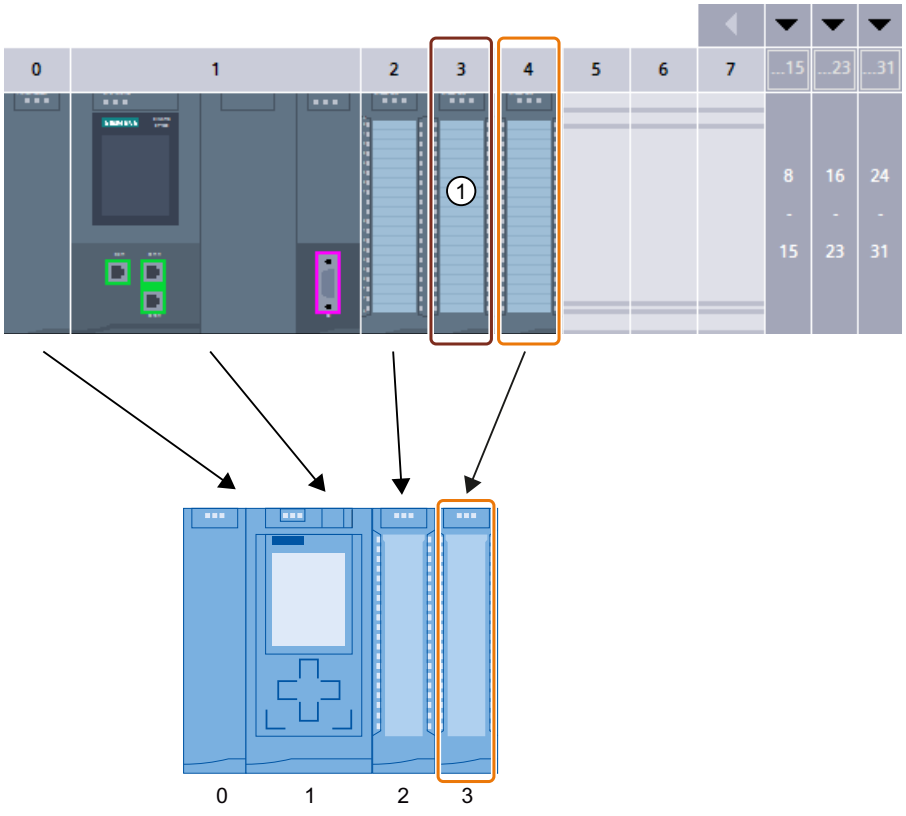
"Monitor" option

With the "Monitor" option, you enable/disable port diagnostics. You can only enable monitoring if the device supports this function.

Below is a list of what is monitored during operation by the device when monitoring is enabled - regardless of whether you have interconnected the port or not:

- The link status is monitored; in other words, diagnostics is generated when the link is down (e.g. with a wire break or a removed connector). With fiber-optic ports (FO), the link power margin is monitored so that a staged maintenance diagnostics is obtained.
- The media settings are monitored; in other words, a diagnostics message is generated when the local port setting (transmission rate/duplex) during operation does not match the setting of the partner port.
- If the port is interconnected: The cable length/signal delay time is monitored; in other words, a diagnostics message is generated if the locally detected cable length/signal delay time does not match the cable length/signal delay time detected by the partner.

Disabling monitoring



Monitoring does **not** make sense in the following cases:

- The option "Alternative partners" is enabled at the local port, for example, for a docking port of a docking station (tool changer). In this case, a link status change is a normal operational situation.
- The partner port belongs to a non-PROFINET device. Only ports of PROFINET devices transfer their port settings such as the transmission rate, duplex setting etc.
- The local port is connected to a media converter (passive network component with different signal delay times for Ethernet frames).
- At the local port, the option "End of topology discovery" is enabled in the boundaries settings.

Monitoring of the desired topology

With the "Monitoring" option, no monitoring is linked to the adherence to the desired topology. This means that whether the configured interface and port properties such as device name, port name and cable length match the current settings is not influenced by the "Monitoring" option.

Adherence to the desired topology is checked automatically when you interconnect the local port with a partner port; the partner port must not then be disabled. The port properties indicate whether the monitoring of the desired topology is performed or is impossible (port interconnection, partner port refer, to the figure below ①).

ConfDB

		Name	Data type	Start value	...	...	...	...	Comment
1		Static							
2		ConfigControl	Struct			☑	☑		
3		Block_length	USInt	9		☑	☑		4+number of slots
4		Block_ID	USInt	196		☑	☑		
5		Version	USInt	4		☑	☑		
6		Subversion	USInt	0		☑	☑		
7		slot_0	USInt	0		☑	☑		configured slot_0 / assigned "real" slot 0
8		slot_1	USInt	1		☑	☑		configured slot_1 / assigned "real" slot 1
9		slot_2	USInt	2		☑	☑		configured slot_2 / assigned "real" slot 2
10		slot_3	USInt	16#FF		☑	☑		configured slot_3 / not used ①
11		slot_4	USInt	3		☑	☑		configured slot_4 / assigned "real" slot 3

① Display of whether the device can check the actual properties of the partner port against the configured properties of the partner port. This adherence to the desired topology is checked automatically when you interconnect the local port with a partner port.

② Setting the monitoring to link down, media settings and cable length/signal delay time. At runtime, the local port compares its own settings with the settings of the partner port.

Option "Enable autonegotiation "

The autonegotiation setting can only be changed if a concrete medium (for example, TP 100 Mbps full duplex) is selected. Whether or not a concrete medium can be set depends on the properties of the module.

If autonegotiation is disabled, this causes the port to be permanently specified, as for example, is necessary for a prioritized startup of the IO device.

You must make sure the partner port has the same settings because, with this option, the operating parameters of the connected network are not detected and the data transmission rate and transmission mode can therefore not be optimally set.

Note

When a local port is interconnected, STEP 7 makes the setting for the partner port if the partner port supports the setting. If the partner port does not support the setting, an error message is generated.

Port options for using the GBIT PROFINET interface

The PROFINET interface (X3) of the CPU 1518-4 PN/DP supports a maximum transmission rate of 1000 Mbps (GBIT).

In order to achieve this transmission rate, the following requirements must be met:

- CPU Firmware Version V1.7 or higher.
- Devices on the same PROFINET subnet must also support the 1000 Mbps transmission rate.
- The network infrastructure (network cables and outlets) must be category CAT 5e or better.
- The port options of PROFINET interface X3 must be set as follows:
  - “Transmission rate/Duplex”: Automatic
  - “Autonegotiation”: Activated

See also

Wiring rules for disabled autonegotiation (Page 1796)

Boundaries at the port (Page 1797)

Wiring rules for disabled autonegotiation

Requirement

You have made the following settings for the port in question, for example, to accelerate the startup time of the IO device:

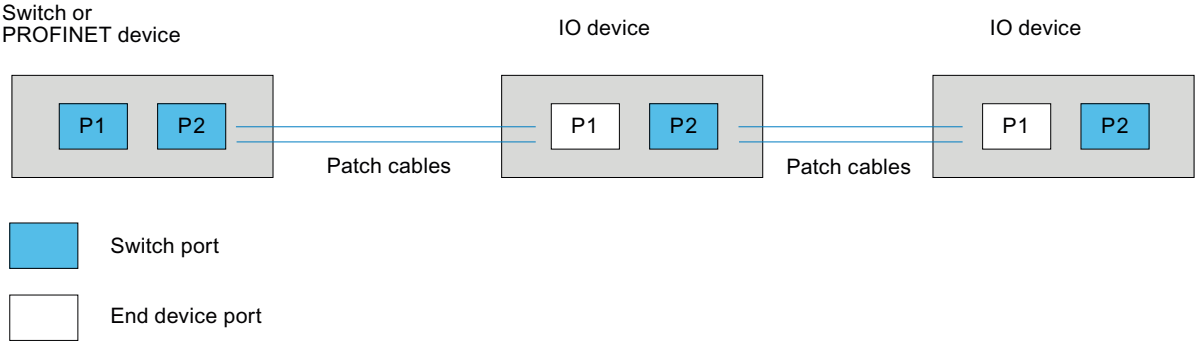
- Fixed transmission speed
- Autonegotiation incl. autocrossing disabled

This saves you the time required to negotiate the transmission rate during startup.

If you have disabled autonegotiation, you must observe the wiring rules.

Wiring rules for disabled autonegotiation

PROFINET devices have the following two types of ports:



Type of port	PROFINET devices	Note
Switch port with crossed pin assignment	For IO devices: Port 2 For S7 CPUs with 2 ports: Ports 1 and 2	Crossed pin assignment means that the pin assignment for the ports for sending and receiving between the respective PROFINET devices is exchanged internally.
End device port with uncrossed pin assignment	For IO devices: Port 1 For S7 CPUs with one port: Port 1	-

Validity of the wiring rules

The cabling rules described in the following paragraph apply exclusively to the situation in which you have specified a fixed port setting.

Rules for cabling

You can connect several IO devices in a line using a patch cable (one-to-one wiring of both connectors). To do this, you connect port 2 (P2) of the IO device to port 1 (P1) of the next IO device. The following graphic gives an example with two IO devices.

Boundaries at the port

Requirement

The respective device must support boundaries settings in order to work with boundaries. If the device for PROFINET does not support boundary settings, the corresponding parameters are disabled, such as in the CPU 1215C V3, for example.

Enable boundaries

"Boundaries" are limits for transmission of certain Ethernet frames. The following boundaries can be set at a port:

- "End of detection of accessible devices"
  DCP frames for detection of accessible devices are not forwarded. Devices located behind this port are no longer displayed in the project tree under "Accessible devices". Devices located behind this port can no longer be reached by the CPU.
  The device must have more than one port for this function.
- "End of topology discovery"
  LLDP frames (Link Layer Discovery Protocol) for topology detection are not forwarded.
- "End of sync domain"
  Sync frames transmitted for synchronization of devices within a sync domain are not forwarded.
  For example, if you operate a PROFINET device with more than two ports in a ring, you should prevent the sync frames from being fed into the ring by setting a sync boundary (at the ports not inside the ring).
  The device must have more than one port for this function.
  Additional example: If you want to use several sync domains, configure a sync domain boundary for the port connected to a PROFINET device of the other sync domain.

Restrictions

The following restrictions must be observed:

- The individual check boxes can only be used if the port supports the function in question.
- If a partner port has been defined for the port, the following check boxes cannot be used:
  - "End of detection of accessible devices"
  - "End of topology discovery"

Enabling device replacement without exchangeable medium

Replacing an IO device without exchangeable medium

It is often necessary to replace IO devices in automation systems. The IO devices are generally assigned a device name by either inserting an exchangeable medium or via the programming device. The IO controller uses this device name to identify the IO device.

Subject to certain conditions, IO devices can also receive their device names without the insertion of an exchangeable medium (e.g., memory card) or without a programming device. For this purpose, the IO controller uses Ethernet mechanisms (LLDP protocol; Link Layer Discovery Protocol) to analyze the relationships between the individual IO devices and the IO controller. From these relationships, the IO controller detects which IO device was replaced and assigns the configured device name to it.

Requirements

- A port interconnection is already configured.
- The affected IO devices in the automation system must support device replacement without exchangeable medium (LLDP protocol).

Note

Use only new IO devices as replacement devices, or restore IO devices already configured to the delivery state prior to commissioning.

For S7-1500 CPUs with firmware version V1.5 or higher, it is not necessary to reset IO devices with an existing parameter assignment to delivery state. Requirement: The "Permit overwriting of device names of all assigned IO devices" option is selected for the IO controller ("Advanced option > Interface options" area of the properties of the PROFINET interface).

Procedure

In order to enable the replacement of an IO device without exchangeable medium, proceed as follows:

1. In the device or network view, select the PROFINET interface of the corresponding IO controller.
2. In the interface properties under "Advanced settings > Interface options", select the "Support device replacement without exchangeable medium" check box.

The option "Support device replacement without exchangeable medium" also permits automatic commissioning, which means you can commission the IO system with the IO devices without assigning their device names in advance.

IO devices without corresponding functionality

When individual IO devices in the automation system do not support device replacement without exchangeable medium, a corresponding alarm is output for the IO device. It is possible to use the functionality nevertheless. However, all of the following conditions have to be fulfilled:

- The function "Device replacement without exchangeable medium" is activated in the higher-level IO controller.
- The IO device supports the LLDP protocol.
- At least one "neighbor" of the IO device supports
  - The function "Device replacement without exchangeable medium" as an IO controller or
  - The LLDP protocol as an IO device.

When you configure the environment of the IO device so that the conditions described above are met for the "Device replacement without exchangeable medium", the usage of the function is possible even if the IO device does not support the functionality directly.

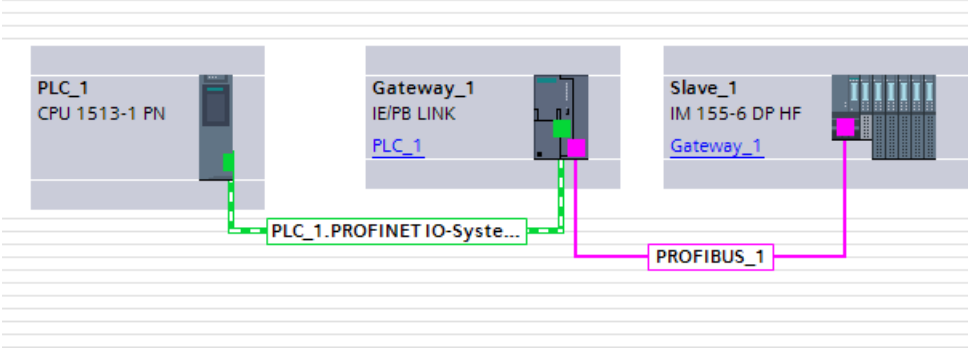
Assigning the device name and IP address (Page 1769)

Components with the the device replacement without exchangeable medium function (http://support.automation.siemens.com/WW/view/en/36752540)

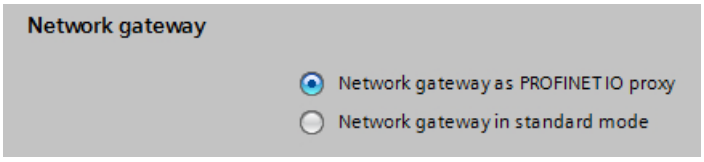
Connect the DP slave via the IE/PB Link to a PROFINET IO system



Requirements

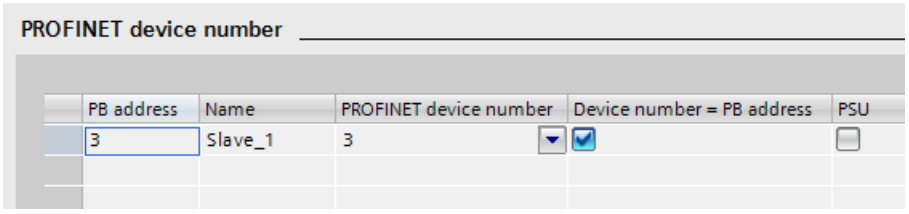
- STEP 7 as of V12
- S7-1500 CPU as of firmware version 1.7
- ET 200SP CPU as of firmware version 1.7
- S7-1500 software controller
- S7-300/400 CPU

Procedure for connecting a DP slave via an IE/PB Link



To connect a DP slave to a PROFINET IO system via an IE/PB Link in STEP 7, follow these steps:

1. Drag a PROFINET CPU, e.g. 1513-1 PN, from the hardware catalog to the network view of STEP 7.
2. Drag an IE/PB Link PN IO from the hardware catalog into the network view of STEP 7. The IE/PB Link PN IO is located under Network components > Gateways > IE/PB Link PN IO.
3. Assign the IE/PB Link PN IO to the CPU.
4. Drag a PROFIBUS interface module, e.g. IM155-6 DP HF, from the hardware catalog to the network view.
5. Assign the interface module to the IE/PB Link.



6. Select the IE/PB Link PN IO in the network view of STEP 7.

7. In the Inspector window, go to the "Gateway" area and select the "Network gateway as PROFINET IO proxy" option.

8. In the PROFINET device number area, you can assign a PROFINET device number for the DP slave.
   If you have selected the "Device number = PB address" check box (default), STEP 7 automatically assigns the device number according to the PROFIBUS address of the slave. In addition, you no longer need to update the device number if the PROFIBUS address changes.

Configuration using IE/PB link PN IO (Page 1765)

Setup recommendations for optimizing PROFINET

Optimizing PROFINET with RT

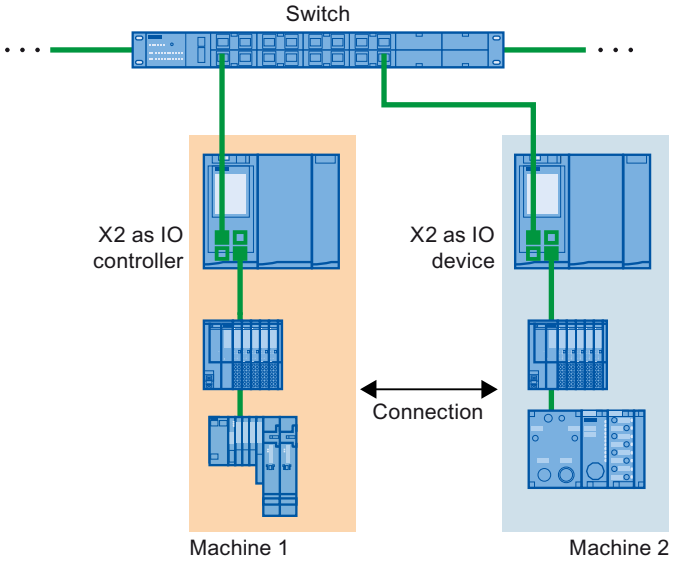
PROFINET provides you with high-performance communication on all levels.

The figure below shows an example of an optimized PROFINET topology.

When setting up your PN network topology, take care that the various automation applications are distributed among separate network branches so that a sufficient bandwidth reserve will be available for future expansions.

- When you integrate standard Ethernet devices into the network topology or use standard Ethernet communication, take into account the network load caused by standard Ethernet and adapt the network topology as appropriate (max. bandwidth 100 Mbps).
- For communication with higher-level networks with a high data volume, use the most direct paths possible to the higher-level network infrastructure.

Also observe the Installation Guideline of the PROFIBUS User Organization.



Setting up PROFINET with IRT

Keep in mind the following rules for setting up and operating a PROFINET IO system in IRT mode. These rules will ensure best possible operation of your PROFINET IO system.

- When using IRT, you must configure the topology. This will enable exact calculation of the update time, bandwidth, and other parameters.
- If you would like to use multiple sync domains, configure a sync boundary for the port which is currently connected to the PROFINET device of another sync domain.
- In a sync domain, you can only configure one sync master at a time.
- A PROFINET IO system may only be part of a single sync domain.
- When you configure PROFINET devices in a sync domain and want to synchronize with IRT, the PROFINET devices concerned must support IRT communication.
- If possible, use the same PROFINET device as the PROFINET IO controller and sync master.
- If only some of the PROFINET devices in a PROFINET IO system are synchronized, please keep in mind the following: Assign PROFINET devices that are not participating in the IRT communication to the RT class "RT" and the synchronization role "unsynchronized" in the sync domain.

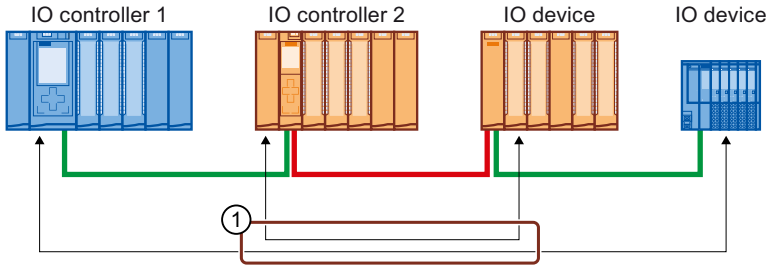
Applications for CPU with multiple PROFINET IO interfaces

- Connecting machines: Your configuration contains machines located on separate IO lines. You can operate real-time communication between the CPUs over X2 PROFINET IO interfaces. Use the I-device or shared I-device function for this purpose.
  The figure below shows an example configuration for 2 machines connected over the X2 interface with an I-device relationship.

- Distribution by automation tasks:
  - For automation tasks with high performance and deterministic requirements, use PROFINET with IRT over the X1 interface.
  - For other tasks that you can implement with RT, use the X2 interface.

If you use interface X2 as the PROFINET IO interface for one of the following CPUs, this can affect performance:

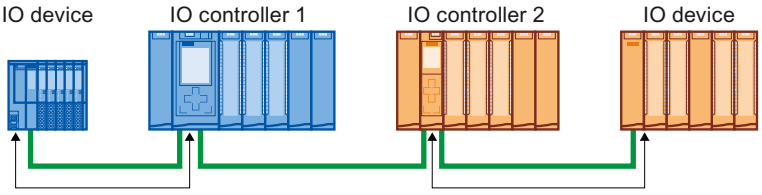
- CPU 1515(F)-2 PN
- CPU 1515T-2 PN
- CPU 1516(F)-3 PN/DP
- CPU 1516(F)pro-2 PN



You can find additional information in the Cycle and Response Times function manual.

Topological overlap of IO systems in multi-controller applications

In a configuration with multiple IO controllers, shared paths are subject to the combined network loads of all connected PROFINET IO systems.



To avoid high communication loads in multi-controller applications, observe the following recommendations:

- Avoid paths that are shared by multiple IO systems.
  The figure below shows a configuration with two PROFINET IO systems that use the same paths.

① Shared path

In the figure below, the two PROFINET IO systems do not use shared paths.

- If separation is not possible: Increase the update time for the affected IO devices.

Installation guidelines of the PROFIBUS user organization

The installation guidelines can be found on the Internet.

Limitation of the data infeed into the network

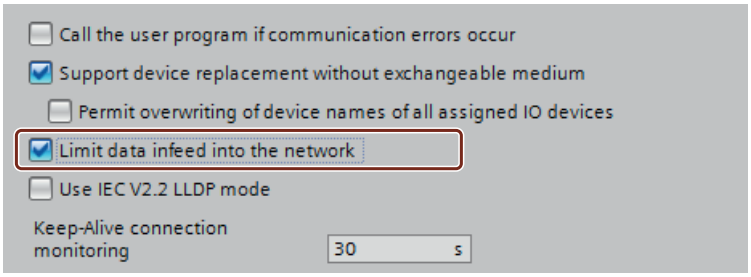
Limiting the data infeed into the network on PROFINET interfaces

The "Limit data infeed into the network" function limits the network load of standard Ethernet communication which is fed into the network by the interface to a maximum value. This does not apply to cyclic real-time communication (RT/IRT).

In a PROFINET IO system, critical network loads can occur quickly with standard Ethernet communication. All devices in a PROFINET IO system should support the "limitation of the data infeed into the network".

If you use devices that feed a lot of "standard Ethernet communication" into the PROFINET IO system, you should adapt the topology, if necessary.

Depending on the interface, you can activate or deactivate the "Limit data infeed into the network" function. If you use the X1 interface of an S7-1500 CPU as the IO controller or I-device, the "Limit data infeed into the network" function is always enabled. Example: If you are not using the X1 interface of an S7-1500 CPU as IO controller or I-device, you can enable or disable the function.



Uses of the limitation of the data infeed to the network

- Division of the bandwidth for standard Ethernet communication between devices:
  In PROFINET networks cyclic real-time communication and standard Ethernet communication share the same network. This means that only a limited bandwidth remains for standard Ethernet communication. The limitation of the data infeed ensures that the remaining bandwidth for standard Ethernet communication is not used just by one device, but is divided between several devices.
- Smoothing peaks in the data infeed:
  The limitation of the data infeed smooths peak loads of standard Ethernet communication (for example, from Open User Communication, access by the Web server).
- Limiting problems in the data infeed:
  If applications in a device generate too much data, this data is not forwarded to the PROFINET network. Negative effects (for example data loss, communication breakdown) remain limited to the device and its communications partner. Other nodes are not disturbed.

Setting limitation of the data infeed into the network for a CPU

To set the limitation of the data infeed into the network ("infeed load limitation"), follow these steps:

1. In the network view of STEP 7, select the interface of the CPU.
2. In the Inspector window, go to "Properties" > "General" > "Advanced options" > "Interface options".
3. Select or clear the "Limit data infeed into the network" check box.

Using GSD files

GSD files for IO devices

Basic information on GSD files of IO devices

The properties of PROFINET IO devices are not stored in a keyword-based text file (as for PROFIBUS DP slaves), but in an XML file whose structure and rules are determined by a GSDML schema.

The language used to describe the GSD files is GSDML (Generic Station Description Markup Language). It is defined by the GSDML schema. A GSDML schema contains validation rules

that allow it, for example, to check the syntax of a GSD file. GSDML schemas (as schema files) are acquired by IO device manufacturers from PROFIBUS International.

Functional enhancements in the area of PROFINET IO will have an effect on the GSDML specification and the corresponding schema. A new version of the specification and of the schema is created by the functional enhancement.

Names of GSD files for IO devices

One possible example of a GSD file name for IO devices is:

"GSDML-V1.0-Siemens-ET200S-20030616.xml"

Name component	Explanation
GSDML	String at the start of each GSD file for IO devices
V1.0	Version of the GSDML schema
Siemens	Manufacturer
ET200S	Name of the device
20030616	Version code (date)
.xml	File extension

Versioning of GSD files for IO devices

The version information for GSD files for PROFINET IO devices consists of two parts:

- Version of the GSDML schema: This determines the language scope used by a GSD file.
- Version number in form of a date: The version number of GSD files is incremented, for example, after elimination of an error or introduction of a functional enhancement.

Functional enhancements may result in a new version of the GSDML schema. A new version of a GSDML schema might only be supported with restrictions.

Installing the GSD file

Introduction

A GSD file (general station description file) contains all properties of an IO device. If you want to configure an IO device that is not available in the hardware catalog, you must install the GSD file provided by the manufacturer. IO devices installed via GSD files are displayed in the hardware catalog and can then be selected and configured.

Requirement

- The hardware and network editor is closed.
- You have access to the required GSD files in a directory on the hard disk.

Procedure

To install a GSD file, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. In the "Installed GSDs" tab, select the directory in which the GSD files are stored.
3. Choose one or more files from the list of displayed GSD files.
4. Click on the "Install" button. The selected GSD files are now being installed.
5. To create a log file for the installation, click on the "Save log file" button.
   Any problems during the installation can be tracked down using the log file.
6. Click "Close". You will be notified that the IO devices from the installed GSD files are entered into the hardware catalog. This process can take a few seconds.

By installing a GSD file you have added the IO device described in the file to the hardware catalog.

Result

You will find the new IO devices installed by means of GSD files in the hardware catalog under "Additional field devices > PROFINET IO".

GSD files are always saved together with the project, which means all information relevant for display of the device (including symbols) is also available in the saved project.

See also

Overview of hardware and network editor (Page 525)

Deleting GSD file

Introduction

You can delete installed DP slaves using GSD files. These DP slaves are then no longer displayed in the hardware catalog.

Requirement

- The hardware and network editor is closed.
- You will find the new IO devices installed by means of GSD files in the hardware catalog under "Additional field devices > PROFINET".

Procedure

To delete a GSD file, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. In the "Installed GSDs" tab, select the directory in which the GSD file is stored.
3. Select the file that is to be deleted from the list of displayed GSD files.
4. Click the "Delete" button.

The selected GSD file was deleted and the DP slave is no longer located in the hardware catalog.

Finding unused GSD files

Introduction

When you add a GSD-based hardware component to your hardware configuration, different GSD files are added to the project data. If the GSD-based hardware component is once again deleted from the configuration, the GSD files remain in the data inventory of the project. The GSD files are no longer needed in the project if the corresponding GSD-based hardware component is not used in the hardware configuration again. You can find files that are no longer needed in the project with a search function and delete them.

Requirement

- A project must be open.
- The project must not be online.
- The project must not be write-protected.

Procedure

To find and delete unused GSD files, follow these steps:

1. In the "Options" menu, select the "Manage general station description files (GSD)" command.
2. Click on the "Find unused GSDs" button in the "GSDs in the project" tab.

   Note

   Unused GSD files are only available if at least one GSD-based hardware component was added to the configuration and then removed from the configuration. Unused GSD files in the project libraries are included in the search. GSD-based hardware components that are still being used in the configuration are not considered to be unused.

   Installed GSD-based hardware components that are included in the hardware catalog but have not been used in the hardware configuration of the project yet, could not have stored unused GSD data in the project.

3. If GSD files that are no longer needed were found in the project data, you can now delete them. To do so, click the "Delete" button.

GSD files that are no longer needed are deleted from the project data. The GSD-based hardware component is still available in the hardware catalog and, if necessary, can be added to the configuration once again. The necessary GSD data are once again copied to the project data in this case.

Note

If you delete a GSD-based hardware component with "Options > Manage general station description files (GSD) > Installed GSDs", it is deleted from the hardware catalog. However, unused GSD files of this hardware component can still be a part of the project data and can be deleted with the function for finding the unused GSD files.

NOTICE
Actions that cannot be undone
When you delete GSD files that are not being used as an action, the action stack for actions that can be undone is deleted. This means the action of deleting unused GSD files as well as all previous actions can no longer be undone.

See also

Basics of undoing and redoing actions (Page 316)

Changing the revision of a GSD file

Changing the revision of a GSD file

You can change the revision of a GSD file for an IO device:

- Only for the current IO device
- All suitable IO devices within the IO system
- All suitable IO devices within the complete project

First, all existing GSD files for the current IO device are shown. The only difference between the GSD files shown is their revision status. The currently used GSD file is highlighted.

Requirement

- The I/O data is the same for all IO devices whose revision is to be changed.
- The article number has not changed.
- The number of submodules is identical.
- The configuration data has not changed.
- There must be no module or submodule in a slot that is invalid after the new GSD file has been created.

Procedure

To change the revision of one or more IO devices, proceed as follows:

1. Select the IO device whose GSD file revision is to be changed.
2. Click on the "Change revision" button under "General> Catalog information" in the properties of the IO device.
   The "Change revision" dialog box opens.
3. Select the GSD revision you want to use in the "Available revisions" table.
4. Under "Use selected revision for", select the devices whose version are to be changed:
   - Only for the current IO device
   - For all suitable IO devices in the IO system
   - For all suitable IO devices in the project
5. Click the "Apply" button.

10.1.4.8 Bus coupling with PN/PN coupler

Application and function

Application

The PN/PN coupler is used to link two Ethernet subnets with one another and to exchange data. That way use data about input or output address areas or datasets can be used. The maximum size of the transferable input and output data is 1024 bytes. The division into input and output data is preferable, so that e.g. 800 byte input data and 200 byte output data can be configured.

As a device, the PN/PN coupler has two PROFINET interfaces, each of which is linked to one subnet.

In the configuration, two IO Devices are produced from this one PN/PN coupler which means that there is one IO Device for each station with its own subnet. The other part of PN/PN coupler in each case is known as the bus node. Once configuring is complete, the two parts are joined.

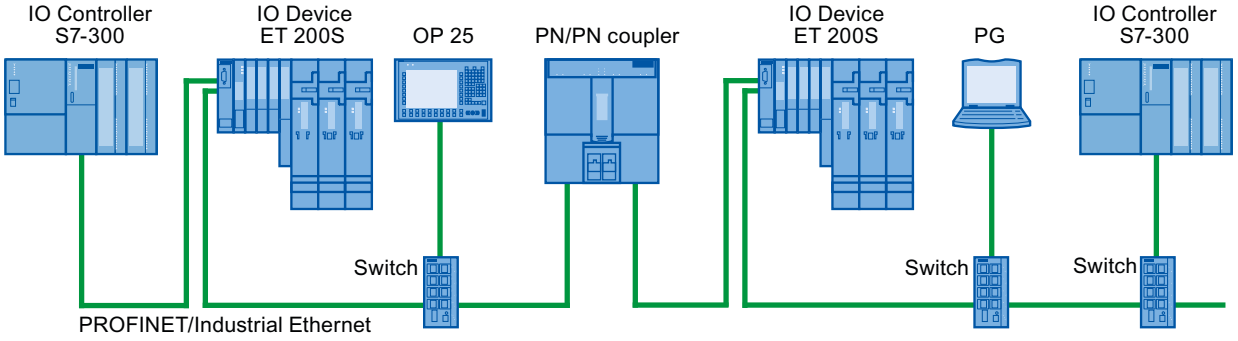


Figure 10-19 Coupling two PROFINET IO subnets with one PN/PN coupler

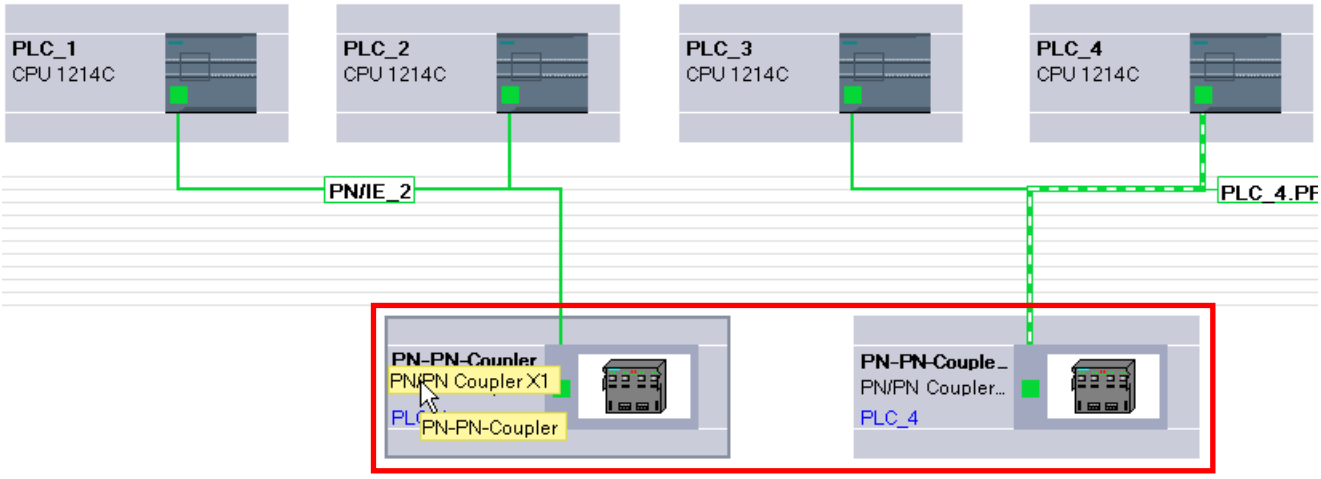
Additional information

For additional information on "PN/PN couplers", refer to Service & Support on the Internet (http://support.automation.siemens.com/WW/view/en/44319532).

Linking Ethernet subnets



Linking Ethernet subnets with a PN/PN coupler

You can link Ethernet subnets with the standard device PN/PN coupler.

To link Ethernet subnets, follow these steps:

1. Create your Ethernet subnets.
2. Select the standard field devices in the hardware catalog. Find the PN/PN coupler as head module in the "PROFINET IO" folder.

3. In the network view, drag the two components X1 and X2 to the required version of the PN/PN coupler per drag-and-drop operation. The components form a device, but are shown separately to make handling easier.
4. Connect the Ethernet interface of the PN/PN coupler X1 to the first Ethernet subnet.
5. Connect the Ethernet interface of the PN/PN coupler X2 to the second Ethernet subnet. The Ethernet subnets are now linked through the two components of the PN/PN coupler.

10.1.4.9 Integrating external tools

Integrating S7-external tools

Introduction

Tools external to STEP 7 ("Device Tools") with a special call interface (Tool Calling Interface) can be used to configure distributed devices. Such devices are also referred to as "TCI capable".

The performance range of these tools exceeds the possibilities provided within GSD configuration, for example, they can provide expanded graphical input options.

Distributed devices can be as follows:

- PROFIBUS DP slaves
- Modules within a DP slave
- PROFINET IO devices
- Modules within an IO device

Note

Warranty and liability

Siemens accepts no liability for third-party software (device tools) called with the TCI (Tool Calling Interface) or for proper interaction with the associated devices.

Requirement

The call interface of the tool complies with the TCI specification. Parameters and commands are forwarded to the distributed device via this call interface.

Such tools have to be installed using a setup provided by the manufacturer. The "S7-PCT" (Port Configuration Tool) device tool for IO-Link master modules and IO-Link devices is an exception; this is supplied with STEP 7. Special note: After the installation, the tool is not shown in the list of installed software or in the list of software products in the project.

The GSD file of the distributed device that is to be configured with the Device Tool must be installed.

Starting the device tool

The command for starting the device tool is available in the shortcut menu of the TCI-capable device in the shortcut menu of the graphical and tabular device view: "Start device tool".

See also

Starting the SIMATIC S7-PCT (Page 1814)

Starting the SIMATIC S7-PCT

Introduction

The "S7-PCT" (Port Configuration Tool) device tool is installed with STEP 7.

The tool is used to assign parameters to the ports of IO-Link modules such as 4SI IO-Link (S7-1200, ET 200S) or 4IOL+8DI+4DO (ET 200eco PN).

Requirement

You have configured the corresponding CPU, the DP slave or the IO device with an IO-Link module.

Procedure

To start via the graphical device view, follow these steps:

1. Select the IO-Link module in the device view.
2. Select "Start device tool" from the shortcut menu.

OR, to start with the tabular device view, follow these steps:

1. Select the IO-Link module in the device view.
2. Arrange the areas in the work area in such a way that the tabular device overview is visible (it is located between the device view and the inspector window).
3. Select the row with the IO-Link module in the device overview.
4. Select "Start device tool" from the shortcut menu.

Result

The tool starts and you can configure the ports.

See also

Integrating S7-external tools (Page 1813)

10.1.4.10 Loading a configuration

Introduction to loading a configuration

In order to commission a device, identical configurations must be stored on the programming device/PC and on the connected devices. To synchronize the configurations on the programming device/PC and the connected devices, you load a configuration. Configuration data can be loaded in two directions:

- From the programming device/PC to a device
- From the device to a PG/PC

See also

Uploading project data from a device (Page 354)

General information on loading (Page 348)

Downloading a configuration to a device (Page 1815)

Downloading project data to a device (Page 350)

General information on loading to PG/PC (Page 1816)

Special features during startup (Page 962)

Downloading a configuration to a device

Loading the hardware configuration

After you have inserted a new device in the project and configured it or if you have modified an existing hardware configuration, the next step is to load the current configuration to the device. This ensures that the same configuration is set on the programming device/PC and on the module that is physically present. Use the "Online > Download to device (Page 350)" menu command for this.

In the first download, the complete hardware configuration is downloaded. In subsequent downloads, only changes to the hardware configuration are downloaded.

You have the following options for loading the hardware configuration:

- Loading in the device or network view
- Loading in the project tree
- Loading to an accessible device

WARNING
Perform load operation only in STOP mode Following loading, the machine or process may behave unexpectedly if the parameter assignment is incorrect. A CPU must be set to STOP mode for the load operation to rule out possible damage to equipment or personal injury.

Special considerations for loading isochronous applications

Isochronous applications consist of a hardware configuration part and a software part.

Example: If you change the number of an IO system, the delay time, or the assignment of a process image partition of the isochronous I/O in the hardware configuration, this affects the parameters of the isochronous mode interrupt OB and thus also the software part.

With isochronous applications, you should always load the complete project (hardware and software). With partial loading (loading hardware and software separately at different times), inconsistencies can arise that, for example, can prevent CPU startup or isochronous operation of the application.

See also

General information on loading (Page 348)

Loading a configuration to PG/PC

General information on loading to PG/PC

Introduction

If you bring your PG/PC to a plant and the STEP 7 project used to create the configuration of this plant is not available, load the configuration to a new project on your PG/PC, for example. Use the "Online > Loading the device as new station (hardware and software) (Page 354)" menu command for this.

The list of accessible devices in the project tree is always used when loading a device to your programming device. You can select multiple devices and load them to the project at the same time.

Requirements

- The hardware configuration in the device must be created in TIA Portal, V12 or higher. A hardware configuration present in the device that was created with an older version cannot be loaded and must be upgraded.
- Modules present in the device from GSD (ML), HSPs, or service packs must be installed in TIA Portal on the PG/PC.

- A project must be open. This project can be a new (empty) project or an existing project.
- The opened project is in offline mode.

Scope of load operation

The following list shows an overview of the loadable components of a configuration:

- The device (e.g., a CPU) with all I/O modules and all parameter settings
- PROFIBUS master systems and all PROFIBUS-relevant settings
- PROFINET IO systems and all PROFINET-relevant settings
- I devices and I slaves
- Settings for direct data exchange

After loading a CPU, all other modules within the address area of the CPU are also loaded.

The following connections are also loaded when the configuration is loaded:

- S7 connections (including routed connections) in combined PB/IE networks, including via IE-CP or PB-CM interfaces. S7 connections are automatically accepted as configured at one end when a device configuration is loaded, even if the S7 connection was configured at both ends in the original project. When both connection partners are loaded, the connection is joined together again during the next compilation.
- TCP connections via CPU-internal Ethernet interface, UDP/ISOonTCP connections, and TCP, UDP, ISO, and ISOonTCP connections via IE-CP interface
- Connections via the OUC connection parameter assignment for projects from STEP 7 V13 and higher

Note

The hardware configuration loaded to PG/PC is not completely identical to the configuration originally loaded to the device. Note the additional information on loading, in particular with regard to partially loaded configuration data in the case of cross-device communication.

Loading PC systems, such as WinAC or PC-based automation, is not possible.

See also

General information on loading (Page 348)

Loading specific device configurations

Information on loading

When device configurations are loaded to the PG/PC, all assigned parameters are transferred from the device to the project. If the CPU is connected to a subnet, all parameters of the device are loaded and the CPU is displayed in the network view as networked.

Note

CPUs reset to their factory settings do not have any hardware configuration. Therefore, nothing is loaded in this case after "Load to PG/PC" is selected in the "Online" menu.

Loading S7-300/400 configurations

To avoid conflicts when loading a device to an existing project, the following rules must be followed:

- Device names for CPUs, PROFIBUS slaves (DP slaves, I-slaves) and PROFINET devices (IO devices, I devices) must be unique
- The combination of network name, subnet ID, and IP/DP address for modules must be unique

If conflicts occur, the load operation is canceled and an alarm provides information about the problems that occurred. You can then adapt the project correspondingly or install missing components and then repeat the load operation.

Alarm configurations are not loaded to PG/PC.

Loading S7-1200/1500 configurations

Take the following into consideration when loading:

- CPUs of the S7-1200 series with firmware version V1.0 are not supported when loading.
- Device-specific diagnostic interrupts of the S7-1200 are not supported when loading. For device-specific diagnostic interrupts of the S7-1200 to be generated on the PG/PC once again, the hardware configuration must be compiled once again.
- Module comments of the S7-1200/1500 are loaded from the device to the PG/PC if the same project language is set that was used during loading to the device. You can deselect the loading of comments, if desired.

Note

All types of PC systems, such as WinAC, Embedded Controller, CP 1616 or PC CPs, do not support loading to PG/PC.

Loading distributed I/O

The following functionalities and settings of the distributed I/O are loaded:

- DP master systems/IO systems with associated DP masters/IO controllers (CPUs and CPs), DP slaves/IO devices, the utilized modules and their parameter assignment and properties, such as options handling, status bytes, or SYNC/FREEZE
- Connection of process image partitions (PIP) to organization blocks (OB). Applies to the module and OB properties
- Configured hardware interrupts with the associated properties
- DP master systems with I-slave
- CPs as PROFIBUS I-slave or PROFINET I-device
- Direct data exchange

Master-slave relationships between the I-slave/I-device and assigned DP master/IO controller are only established in the project if both the master as well as the I-slave are loaded to the PG. It does not matter whether you load the DP master/IO controller or the I-slave/I-device first. As soon as both devices are loaded, the master-slave/controller-device relationships will also be re-established.

Loading subnets and devices with MPI, PROFIBUS, Ethernet, and PtP

The following special considerations apply to loading subnets and end points of connections for MPI, PROFIBUS, Ethernet, and PtP with their respective connection properties:

- If a device with PROFIBUS interface is loaded, the bus parameters of the device will initially be different from the settings in the original project. The bus parameters will only match those of the original project after all devices involved are loaded and no additional devices are on the same bus.
- Passive communication devices that are not connected as DP slaves or IO devices to a corresponding master system or IO system do not participate in the data exchange. They are therefore not loaded.
- All devices involved should therefore be loaded for cross-device configurations. A warning is output during compiling of the project for missing network stations. Missing routing information due to communication stations that are not loaded is displayed as warning during compilation. If the configuration is loaded from the PG/PC back to the device, different routing information results.

When you compile the project after loading devices to the PG/PC, STEP 7 checks if all devices to which communication relationships have been configured are available. If devices are missing, you receive an alarm with the number of missing communication stations.

NOTICE
Cross-device communication When you load a configuration with cross-device communication to the PG/PC, you must also load all corresponding network stations to the PG/PC. If required network stations are missing and the configuration is loaded back to the device, there is no guarantee that cross-device communication is working again.

Loading configurations with web server

Information on loading

The hardware configuration of a CPU also contains the Web server settings. A number of restrictions apply to loading a Web server configuration to the PG/PC:

- The assignment of the Web server language and project language is not loaded for S7-300/400. The project texts are not loaded and an alarm is output that no project languages are assigned. The languages assigned in STEP 7 are loaded without restriction for S7-1200/1500 CPU.
- User administration data of the S7-1200/1500 can be loaded but not edited. You can use a check box to select whether you want to use the existing data as read-only data or discard these data and enter new data.
- Watch tables of the Web server are not loaded.

The source files of the user-defined web pages (HTML pages, Java scripts, etc.) are not loaded. The program blocks generated during loading can only be edited if you enter the properties and the HTML page yourself.

See also

Information about the web server (Page 1050)

Loading configurations with PROFIBUS

Information on loading

A DP master is loaded to PG/PC. The DP master system and all connected DP slaves are inserted into the project. The respective settings remain unchanged. If a suitable PROFIBUS subnet has already been created, the loaded devices with PROFIBUS interface are connected to the existing subnet.

As a prerequisite for loading DP master systems with standard slaves, the corresponding GSD files must be installed in the TIA Portal and available in the hardware catalog. If a required GSD file is not available in the same version as in the device, differences are identified during the consistency check.

Note

Direct data exchange in a configuration is only loaded if all communication partners involved in the direct data exchange are loaded to the PG/PC.

Isochronous mode

Note the following when loading DP master systems with activated PROFIBUS functionality "Isochronous mode":

- Bus parameters and the settings for isochronous mode are only identical after the device is loaded to the PG/PC if all devices relevant for calculation of isochronous mode are loaded.
- Only mono-master systems with isochronous mode are supported. Therefore, only configurations with just one DP master on the PROFIBUS subnet are loaded.

I-slave

Master-slave relations between DP master and I slave are only established in the project if both the DP master and the I slave are downloaded to the PG. It does not matter whether you load the DP master or the I-slave first. If you load the DP master from a DP master system with connected I-slave, the DP master and its DP slaves are loaded. An I-slave proxy is loaded as dummy module for an involved I-slave.

For I-slave proxy devices:

- DP master can be complied and loaded
- Properties are displayed but cannot be changed
- Diagnostics in the project tree is not carried out

In the network view, proxy devices are represented with a question mark:

It is possible to load a DP master with connected I-slave proxy from the PG/PC to the device.

Replacing the I-slave proxy

In order to edit the I-slave in the project, you must load the I-device from the device to the PG/PC. The I-slave proxy is hereby replaced by the full I-slave with its subordinate DP slaves.

You have the following options for replacing the I-slave proxy with the corresponding I-slave:

- In the menu bar with the command "Online >Upload device as new station (hardware and software)
- With selected I-slave proxy using the shortcut menu command "Upload from device > Hardware and software".
- In the toolbar with the button "Upload from device".

Note

The replacement of I-slave proxy devices is only possible if the required I-device is available in the hardware catalog.

I-slaves protected by a password are not loaded.

Loading configurations with PROFINET

Information on loading

If you have selected a CPU in the list of accessible devices and perform an load operation to PG/PC, all IO controllers and IO devices associated with this device along with their IO systems will be loaded. Settings for the topology are also transferred. If there is already a suitable Ethernet network in the project, the loaded devices are integrated into the existing network.

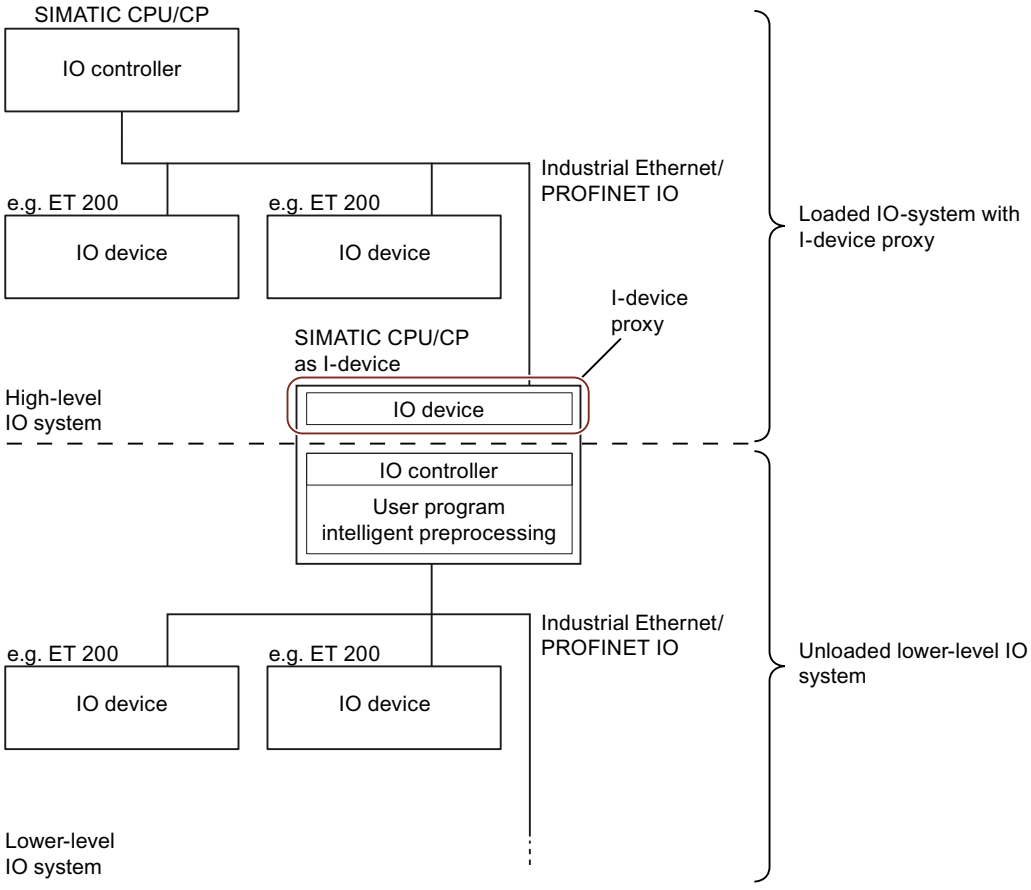
Relationships between the IO controllers and IO devices are only established within the project if both the IO controller as well as the I-device are loaded to the PG. It does not matter whether you load the IO controller or the I-devices first.

Supported functions

The following functionalities and settings are loaded:

- PROFINET configurations (RT and IRT) in IO systems with the associated IO controllers (CPUs and CPs), IO devices, and the modules used
- Logical addresses and interface properties
- Port interconnections
- Isochronous mode
- Sync domains/MRP domains
- Redundancy role "Client" or "Manager" for MRP configurations

Note

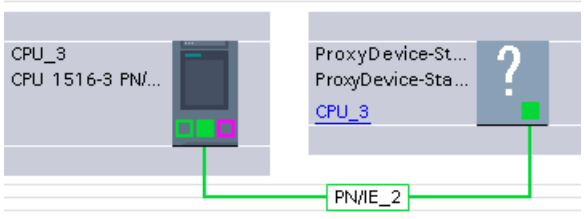


Empty Sync domains and MRP domains are not included in the loading.

GSD-based IO devices

As a prerequisite for loading GSD-based IO devices, the corresponding GSD files must be installed in the TIA Portal and available in the hardware catalog. If a required GSD file is not available in the same version as in the device, differences are identified during the consistency check.

I-device



If you load the IO controller from an IO system with connected I-device, the IO controller and its IO devices will be loaded. An I-device proxy is loaded as dummy module for an involved I-device. The CPU parameter assignment, including the parameter assignment of the CPU's "own" (subordinate) IO system, is missing in the I-device proxy. Only the interface to the higher-level IO controller is loaded.

For I-device proxy devices:

- IO controller can be compiled and loaded
- Properties are displayed but cannot be changed
- Diagnostics in the project tree is not carried out

In the network view, proxy devices are represented with a question mark:

It is possible to load an IO controller with connected I-device proxy from the PG/PC to the device.

Replacing the I-device proxy

In order to edit the I-device in the project, you must load the I-device from the device to the PG/PC. This replaces the I-device proxy with the complete I-device along with its subordinate IO devices.

You have the following options for replacing the I-device proxy with the corresponding I-device:

- In the menu bar with the command "Online >Upload device as new station (hardware and software)
- With selected I-device proxy using the shortcut menu command "Upload from device > Hardware and software".
- In the toolbar with the button "Upload from device".

Note

The replacement of I-device proxy devices is only possible if the required I-device is available in the hardware catalog.

I-devices protected by a password are not loaded.

An I-device proxy representing a SIMOTION I-device cannot be loaded and replaced.

Configurations with IE/PB link

If one of the following configurations with IE/PB Link PN IO as PROFINET IO device is present, the complete configuration with all subordinate PROFIBUS devices is loaded:

- CPU/CP of S7-300/400
- PC station and connected PROFIBUS master system

The complete configuration consists of the following:

- CPU
- CP configuration
- PROFINET IO system with connected IE/PB link
- PROFIBUS master system of the IE/PB link with connected DP slaves

An example configuration consists of an S7-300 CPU with a CP as PROFINET IO controller. An IE/PB link as IO device is connected to the IO controller. As the PROFIBUS DP master, the IE/PB link polls a PROFIBUS DP slave, e.g., ET 200L. If you load the CPU from the device to the PG/PC, the complete configuration is loaded.

Note

If the IE/PB link is not operated as a PROFINET IO proxy but rather as a gateway in standard mode, the IE/PB link functions as a CPU and can be loaded separately.

Loading Shared Devices

The following applies to loading comments: If an input/output module with the Module-internal Shared Input (MSI) or Module-internal Shared Output (MSO) function consists of only one submodule, the submodule does not have its own comment. Instead, it uses the comment of the input/output module. The module must be subdivided into several submodules for the input/output module and all submodules to have their own comment fields.

Loading HMI devices

Information on loading

We distinguish between the following cases when loading HMI devices to PG/PC:

- HMI devices connected to a DP master as DP slave or to an IO controller as IO device are loaded as DP slave or IO device respectively (for example, PP 17-I PROFIsafe).
- HMI devices in a master system as I-slave or in an IO system as I-device are loaded as I-slave proxies or I-device proxies (Page 1822) (for example, SIMATIC Comfort Panels). The settings of the device proxy are read-only.
- HMI devices are not loaded if they are connected to a subnet (PROFIBUS or PROFINET) but not to a master system or IO system (for example, KP600 Basic color DP).

Going online with loaded configurations

You can go online with the loaded project or with loaded portions of the project.

Requirement

The hardware configuration loaded from the device to the PG/PC has been compiled. The statuses of the central and distributed modules are only correctly displayed after compilation.

Note

If you go online before compiling, the diagnostics icon “?” is displayed (diagnostics not possible). A corresponding alarm is displayed under "Info > General" in the Inspector window.

Dependencies

Depending on how completely the hardware configuration was loaded to the PG, restrictions apply to going online and to diagnostics:

- Completely loaded device with all associated central and distributed modules, such as DP slaves or IO devices:
  Going online and diagnostics are possible.
- Loaded device with connected I-devices/I-slaves:
  - I device/I slave is not loaded: Going online for the device and its modules is possible. For the dependent components of the configuration that are not loaded, device proxies are handled with only minimum diagnostics support. The online status is represented as an icon. The standard diagnostics is shown in the online and diagnostics view. I&M data are not loaded.
  - I device/I slave is also loaded: Going online is possible for all devices; diagnostics is fully supported.

10.1.5 Additional information on configurations

10.1.5.1 Identification systems

RFID systems

Blocks

Ident profile and Ident blocks

You will find detailed information on the Ident profile in the manual "Ident Profile and Ident Blocks, Standard Function for Ident Systems" on the pages of "Industry Online Support (https://support.industry.siemens.com/cs/ww/en/ps/14971/man)".

Programming Ident blocks

Basic blocks

Read

The "Read" block reads the user data from the transponder and enters this in the "IDENT_DATA" buffer. The physical address and the length of the data are transferred using the "ADDR_TAG" and "LEN_DATA" parameters. With the RF68xR readers, the block reads the data from memory bank 3 (USER area). Specific access to a certain transponder is made with the "EPCID_UID" and "LEN_ID".

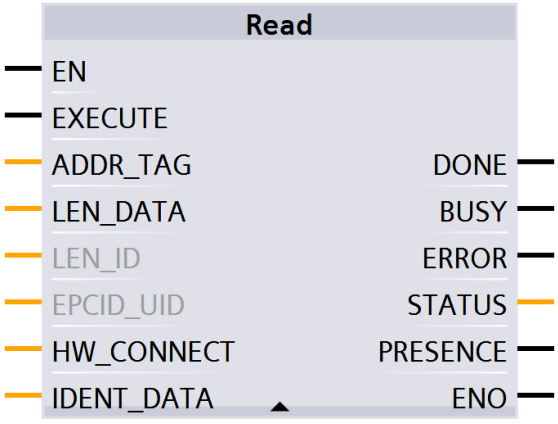


Figure 10-20 "Read" block

Table 10-108 Explanation of the "Read" block

Parameter	Data type	Default values	Description
ADDR_TAG	DWord	DW#16#0	Physical address on the transponder where the read starts. You will find more information on addressing in the section "AUTOHOTSPOT". With MV: The length of the read code is located starting at address "0" (2 bytes). The read code is located starting at address "2". [1)]
LEN_DATA	Word	W#16#0	Length of the data to be read
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)

Parameter	Data type	Default values	Description
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] ("LEN_ID = 8") Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
IDENT_DATA	Any / Variant	0	Data buffer in which the read data is stored. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

[1)] You will find further information on working with optical reader systems in the operating instructions "SIMATIC MV420 / SIMATIC MV440".

Read_MV

The "Read_MV" block reads out the read result of a camera. The length of the data to be read is calculated automatically by the camera based on the length of the created receive buffer. The actual length of the read result is output in the "LEN_DATA" output parameter. The data will be saved in the "IDENT_DATA" data buffer. If the buffer is too small, the error message "0xE7FE0400" appears and the expected length is output at "LEN_DATA".

To achieve an optimum speed, we recommend that you adapt the length of the data type "IDENT_DATA" so that this is as close as possible to the maximum expected length of the read result (2 bytes code length + read code).

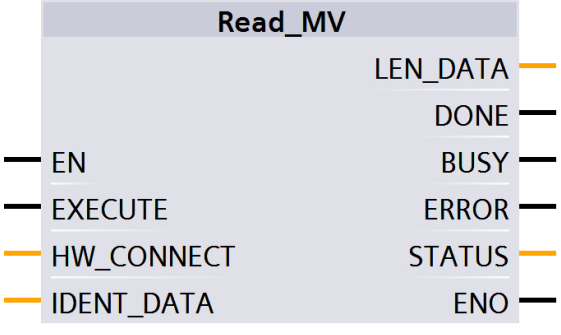

Figure 10-21 "Read_MV" block

Table 10-109 Explanation of the "Read_MV" block

Parameter	Data type	Default values	Description
IDENT_DATA	Any / Variant	0	Read result The length of the read code is located in bytes 0 and 1.
LEN_DATA	Word	W#16#0	Length of the read result ≙ 2 bytes code length + read code Note: For Variant, an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.

Reset_Reader

The "Reset_Reader" block can currently only be used in conjunction with the RF680R and RF685R readers or the RF120C communications module with a reader connected.

Using the "Reset_Reader" block, you can reset all reader types of the Siemens RFID systems. All the readers are reset to the settings stored in the device configuration of the RF120C or that were configured in the RF68x reader using the WBM. The "Reset_Reader" block does not have any device-specific parameters and is executed using the "EXECUTE" parameter.

You will find descriptions of other Reset blocks for operation with the communications modules RF180C and ASM 456 or optical reader systems in the section "AUTOHOTSPOT".

With the "Reset_Reader" block and the other reset blocks, you can interrupt any active Ident block at any time. These blocks are then ended with "DONE = true" and "ERROR = false".

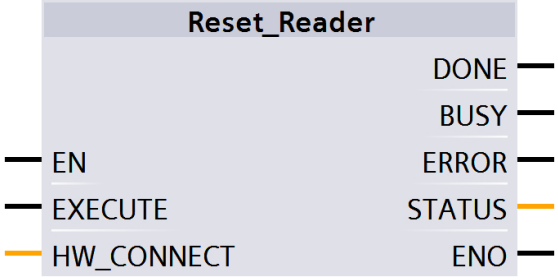

Figure 10-22 "Reset_Reader" block

Set_MV_Program

With the aid of the "Set_MV_Program" block, you can change the program in a camera. The required program number is transferred using the "PROGRAM" parameter.

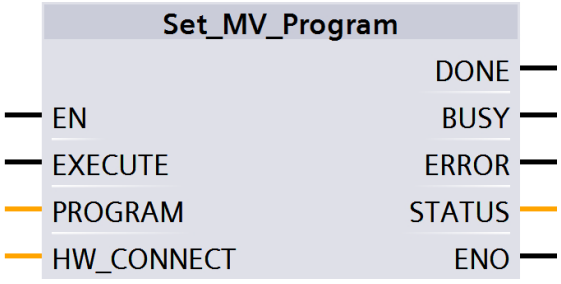

Figure 10-23 "Set_MV_Program" block

Table 10-110 Explanation of the "Set_MV_Program" block

Parameter	Data type	Default values	Description
PROGRAM	Byte	B#16#1	Program number Range of values: 0x01 ... 0x0F

Write

The "Write" block writes the user data from the "IDENT_DATA" buffer to the transponder. The physical address and the length of the data are transferred using the "ADDR_TAG" and "LEN_DATA" parameters. With the RF68xR readers, the block writes the data to memory bank 3 (USER area). Specific access to a certain transponder is made with the "EPCID_UID" and "LEN_ID".

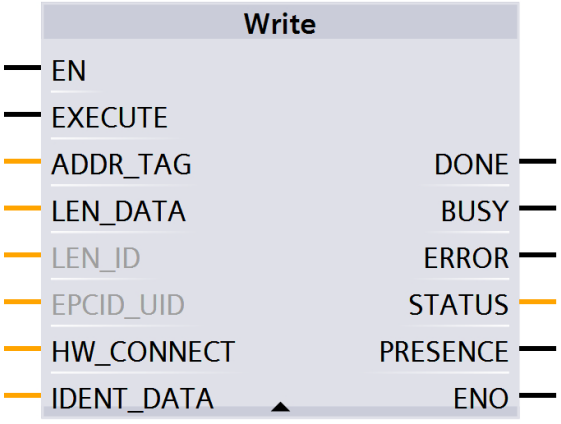

Figure 10-24 "Write" block

Table 10-111 Explanation of the "Write" block

Parameter	Data type	Default values	Description
ADDR_TAG	DWord	DW#16#0	Physical address on the transponder where the write starts. You will find more information on addressing in the section "AUTOHOTSPOT". With MV: Address is always 0. [1]
LEN_DATA	Word	W#16#0	Length of the data to be written
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] (LEN_ID = 8) Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
IDENT_DATA	Any / Variant	0	Data buffer with the data to be written. With MV: The first byte encodes the corresponding MV command.[1] Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

[1] You will find further information on working with optical reader systems in the operating instructions "SIMATIC MV420 / SIMATIC MV440".

Extended blocks

Config_Upload/-_Download

Using the "Config_Upload" and "Config_Download" blocks, you can read out ("Config_Upload") or write ("Config_Download") the configuration of the RF680R/RF685R readers via the control program.

The configuration data is not interpretable data. Save the data on the controller so that it can be written to the reader again if a device is replaced. Bytes 6-9 (see table below) contain a configuration ID with a unique version identifier. With the configuration ID, when performing a

"Config_Upload", you can check whether the configuration data read matches the configuration data stored on the controller. The configuration data has the following structure:

Table 10-112 Structure of the configuration data

Byte	Name
0	Structure identifier (2 bytes)
2	Length information (4 bytes) Length of the version identifier and parameter block
6	Version identifier (4 bytes) Based on the identifier, you can uniquely identify the configuration. This is a time stamp in Linux format. The time stamp indicates how many seconds have passed since January 1, 1979, 00:00 (midnight). The identifier is assigned when a configuration is generated.
10 ... end "DATA"	Parameter block

"Config_Upload/Config_Download" can be executed on every channel of the RF680R/ RF685R. It is always the same configuration data that is transferred.

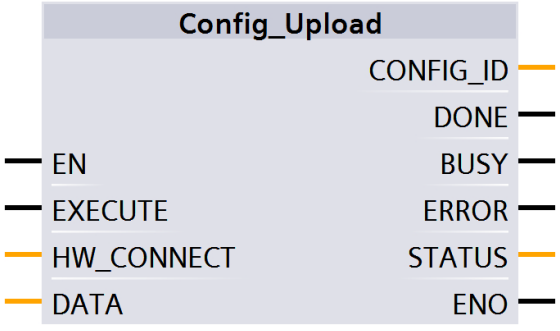

Figure 10-25 "Config_Upload" block

Table 10-113 Explanation of the "Config_Upload" block

Parameter	Data type	Description
DATA	Any / Variant	Data buffer for configuration data. The real length of the data depends on the complexity of the configuration and the firmware version of the reader. With a standard configuration of the RF680R/RF685R reader, we recommend a memory size of 4 KB. If you use advanced reader configurations (filtering) or want to change the configuration in the future without needing to adapt the memory size of "DATA", we recommend a memory size of 8-16 KB. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.
CONFIG_ID	DWord	Version identifier (4 bytes) Based on the identifier, you can uniquely identify the configuration. This is a time stamp in Linux format. The time stamp indicates how many seconds have passed since January 1, 1979, 00:00 (midnight). The identifier is assigned when a configuration is generated.

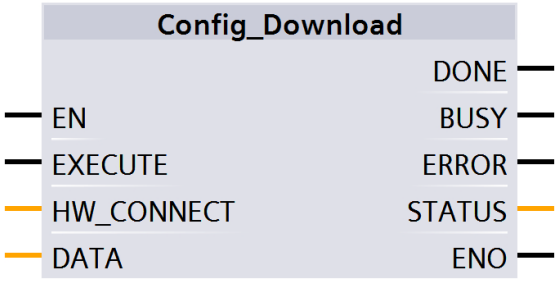

Figure 10-26 "Config_Download" block

Table 10-114 Explanation of the "Config_Download" block

Parameter	Data type	Description
DATA	Any / Variant	Data buffer for configuration data. The real length of the data depends on the complexity of the configuration and the firmware version of the reader. With a standard configuration of the RF680R/RF685R reader, we recommend a memory size of 4 KB. If you use advanced reader configurations (filtering) or want to change the configuration in the future without needing to adapt the memory size of "DATA", we recommend a memory size of 8-16 KB. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.

Inventory

The "Inventory" block activates the taking of inventories. With the RF620R and RF630R readers, inventories are always taken as soon as the antenna is turned on.

Special feature of the RF680R, RF685R readers

Note that the length of the data buffer ("IDENT_DATA") must correspond to at least the length of the maximum expected data. If more transponders are identified and data read out than have space in the assigned buffer length of "IDENT_DATA", the data of these transponders is lost. This reaction is indicated by the error "E7FE0400h" (buffer overflow).

For the RF680R and RF685R readers, the parameters "DURATION" and "DUR_UNIT" are also available. Using the parameters, you can specify the duration of the inventories.

With the RF680R/RF685R readers. there are four different modes that you can select with the "ATTRIBUTE" parameter.

- At the start, a certain duration/number (period of time, number of inventories, number of "observed" events or identified transponders) is specified. A distinction is made between the following options:
  - Duration
    Take inventories for a specified period of time
  - Number of inventories
    Take a specified number of inventories
  - Number of "observed" events
    Take inventories until a specified number of transponders have been identified at the same time.

  Inventories are then taken by the reader for this time or number of inventories. When the specified time/number is reached, the block is ended and returns all identified transponders in "IDENT_DATA". In other words, other commands can only be executed when all inventories have been taken completely. The unit (time or number) is specified using "DUR_UNIT" and the value (time value or number) using "DURATION". This mode can be executed using the attributes "0x80" and "0x81". Depending on the attribute, more or less data is supplied about the identified transponders.
- With the attributes "0x86" (start "Presence_Mode") and "0x87" (end "Presence_Mode"), inventories can be taken permanently. The presence of a transponder can then always be queried using "PRESENCE" without needing to start the block with "EXECUTE". No information about the identified transponders is returned when the command executes! To obtain information about the identified transponders, use one of the two calls listed above (with time / number of inventories = 0).
  When this mode is active, commands relating to transponders are not executed immediately but only when a transponder is identified. This achieves shorter reaction times since the command is already pending when the transponder enters the antenna field.
  The "Presence_Mode" is practical in the context of the "Repeat command" function.

The "NUMBER_TAGS" output parameter is used to output the number of identified transponders. With the attributes "0x80" and "0x81" on completion of the read operation, the sum of all identified transponders is displayed. With the attribute "0x86" the number of currently identified transponders is shown at the "NUMBER_TAGS" output parameter (max. 15), without needing to start the module with "EXECUTE".

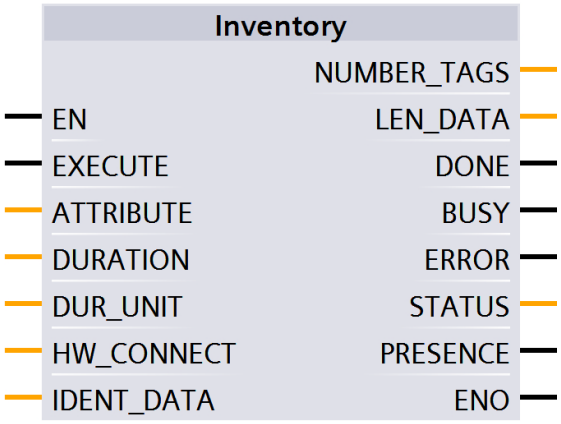

Figure 10-27 "Inventory" block

Table 10-115 Explanation of the "Inventory" block

Parameter	Data type	Default values	Description
ATTRIBUTE	Byte	B#16#0	Selecting the status mode: • RF300, MOBY U: 0x00 • RF620R, RF630R: 0x82 (read out next data record), 0x83, 0x85, 0x90, 0x91, 0x92 • RF680R, RF685R: 0x80, 0x81, 0x86, 0x87
DURATION	Word	W#16#0	RF680R, RF685R: Duration dependent on "DUR_UNIT" Period of time or number of inventories or number of "Observed" events Example: • 0x00 ≙ no inventory • 0x01 ≙ one inventory
DUR_UNIT	Word	W#16#0	RF680R, RF685R: Unit for "DURATION" • 0x00 ≙ time [ms] • 0x01 ≙ inventories • 0x02 ≙ number of "Observed" events
IDENT_DATA	Any / Variant	0	Data buffer for inventory data Note: For Variant, an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.
NUMBER_TAGS	Int	0	Number of transponders in the antenna field
LEN_DATA	Word	W#16#0	Length of the valid data

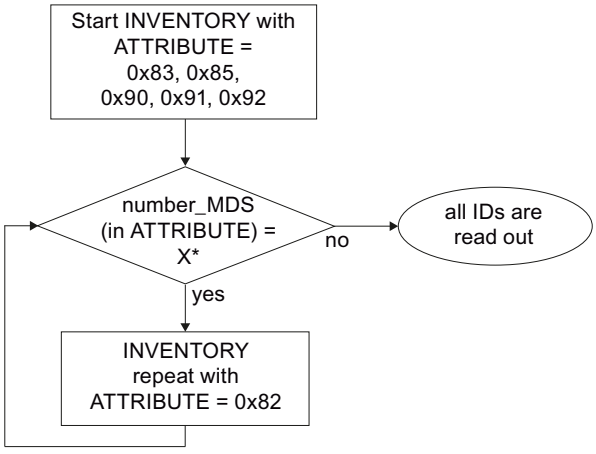
ID[10]	"IID_IN_I_20Byte"	
ID[11]	"IID_IN_I_20Byte"	

Note

Number of IDs transferred

"number_MDS" specifies the number of IDs (1 to 11 handle IDs and EPC-IDs) transferred with the "INVENTORY" block. To receive the IDs of all transponders located in the antenna field, it may be necessary to run the "INVENTORY" block again with ATTRIBUTE "0x82".



You will find more detailed information on the individual status modes in the manuals matching the modes "FB 45", "FB55" and "SIMATIC RF620R/RF630R".

The identifiers of the status modes correspond to the following identifiers in the other manuals:

0x82 ≙ 0x02
0x83 ≙ 0x03
0x85 ≙ 0x05
0x90 ≙ 0x10
0x91 ≙ 0x11
0x92 ≙ 0x12

Programming ATTRIBUTE "0x82"

If the number of transponders in the antenna field is unknown, repeat the "INVENTORY" block with the ATTRIBUTE = "0x82".

* The number of returned IDs "X" depends on the "ATTRIBUTE" used.

Figure 10-28 Program sequence of ATTRIBUTE "0x82" with unknown transponder populations

Results for RF680R, RF685R

The number of "TAG_DATA[x]" elements of the data types of the ATTRIBUTES "0x80" and "0x81" depends on the number of transponders to be expected. For this reason, you need to assemble the receive buffer yourself. Not the following structure when creating the receive buffer :"IDENT_DATA"/data type:

- The first element "NUM_MDS" is always of the type "WORD".
- The next element "TAG_DATA" is always of the type "ARRAY". The number of transponders to be expected ("n") must be entered in the "ARRAY".

The following tables show an example of the structure of the receive buffer "IDENT_DATA"/ data type for the ATTRIBUTES "0x80" and "0x81".

Table 10-120 ATTRIBUTE "0x80"

Name	Type	Comment
NUM_MDS	WORD	Number of MDS
TAG_DATA	ARRAY[1..n]of IID_IN_I_80	Length of EPC ID

[1)] Indicates how often the transponder was identified via the air interface before it changed to the "Observed" status.

Read_EPC_Mem

The "Read_EPC_Mem" block reads data starting at address 4 from the EPC memory of the RF600 transponder. Access is to memory cell 1 as of the start address. The length of the EPC memory to be read out is specified by the "LEN_DATA" parameter.

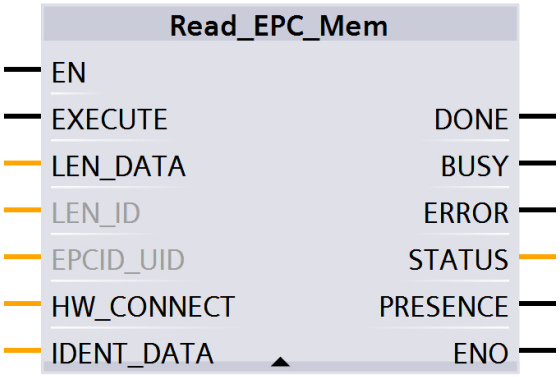

Figure 10-29 "Read_EPC_Mem" block

Table 10-122 Explanation of the "Read_EPC_Mem" block

Parameter	Data type	Default values	Description
LEN_DATA	Word	W#16#0	Length of the EPC memory to be read out (1 ... 62 bytes)
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] ("LEN_ID = 8") Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
IDENT_DATA	Any / Variant	0	Data buffer in which the read EPC memory data is stored. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

Read_TID

The "Read_TID" block reads data from the TID memory area (Tag Identification Memory Bank) of the RF600 transponder. The length of the TID to be read is specified by the "LEN_DATA" parameter. The length of the TID varies depending on the transponder and can be found in the transponder data sheet.

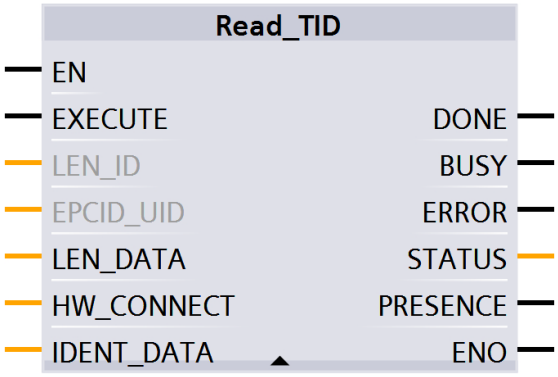

Figure 10-30 "Read_TID" block

Table 10-123 Explanation of the "Read_TID" block

Parameter	Data type	Default values	Description
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] ("LEN_ID = 8") Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
LEN_DATA	Word	W#16#4	Length of the EPC memory to be read out (1 ... 62 bytes)
IDENT_DATA	Any / Variant	0	Read TID Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

Read_UID

The "Read_UID" block reads the UID of an HF transponder. The UID always has a fixed length of 8 bytes.

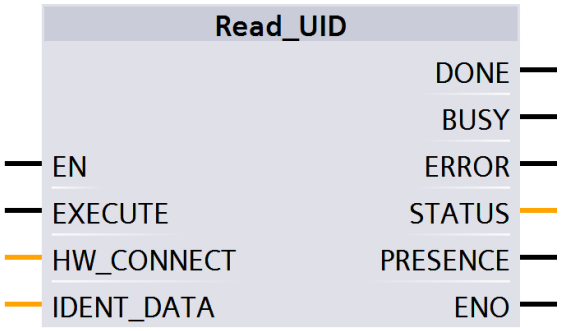

Figure 10-31 "Read_UID" block

Table 10-124 Explanation of the "Read_UID" block

Parameter	Data type	Description
IDENT_DATA	Any / Variant	UID Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.

Set_Ant

With the aid of the "Set_Ant" block, you can turn antennas on or off. There are different blocks for RF300 and RF600. The "Set_Ant_RF300" block can also be used for RF200, MOBY D and MOBY U. The "Set_Ant_RF600" block relates only to the RF620R and RF630R readers.

Set_Ant_RF300

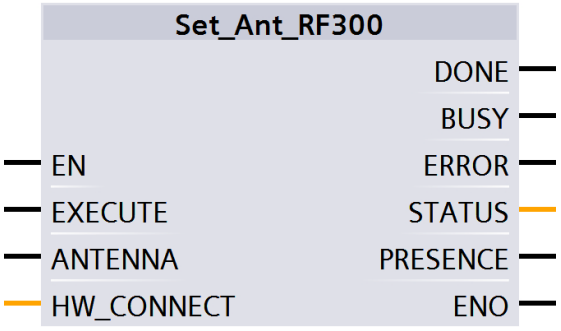

Figure 10-32 "Set_Ant_RF300" block

Table 10-125 Explanation of the "Set_Ant_RF300" block

Parameter	Data type	Description
ANTENNA	Bool	0 = turn antenna off 1 = turn antenna on

Set_Ant_RF600

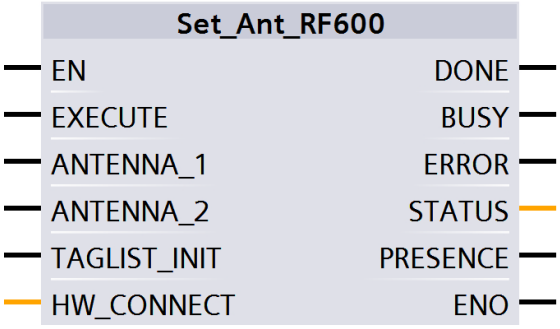

Figure 10-33 "Set_Ant_RF600" block

Table 10-126 Explanation of the "Set_Ant_RF600" block

Parameter	Data type	Description
ANTENNA_1	Bool	0 = turn antenna 1 off 1 = turn antenna 1 on
ANTENNA_2	Bool	0 = turn antenna 2 off 1 = turn antenna 2 on
TAGLIST_INIT	Bool	0 = TagList is reset 1 = the existing TagList continues to be used

Set_Param

With the "Set_Param" block, you can change UHF parameters on an RF680R/RF685R during runtime (e.g. the antenna power).

Note

Settings saved only temporarily

Note that the parameters in the "Set_Param" block are only stored temporarily. If the power for the reader is interrupted, the stored values are lost and must be set again.

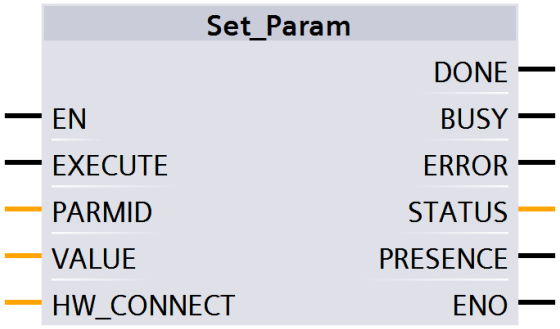

Figure 10-34 "Set_Param" block

Table 10-127 Explanation of the "Set_Param" block

Parameter	Data type	Default values	Description
PARMID	DWORD	0x00	Parameter identifier
VALUE	DWORD	0x00	Parameter value

Table 10-128 Parameter values

PARMID (hex)	PARMID (ASCII)	Parameter	VALUE
0x41315057	A1PW	Antenna 01: Radiated power	Range of values: 0.5 ... 33 Increment: 0.25 Radiated power of the antenna in [dBm]. Bytes 1 and 2 are not used, byte 3 represents the integer and byte 4 the decimal place. Example: A radiated power of 10.25 dBm represents a "VALUE" of "0x0A19".
0x41325057	A2PW	Antenna 02: Radiated power	
0x41335057	A3PW	Antenna 03: Radiated power	
0x41345057	A4PW	Antenna 04: Radiated power	
0x41315452	A1TR	Antenna 01: RSSI threshold	Range of values: 0 ... 255 Threshold value for RSSI. Transponders with lower values are discarded. Value without unit without a direct relationship with the radiated power.
0x41325452	A2TR	Antenna 02: RSSI threshold	
0x41335452	A3TR	Antenna 03: RSSI threshold	
0x41345452	A4TR	Antenna 04: RSSI threshold	
0x5331444C	S1DL	Read point 01: RSSI delta	Range of values: 0 ... 255 Difference for RSSI values. Transponders with lower values relative to the transponder with the highest RSSI value are discarded. Value without unit without a direct relationship with the radiated power.
0x5332444C	S2DL	Read point 02: RSSI delta	
0x5333444C	S3DL	Read point 03: RSSI delta	
0x5334444C	S4DL	Read point 04: RSSI delta	

PARMID (hex)	PARMID (ASCII)	Parameter	VALUE
0x4131504F	A1PO	Antenna 01: Polarization	Range of values: 0, 1, 2, 4 Polarization of the antenna (for intelligent antennas e.g. internal antenna RF685R) • 0: default, undefined • 1: circular • 2: vertical linear • 4: horizontal linear Input is bit coded. Combinations are possible (adding values).
0x4132504F	A2PO	Antenna 02: Polarization	
0x4133504F	A3PO	Antenna 03: Polarization	
0x4134504F	A4PO	Antenna 04: Polarization	
0x52364353	R6CS	Modulation scheme	Range of values: 32, 33, 34, 35, 37, 65 Modulation scheme of the read point Specification of which transponder types are identified (ISO 18000-63/-6B).
0x57544348	WTCH	Date and time	Range of values: 01.01.2000 00:00 a.m. ... 19.01.2038 3:14 a.m. 01.01.2000 01:00 a.m. ≙ 946684800 Date and time (UTC) Time in seconds since 01.01.1970; Setting of the internal reader clock, the date and time are set.
0x57544F44	WTOD	Time	Range of values: 0:00 – 23:59 p.m. S7 time (TOD, UTC) Milliseconds since midnight; Setting of the internal reader clock, only the time is changed but not the date.
0x57444154	WDAT	Date	Range of values: 01.01.2000 ... 18.01.2038 S7 date Days since 01.01.1970; Setting of the internal reader clock, only the date is changed but not the time.

Write_EPC_ID

The "Write_EPC_ID" block overwrites the EPC-ID of the RF600 transponder and adapts the length of the EPC-ID in the memory of the transponder. The new EPC-ID length to be written is specified with the "LEN_ID_NEW" parameter and the previous EPC-ID is specified using the "LEN_ID" and "EPCID_UID" parameters.

Make sure that when you execute the block only one transponder is located in the antenna field. This ensures that the identification when writing the ID is unique. If there is more than one transponder in the antenna field, a negative response is returned.

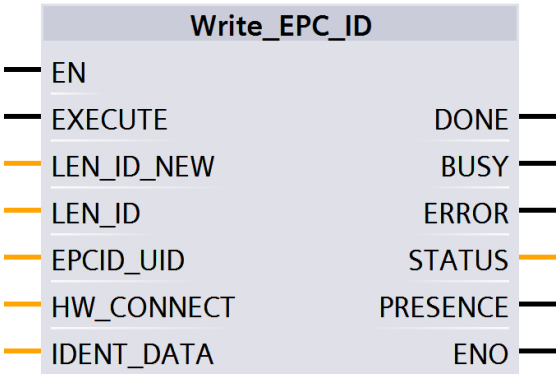

Figure 10-35 "Write_EPC_ID" block

Table 10-129 Explanation of the "Write_EPC_ID" block

Parameter	Data type	Default values	Description
LEN_ID_NEW	Byte	W#16#0C	Length of the current EPC-ID
LEN_ID	Byte	B#16#0	Length of the previous EPC-ID
EPCID_UID	Array[1...62] of Byte	0	Previous EPC ID
IDENT_DATA	Any / Variant	0	Current EPC ID Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

Write_EPC_Mem

The "Write_EPC_Mem" block overwrites the EPC memory of the RF600 transponder starting at address 4. The length of the EPC memory to be overwritten is specified by the "LEN_DATA" parameter.

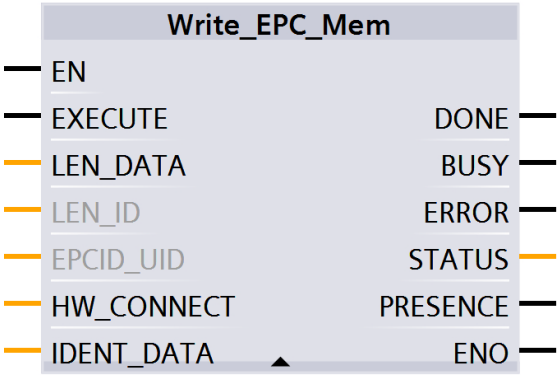

Figure 10-36 "Write_EPC_Mem" block

Table 10-130 Explanation of the "Write_EPC_Mem" block

Parameter	Data type	Default values	Description
LEN_DATA	Word	W#16#0	Length of the EPC memory to be overwritten (1 ... 62 bytes)
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] ("LEN_ID = 8") Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
IDENT_DATA	Any / Variant	0	Data buffer with the EPC memory data to be overwritten. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

AdvancedCMD

With the "AdvancedCmd" block, every command can be executed including commands not represented by other blocks. This general structure can be used for all commands and is intended only for trained users.

This gives you the option of sending the command as a chained command. To allow this, the block provides a CMD buffer for 100 commands. All chained commands must be entered starting at the first position in the buffer. For every chained command, the "chained bit" must also be set in the CMD structure. The "chained bit" is not set in the last command in the chain. You will find further information on the "chained bit" in the section "AUTOHOTSPOT".

The entire command structure must be specified in the "CMD" input parameter. You create the structure for the "CMD" parameter in a data block.

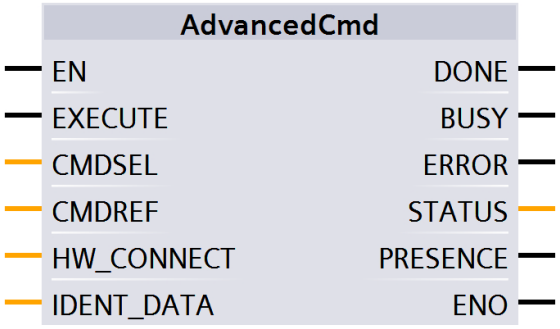

Figure 10-37 "AdvancedCmd" block

Table 10-131 Explanation of the "AdvancedCmd" block

Parameter	Data type	Default values	Description
CMDSEL	Int	1	Selection of the command to be executed "CMDREF"; 1 ⇒ 1. Command, ... The value of the "CMDSEL" parameter can never be > 100.
CMDREF	Any / Variant	--	You will find a detailed description of the parameter in the sections: • "AUTOHOTSPOT" • "AUTOHOTSPOT"
IDENT_DATA	Any / Variant	0	Buffer for data to be written or read. Note: For Variant, currently only an "Array_of_Byte" with a variable length can be created. For Any, other data types/ UDTs can also be created.

Reset blocks

The reset blocks described in this section are required when you want to operate the optical reader systems MV420, MV440 or the communications modules RF180C, ASM 456 with a SIMATIC S7-1200/S7-1500 controller. As an alternative you can also use these blocks for the RF120C if you have selected the appropriate setting in the device configuration.

In the system, these reset blocks have the same function as the "Reset_Reader" block described earlier. However, with the blocks described here, you need to set reader-dependent parameters.

Remember that the default value will be used automatically if you do not select a value manually.

Reset_MOBY_D

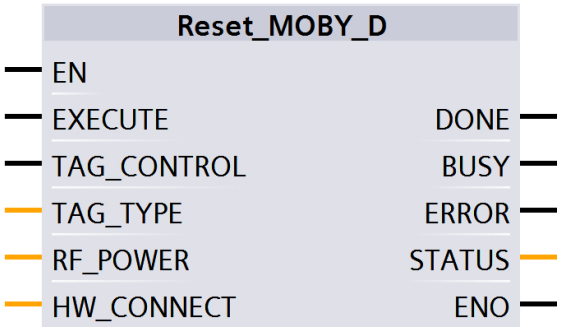

Figure 10-38 "Reset_MOBY_D" block

Table 10-132 Explanation of the "Reset_MOBY_D" block

Parameter	Data type	Default values	Description
TAG_CONTROL	Bool	True	Presence check
TAG_TYPE	Byte	1	Transponder type: • 1 = every ISO transponder
RF_POWER	Byte	0	Output power RF power from 0.5 W to 10 W in increments of 0.25 W (range of values: 0x02 ... 0x28)

Reset_MOBY_U

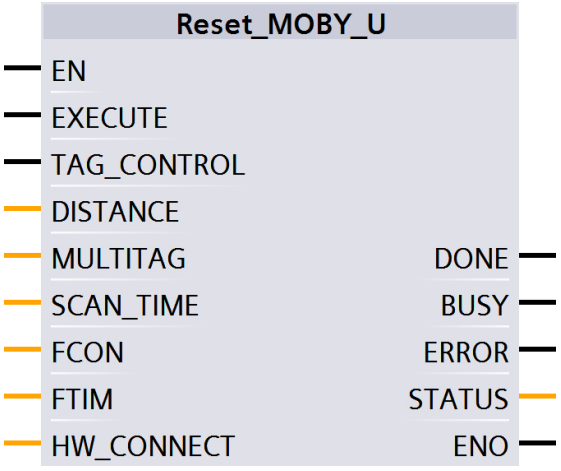

Figure 10-39 "Reset_MOBY_U" block

Table 10-133 Explanation of the "Reset_MOBY_U" block

Parameter	Data type	Default values	Description
TAG_CONTROL	Bool	True	Presence check
DISTANCE	Byte	23h	Range limitation (range of values: 0x02 ... 0x23 or 0x82 ... 0xA3 for reduced transmit power)
MULTITAG	Byte	1	Maximum number of transponders that can be processed at the same time in the antenna field. (Range of values: 0x01 ... 0x12)
SCAN_TIME	Byte	0	Scanning time: Standby time of the transponder (range of values: 0x00 ... 0xC8)
FCON	Byte	0	field_ON_control: BERO mode (range of values: 0x00 ... 0x03)
FTIM	Byte	0	field_ON_time: Time for BERO mode (range of values: 0x00 ... 0xFF)

Reset_MV

To reset cameras of the optical reader systems, call the block and activate the "EXECUTE" parameter.

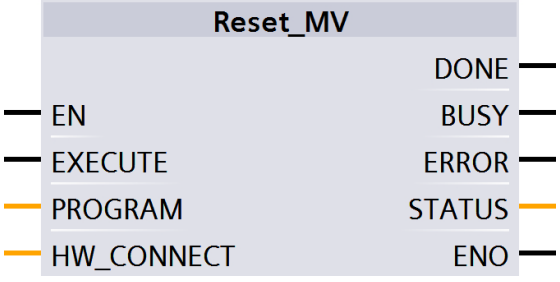

Figure 10-40 "Reset_MV" block

Table 10-134 Explanation of the "Reset_MV" block

Parameter	Data type	Description
PROGRAM	Byte	Program selection • B#16#0: Reset without program selection or in the case of diagnostics, the error code for "IN_OP = 0" is shown at the "STATUS" output parameter. • B#16#1 ... B#16#0F: Number of the program to be started ⇒ Reset with program selection (as of firmware V5.1 of the MV4x0)

Reset_RF200

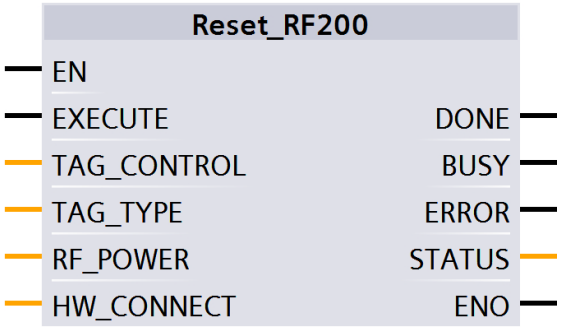

Figure 10-41 "Reset_RF200" block

Table 10-135 Explanation of the "Reset_RF200" block

Parameter	Data type	Default values	Description
TAG_CONTROL	Byte	1	Presence check
TAG_TYPE	Byte	1	Transponder type: • 1 = every ISO transponder • 3 = MDS D3xx - optimization
RF_POWER	Byte	4	Output power; only relevant for RF290R RF power from 0.5 W to 5 W in increments of 0.25 W (range of values: 0x02 ... 0x14). Default value 0x04 ≙ 1 W.

Reset_RF300

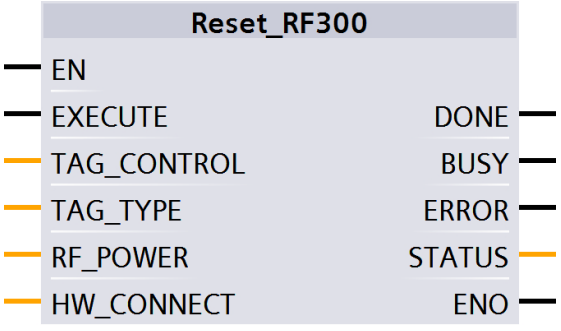

Figure 10-42 "Reset_RF300" block

Table 10-136 Explanation of the "Reset_RF300" block

Parameter	Data type	Default values	Description
TAG_CONTROL	Byte	1	Presence check • 0 = Off • 1 = on • 4 = presence (antenna is off. The antenna is turned on only when a Read or Write command is sent.)
TAG_TYPE	Byte	0	Transponder type: • 1 = every ISO transponder • 0 = RF300 transponder
RF_POWER	Byte	0	Output power; only relevant for RF380R RF power from 0.5 W to 2 W in increments of 0.25 W (range of values: 0x02 ... 0x08). Default value 0x00 ≙ 1.25 W.

Reset_RF600

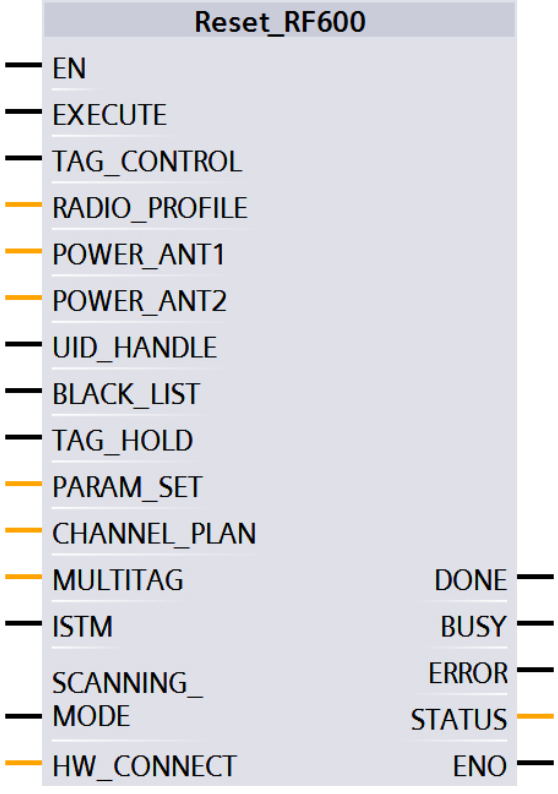

Figure 10-43 "Reset_RF600" block

Table 10-137 Explanation of the "Reset_RF600" block

Parameter	Data type	Default values	Description
TAG_CONTROL	Bool	True	Presence check
RADIO_PROFILE	Byte	1	Scanning time: Wireless profile according to EPC Global (range of values: 0x01 ... 0x09 depending on the reader variant)
POWER_ANT1	Byte	0	Transmit power for antenna 1 or internal antenna (range of values: 0x00 ... 0x0F)
POWER_ANT2	Byte	0	Transmit power for antenna 2 or external antenna (range of values: 0x00 ... 0x0F)
UID_HANDLE	Bool	False	Meaning of the UID in the command: True = Handle ID, only the least significant 4 bytes of the UID are evaluated; False = UID/EPC-ID with a length of 8 bytes
BLACK_LIST	Bool	False	True = activate black list
TAG_HOLD	Bool	False	True = activate Tag Hold
PARAM_SET	Byte	0	Field_ON_Control (0 = fast; range of values: 0x00, 0x02)
CHANNEL_PLAN	Byte	0F	Field_ON_Time (range of values: 0x00 ... 0x0F; ETSI only)
MULTITAG	Byte	1	Maximum number of transponders that can be processed at the same time in the antenna field. (Range of values: 0x01 ... 0x50)
ISTM	Bool	False	True = activate intelligent single tag mode
SCAN-NING_MODE	Bool	False	True = activate scanning mode [1]

[1] Is not currently possible with the Ident blocks.

Reset_Univ

The "Reset_Univ" block is a universal reset block with which all identification systems can be reset. Use this block only after consulting Support.

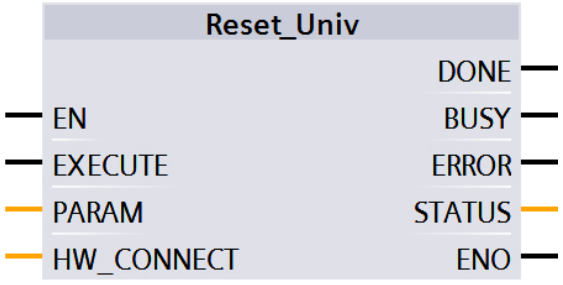

Figure 10-44 "Reset_Univ" block

Table 10-138 Explanation of the "Reset_Univ" block

Parameter	Data type	Description
PARAM	Array [1...16] of Byte	Data for reset frame The data to be set here can be made available by Support when necessary for special settings.

Table 10-139 Structure of the "PARAM" parameter

Byte	1	2...5	6	7...8	9	10	11	12	13...14	15	16
Value	04h	0	0Ah	0	scan-ning_ time	param	op-tion_ 1	dis-tance_ limiting	Num-ber of trans-pond-ers	field_ on_ control	field_ on_ time

Status blocks

Reader_Status

The "Reader_Status" block reads status information from the reader. For the various reader families, there are different status modes that you can select using the "ATTRIBUTE" parameter.

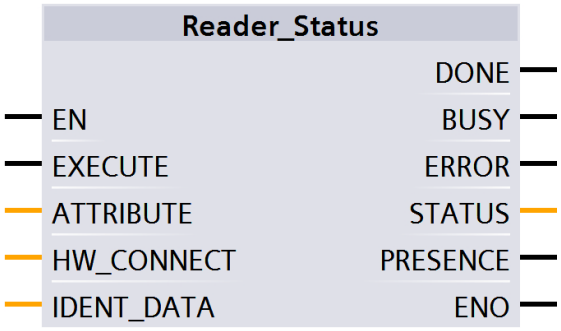

Figure 10-45 "Reader_Status" block

Table 10-140 Explanation of the "Reader_Status" block

Parameter	Data type	Default values	Description
ATTRIBUTE	Byte	B#16#81	Identifier of the status modes / possible entries: • RF200: 0x81 • RF300: 0x81, 0x86, 0xEF • RF620R, RF630R: 0x87, 0x88, 0xA0, 0xA1 • RF680R, RF685R: 0x89 • MOBY U: 0x81, 0x84, 0x85 • MOBY D: 0x81
IDENT_DATA	Any / Variant	0	Event values depending on attributes Note: For Variant, an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.

Results

Apply the correct data type that is assigned to the ATTRIBUTE value at the "IDENT_DATA" input of the block so that the data can be correctly interpreted.

Note that the UDTs can only be used when the blocks "Reader_Status" or "Tag Status" used.

Table 10-141 ATTRIBUTE "0x81" (data type "IID_READSTAT_81_RF2_3_U")

0x92 ≙ 0x12
0xA0 ≙ 0x20
0xA1 ≙ 0x21

Tag_Status

The "Tag_Status" block reads the status information of the transponder. For the various transponder types and reader families, there are different status modes that you can select using the "ATTRIBUTE" parameter.

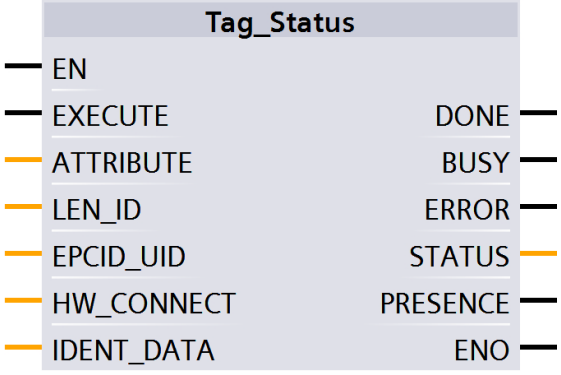

Figure 10-46 "Tag_Status" block

Table 10-148 Explanation of the "Tag_Status" block

Parameter	Data type	Default values	Description
ATTRIBUTE	Byte	B#16#0	Identifier of the status modes / possible entries: • RF200: 0x83 • RF300: 0x04, 0x82, 0x83 (only ISO transponders) • RF620R, RF630R: 0x84, 0x85 • MOBY D: 0x83 [1)] • MOBY U: 0x80
LEN_ID	Byte	B#16#0	Length of the EPC-ID/UID Default value: 0x00 ≙ unspecified single tag access (RF680R, RF685R)
EPCID_UID	Array[1...62] of Byte	0	Buffer for up to 62 bytes EPC-ID, 8 bytes UID or 4 bytes handle ID. • 2 - 62-byte EPC-ID is entered at the start of the buffer (length is set by "LEN_ID") • 8-byte UID is entered at the start of the buffer ("LEN_ID = 8") • 4-byte handle ID must be entered in the array element [5]-[8] ("LEN_ID = 8") Default value: 0x00 ≙ unspecified single tag access (RF620R, RF630R)
IDENT_DATA	Any / Variant	0	Event values depending on attributes Note: For Variant, an "Array_of_Byte" with a variable length can be created. For Any, other data types/UDTs can also be created.

1) SLG D10S only

Results

Note that the UDTs can only be displayed when the blocks "Reader_Status" or "Tag_Status" are used.

reserved5	ARRAY[1..137] of BYTE	

[1] The internal time stamp of the reader that relates to this event is output. The internal reader time stamp is not synchronized with UTC.

[2] The value "Reads" indicates the total transponder recognitions (inventories) regardless of the set smoothing parameters. In this way, in extreme situations, the "Reads" counter can reach extremely high values without the transponder ever reaching the "Observed" status.

[3] The "current_Power" value is specified as transmit power in 0.25 dBm steps (ERP/EIRP). A "current_Power" value of "72" (0x48) therefore corresponds to 18 dBm (ERP/EIRP).

You will find more detailed information on the individual status modes in the manuals matching the modes "FB 45", "FB55" and "SIMATIC RF620R/RF630R".

The identifiers of the status modes correspond to the following identifiers in the other manuals:

0x83 ≙ 0x03
0x84 ≙ 0x04
0x85 ≙ 0x05

Programming the Ident profile

Structure of the Ident profile

Note

Parallel operation using Ident blocks and Ident profile is not possible

Note that the CM or reader cannot be operated at the same time using the Ident blocks and the Ident profile.

The blocks described in the section"AUTOHOTSPOT" represent a simplified interface of the Ident profile. If the functionality available with the blocks is not adequate for your application, you can use the Ident profile as an alternative. Using the Ident profile, you can set complex command structures and work with command repetition. The following graphic shows the Ident profile including the commands that can be implemented with it.

Note

Ident profile for trained users

The Ident profile is a complex block containing all the functionality of the Ident blocks. The Ident profile was developed specially for trained block users who want to configure complex functions with their own blocks. For untrained users, we recommend using the Ident blocks.

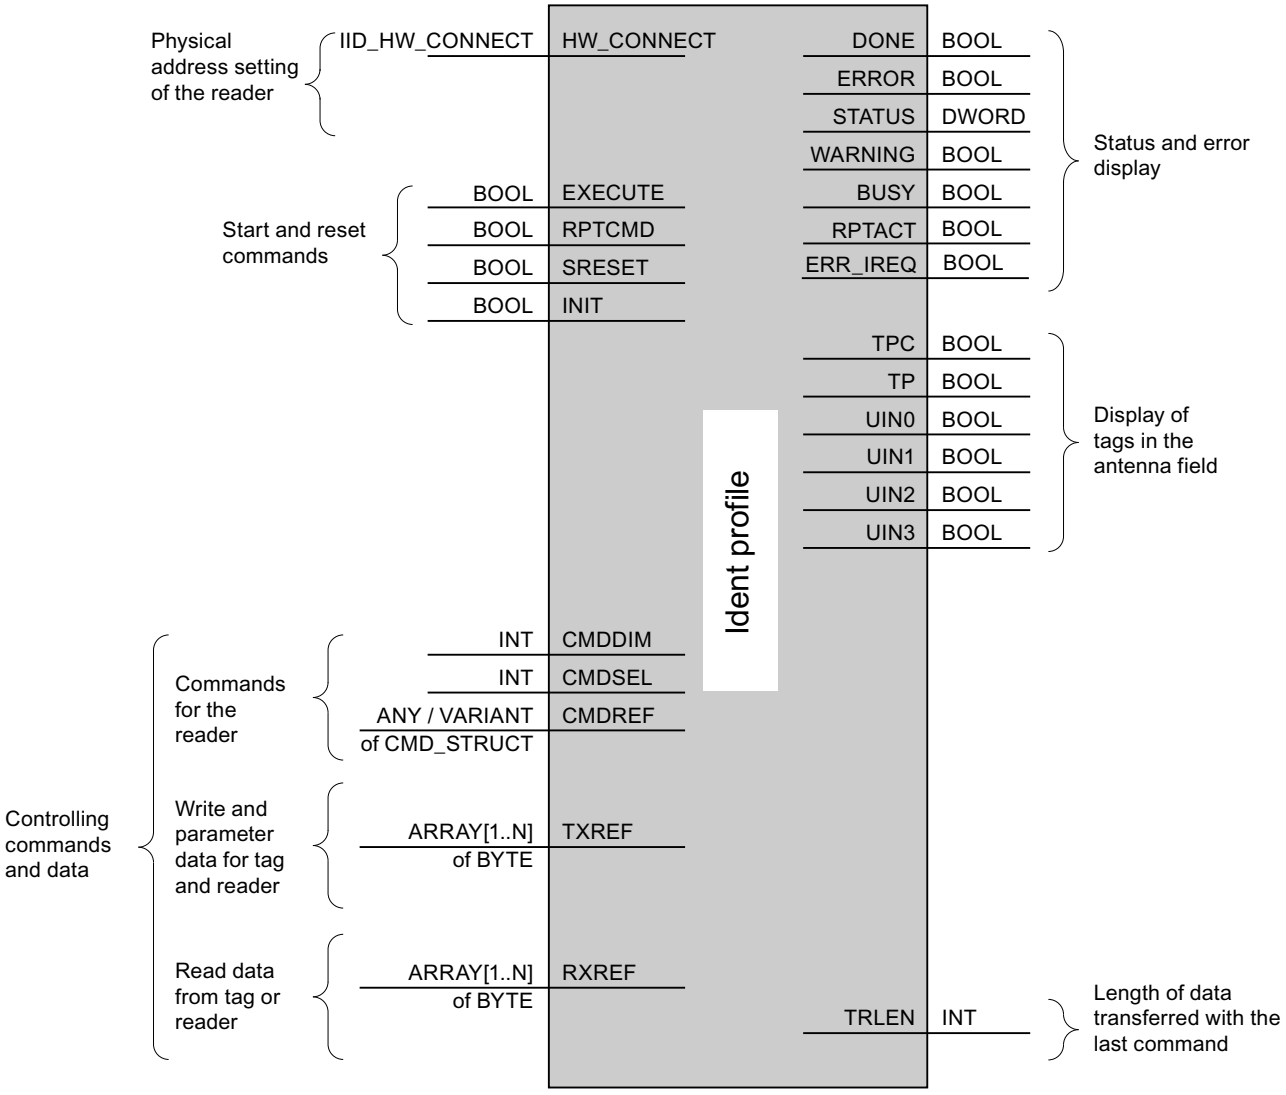

Figure 10-47 The input parameters of the Ident profile

Note

Working with multiple channels

If you work with several channels, you must ensure that for each channel, the block is called with a separate instance DB.

Interface description

Table 10-155 Input parameter

Input parameter	Data type	Default value	Description
HW_CONNECT	HW_CONNECT	--	Own data type for physical addressing of communications modules and readers and for synchronizing the blocks used for each reader. The addressing is as described in the section "AUTOHOTSPOT".
EXECUTE	BOOL	FALSE	TRUE = triggers a new command Before starting you need to set the command and the corresponding parameters in the memory linked to "CMDREF".
RPTCMD	BOOL	FALSE	TRUE = Repeating the command currently being executed or the next command to be executed by communications module
SRESET	BOOL	FALSE	TRUE = Cancellation of the command currently processed on the communications module
INIT	BOOL	FALSE	TRUE = Communications module executes a Reset and is re-assigned parameters
CMDDIM	INT	10	Number of commands in the parameter "CMDREF"
CMDSEL	INT	0	Selection of the command to be executed "CMDREF"; 1 ⇒ 1. command, ... The value of the "CMDSEL" parameter can never be higher than the value of the "CMDDIM" parameter.
CMDREF	ARRAY[1...10] of CMD_STRUCT	--	Command field The field can hold up to 10 commands. The commands are complex variables of the type "CMD_STRUCT". You will find more information on "CMDREF" in the section "AUTOHOTSPOT".
TXREF	ARRAY[1...n] of BYTE	--	Reference to global memory area for send data. The memory area can be shared with other block instances. The value "n" of the individual blocks is variable and can be up to 32 KB in size.
RXREF	ARRAY[1...n] of BYTE	--	Reference to global memory area for receive data. The memory area can be shared with other block instances. The value "n" of the individual blocks is variable and can be up to 32 KB in size.

Table 10-156 Output parameter

Output parameter	Data type	Default value	Description
DONE	BOOL	FALSE	TRUE = Command was executed free of errors.
ERROR	BOOL	FALSE	TRUE = Error was detected. The error is output in the "STATUS" parameter. The bit is reset automatically when a new command is started.

Output parameter	Data type	Default value	Description
STATUS	DWORD	FALSE	Warning and error If "ERROR = TRUE" or "WARNING = TRUE", the error or warning information is contained in the "STATUS" parameter. For more information, refer to the section "AUTOHOTSPOT".
WARNING	BOOL	FALSE	TRUE = Warning was detected. The warning is output in the "STATUS" parameter. If the "ERROR" parameter is not set at the same time, the data was correctly processed. The bit is reset automatically when a new command is started.
BUSY	BOOL	FALSE	TRUE = the block is executing a command. Other commands except for "INIT" and "SRESET" cannot be started.
RPTACT	BOOL	FALSE	TRUE = "RPTCMD" is active The acknowledgement bit shows that the "Repeat mode" of the CM/reader is active.
ERR_IREQ	BOOL	FALSE	TRUE = An error has occurred on the communications module or reader (e.g. at power-up or connection termination)
TPC	BOOL	FALSE	Transponder Presence Changed (only when the Presence_Mode is active) TRUE = A new transponder enters the antenna field of the reader or a transponder has left the antenna field. The parameter is set to "FALSE" after the successful execution of the next "INVENTORY" (0x80, 0x81, 0x87) or "INIT" command.
TP	BOOL	FALSE	Transponder Presence TRUE = There is a transponder in the antenna field of the reader.
UIN0	BOOL	FALSE	With RFID readers, the number of transponders in the antenna field is indicated. With optical reader devices, the various statuses of the reader device are displayed. UIN0: Corresponds to IN_OP bit of the reader device UIN1: Corresponds to RDY bit of the reader UIN2 + UIN3: These two bits are interpreted as an unsigned value (bit 2 is the less significant bit) that represents the number of available decoded codes. If the value is = 3, three or more decoded codes are available.
UIN1	BOOL	FALSE	
UIN2	BOOL	FALSE	
UIN3	BOOL	FALSE	
TRLEN	INT	0	Number of data elements received after successful execution of the command.

Data structure of the Ident profile

Each time the Ident profile is called, you need to supply the parameters ("HW_CONNECT", "CMDREF", "TXREF" and "RXREF") with values as described in section "Structure of the Ident profile (Page 1870)".

The call for the Ident profile is always via the input parameter "HW_CONNECT" and the "IN/OUT" parameters "CMDREF", "TXREF" and "RXREF". All three parameters need to be created

in a data block. The relationship between the three "IN/OUT" parameters is described in greater detail below:

- CMDREF (command buffer):
  Array[1...10] of CMD_STRUCT
- TXREF (send buffer):
  Array[1...n] of Byte
- RXREF (receive buffer):
  Array[1...n] of Byte

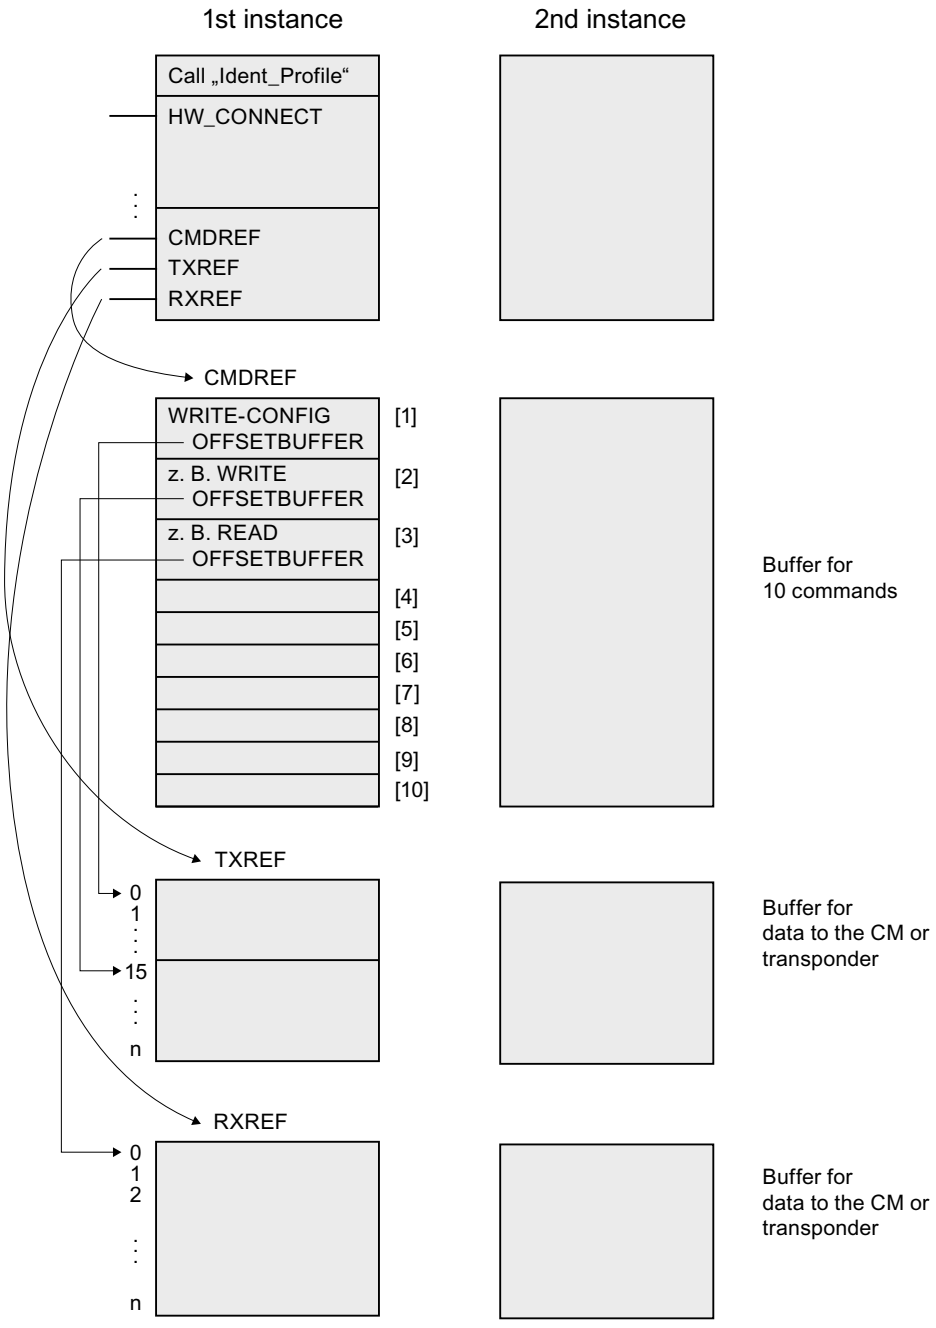

Figure 10-48 Data structure example of the Ident profile

Explanation of the data structure example

- CMDREF[1]:
  Command "WRITE-CONFIG", OFFSETBUFFER = 0
  At the CMDREF[1] point you need to set the "WRITE-CONFIG" command so that the "INIT/ Reset" is correctly executed.
- CMDREF[2]:
  Command "WRITE", OFFSETBUFFER = 15
- CMDREF[3]:
  Command "READ", OFFSETBUFFER = 0

If the "CMDREF[2]" command is selected, a write command is started and the data to be written is fetched starting at byte 15 of the "TXREF" parameter. If the "CMDREF[3]" command is selected, the read data is stored starting at byte 0 in the "RXREF" parameter.

Communications modules

Communications module RF120C

"Reader" parameter group

The "Reader" parameter group contains the following:

- Diagnostics: Setting to decide whether or not hardware diagnostics messages are output.
- Connected device: Selection of the connected Ident device / system. Depending on the selection you make, the "Ident system" parameter group is adapted.

"Diagnostics" parameter

Parameter assignment options:

- None
  Apart from standard diagnostics messages, no other diagnostics messages are generated.
- Hard Errors
  Extended diagnostics messages are generated if the following events occur.
  - Hardware error (memory test)
  - Firmware error (checksum)
  - Connection to reader lost
  - Short-circuit fault/interruption if supported by the hardware

Further information

For further information on diagnostics, refer the documentation for the RF120C communications module with application blocks for S7-1200 and S7-1500.

"Ident system" parameter group

In the "ID system" parameter group the parameters for the selected identification system are set.

The table shows the parameters that exist with all identification systems (RFID and optical reading systems).

Table 10-157 Standard parameters for all identification systems

Parameter	Parameter value	Default value	Description
Transmission speed	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	After changing the transmission speed, the reader must be turned off and on again.
Presence check	On Off (RF field off) Off (RF field on)	On	On = presence is reported as soon as there is a transponder in the antenna field of the reader Off (RF field on) = the presence check in the FB is suppressed. The antenna on the reader is nevertheless turned on as long as it has not been turned off by a command. Off (RF field off) = the antenna is turned on only when a command is sent and it then turns itself off again (RF300 only)
Reset error LED	On Off	Off	On = the flashing of the error LED on the RF120C is reset by each FB reset. Off = the error LED always indicates the last error. The display can only be reset by turning off the RF120C.

The following parameters are system specific according to the selection you made in the "Reader" parameter group.

RF200

Table 10-158 RF200 general

Parameter	Parameter value	Default value	Description
-	-	-	Only the standard parameters are available.

Table 10-159 RF290R

Parameter	Parameter value	Default value	Description
RF power	0.50 - 5.00 W	1.00 W	Setting for the output power of the reader.

RF300

Table 10-160 RF300 general

Parameter	Parameter value	Default value	Description
Transponder type	RF300 ISO 15693	RF300	Selection of the transponders used.

Table 10-161 RF380R

Parameter	Parameter value	Default value	Description
RF power	0.50 - 2.00 W	1.25 W	Setting for the output power of the reader.
Transponder type	RF300 ISO 15693	RF300	Selection of the transponders used.

RF600

Table 10-162 Ident system: RF600

Parameter	Parameter value	Default value	Description
Max. no. of transponders	1 - 80	1	Number of transponders expected in the antenna field. Permitted values: • 1 - 40 for RF620R • 1 - 80 for RF630R with 2 antennas • 1 - 40 for RF630R with 1 antenna The value stored in "multitag" defines the expected number of transponders to be read (EPC-ID) in the inventory. The value does not restrict the number of transponders to be processed in the antenna field. To ensure an efficient inventory of transponders in the antenna field, make sure that the values specified here do not deviate by more than approximately 10% from the maximum number of transponders to be expected in the antenna field.
Reader type	RF620R ETSI RF620R FCC RF620R CMIIT RF630R ETSI RF630R FCC RF630R CMIIT	RF620R ETSI	Selection of the reader used. By selecting a reader, you open the "Reader type" parameter group. The parameters are described in the following table.

Reader type (RF600 only)

In the parameter group "Reader type", further specific parameters are set for the reader type selected in the "ID system" parameter group.

Table 10-163 RF600 menu: Reader type

Parameter	Parameter value	Default value	Description
Wireless profile	-	-	Selection of the relevant wireless profile for ETSI, FCC or CMIIT.
Multitag mode	UID = EPC-ID (8 bytes) UID = Handle ID (4 bytes)	UID = EPC-ID (8 bytes)	• UID = EPC-ID (8 bytes) 8 byte UID of the bytes 5-12 of the 12 byte long EPC-ID • UID = handle ID (4 bytes) 4 byte UID as handle ID for access to transponders with an EPC-ID of any length
Intelligent Single Tag Mode (ISTM)	On Off	Off	Enable/disable the "Intelligent Single Tag Mode ISTM" algorithm [1]
Black List	On Off	Off	Enable/disable the "Black list" [1]
Radiated power internal antenna (RF620R)	0 - B	4	Setting the radiated power for the internal antenna [1] [2]
Internal antenna (RF620R)	-	-	Enable/disable the internal antenna. With the RF620R, either only the internal or only the external antenna can be set.
Transmit power (external antenna RF620R)	0 - 9	4	Setting the transmit power for the external antenna [1] [2]
External antenna (SetAnt block required) (RF620R)	-	-	Enable/disable the external antenna. With the RF620R, either only the internal or only the external antenna can be set.
Transmit power ANT 1 (RF630R)	0 - 9	4	Setting the transmit power for antenna 1 [1] [2]
Transmit power ANT 2 (RF630R)	0 - 9	4	Setting the transmit power for the antenna 2 [1] [2]
Communications speed	Reliable detection Fast detection	Reliable detection	[1]
Tag hold	On Off	Off	Enable/disable "Tag hold" [1]
Scanning mode	On Off	Off	Enable/disable the "Scanning mode" [1]
Channel assignment (only with wireless profile ETSI)	-	-	Selection of the wireless channels to be used [1]

[1] You will find further information in the "Configuration manual RF620R/RF630R".*

[2] The values for the transmit/radiated power of the antennas can be found in the following table.

* You will find the configuration manual RF620R/RF630R here (http://support.automation.siemens.com/WW/view/en/10805817).

Table 10-164 Transmit / radiated power of the antennas

Hex value	RF630R transmit power	RF620R radiated power (internal antenna)			RF620R transmit power
		ETSI	FCC	CMIIT	
	dBm / (mW)	dBm / (mW) ERP	dBm / (mW) EIRP	dBm / (mW) ERP	dBm / (mW)

B (...F)	27 / (501)	29 / (794)	31 / (1259)	29 / (794)	27 / (501)

SLG D10S

Table 10-165 SLG D10S

Parameter	Parameter value	Default value	Description
RF power	0.50 - 10.00 W	1.00 W	Setting for the output power of the reader.
Transponder type	ISO I-Code (e.g. MDS D139)	ISO	Selection of the transponders used.

SLG D11S/D12S

Table 10-166 SLG D11S/D12S

Parameter	Parameter value	Default value	Description
Transponder type	ISO I-Code (e.g. MDS D139)	ISO	Selection of the transponders used.

MOBY U

Table 10-167 MOBY U

Parameter	Parameter value	Default value	Description
Standby time	0 - 1400 ms	0 ms	Standby time (scanning_time) for the transponder. If the transponder receives a further command before the standby time has elapsed, this command can be executed immediately. If the transponder receives a command after standby time has elapsed, command execution is delayed by the "sleep_time" of the transponder.
Distance limitation	0.2 m 0.5 m 1.0 m 1.5 m 2.0 m 2.5 m 3.0 m 3.5 m	1.5 m	-
Max. no. of transponders	1 - 12	1	Maximum number of transponders that can be processed at the same time in the antenna field.

Parameter	Parameter value	Default value	Description
BERO mode	Without BEROs 1 or 2 BEROs 1st BERO on, 2nd BERO off Synchronization by cable connection	Without BEROs	• Without BEROs No reader synchronization • 1 or 2 BEROs The BEROs are logically ORed. The antenna field is turned on during the actuation of a BERO. • 1st BERO on, 2nd BERO off The 1st BERO switches the antenna field on and the 2nd BERO switches the antenna filed off. If there are two BEROs and a "BERO time in s" is set, the antenna field is automatically turned off if the 2nd BERO does not switch within this BERO time. If no "BERO time in s" is set, the antenna field remains turned on until the 2nd BERO is activated. • Synchronization by cable connection Enable reader synchronization via cable connection (see manual on configuration, installation and service for MOBY U).
BERO time in s	0 - 255 s	0 s	Can only be set if the BERO mode is set to "1st BERO on, 2nd BERO off". • 0 The time monitoring is disabled. To switch the field off, the 2nd BERO is required. • 1 ... 255 s Operating time for the reader field

General Reader

Table 10-168 General Reader

Parameter	Parameter value	Default value	Description
Input box for byte sequence (hexadecimal)	00000000	00000000	Expert mode With this function, you can specify the reset parameters directly in hexadecimal notation. This setting may only be selected if you have previously received the hexadecimal string for the setting from a member of the SIEMENS staff.

Parameters via FB / optical readers

Table 10-169 Parameters via FB / optical readers

Parameter	Parameter value	Default value	Description
MOBY mode	RF200/RF300/ RF600; MV4x0; MO-BY U/D	RF200/RF300/ RF600; MV4x0; MO-BY U/D	Only the mode "RF200/RF300/RF600; MV4x0; MOBY U/D" is supported. For further information on resetting a function block, refer to the documentation for the RF120C communications module with application blocks for S7-1200 and S7-1500. *

* You will find information on the documentation here (https://support.industry.siemens.com/cs/ww/en/ps/14971/man).

Communications module RF170C

Communications module for Ident systems - RF170C, RS422/RS232

The module RF170C RS422/RS232 is a communications module for Ident systems for the I/O system ET 200pro. Several RF170C RS422/RS232 communications modules can be mounted and operated on an IM 154-8 CPU and on an interface module IM 154-1 DP, IM 154-2 DP High Feature or IM 154-4 PN High Feature of the ET 200pro.

A maximum of two readers can be connected to the RF170C RS422/RS232. The connected readers are processed at the same time

The function blocks FB 45, FC 45 and the program block for the Ident profile/RFID standard profile allow simple programming using the SIMATIC S7 tools. The function blocks FB 45, FC 45 and the program block for the Ident profile/RFID standard profile can be operated both on the S7-300 and the S7-400. For the S7-1200 and S7-1500 controllers, the Ident profile must be used.

The transponder data is accessed by means of normal addressing or file handler addressing.

Physical addressing of the transponder

Physical addressing of a transponder is also referred to as normal addressing. When using normal addressing you can set up the data structure of a transponder yourself You decide which physical address which data is written to. The addressing of the transponder memory generally begins at the address 0x0000 hex and ends at an end address that corresponds to the size of the transponder memory.

File handler addressing of the transponder

With file handler addressing you specify a file name for access to the data. The file name consists of eight ASCII characters. The file handler manages the user data on the transponder independently. You do not need to configure any data structures on the transponder.

"Module parameters" parameter group

In this parameter group, you can configure all module-specific parameters of the RF170C RS422/RS232.

Table 10-170 Parameters in the "Module parameters" parameter group

Parameter	Parameter value	Default value	Description
User Mode	Ident profile/RFID standard profile FB 45 / FC 45 FB 55 / FC 55	Ident profile/RFID standard profile	Selection depends on the communications module and and Ident system being used. With this parameter you select the block: • Ident profile/RFID standard profile: The program block for the Ident profile/RFID standard profile is used on the controller. • FB 45 / FC 45: Single tag mode FB 45 (PROFIBUS/ PROFINET) or FC 45 (PROFIBUS) is used on the controller. • FB 55 / FC 55: Multitag mode. FB 55 (PROFIBUS/ PROFINET) or FC 55 (PROFIBUS) is used on the controller.
MOBY Mode	RF200/RF300/RF600; MV4x0; MOBY U/D MOBY I/E MV3xx Freeport protocol RF300 filehandler	RF200/RF300/ RF600; MV4x0; MOBY U/D	Selection depends on the communications module and and Ident system being used. With this parameter, you set the mode of the communications module. • RF200/RF300/RF600; MV4x0; MOBY U/D • MOBY I/E • MV3xx • Freeport protocol • RF300 filehandler Normal addressing: The transponder is addressed with physical addresses. Filehandler: Prior to use, the transponder needs to be formatted.
Transmission speed	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	Selection depends on the communications module and and Ident system being used. With this parameter you set the transmission speed between the communications module and reader. When the RFID reader is connected: After changing the transmission speed, the reader must be turned off and on again. With a connected optical reader: The transmission speed selected here must match the transmission speed selected in the firmware of the reader.

Parameter	Parameter value	Default value	Description
Diagnostics messages	None Hard errors	None	Selection depends on the communications module and and Ident system being used. With this parameter you set whether hardware diagnostics messages will be reported. • None: Apart from standard diagnostics, no other alarms are generated. • Hard errors: Critical hardware errors are reported by the S7 diagnostics.
Suppression of Error LED	None Channel 1 Channel 2	None	Disabling the Error LED (ERR) of a channel. The communications module has two channels to which the readers / optical readers can be connected. The Error LED of the other channel flashes permanently when only one of the channels is being used. With the help of the suppression, you can disable the Error LED of the unused channel.
Interface	RS-232 RS-422	--	Selection of the interface type that the connected hardware (reader / optical reader) uses.

"Message Frame" parameter group

The "Frame" parameter group is only displayed when you have selected the parameter value "Freeport protocol" in the "MOBY Mode" parameter of the module parameters. In this parameter group, you can configure all parameters specific to the "Freeport protocol".

Table 10-171 Parameters in the "Frame" parameter group

Parameter	Parameter value	Default value	Description
Data bits	7 8	8	Selection of the number of bits on which a character is represented.
Parity	None Odd Even Fixed value 1 Fixed value 0	None	Parity selection A sequence of data bits can be expanded by a parity bit. With its value "0" or "1", the parity bit is added to the sum of all bits (data bits and parity bits) to form a defined status. This increases data reliability. • None: Data is sent without a parity bit. • Odd: The parity bit is set so that the sum of the data bits (including the parity bit) is odd when the signal state is "1". • Even: The parity bit is set so that the sum of the data bits (including the parity bit) is even when the signal state is "1". • Fixed value 1: The parity bit is set permanently to the value "1". • Fixed value 0: The parity bit is set permanently to the value "0".
Stop bits	1 2	1	Selection of the number of stop bits that indicate the end of a character. The stop bits are appended to every transferred character during transmission.

Parameter	Parameter value	Default value	Description
Specifying end detection	After character delay time elapses On receipt of fixed number of characters On receipt of the end delimiter(s):	After character delay time elapses	Specifies the end detection of a received frame. • After character delay time elapses: The frame has neither a fixed length nor defined end delimiters. The end of a frame is indicated by a gap in the character sequence. The size of this gap is specified by the character delay time. • On receipt of fixed number of characters: The length of the received frame is always the same. When data is received, the end of the frame is recognized when the set number of characters has been received. • On receipt of the end delimiter(s): At the end of the frame there are one or two defined end delimiters. When data is received, the end of the frame is recognized when the set end delimiter is received.
No. of end delimiters	1 2	1	Selection of the number of end delimiters. A maximum of 2 end delimiters can be configured. When data is received, the end of the frame is recognized when the selected end delimiter combination is received.
1st end delimiter	0...7F / 0...FF	3	Input of the 1st end delimiter of maximum two end delimiters for end criteria “On receipt of the end delimiter(s)”. The selected end delimiter or the selected end delimiter combination limits the length of the frame. Parameter value depending on the "Data bits" parameter.
2nd end delimiter	0...7F / 0...FF	0	Input of the 2nd end delimiter of maximum two end delimiters for end criteria “On receipt of the end delimiter(s)”. The selected end delimiter or the selected end delimiter combination limits the length of the frame. Parameter value depending on the "Data bits" parameter.
Frame length	1...233 / 1...229	233	Entry of the frame length in bytes for the end criterion "On receipt of fixed number of characters".
Character delay time	0...65535	15	Entry of the time [ms] that may elapse until a frame end is recognized. Select the character delay time dependent on the send behavior of your communications partner. Depending on the data transmission speed the character delay time is limited to a minimum value. Note that the ASCII driver pauses between two message frames when sending.

"I/O addresses" parameter group

Inputs

1. Assign a start address to the module.
2. If you want to assign the address area to a process image partition, select the desired process image partition in the "Process image" drop-down list.

Outputs

1. Assign a start address to the module.
2. If you want to assign the address area to a process image partition, select the desired process image partition in the "Process image" drop-down list.

Note

Input and output address must be identical.

RF180C communications module

Communications module for Ident systems - RF180C

The module RF180C is a communications module for Ident systems for PROFIBUS IO.

A maximum of two readers can be connected to the RF180C. The connected readers are processed at the same time

The function blocks FB 45, FB 55, and the program block for the RFID standard profile allow simple programming using the SIMATIC S7 tools. The function blocks FB 45, FB 55,and the program block for the RFID standard profile can be operated both on the S7-300 and the S7-400.

The transponder data is accessed by means of normal addressing or file handler addressing.

Physical addressing of the transponder

Physical addressing of a transponder is also referred to as normal addressing. When using normal addressing you can set up the data structure of a transponder yourself You decide which physical address which data is written to. The addressing of the transponder memory generally begins at the address 0x0000 hex and ends at an end address that corresponds to the size of the transponder memory.

File handler addressing of the transponder

With file handler addressing you specify a file name for access to the data. The file name consists of eight ASCII characters. The file handler manages the user data on the transponder independently. You do not need to configure any data structures on the transponder.

"Module parameters" parameter group

In this parameter group, you can configure all module-specific parameters of the RF180C.

Table 10-172 Parameters in the "Module parameters" parameter group

Parameter	Parameter value	Default value	Description
User Mode	FB 45 FB 55 RFID standard profile	FB 45	Selection depends on the communications module and and Ident system being used. With this parameter you select the block: • FB 45: Single tag mode FB 45 (PROFIBUS/ PROFINET) is used on the controller. • FB 55: Multitag mode. FB 55 (PROFIBUS/ PROFINET) is used on the controller. • RFID standard profile The program block for the RFID standard profile is used on the controller.
MOBY Mode	MOBY I/E normal addressing MOBY I file handler RF200/RF300/RF600; MOBY U/D normal adr. MOBY U file handler RF300 filehandler	RF200/RF300/ RF600; MOBY U/D normal addr.	Selection depends on the communications module and and Ident system being used. With this parameter, you set the mode of the communications module. • MOBY I/E normal addressing • MOBY I file handler • RF200/RF300/RF600; MOBY U/D normal adr. • MOBY U file handler • RF300 filehandler Normal addressing: The transponder is addressed with physical addresses. Filehandler: Prior to use, the transponder needs to be formatted.
Transmission speed	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	Selection depends on the communications module and and Ident system being used. With this parameter you set the transmission speed between the communications module and reader. When the RFID reader is connected: After changing the transmission speed, the reader must be turned off and on again. With a connected optical reader: The transmission speed selected here must match the transmission speed selected in the firmware of the reader.

Parameter	Parameter value	Default value	Description
Diagnostics messages	None Hard errors Hard/Soft Errors	None	With this parameter you set whether hardware diagnostics messages will be reported. • None: Apart from standard diagnostics, no other alarms are generated. • Hard errors: Critical hardware errors are reported by the S7 diagnostics. • Hard/Soft Errors: Critical hardware faults and errors occurring when processing commands are reported by the S7 diagnostics.
Suppression of Error LED	None Channel 1 Channel 2	None	Disabling the Error LED (ERR) of a channel. The communications module has two channels to which the readers / optical readers can be connected. The Error LED of the other channel flashes permanently when only one of the channels is being used. With the help of the suppression, you can disable the Error LED of the unused channel.

ASM 456 communications module

Communications module for Ident systems - ASM 456

The ASM 456 module is a communications module for Ident systems for PROFIBUS DP V1.

A maximum of two readers can be connected to the ASM 456. The connected readers are processed at the same time

The function blocks FB 45, FC 45, FB 55, FC 55, FC 56 and the program block for the Ident profile/RFID standard profile allow simple programming using the SIMATIC S7 tools. The function blocks FB 45, FC 45, FB 55, FC 55, FC 56 and the program block for the Ident profile/ RFID standard profile can be operated both on the S7-300 and the S7-400. For the S7-1200 and S7-1500 the Ident profile must be used.

The transponder data is accessed by means of normal addressing or file handler addressing.

Physical addressing of the transponder

Physical addressing of a transponder is also referred to as normal addressing. When using normal addressing you can set up the data structure of a transponder yourself You decide which physical address which data is written to. The addressing of the transponder memory generally begins at the address 0x0000 hex and ends at an end address that corresponds to the size of the transponder memory.

File handler addressing of the transponder

With file handler addressing you specify a file name for access to the data. The file name consists of eight ASCII characters. The file handler manages the user data on the transponder independently. You do not need to configure any data structures on the transponder.

"Device-specific parameters" parameter group.

In this parameter group, you can configure all module-specific parameters of the ASM 456.

Table 10-173 Parameters in the "Module parameters" parameter group

Parameter	Parameter value	Default value	Description
User Mode	Ident profile/RFID standard profile FB 45 / FC 45 FB 55 / FC 55 FC 56	Ident profile/RFID standard profile	Selection depends on the communications module and and Ident system being used. With this parameter you select the block: • Ident profile/RFID standard profile: The program block for the Ident profile/RFID standard profile is used on the controller. • FB 45 / FC 45: Single tag mode FB 45 (PROFIBUS/ PROFINET) or FC 45 (PROFIBUS) is used on the controller. • FB 55 / FC 55: Multitag mode. FB 55 (PROFIBUS/ PROFINET) or FC 55 (PROFIBUS) is used on the controller. • FC 56 File handler for S7-300 and S7-400
MOBY Mode	RF200/RF300/RF600; MV4x0; MOBY U/D RF680R/RF685R MOBY I/E normal addressing RF300 filehandler MOBY U file handler MOBY I File handler	RF200/RF300/ RF600; MV4x0; MOBY U/D	Selection depends on the communications module and and Ident system being used. With this parameter, you set the mode of the communications module. • RF200/RF300/RF600; MV4x0; MOBY U/D • RF680R/RF685R • MOBY I/E normal addressing • RF300 filehandler • MOBY U file handler • MOBY I file handler Normal addressing: The transponder is addressed with physical addresses. Filehandler: Prior to use, the transponder needs to be formatted.

Parameter	Parameter value	Default value	Description
Transmission speed	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	Selection depends on the communications module and and Ident system being used. With this parameter you set the transmission speed between the communications module and reader. When the RFID reader is connected: After changing the transmission speed, the reader must be turned off and on again. With a connected optical reader: The transmission speed selected here must match the transmission speed selected in the firmware of the reader.
Diagnostics messages	None Hard errors Hard/soft errors low priority Hard/soft errors high priority	None	Selection depends on the communications module and and Ident system being used. With this parameter you set whether hardware diagnostics messages will be reported. • None: Apart from standard diagnostics, no other alarms are generated. • Hard errors: Critical hardware errors are reported by the S7 diagnostics. • Hard/soft errors low priority Critical hardware errors and errors that occur during command processing are reported by the S7 diagnostics. The "Ext_Diag" bit is not set. • Hard/soft errors high priority Critical hardware errors and errors that occur during command processing are reported by the S7 diagnostics. The "Ext_Diag" bit is set.
Suppression of Error LED	None Channel 1 Channel 2	None	Disabling the Error LED (ERR) of a channel. The communications module has two channels to which the readers / optical readers can be connected. The Error LED of the other channel flashes permanently when only one of the channels is being used. With the help of the suppression, you can disable the Error LED of the unused channel.

ASM 475 communications module

What you should know about the ASM 475

Introduction

Up to eight ASM 475 interface modules can be plugged in and operated in a rack of the SIMATIC S7-300. If you have a configuration with several racks (max. four racks), the ASM 475 can be plugged in and operated in each rack. This means that with the maximum configuration of a SIMATIC S7-300, 32 ASM 475 modules can be operated.

A maximum of two SLGs (write/read devices) can be connected to the ASM 475. The processing of the connected SLGs is parallel. FC45 allows simple programming using the SIMATIC S7 tools.

FC45 can be used both in the S7-300 and S7-400.

With S7-400, the ASM 475 is connected via an ET 200M.

Note that the

- IM 153-1 must have at least order number 6ES7 153-1AA03-0XB0 or 6ES7 153-1AA83-0XB0 and
- IM 153-2 at least order number 6ES7 153-2AA02-0XB0 or 6ES7 153-2AB01-0XB0.

Access to the MDS data is with normal addressing.

Physical addressing of the MDS (mobile data storage)

The physical addressing of an MDS is also known as **normal addressing**. Users set up the structure of the MDS themselves. They know the physical MDS address to which data is written. The addressing of the MDS storage generally begins at 0000 hex and ends at an end address corresponding to the size of the MDS storage.

File handler addressing of the MDS

For file handler addressing, the user specifies a file name for access to the data. The file name consists of eight ASCII characters. The file handler manages the user data independently on the MDS. The user does not need to configure data structures on the MDS.

Prior to use, the MDS needs to be formatted.

Reader

RF680R/RF685R reader

Readers RF680R/RF685R for the UHF range

The UHF readers RF680R and RF685R are intended for use in logistics and automation, for example on a production line but are equally suitable for applications in logistics. To meet these requirements, the readers were equipped with a high transmit power and degree of protection (IP65). The readers are equipped with extensive diagnostics options and can process ISO 18000-6C and ISO 18000-6B transponders.

The RF685R has one special feature with its internal, adaptive antenna. This significantly increases the reliability of read and write actions even under difficult radio conditions.

The RF680R and RF685R readers are either integrated without problems in SIMATIC S7 automation systems via an integrated PROFINET connector or via the RS-422 interface and the ASM 456 communications module via PROFIBUS. Suitable programming blocks are available. A second Ethernet interface (both M12) can be used for diagnostics during operation so that the connection to the higher-level system does not need to be interrupted.

The WBM (Web Based Management) allows commissioning, configuration and diagnostics of the devices using an Internet browser. This makes additional updates and installation of configuration and diagnostics software unnecessary.

"Web Based Management" parameter group

In this parameter group you can start the Web Based Management.

Table 10-174 Parameters in the "Web-based management" parameter group

Parameter	Description
Web Based Management (WBM)	Starting the Web Based Management of the reader. The Web Based Management provides a wide range of functions for configuring the readers. Note: The WBM can only be started if either the PROFINET connection between the CPU and reader is established or the reader was assigned the IP address stored in the project. This means that the device name has been assigned and the TIA configuration must be loaded on the SIMATIC controller.

"Module parameters" parameter group

In this parameter group, you can configure all module-specific parameters of the RF680R/ RF685R readers.

Table 10-175 Parameters in the "Module parameters" parameter group

Parameter	Parameter value	Default value	Description
RFID read point alarm	Off On	Off	Enabling/disabling read-point related diagnostics messages.

"Configuration management" parameter group

In this parameter group you can load or save the configuration data.

Table 10-176 Parameters in the "Configuration management" parameter group

Parameter	Description
User name	User name of a user created on the reader Note that the user must have the required rights.
Password	Entry of the password for the user
Load configuration to device	Loading configuration data on the reader from the STEP 7 project.
Check the configuration in the project.	Saving configuration data of the reader in the current STEP 7 project.

Requirement

The following requirements must be met to allow configuration data to be loaded or saved:

- The correct IP address of the reader is entered in the "PROFINET interface [X1]".
- The user name and corresponding password have been created in the WBM.
- The entered user has the required rights to run the download/upload.

Note

User name and password only necessary if user management is enabled

The "User name" and "Password" text boxes only need to be completed if the user management of the WBM is enabled.

"RFID communication" parameter group

In this parameter group you can configure the address range of the RFID communication.

Table 10-177 Parameters in the "RFID communication" parameter group

Parameter	Description
General	General settings Input boxes for the name of the communication and for a comment.
I/O addresses	Specify the I/O address of the reader ("LADDR") This parameter is used in the "IID_HW_CONNECT" variable.
Hardware identifier	Specify the hardware identifier of the reader ("HW-ID") This parameter is used in the "IID_HW_CONNECT" variable.

"Digital inputs/outputs" parameter group

In this parameter group you can configure the address range of the digital inputs / outputs.

Table 10-178 Parameters in the "Digital inputs / outputs" parameter group

Parameter	Description
General	General settings Input boxes for the name of the of the digital inputs / outputs and for a comment.
I/O addresses	Specify the I/O address of the digital inputs/outputs Using the set address range (I/O address), the digital inputs/outputs configured in the WBM of the reader can be accessed.
Hardware identifier	Specify the hardware identifier of the digital inputs/outputs.

Technology object "SIMATIC Ident"

Overview of the steps in configuration

Introduction

The technology object for SIMATIC Ident products allows simple parameter assignment of an Ident system in the TIA Portal. It provides an interface with simple parameter assignment between the configured hardware and the function blocks in the "SIMATIC Ident" library.

With the aid of the "Configuration" object you can select a configured device, decide on the channel / the read point and if necessary specify the connected Ident system. The technology object therefore automatically determines all the parameters required for operation.

The "Diagnostics" object displays the last 5 error messages signaled by the Ident device to the function blocks. In addition to this for every error message an error description and detailed information about the executed command are displayed.

The following overview shows the basic procedure for adding and configuring a "SIMATIC Ident" technology object.

Procedure

Follow the steps below to configure the "SIMATIC Ident" technology object:

Step	Description
1	Adding a technology object (Page 1897)
2	AUTOHOTSPOT
3	Calling the Ident instruction in the user program (Page 1904)
4	Load technology object in CPU
5	AUTOHOTSPOT

Adding a technology object

Adding a technology object in the project navigator

When you add a technology object, a data block is generated. The configuration of the technology object is stored in this data block.

Requirements

To use the "SIMATIC Ident" technology object the following requirements must be met:

- A project (V14 SP1 or higher) was created.
- According to the hardware used, the connected devices were added to the hardware configuration ("Devices & Networks"), networked with each other and configured.
- The project contains at least one S7 controller (S7-1200 or S7-1500) and at least one device (e.g. communications module, reader, optical reader).

Procedure

Follow the steps below to add a technology object:

1. Open the CPU folder in the project tree.
2. Open the "Technology objects" folder.
3. Double-click on ""Add new object".
   The "Add new object" dialog box opens.
4. Click the "SIMATIC Ident" button.
5. In the "Version" column select the newest version (as of "V5.0").
6. Select the object "TO_Ident".
7. Type in an individual name for the technological object in the "Name" input field.
8. Click "More information" if you want to store your own information for the technology object.
9. Confirm with "OK".

Result

The new technology object is created and saved to the "Technological objects" folder in the project tree.

Configuring a technology object

Working with the configuration dialog

You configure the properties of the technology object in the configuration window. To open the configuration window of the technology object, follow these steps:

1. In the project tree, open the "Technological objects" folder.
2. Open the technology object the project tree.
3. Double-click on the "Configuration" object.

The configuration is divided into the following categories:

- Basic parameters
- Ident device parameters
- Reader parameters

Symbols of the configuration window

Symbols in the area navigation of the configuration and Inspector window show additional information about the completeness of the configuration:

	The configuration contains default values and is complete The configuration only contains default values. With these preset values you can use the technology object without additional changes.
	The configuration contains values defined by the user or automatically adapted values and is complete All input fields of the configuration contain valid values and at least one default value was modified.
	The configuration is valid but contains unexpected values At least one input field or a drop down list contains an unexpected value. The corresponding field, or the drop-down list is displayed on a yellow background. When you click on it, the roll-out warning message shows you the cause of the warning.
	The configuration is incomplete or incorrect At least one input field or a drop down list contains no or an invalid value. The corresponding field, or the drop-down list, is displayed on a red background. Click the roll-out error message to identify the cause of the error.

Configuring basic parameters

In this parameter group, you can configure the module-specific parameters of your system.

Table 10-179 Parameters in the "Basic parameters" parameter group

Parameter	Description
Ident device	Click "..." and select the Ident device to be configured in the folder "Distributed I/O" or "Local modules". The following devices can be selected: • ASM 456 • RF120C, RF170C, RF180C • RF68xR • MV4x0
Channel	Open the drop down list and select the channel of the communications module to which the device to be configured is connected.
Reader parameter assignment	Open the drop down list and select the device/system connected to the Ident device that needs parameter assignment.
Read point	Requirement: In the "Reader parameter assignment" parameter the readers RF680R or RF685R were selected. Open the drop down list and select the read point to be used.

Configuring Ident device parameters

Depending on the selected Ident device, the following Ident device parameters are displayed in this parameter group. The displayed Ident device parameters are adopted automatically from the device configuration of the connected devices.

Note that not all parameter values adopted and displayed from the device configuration of the connected devices are permitted in conjunction with the technology object. If non-permitted

values are set in the device configuration you can change these either automatically with the "Autoconfiguration" button or manually using the device configuration.

Table 10-180 Parameters in the "Ident device parameters" parameter group

Parameter	Possible displayed parameter value	Permitted parameter values	Description
User Mode	Ident profile/RFID standard profile FB 45 / FC 45 FB 55 / FC 55	Ident profile/RFID standard profile	With this parameter you select the block. Note that only the following parameter values are permitted in conjunction with the technology object. • Ident profile/RFID standard profile: The program block for the Ident profile/RFID standard profile is used on the controller.
MOBY Mode	RF200/RF300/RF600; MV4x0; MOBY U/D RF680R/RF685R MOBY I/E Normal addressing RF300 file handler MOBY U file handler MOBY I file handler	RF200/RF300/RF600; MV4x0; MOBY U/D RF680R/RF685R	With this parameter, you set the mode of the communications module. Note that only the following parameter values are permitted in conjunction with the technology object. • RF200/RF300/RF600; MV4x0; MOBY U/D • RF680R/RF685R
Connected device	Parameters via FB / optical readers	Parameters via FB / optical readers	This parameter is only displayed in conjunction with the communications module RF120C. Note that only the following parameter values are permitted in conjunction with the technology object. • Parameters via FB / optical readers

"Autoconfiguration" button

The displayed HWCN parameters are adopted automatically from the device configuration of the connected devices. Note that not all parameter values are permitted in conjunction with the technology object. Non-permitted parameter values are highlighted in color.

Click the "Autoconfiguration" button to set the permitted parameter values automatically. The changed parameter values are adopted automatically in the device configuration of the connected devices from the technology object.

Note

Behavior with MV4x0 and RF68xR

Note that with the devices MV4x0 and RF68xR the "Auto configuration" button does not work. With these devices you need to enter the HWCN parameters in the device configuration of the connected devices manually.

Configuring reader parameters

Depending on the set basic parameters you can configure the following reader parameters in this parameter group.

Table 10-181 Overview of the "Reader parameters"

Reader parameter assignment in "Basic parameters"	Transmission speed	Presence check	Reset error LED	HF power	Max. number of transponders	Transponder type			Program selection with reset	Byte sequence of the reset parameter [hex]
						ISO Mode	RF300	MOBYE		
RF200 general	✓	✓	✓	-	✓	✓	-	-	-	-
RF290R	✓	✓	✓	✓	✓	✓	-	-	-	-
RF300 general	✓	✓	✓	-	✓	✓	✓	-	-	-
RF380R	✓	✓	✓	✓	✓	✓	✓	-	-	-
RF300 Gen 2 general	✓	✓	✓	-	✓	✓	✓	✓	-	-
RF380R Gen 2	✓	✓	✓	✓	✓	✓	✓	✓	-	-
RF680R [1]	-	-	-	-	-	-	-	-	-	-
RF685R [1]	-	-	-	-	-	-	-	-	-	-
MV4x0 [1]	-	-	-	-	-	-	-	-	✓	-
General readers	✓	-	-	-	-	-	-	-	-	✓

[1] The device-specific parameters of these devices are set in the WBM of the relevant devices.

Table 10-182 Parameters in the "Reader parameters" parameter group

Parameter	Parameter value	Default value	Description
Transmission speed	19.2 kBd 57.6 kBd 115.2 kBd	115.2 kBd	The selection depends on the communications module and Ident system being used. Note that the value specified here is adopted automatically from the device configuration of the connected devices. With this parameter you set the transmission speed between the communications module and reader. When the RFID reader is connected: After changing the transmission speed, the reader must be turned off and on again (cycle power). When an optical reader is connected: The transmission speed selected here must match the transmission speed selected in the firmware of the reader.
Presence check	On Off (RF field on) Off (RF field off)	On	On = As soon as there is a transponder in the antenna field of the reader, its presence is reported. Off (RF field on) = the presence check in the FB is suppressed. The antenna on the reader is nevertheless turned on as long as it has not been turned off by a command. Off (RF field off) = the antenna is turned on only when a command is sent and it then turns itself off again (RF300 only).
Reset error LED	On Off	On	On = the flashing of the error LED on the communications module is reset by each FB reset. Off = the error LED always indicates the last error. The display can only be reset by turning off the communications module.
HF power [1]	0.50 ... 2.00 0.50 ... 5.00	1.00 1.25	Setting for the output power of the reader. The selectable values depend on the connected device.
Max. number of transponders	1 ... 4	1	Number of transponders expected in the antenna field. The selection depends on the connected device.
Transponder type	[1]	[1]	Selection of the transponder types used. The selection depends on the connected device.
Program selection with reset	No program change 1 ... 15	No program change	Selection of the program that will be used after restarting the optical reader. If the parameter "No program change" is set, after restarting the device the last active program is selected.
Byte sequence of the reset parameter [hex]	[1]	[1]	Hexadecimal representation of the byte sequence of the reset parameter of the reader.

[1] You will find a detailed description of this parameter in the following paragraphs:

The "HF power" parameter

The selectable values depend on the value specified in the parameter "Reader parameter assignment".

- RF290R
  - Range of values: 0.50 ... 5.00 W
  - Default value: 1.00 W
- RF380R; RF380R (gen 2)
  - Range of values: 0.50 ... 2.00 W
  - Default value: 1.25 W

The "Transponder type" parameter

Selection of the transponders used. The selection depends on the value specified in the parameter "Reader parameter assignment". The following transponder types can be selected:

- ISO Mode
- RF300
- MOBY E

If you select "ISO mode", the following selection options are displayed depending on the reader parameter assignment:

Reader parameter assignment	Values
RF200 general RF290R	ISO 15693 ISO 15693 (Infineon)
RF300 general RF380R	RF300 ISO 15693 general ISO 15693 (Infineon) ISO 15693 (Fujitsu) ISO 15693 (NXP) ISO 15693 (TI) ISO 15693 (STM)
RF300 general (gen 2) RF380R general (gen 2)	ISO 15693 general ISO 15693 (Infineon) ISO 15693 (Fujitsu) ISO 15693 (NXP) ISO 15693 (TI) ISO 15693 (STM) ISO 15693 (Fujitsu - 8 kB)

The parameter "Byte sequence of the reset parameter [hex]"

With this parameter you can specify the Reset parameter in hexadecimal format. This setting may only be selected if you have previously received the hex string for the setting from a member of the SIEMENS staff.

The following Reset parameters are available:

Byte	1	2...5 [1]	6	7...8	9	10	11	12	13...14	15	16
Value	0x04	0x00	0x0A	0x00	scan-ning_ time	param	op-tion_1	distance_ limiting	multitag	field_on_ control	field_on_ time

[1] In the communications module RF180C as of V2.2 in conjunction with MOBY U byte 4 is preset with the calendar week and 5 with the year.

Calling the Ident instruction in the user program

Procedure

Proceed as follows to call the instruction in the user program:

1. Open the CPU folder in the project tree.
2. Open the "Program blocks" folder.
3. Double-click on the OB for cyclic program execution.
   The block is opened in the working area.
4. In the "Instructions" window open the group "Optional packages" and the "SIMATIC Ident" folder.
   The folder and the subfolders contain the instructions.
5. Select an instruction and drag it to your OB.
   The "Call options" dialog is opened.
6. From the "Name" list select an instance data block or enter the name for a new instance data block.
7. Confirm with "OK".
8. Select the configured technology object and drag it to the parameter "HW_CONNECT".

Reset the readers using the "Ident profile" or the "Reset_Reader" block

There are various methods for resetting readers:

- If you work with the Ident blocks, reset all reader types with the "Reset_Reader" block. This transfers the values set in the technology object to the readers.
- If you work with the Ident profile, when you set the "INIT" bit, the values set in the technology object are transferred to the readers.
- If you want to send your own "WRITE CONFIG" command, instead of the "INIT" bit you need to use the "EXECUTE" bit.

If a Reset parameter of the technology object needs to be changed at runtime, the relevant value can be overwritten in the data block of the technology object using the user program. The Reset parameters are located in the data block of the technology object in "Static.CONFIGURATION.param_buffer[]".

You will find detailed information on the Ident profile in the manual ""Ident Profile and Ident Blocks, Standard Function for Ident Systems" on the pages of "Industry Online Support (https://support.industry.siemens.com/cs/ww/en/ps/14971/man)".

Loading the configuration on the CPU

After configuration you need to load the changes from the technology object or the S7 controller on the connected devices.according to

Load to device

When loading to the devices note that a distinction is made between "Software (changes only)" and "Hardware and software (changes only)". If only changes to the software were made, loading is via the technology object. If changes were made to the hardware and software, loading is via the S7 controller.

NOTICE
Load to device when using the "Autoconfiguration" button If the "Autoconfiguration" button was used during configuration, you need to load the changes on the connected devices via the S7 controller ("Hardware and software (changes only)").

Diagnosing a technology object

After configuration of the technology object is complete, you can monitor the devices configured in the technology object using the diagnostics function.

Requirements

- There is an online connection between STEP 7 (TIA Portal) and the S7 controller.
- The Ident instruction is called in the user program.
- A technology object was created and loaded on the S7 controller-
- The S7 controller is in "RUN" mode.

Procedure

To open the display editor for the diagnostics function, follow these steps:

1. In the project tree, open the "Technological objects" folder.
2. Open the relevant technology object in the project tree.
3. Double-click on the "Diagnostics" object.
4. Click on the symbol."Monitor all" to activate the monitoring mode.

Display

The following values are read by the technology object and displaed:

Table 10-183 Displayed values of "Block diagnostics"

Displayed values	Description
Date and time	Shows the date and time when the error occurred.
Command	Shows the command with which the error occurred.
Error description	Shows a brief description of the error that occurred. Note: The last five error messages are displayed and described in the table. If a new error message is displayed, the previously displayed error messages are moved one line down. A maximum of five error messages are displayed.
Error message	Shows the error message of the error that occurred
Error description	Shows a detailed description of the error that occurred
Date and time	Shows the date and time when the error occurred.
Command code	Show the command code of the command with which the error occurred.
Command	Shows the command with which the error occurred.
Attribute	Shows the attribute of the command with which the error occurred.

Optical reading systems

Optical readers MV420/MV440

Optical readers MV420/MV440

The optical reading systems MV420/MV440 were designed specifically for the recognition and evaluation of numerous machine-readable codes, plaint text and objects in industrial production.

The readers can be operated both in the controllers S7-300, S7-400, S7-1200 and S7-1500 as well as with various third-party controllers. The connection to the controller is via PROFINET IO (FB79/Ident profile), TCP, RS-232 or via communications modules.

The function blocks FB79 and the Ident profile allow simple programming using the SIMATIC S7 tools.

"Operating mode" parameter group

In this parameter group, you can configure the mode of the optical readers MV420/MV440.

Table 10-184 Parameters in the "Operating mode" parameter group

Parameter	Parameter value	Default value	Description
Function block	FB79 Ident profile	FB79	With this parameter you select the block: • FB79 Compatible with the "VS130-2" reader; Compatible controllers: S7-300 and S7-400 • Ident profile Complex Ident block with MV-specific blocks; Compatible controllers: S7-300, S7-400, S7-1200 and S7-1500

10.1.5.2 Distributed I/O

Distributed I/O systems

SIMATIC ET 200 - The right solution for all applications

SIMATIC ET 200 provides the most varied range of distributed I/O systems.

- Solutions for use in the control cabinet
- Solutions without control cabinet directly at the machine

Additionally, there are also components that can be used in explosive areas. SIMATIC ET 200 systems for construction without a control cabinet are contained in robust, glass-fibre reinforced plastic casing and are therefore shock-resistant, resistant to dirt and watertight.

Their modular design allows the ET 200 systems to be easily scaled and expanded in small steps. Fully-integrated auxiliary modules lower costs and also provide a wide range of possible applications. There are several combination possibilities available:

- Digital and analog I/OS
- Intelligent modules with CPU functions,
- Safety technology,
- Pneumatics,
- Frequency converters
- Various technology modules.

Communication via PROFIBUS and PROFINET, uniform engineering, clear diagnostic possibilities as well as optimal connection to SIMATIC controller and HMI devices vouch for the unique consistency provided by Totally Integrated Automation.

The following table provides an overview of I/O devices for use in the control cabinet:

I/O device	Properties
ET 200L	• Cost-effective digital block I/O • Digital electronic blocks up to 32 channels
ET 200M	• Modular design with standard modules from SIMATIC S7-300 • Failsafe I/O modules • Use in hazardous areas up to Zone 2, sensors and actuators up to Zone 1 • High level of plant availability, for example by plugging and unplugging during operation
ET 200MP	• Modular design with standard SIMATIC S7-1500 modules • Isochronous PROFINET IO with send clocks up to 250 µs • IO device with PROFINET IO interface • DP slave with PROFIBUS DP interface • Technology modules for counting, positioning, time-based IO
ET 200S	• Highly modular design with multiple conductor connections • Multifunctional due to a wide range of modules • I-device • Use in explosive areas (Zone 2)
ET 200S COMPACT	• Highly modular design with multiple conductor connections • Multifunctional due to a wide range of modules • Use in explosive areas (Zone 2) • Integrated DE/DA

I/O device	Properties
ET 200SP	• Compact modules • Permanent wiring with one or more wire connection • PROFINET interface with 3 ports • Isochronous PROFINET IO with the profiles PROFIsafe and PROFIenergy • I-device • Modules for counting, positioning, weighing and measuring • Fail-safe CPUs and modules
ET 200iSP	• Modular design, also possible with redundancy • Robust and intrinsically safe design • Use in explosive areas up to Zone 1/21; sensors and actuators even up to Zone 0/20 • High level of plant availability, for example by plugging and unplugging during operation

The following table provides an overview of I/O devices for use without a control cabinet:

I/O device	Properties
ET 200AL	• Simple installation in all locations, in the smallest spaces • Connection to PROFINET IO, PROFIBUS DP or ET 200SP • High degree of protection IP65/IP67 For temperatures from -25 °C to +55 °C, acceleration up to 5 g • Connection of sensors and actuators using M8 and M12 connector system
ET 200eco PN	• Cost-efficient, space-saving block I/OS • Digital modules up to 16 channels (also configurable) • Analog modules, IO-link master and load voltage distributor • PROFINET connection with 2-port switch in each module • Can be flexibly distributed via PROFINET in line or star shape directly within the plant
ET 200eco	• Cost-effective digital block I/O • Flexible connection possibilities • Failsafe modules • High level of plant availability

I/O device	Properties
ET 200pro	• Modular design with compact housing • Easy assembly • Multifunctional due to a wide range of modules • I-device • High level of plant availability due to plugging and unplugging during operation and permanent wiring • Comprehensive diagnostics
ET 200R	• Specially for use on robots • Assembled directly on the chassis • Resistant to weld spatter due to robust metal housing

Configuring HART variables

Introduction

Numerous HART field devices make available additional measured quantities (e.g. sensor temperature). These can be read if they are set accordingly in the field device configuration. Using the HART variables. it is possible to apply the set measured values directly from the field device into the I/O area of your automation system.

Regardless of the number of configured channels, a maximum of 8 HART variables can be assigned for HART modules and no more than 4 HART variables per channel. You assign the HART variables to a channel in the properties for the module ("HART variable settings" area). To do this, check the manual of the corresponding module.

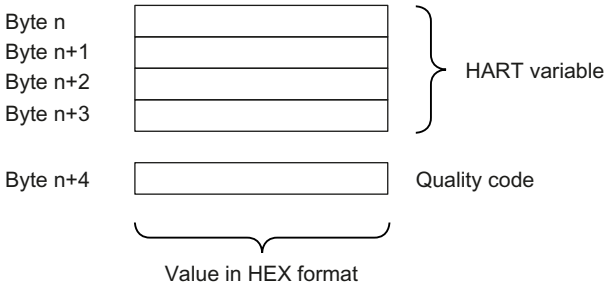
Address assignment

By default, the HART modules occupy 16 input/output bytes (user data). If you configure HART variables, the modules occupy an additional 5 bytes for each HART variable.

If you use all 8 HART variables, the HART input module occupies a total of 56 input/output bytes (16 bytes + 8 x 5 bytes = 56 bytes).

The "None" configuration occupies no additional input bytes.

Configuration of HART variables



You can configure up to 4 HART variables for a channel

- PV (Primary Variable)
- SV (Secondary Variable)
- TV (Tertiary Variable)
- QV (Quaternary Variable)

CiR is a placeholder that reserves the address space for a HART variable. You must configure the HART variables you are not using with the "None" parameter.

Configuration of HART variables

Each HART variable occupies 5 bytes of input data and is structured as follows:

The quality code can accept different values depending on the module. To do this, check the manual of the corresponding module.

ET 200iSP

ET 200iSP Distributed I/O Station

Definition

The ET 200iSP distributed I/O station is a highly modular and intrinsically safe DP slave with degree of protection IP 30.

Area of application

The ET 200iSP distributed I/O station can be operated in potentially explosive atmospheres characterized by gas and dust:

Approval	ET 200iSP Station*	Inputs and outputs
ATEX	Zone 1, Zone 21	up to Zone 0, Zone 20 **
IECEx	Zone 2, Zone 22	up to Zone 0, Zone 20 **
* In combination with an appropriate enclosure ** for electronic module 2 DO Relay UC60V/2A: up to Zone 1, Zone 21		

The ET 200iSP distributed I/O station can, of course, also be used in the safety area.

You can insert almost any combination of ET 200iSP I/O modules directly next to the interface module that transfers the data to the DP master. This means you can adapt the configuration to suit your on-site requirements.

Every ET 200iSP consists of a power supply module, an interface module and a maximum of 32 electronic modules (for example digital electronics modules). Remember not to exceed the maximum current consumption.

Terminal modules and electronic modules

In principle, the ET 200iSP distributed I/O station consists of various passive terminal modules onto which you plug the power supply and the electronic modules.

The ET 200iSP is connected to PROFIBUS RS 485-IS by means of a connector on terminal module TM-IM/EM. Every ET 200iSP is a DP slave on the PROFIBUS RS 485-IS.

DP master

All ET 200iSP modules support communication with DP masters that are compliant with *IEC 61784-1:2002 Ed1 CP 3/1* and operate with "DP" transmission protocol (DP stands for distributed peripherals or distributed I/O).

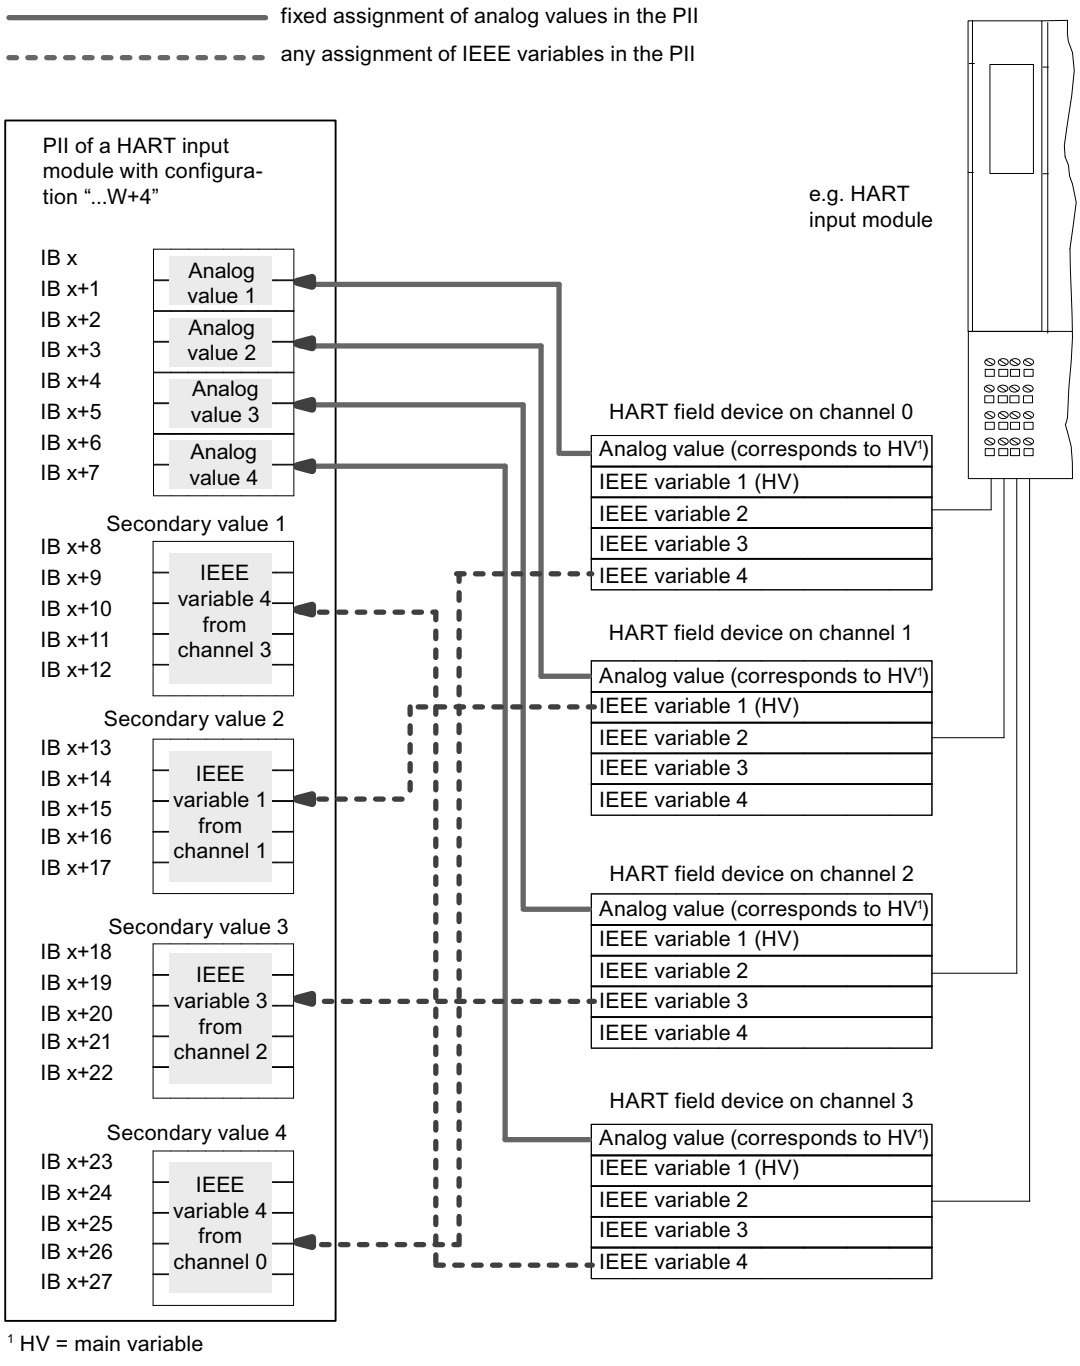
Assigning the channel and IEEE tag

Properties

Analog electronic modules 4 AI I 2WIRE/HART, 4 AI I 4WIRE/ HART and 4 AO I HART support up to four IEEE tags.



The process input image (PII) provides up to 20 bytes per module for the IEEE tags. Thus, four blocks of 5 bytes each are available for the four IEEE tags within the PII.

Requirements

The HART field device must support the assigned number of IEEE tags.

Assigning IEEE tags

You assign the IEEE tags of the field devices to any one of the four blocks in the PII.

[1] HV = main variable

Assigning parameters to reference junctions for thermocouples

Compensation of the reference junction temperature

There are various ways of obtaining the reference junction temperature in order to get an absolute temperature value from the temperature difference between the reference junction and the measuring point.

Table 10-185 Compensation of the reference junction temperature

Option	Explanation	Reference junction parameters
No compensation	You record not only the temperature of the measurement point. The temperature of the reference junction (transition from Cu line to thermocouple line) also affects the thermo-electromotive force. The measured value then includes an error.	None
Use of a Pt100 Climatic Range resistance thermometer to record the reference junction temperature (best method)	You can record the reference junction temperature using a resistance thermometer (Pt100 Climatic Range). If parameterized accordingly, this temperature value is distributed to the 4 AI TC modules in the ET 200iSP where it is offset against the temperature value obtained at the measuring location. Number of reference junctions: 2	The parameter assignment of the IM 152 and the 4 AI TC must be coordinated: • 4 AI RTD assigned parameters for Pt100 climatic range in correct slot; • 4 AI TC: Reference junction : "yes"; select reference junction number "1" or "2" • IM 152-1:Assignment of the reference junction to a slot with 4 AI RTD; channel selection;
Internal compensation 4 AI TC	The TC sensor module (temperature sensor) is mounted onto the terminals of terminal module EM 4 AI TC. The temperature sensor reports the temperature of the terminals to the 4 AI TC. This value is then calculated together with the measured value from the channel of the electronic module.	• 4 AI TC: Reference junction number "internal"

Compensation by means of a resistance thermometer at the 4 AI RTD

If thermocouples that are connected to the inputs of the 4 AI RTD have the same reference junction, compensate by means of a 4 AI RTD.

For both channels of the 4 AI TC module, you can select "1", "2" or "internal" as the reference junction number. If you select "1" or "2", the same reference junction (RTD channel) is always used for all four channels.

Setting parameters for the reference junction

You set the reference junctions for the 4 AI TC electronic modules by means of the following parameters:

Table 10-186 Reference junction parameters

Parameter	Module	Range of values	Explanation
Slot reference junction 1 to slot 2	IM 152	none, 4 to 35	With this parameter, you can assign up to 2 slots (none, 4 to 35), on which the channels for reference temperature measurement (calculating the compensation value) are located.
Input reference junction 1 to 4 input reference junction	IM 152	RTD on channel 0 RTD on channel 1 RTD on channel 2 RTD on channel 3	This parameter allows you to set the channel (0/1/2/3) for measuring the reference temperature (calculation of the compensation value) for the assigned slot.
Reference junction E0 to reference junction E3	4 AI TC	None yes	This parameter allows you to enable the use of the reference junction.
Reference junction number	4 AI TC	1 2 Internal	This parameter allows you to assign the reference junction (1, 2) that contains the reference temperature (compensation value).

Fundamentals of Time Stamping

Properties

Time stamping is possible with the IM 152 in customer applications using FB 62 (FB TIMESTMP).

Principle of operation

A modified input signal is assigned a time stamp and stored in a buffer (data record). If time stamped signals exists or a data record is full, a hardware interrupt is generated to the DP master. The buffer is evaluated with "Read data record". Special messages are generated for events that influence the time stamping (communication with the DP master interrupted, frame failure of time master, ...).

Parameter Assignment

With the parameter assignment you define which IM 152 user data will be monitored. For the time stamping these are digital inputs that are monitoring for signal changes.

Parameter	Setting	Description
Time stamping	• disabled • enabled	Activate the time staming for the channels of the electronics module 8 DI NAMUR.
Edge evaluation incoming event	• rising edge • falling edge	Determine the type of signal change that will be time-stamped.

Counting

Count properties

Counting functions

The 8 DI NAMUR electronics module has configurable counting functions:

- 2 x 16-bit up counters (standard counting function) or
- 2 x 16-bit down counters (standard counting function) or
- 1 x 32-bit down counter (cascading counter function)
- Setting a setpoint with the PIQ
- GATE function
- You can configure the control signals of the counters:
  - Configuration channel 0..1: "Counter", channel 2..7: "DI": Two counters are configured. The control signals of the counters are stored in the PIQ (process image output).
  - Configuration channel 0..1: "Counter", channel 2..7: "Control": Two counters are configured. The control signals of the counters are stored in the PIQ (process image output). They are also controlled by the digital inputs of the 8 DI NAMUR.

See also

Principle of operation (Page 1917)

Configuring counters (Page 1920)

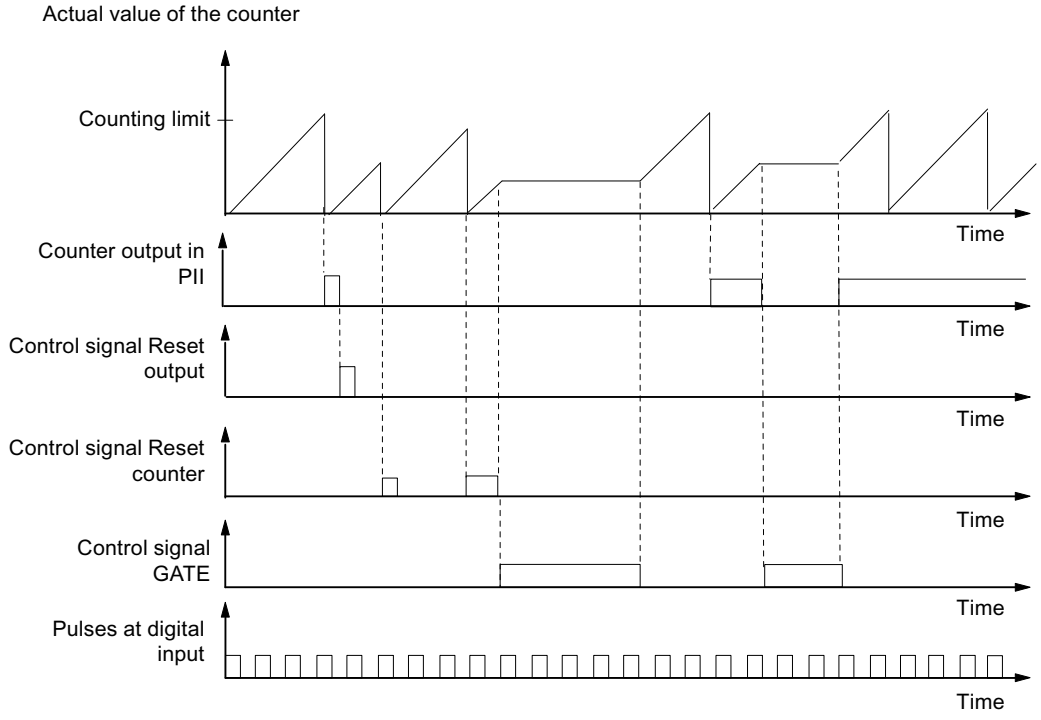
Assigning parameters to counters (Page 1922)

Principle of operation

16-bit up counters (standard counting function)

The counting range is 0 to 65,535.

With each count pulse at the digital input, the count is incremented by 1. Once the count limit is reached, the counter is reset to 0 and it counts up again from this value.



If there is counter overflow, the corresponding output is set in the PII.

A positive edge of the *Reset output* control signal resets the output in the PII. This does not affect the current count value.

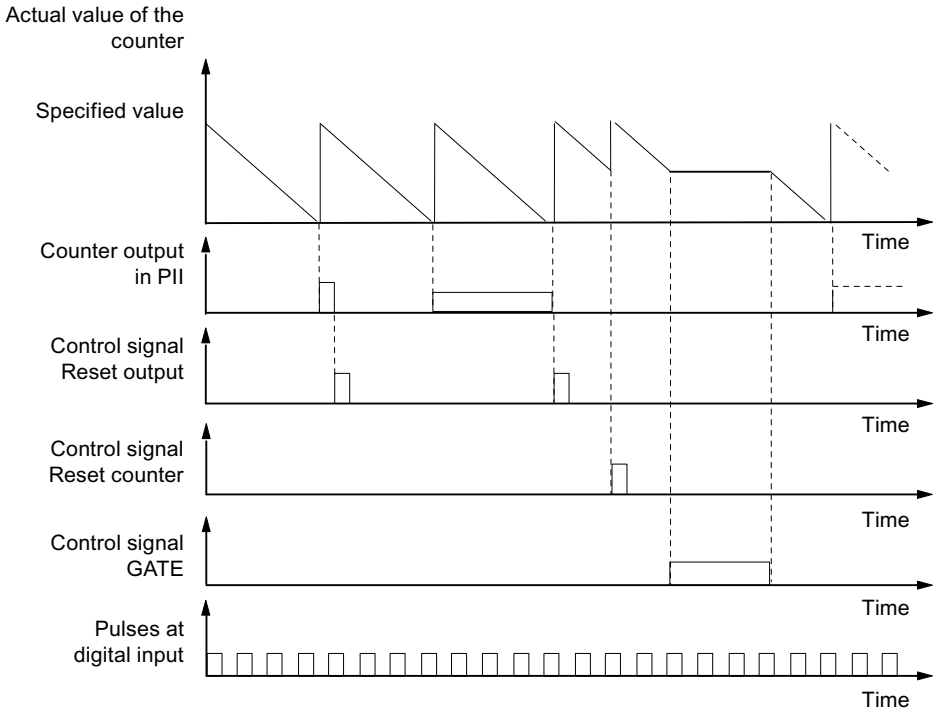
In 16-bit up counting operations, the system does not set any outputs in the PIQ. These are always reset.

The positive edge of the *Reset counter* control signal sets the counter to 0 and resets the set counter output.

The *GATE* control signal pauses the counting on a positive edge. Count pulses are processed at the digital input again, but only at the negative edge. The *Reset counter* control signal is also effective when *GATE* is active.

16-bit down counters (periodic counting function)

The maximum counting range is always 65,535 to 0.



When the counter is started, the actual value is set to the selected setpoint. Each counted pulse reduced the actual value by 1. Once the actual value reaches 0, the corresponding output in the PII is turned on and the actual value is set to the selected setpoint. The counter then counts down from this value.

The positive edge of the *Reset counter* control signal resets the selected setpoint and the corresponding output in the PII.

A positive edge of the *Reset output* control signal resets the output in the PII. This does not affect the current count value.

The *GATE* control signal pauses the counting on a positive edge. At the same time, the assigned output in the PII is reset. Count pulses are processed at the digital input again, but only at the negative edge. The *Reset output* and *Reset counter* control signals are also effective when *GATE* is active.

The setpoint of the counter is set and changed using the PIQ. The setpoint is adopted on a positive edge of the *Reset counter* control signal or when the counter has reached zero.

32-bit down counter (cascading counter function)

The maximum counting range is always 4294967295 to 0.

The principle of operation is identical to that of the 16-bit down counter. Channel 1 has no function.

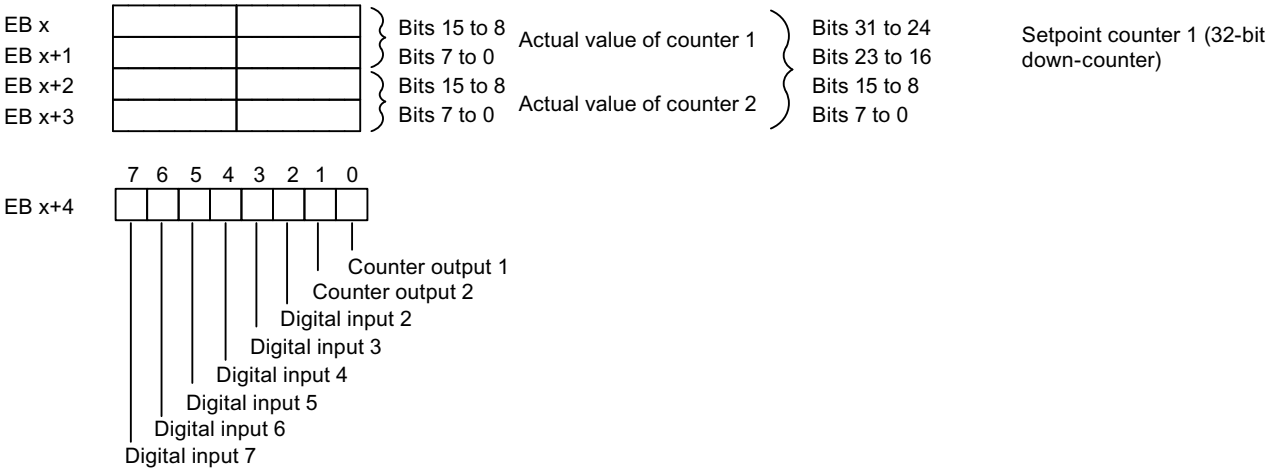
See also

Count properties (Page 1917)

Configuring counters

Procedure

1. Using the mouse, pull module 8 DI Namur from the hardware catalog into distributed I/O station ET 200iSP.
2. Select the required configuration (channel 0..1: "Counter", channel 2..7: "DI" or "Control"). In the module properties (inspector window), you can find this setting under "Parameters > Inputs > Configuration".



Configuration channel 0..1: "Counter", channel 2..7: "DI"

- Assignment of the digital inputs on the electronic module 8 DI NAMUR

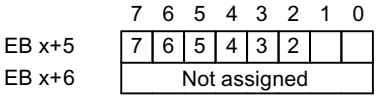


Table 10-187 Assignment of digital inputs for channel 0..1: "Counter", channel 2..7: "DI":

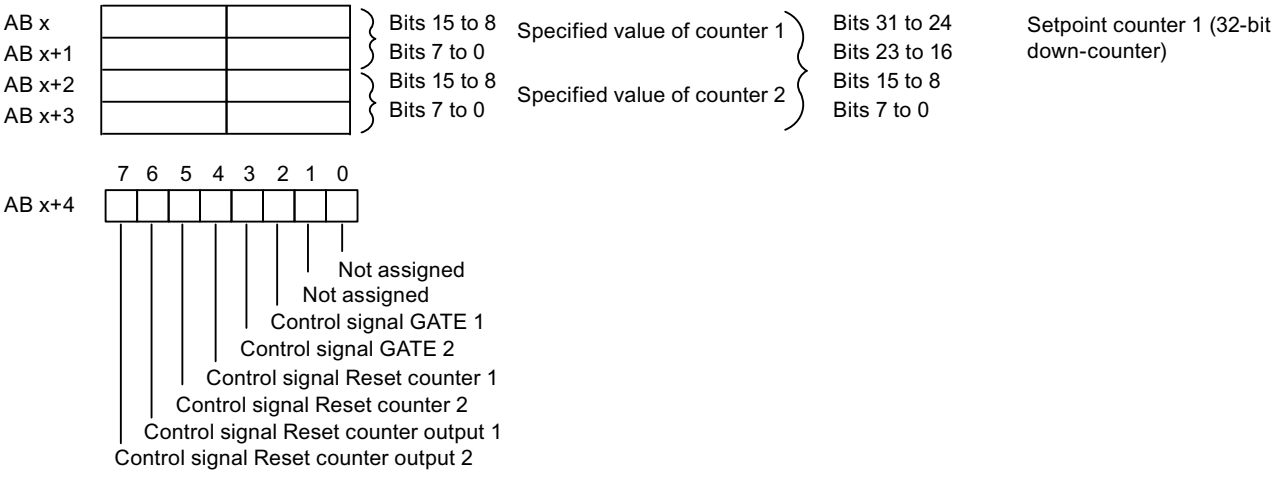
Digital input	Terminal	Assignment
Channel 0	1, 2	Counter 1
Channel 1	5, 6	Counter 2 (does not apply to 32-bit down counters)
Channel 2	9, 10	Digital input 2
Channel 3	13, 14	Digital input 3
Channel 4	3, 4	Digital input 4
Channel 5	7, 8	Digital input 5
Channel 6	11, 12	Digital input 6
Channel 7	15, 16	Digital input 7

- Assignment of the process image input (PII)



S7 format

Value status for channels 2 to 7:
1_B: Input signal is valid
0_B: Input signal is invalid

- Assignment of the process image output (PIQ)

Configuration channel 0..1: "Counter", channel 2..7: "CONTROL"

With this configuration, you can also control the counters over the digital inputs.

- Assignment of the digital inputs on electronic module 8 DI NAMUR
  For further information on input assignments, refer to the technical data for electronic module 8 DI NAMUR.

Table 10-188 Assignment of the digital inputs for 2 Count/ 6 Control

Digital input	Terminal	Assignment
Channel 0	1, 2	Counter 1
Channel 1	5, 6	Counter 2 (does not apply to 32-bit down counters)
Channel 2	9, 10	control signal *GATE 1*
Channel 3	13, 14	control signal *GATE 2*
Channel 4	3, 4	control signal *Reset counter 1*
Channel 5	7, 8	control signal *Reset counter 2*
Channel 6	11, 12	control signal *Reset counter output 1*
Channel 7	15, 16	control signal *Reset counter output 2*

- Assignment of the process image input (PII)
  Assignment is identical to configuration 0..1: "Counter", channel 2..7: "DI".
- Assignment of the process image output (PIQ)
  Assignment is identical to configuration 0..1: "Counter", channel 2..7: "DI".

Assigning parameters to counters

Parameters for the counting function

Only those parameters that are relevant for the counters are explained below. These belong to the parameters of electronic module 8 DI NAMUR and depend on the selected configuration:

Table 10-189 Parameters for the counters

Parameter	Setting	Description
Sensor type counter inputs	• Channel disabled • NAMUR sensor • Single contact, no load resistance	Select the sensor for the respective counter of channels 0 or 1.
Mode for counter 1	• Standard counting function • Periodic counting function • Cascaded counting function	Select the mode for counter 1.
Mode for counter 2	• Standard counting function • Periodic counting function • Cascaded counting function	Select the mode for counter 2. This parameter is not relevant if you have set the "Mode for counter 1" parameter to "Cascaded counter function".

Count properties (Page 1917)

Frequency measurement

Frequency measurement properties

Properties

The electronic module 8 DI NAMUR allows the frequencies to be measured on channel 0 and 1:

- 2 frequency meters from 1 Hz to 5 kHz
- Configurable metering window (GATE)
- The signals of the frequency meter are read in by means of the digital inputs of the electronic module.

See also

Principle of operation (Page 1923)

Configuring frequency meters (Page 1924)

Assigning parameters for the frequency meters (Page 1926)

Principle of operation

Frequency measurement

The signal frequencies are identified from the input signals of channel 0 or 1 of the electronic module. To calculate the frequency the signals are measured within a configurable gate.

The frequency is displayed as 16-bit value in fixed-point format and transferred to the PII.

The frequency meter calculates the frequency according to the follow formula:

$$\text{Frequency [Hz]} = \frac{\text{Number of rising edges at digital input}}{\text{Measuring window [s]}}$$

Exceeding the input frequency

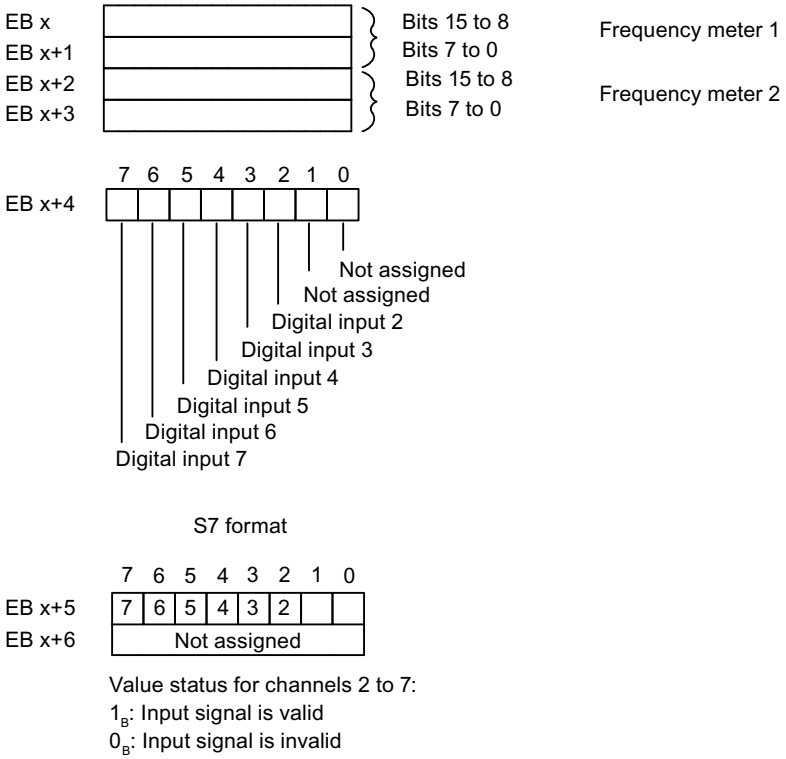
If the input frequency exceeds 5kHz, $7FFF_H$ is reported as actual value. If the input frequency is above approx. 8 kHz it is no longer possible to display correct actual values.

See also

Frequency measurement properties (Page 1923)

Configuring frequency meters

Procedure



1. Using the mouse, pull module 8 DI Namur from the hardware catalog into distributed I/O station ET 200iSP.
2. Select the required configuration (channel 0..1: "Trace", channel 2..7: "DI"). In the module properties (inspector window), you can find this setting under "Parameters > Inputs > Configuration".

Configuration 0..1: "Trace", channel 2..7: "DI"

Assignment of the digital inputs on electronic module 8 DI NAMUR

Digital input	Terminal	Assignment
Channel 0	1, 2	Frequency counter 1
Channel 1	5, 6	Frequency counter 2
Channel 2	9, 10	Digital input 2
Channel 3	13, 14	Digital input 3
Channel 4	3, 4	Digital input 4
Channel 5	7, 8	Digital input 5
Channel 6	11, 12	Digital input 6
Channel 7	15, 16	Digital input 7

Assignment of process image input (PII) for configuration of channel 0..1: "Trace", channel 2..7: "DI"

Assignment of the process image output (PIQ): The PIQ is not assigned.

Frequency measurement properties (Page 1923)

Assigning parameters for the frequency meters

Parameters for frequency meter

Only those parameters that are relevant for the frequency meters are explained below. These are part of the parameters of electronic module 8 DI NAMUR.

Table 10-190 Parameters for the frequency meters

Parameter	Setting	Description
Sensor type frequency inputs	• Channel disabled • NAMUR sensor • Single contact, no load resistance	Select the sensor for the relevant frequency meter for channel 0 or 1.
Measuring window (GATE)	• 50 ms • 200 ms • 1 s	Select the required measuring window for channel 0 or 1. To achieve the highest possible accuracy when metering frequencies, remember the following rules: • High frequencies (> 4 kHz): Set a low measuring window (50 ms) • Variable/medium frequencies: set medium measuring window (200 ms) • Low frequencies (< 1 kHz): Set a high measuring window (1 s)

ET 200eco PN

ET 200eco PN Distributed I/O Device

Definition

The ET 200eco PN distributed I/O device is a compact PROFINET IO device in degree of protection IP 65/66 or IP 67 and UL Enclosure Type 4x, Indoor use only.

Field of application

The fields of application of the ET 200eco PN are derived from its special properties.

- A robust design and degree of protection IP 65/66 or IP 67 make the ET 200eco PN distributed I/O device suitable in particular for use in rugged industrial environments.
- The compact design of the ET 200eco PN is particularly favorable for applications in confined areas.
- The easy handling of ET 200eco PN facilitates efficient commissioning and maintenance.

Properties

The ET 200eco PN has the following properties:

- Integrated switch with 2 ports
- Supported Ethernet services:
  - ping
  - arp
  - Network diagnostics (SNMP)
  - LLDP
- Interrupts
  - Diagnostics interrupts
  - Maintenance interrupts
- Port diagnostics
- Isochronous real-time communication
- Prioritized startup
- Device replacement without programming device
- Media redundancy
- Connection to intelligent sensors/actuators via IO link master interface module.

IO Controller

The ET 200eco PN can communicate with all IO Controllers that conform to IEC 61158.

ET 200eco PN can be configured on a CPU with advanced diagnostics.

Documentation on ET 200eco PN (http://support.automation.siemens.com/WW/view/en/29999018)

Parameter description analog input

Group diagnostics

You can generally enable and disable the diagnostics function of the device with this parameter.

The "Fault" and "Parameter assignment error" diagnostics functions are always independent of the group diagnostics.

Diagnostics, missing 1L+

If you enable this parameter, the check for missing supply voltage is enabled.

Diagnostics, sensor supply short circuit

If you enable this parameter, a diagnostics event is generated if a short-circuit of the sensor supply to ground is detected and the channel is enabled. The sensor supply is monitored for connectors X1, X3, X5 and X7. It is not possible to differentiate which connector has experienced the sensor short circuit.

Interference frequency suppression

With this parameter, you set the integration time of the device, based on the selected interference frequency. Select the frequency of the supply voltage used. Interference frequency suppression **Off** means 500 Hz, which corresponds to an integration time of 2 ms for a measurement channel.

Temperature unit

Specify the unit of the temperature measurement here.

Measurement type (channel-wise)

With this parameter, you set the measurement type, for example, voltage. For any unused channels, you must select the **disabled** setting. For a disabled channel, the conversion time and integration time of the channel = 0 s and the cycle time is optimized.

Measuring range

With this parameter, you set the measuring range of the selected measurement type.

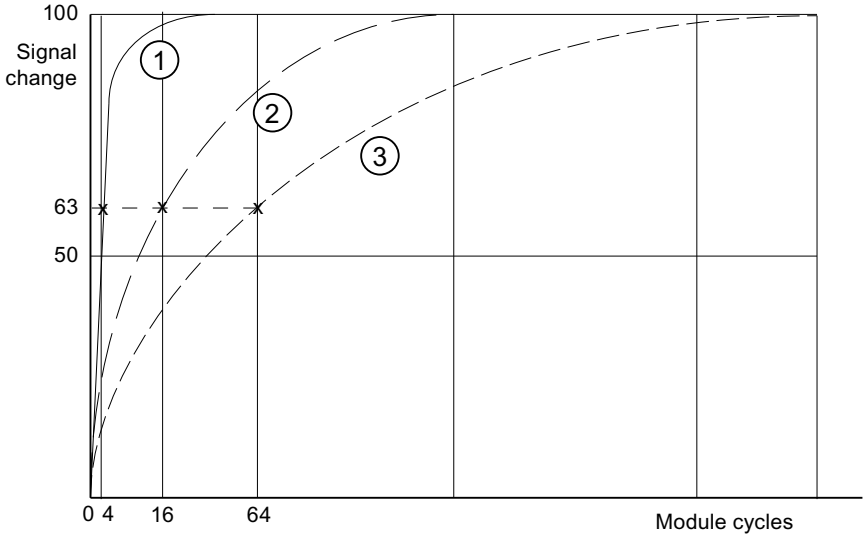
Temperature coefficient (for RTD, thermoresistor)

The correction factor for the temperature coefficients (α-value) indicates by what extent the resistance of specific material changes relatively if the temperature increases by 1 °C.

The α-values conform to EN 60751, GOST 6651, JIS C 1604 and ASTM E-1137.

The temperature coefficient depends on the chemical composition of the material.

Smoothing



Smoothing of the analog values produces a stable analog signal for further processing. The smoothing of analog values is useful when handling wanted signals (measured values) with a slow rate of change, for example, temperature measurements.

The measured values are smoothed by digital filtering. To achieve smoothing, the device generates a mean value from a specified number of converted (digitized) analog values.

You assign a maximum of four levels for the smoothing (none, weak, medium, strong). The level determines the number of module cycles, from which the mean value is generated.

The stronger the smoothing, the more stable the smoothed analog value and the longer it takes until the smoothed analog value is applied following a signal change (see the example below).

The figure below shows the number of cycles a module requires to apply the smoothed analog value at almost 100% after a step response, based on the smoothing function settings. The figure applies to all signal changes at the analog input. The smoothing value defines the number of cycles a module requires to reach 63% of the end value of the changed signal.

① Smoothing, weak
② Smoothing, medium
③ Smoothing, strong

Diagnostics, wire break

When this parameter is enabled, the **Wire break** diagnostics event is generated when a wire break is detected.

Observe the rules outlined below to handle a wire break in the 1 to 5 V and 4 to 20 mA measuring ranges:

Parameter	Event	Measured value	Explanation
Enable wire break[1]	Wire break	$7FFF_H$	Diagnostics, **wire break**
Wire break disabled[1] Underflow enabled	Wire break	8000_H	Measured value after leaving the underrange Diagnostic message **Lower limit value undershot**
Wire break disabled[1] Underflow disabled	Wire break	8000_H	Measured value after leaving the underrange
[1] Measuring range limits for wire break detection and measuring range undershoot detection: • 1 to 5 V: At 0.296 V • 4 to 20 mA: At 1.185 mA			

Diagnostics, underflow

If you enable this parameter, the **Underflow** diagnostics event is generated when the measured value reaches the underflow range.

Diagnostics, overflow

If you enable this parameter, the **Overflow** diagnostics event is generated when the measured value reaches the overflow range.

Reference junction for thermoresistor (TC)

A difference in temperature between the measuring point and the free ends of the thermocouple (terminal point) generates a voltage between the free ends, namely the thermoelectric voltage. The value of this thermoelectric voltage is determined by the temperature difference between the measuring point and the free ends and by the type of material combination of the thermocouple. Since a thermocouple always measures a temperature difference, the free ends at the reference junction must be maintained at a known temperature in order to determine the temperature of the measuring point.

If you specify **Internal compensation**, the temperature of the measuring point in the housing of the I/O device is measured. With the **External compensation** setting, you can connect a compensation box in series in order to increase the accuracy of the temperature measurement.

Parameter description analog output

Group diagnostics

You can generally enable and disable the diagnostics function of the device with this parameter.

The "Fault" and "Parameter assignment error" diagnostics functions are always independent of the group diagnostics.

Diagnostics, missing 1L+

If you enable this parameter, the check for missing supply voltage is enabled.

Diagnostics, sensor supply short circuit

When this parameter is enabled, the system generates a diagnostics event if it detects a short-circuit of the sensor supply to ground. This diagnostics function is activated when the group diagnostics function is enabled.

Response to CPU/Master STOP

Select how the module's outputs will respond to a CPU STOP:

- Shut down
  The I/O device goes to the safe state. The process image output is deleted (=0).
- Keep last value
  The I/O device retains the last value to be output before STOP.
- Substitute value
  The I/O device outputs the value for the channel set beforehand.

Note

Make sure that the plant is always in a safe state if "Keep last value" is selected.

Type of output

With this parameter, you set the output type, for example, voltage. For any unused channels, select the **disabled** setting. For a disabled channel, the conversion time and integration time of the channel = 0 s, and the cycle time is optimized.

Output range

With this parameter, you set the output range of the selected output type.

Diagnostics, wire break (in current mode)

When this parameter is enabled, the **Wire break** diagnostics event is generated when a wire break is detected. This diagnostics event cannot be detected in the zero range.

Diagnostics, short circuit (in voltage mode)

If you enable this parameter, a diagnostics event is generated in the event of a short circuit in the output line. This diagnostics event cannot be detected in the zero range.

Diagnostics, overload

If you enable this parameter, the diagnostics event is generated in the event of an overload.

Substitute values

With this parameter, you enter a substitute value that the module is to output in CPU-STOP mode. The substitute value must be in the nominal range, overrange, or underrange.

ET 200SP

ET 200SP distributed I/O system

Definition

The ET 200SP distributed I/O system is a scalable, highly flexible distributed I/O system for connection of process signals to a central controller via a field bus.

Application area

The ET 200SP is a multi-functional distributed I/O system for various fields of application. The scalable design allows you to configure the system exactly to the specific requirements on location.

The ET 200SP is approved for degree of protection IP 20 and for installation in a control cabinet.

Structure

The ET 200SP is mounted on a mounting rail and comprises:

- An interface module which can communicate with all IO controllers that conform to the PROFINET standard IEC 61158
- Up to 32 I/O modules which can be inserted on passive BaseUnits in any combination
- A server module that completes the design of the ET 200SP.

ET 200SP with own CPU module

ET 200SP with own CPU

The ET 200SP can be equipped with its own CPU, for example with the CPU 1510SP-1 PN or CPU 1512SP-1 PN.

You can connect up to 65 modules of the S7-1500 automation system to this CPU.

Note the configuration rules of the ET 200SP (http://support.automation.siemens.com/WW/view/en/58649293).

Interface module parameters

Status bytes

Status bytes

If you enable the "Status bytes" option, 4 bytes of input data are reserved for the status of the supply voltage of each I/O module.

	7	6	5	4	3	2	1	0
Byte 0	8	7	6	5	4	3	2	1
Byte 1	16	15	14	13	12	11	10	9
Byte 2	24	23	22	21	20	19	18	17
Byte 3	32	31	30	29	28	27	26	25

I/O module slots

Bit = 0: Load voltage missing or I/O module not present

Bit = 1: Load voltage and I/O module present

Note

An inserted or missing server module always reports for the slot bit = 0.

Group diagnostics, missing supply voltage L+

Group diagnostics, missing supply voltage L+

This diagnostics is a group diagnostics that covers the supply voltage status of all I/O modules of a potential group which are defined by BaseUnits with incoming power supply (light-colored BaseUnit BU...D).

The group diagnostics is formed from the states of the supply voltage of the inserted I/O modules within the potential group.

The group diagnostics does not depend on the "Missing supply voltage L+" parameter of the I/O modules being enabled.

The server module does not influence the missing supply voltage L+ group diagnostics.

Requirements for the correct operation of the group diagnostics for missing supply voltage L+:

- I/O modules or BU covers must be inserted on the light-colored and dark-colored BaseUnits. If no I/O module is inserted on a light-colored BaseUnit, the start of this potential group will not be detected by the interface module; the I/O modules of this potential group will thus belong to the previous potential group. A supply voltage L+ group error will then be assigned to the wrong potential group.
  When an I/O module is inserted on the light-colored BaseUnit, the interface module detects the new potential group, re-evaluates the status, and reports a new group diagnostics in the case of an error.
- The server module must be inserted.
  The server module itself does not influence the missing supply voltage L+ group diagnostics.

Configuration control with ET 200SP

Operating principle

Configuration control allows you to operate various real configurations (options) with a single configuration of the distributed I/O device ET 200SP.

Configuration control provides you with the option of configuring the ET 200SP distributed I/O device with its maximum configuration and nevertheless operating it with missing modules. If missing modules are retrofitted later, no new configuration is required and the hardware configuration does not have to be reloaded either.

Using control data record 196, which is transferred to the interface module in the user program, you define a current preset configuration.

- The configured module is not present on a slot.
  - A BU cover can be inserted in this slot instead of the configured I/O module. As there is no configured module on the slot, the term "Configuration control with empty slots" is also used.
  - The module that is configured to the right of the missing module can be inserted on this slot instead of the configured module. The missing module makes the actual configuration appear pushed together. As the configured module is missing but no gap arises in the configuration, this is also referred to as a "Configuration without empty slots".
- The configuration is extended by an already configured module.
  - In the case of configuration control with empty spaces, you extend the configuration by inserting the configured module on the corresponding empty slot.
  - In the case of configuration control without empty spaces, insert the configured module on the right-hand side next to the last module of the ET 200SP.

Requirement

The CPU startup parameter "Compare preset to actual configuration" is set to Startup even if mismatch (default setting). This setting is also selected for the startup parameters of the individual modules of the ET 200SP.

Enabling configuration control

In the properties of the interface module under Module parameters > General > Configuration control, select "Enable reconfiguration of device via user program". This activates configuration control.

Control data record 196 for ET 200SP

The figure below shows the data block 196 for the configuration control of an ET 200SP with four modules.

The value "12" is in the "block_length" element.

If you configure an ET 200SP in STEP 7 with more modules, the data block will be longer. The data record for the maximum configuration with 65 modules is 134 bytes long (configuration with PN interface module).

There are two bytes in the data record for each module.

The positions of these two bytes in the data record each code a module in the original configuration with STEP 7:

- "slot_1" and "info_slot_1" (bytes 4 and 5 in the data record, see figure below) correspond to the module in slot 1 in configuration with STEP 7.
- "slot_2" and "info_slot_2" (bytes 6 and 7) correspond to the module in slot 2 in configuration with STEP 7.
- "slot_3" and "info_slot_3" (bytes 8 and 9) correspond to the module in slot 3 in configuration with STEP 7.
- etc.

"slot_x" byte

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "1" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 1 in the current configuration (slot_1 = 1).
- The value "2" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 2 in the current configuration (slot_1 = 2).
- The value "3" in byte 4 means you are assigning the module originally inserted in slot 1 to slot 3 in the current configuration (slot_1 = 3).
- etc.
- The value "1" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 1 in the current configuration (slot_2 = 1).
- The value "2" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- etc.

If a BU cover can be inserted instead of a module, code this by adding 128 to the slot (bit 7 of the "slot_x" byte is set). Examples:

- The value "129" in slot_1 means you are also assigning the module originally inserted in slot 1 to slot 1 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.
- The value "130" in slot_1 means you are assigning the module originally inserted in slot 1 to slot 2 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.
- The value "131" in slot_1 means you are assigning the module originally inserted in slot 1 to slot 3 in the current configuration. A BU cover can also be used instead of this module. In the real plant configuration, either the module or a BU cover is inserted.

"info_slot_x" byte

If a new potential group is opened with the module, assign the "info_slot_x" byte the value 1 (bit 0 of the byte is set). Examples:

- The value "1" in the "info_slot_2" byte means that a new potential group is opened with module 2.
- The value "1" in the "info_slot_3" byte means that a new potential group is opened with module 3.
- The value "1" in the "info_slot_4" byte means that a new potential group is opened with module 4.

Exception: A new potential group is automatically assigned to the first module in the original configuration in STEP 7. This is not coded in the data record. You can enter any value in "info_slot_1".

You can choose any name for the components of the control data record (for example "slot_1").

Example of control data record 196 for ET 200SP

The figure below shows control data record 196 for an ET 200SP with four modules.

The module inserted in slot 2 in the configuration in STEP 7 can also be inserted in slot 2 in this configuration. It can also be inserted in slot 2 of a BU cover. Otherwise, nothing has changed compared to the original configuration.

Record_196_ET_200SP

	Name	Data type	Default value
1	block_length	USInt	12
2	block_ID	USInt	196
3	version	USInt	2
4	subversion	USInt	0
5	slot_1	USInt	1
6	info_slot_1	USInt	0
7	slot_2	USInt	130
8	info_slot_2	USInt	0
9	slot_3	USInt	3
10	info_slot_3	USInt	0
11	slot_4	USInt	4
12	info_slot_4	USInt	0

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Readback data record 197 for ET 200SP

Readback data record 197 is used to read the actual configuration of a station (in this case, of an ET 200SP).

This readback data record allows you to check the real configuration of the ET 200SP (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other possibilities (wrong module, empty slot, BU cover).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200SP with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_1" and "reserve_1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration,
- "status_slot_2" and "reserve_2" (bytes 6 and 7) correspond to the module in slot 2 in the configuration
- "status_slot_3" and "reserve_3" (bytes 8 and 9) correspond to the module in slot 3 in the configuration,
- etc.

Example

The original configuration in STEP 7 has been changed by a control data record 196 (see example above): In the modified configuration, module 2 can either be inserted in slot 2 or be replaced by a BU cover.

The figure below shows readback data record 197 which ET 200SP outputs to indicate that there is a module in slot 2: The "status_slot_2" byte has the value "1".

The other modules are also available and are inserted in the correct slots.

Record_197_ET_200SP

	Name	Data type	Default value
1	block_length	USInt	12
2	block_ID	USInt	197
3	version	USInt	2
4	subversion	USInt	0
5	status_slot_1	USInt	1
6	reserve_1	USInt	0
7	status_slot_2	USInt	1
8	reserve_2	USInt	0
9	status_slot_3	USInt	1
10	reserve_3	USInt	0
11	status_slot_4	USInt	1
12	reserve_4	USInt	0

The figure below displays the readback data record 197 which ET 200SP outputs to indicate that a BU cover is being used in slot 2: The "status_slot_2" byte has the value "0".

The other modules are available and are inserted in the correct slots.

		Record_197_ET_200SP		
		Name	Data type	Default value
1		block_length	USInt	12
2		block_ID	USInt	197
3		version	USInt	2
4		subversion	USInt	0
5		status_slot_1	USInt	1
6		reserve_1	USInt	0
7		status_slot_2	USInt	0
8		reserve_2	USInt	0
9		status_slot_3	USInt	1
10		reserve_3	USInt	0
11		status_slot_4	USInt	1
12		reserve_4	USInt	0

Reading readback data record 197

You can read readback data record 197 from the ET 200SP with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Additional information and examples

Specific examples of configuration control can be found in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

Further information on ET 200SP can be found in the manuals IM 155-6 PN (http://support.automation.siemens.com/WW/view/en/73184046) and IM 155-6 DP (http://support.automation.siemens.com/WW/view/en/73098660)

You will find a library of the data records and other application examples here:

Configuration control with ET 200AL (Page 1981)

Configuration control for ET 200SP with integrated ET 200AL modules (Page 1939)

Configuration control for ET 200SP with integrated ET 200AL modules

ET 200SP with integrated ET 200AL modules

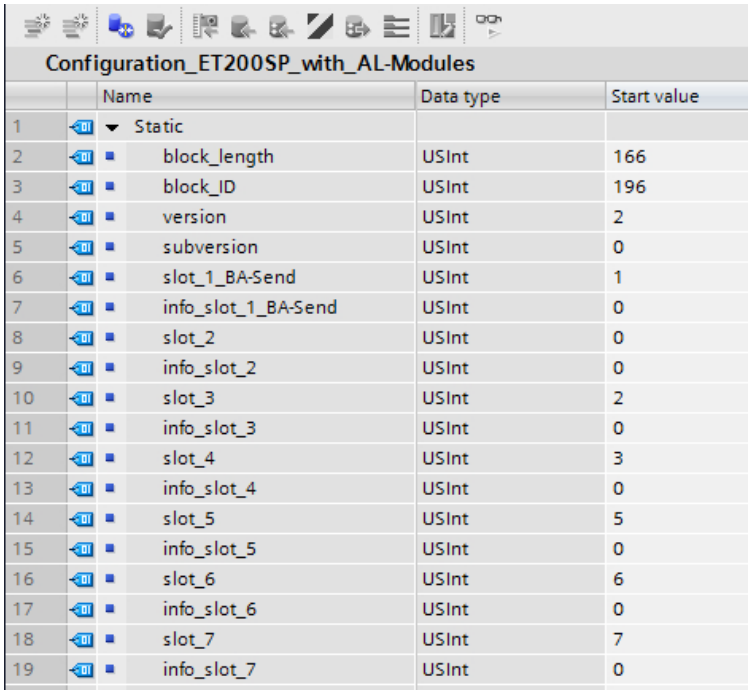
Configuration control for ET 200SP and ET 200AL is described in separate help topics. See the links under "See also".

The steps outlined also apply to configuration control of an ET 200SP with integrated AL modules. The procedure is different for control data record 196 and readback data record 197.

The following help text describes control data record 196 and the readback data record 197 for an ET 200SP expanded with ET 200AL modules.

Control data record 196

The two figures below show parts of control data record 196 for a configuration of an ET 200SP expanded with ET 200AL modules.



This configuration is given as an example:

- The module "BA Send 1xFC" is in slot 1 "slot_1". This module allows you to integrate ET 200AL modules into an ET 200SP. In our configuration example, 16 AL modules are connected to the BA-Send (maximum configuration). If a BA-Send is being used, this module must be inserted in slot 1.
- All slots from 2 to 64 are assigned ET 200SP modules.
- A server module is inserted in slot 65.
- There are 16 AL modules in slots 66 to 81.

The ET 200SP with integrated AL modules, originally configured with STEP 7, is now to be reconfigured from the user program.

The new configuration has the following properties:

- The "BA Send 1xFC" module is inserted in "slot_1_BA-Send" (fixed setting).
- Module 2 "slot_2" is not available in the modified configuration (value "0").
- Module 3 "slot_3" is in slot 2 in the modified configuration (value "2").
- Module 4 "slot_4" is in slot 3 in the modified configuration (value "3").
- All modules from slot 5 to slot 81 are operated in the original configuration with STEP 7.

140	info_slot_68_AL	USInt	0
141	slot_69_AL	USInt	69
142	info_slot_69_AL	USInt	0

The components of control data record 196 (figure above):

- slot_65_SP: This byte relates to the server module in the ET 200SP rack. It ends the backplane bus of the ET 200SP.
- From "slot_66_AL" come the 16 configured ET 200AL modules: Our configuration example does not change the configuration with STEP 7. The byte "slot_66_AL" has the value "66", the byte "slot_67_AL" has the value "67", the byte "slot_68_AL" has the value "68", etc.

Definition of control data record 196

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Component	Value	Description	
0	block_length	e.g. 166 for maximum configuration with 65 ET-200SP modules and 16 ET 200AL modules (with DP interface module, maximum of 33 ET 200SP modules and 16 ET 200AL modules)	The length of the data record is calculated using the formula: 4 + "number of modules" x 2	Header
1	Block ID	196	ID for control data record 196	
2	version	2	Version 2 of control data record 196	
3	subversion	0	Subversion 0 of control data record 196	
4	slot_1_BA-Send	Real slot for SP module 1 Possible value: 1	When AL modules are integrated in ET 200SP, the module "BA Send 1xFC" must always be inserted in slot 1.	1st slot for SP modules Assignment for the configured SP module 1 to a real slot
5	info_slot_1_BA-Send	0 or 1	The value "1" means that a new potential group is opened with this module. (Not evaluated in this byte)	

6	slot_2	Real slot for SP module 2 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 2 is not available)	The configured SP module 2 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module).	2nd slot for SP modules Assignment for the configured SP module 2 to a real slot
7	info_slot_2	1	The value "1" means that a new potential group is opened with this module. A new potential group must always be opened in this byte as BA-Send cannot open a new potential group.	
8	slot_3	Real slot for SP module 3 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 3 is not available)	The configured SP module 3 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module).	3rd slot for SP modules Assignment for the configured SP module 3 to a real slot
9	info_slot_3	1	The value "1" means that a new potential group is opened with this module. .	
:	:	:	:	:
132	slot_65	Real slot for SP module 65 Possible values: 2 to 65 (not 66 to 81, reserved for AL modules) 0 (if the configured module 65 is not available)	The configured SP module 65 can be inserted in any real slot from 2 to slot 65 (2 to 33 for a DP interface module). Slots 66 to 81 are for AL modules (34 to 49 with DP interface module)	65th Slot for SP modules Assignment for the configured SP module 65 to a real slot
133	info_slot_65	0 or 1	The value "1" means that a new potential group is opened with this module (the value is not evaluated in this slot).	

134	slot_66	Real slot for AL module 1 Possible values: 66 to 81 (not 1 to 65, reserved for SP modules) 0 (if the configured AL module 1 is not available)	The configured AL module 1 can be inserted in any slot from 66 to slot 81 (34 to 49 for PROFIBUS).	1st Slot for AL modules Assignment for the configured AL module 1 to a real slot
135	info_slot_66	-	Reserve	
:	:	:	:	:
164	slot_81	Real slot for AL module 16 Possible values: 66 to 81 (not 1 to 65, reserved for SP modules) 0 (if the configured AL module 16 is not available)	The configured AL module 16 can be inserted in any slot from 66 to slot 81 (34 to 49 for DP interface module).	16th Slot for AL modules Assignment for the configured AL module 16 to a real slot
165	info_slot_81	-	Reserve	

Rules

- If the "BA Send 1xFC" module is being used, it must be inserted in slot 1.
- ET 200SP modules are inserted in slots 2 to 65 (slots 2 to 33 for DP interface module).
- AL modules are inserted in slots 66 to 81 (slots 34 to 49 for DP interface module).
- If you expand an ET 200SP with ET 200 AL modules, the 1st AL module is always coded in bytes 134 and 135 of the control data record, the 2nd AL module in bytes 136 and 137, etc., even if not all SP slots are to be occupied by SP modules. Non-assigned SP slots are coded with the value "0".

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-191 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2 Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.

Error code	Meaning
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Readback data record 197 for ET 200SP with AL modules

The actual configuration of an ET 200SP with AL modules can be checked with readback data record 197.

Data record 197 largely corresponds to readback data record 197 for ET 200SP without AL modules; however, it is longer as the additional AL modules also need to be coded.

There are two bytes in the data record for each module. The position of these two bytes in the data record codes a module in the original configuration with STEP 7.

In the figure below:

- The components "status_slot_1" and "reserve_1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration with STEP 7,
- "status_slot_2" and "reserve_slot_2" (bytes 6 and 7) correspond to the module in slot 2,
- "status_slot_3" and "reserve_slot_3" (bytes 8 and 9) correspond to the module in slot 3,
- etc.

The following data record is structured for configuration with 65 SP modules and 16 AL modules. The value "166" therefore appears in the "block_length" element of the data record.

If you configure an ET 200SP in STEP 7 with fewer AL modules, the data block will be shorter.

If you use fewer SP modules in a configuration, this has no effect on the length of data record 197 (with an expansion of ET 200SP with ET 200AL modules).

The "reserve_x" component of readback data record 197 is reserved for future applications.

You can choose any name for the components of the readback data record (for example "status_slot_1").

The figure below shows the start of readback data record 197 for reading the actual configuration of an ET 200SP with AL modules.

DB_read_back_ET_200SP_with_AL

	Name	Data type	Start value
1	Static		
2	block_length	USInt	166
3	block_ID	USInt	197
4	version	USInt	2
5	subversion	USInt	0
6	status_slot_1	USInt	1
7	reserve_slot_1	USInt	0
8	status_slot_2	USInt	1
9	reserve_slot_2	USInt	0
10	status_slot_3	USInt	1
11	reserve_slot_3	USInt	0
12	status_slot_4	USInt	1
13	reserve_slot_4	USInt	0
14	status_slot_5	USInt	1
15	reserve_slot_5	USInt	0
16	status_slot_6	USInt	1
17	reserve_slot_6	USInt	0

It does not show the components "status_slot_7" to "reserve_81" (maximum configuration of an ET 200SP with PN interface module) or "status_slot_7" to "reserve_slot_49" (maximum configuration of an ET 200SP with DP interface module).

Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is inserted in the correct slot
- The value "0" codes all other possibilities (wrong module, empty slot, BU cover).

The figure below shows part of feedback data record 197 for reading the actual configuration of an ET 200SP with AL modules (and PN interface module). ET 200SP modules are inserted up to slot 65, and then the AL modules. For example, a value of "1" in the byte "status_slot_66_AL" means that the 1st AL module actually exists in the plant and is inserted in the correct slot.

128	status_slot_62_SP	USInt	1
129	reserve_slot_62_SP	USInt	0
130	status_slot_63_SP	USInt	1
131	reserve_slot_63_SP	USInt	0
132	status_slot_64_SP	USInt	1
133	reserve_slot_64_SP	USInt	0
134	status_slot_65_SP	USInt	1
135	reserve_slot_65_SP	USInt	0
136	status_slot_66_AL	USInt	1
137	reserve_slot_66_AL	USInt	0
138	status_slot_67_AL	USInt	1
139	reserve_slot_67_AL	USInt	0
140	status_slot_68_AL	USInt	1
141	reserve_slot_68_AL	USInt	0
142	status_slot_69_AL	USInt	1
143	reserve_slot_69_AL	USInt	0

Reading feedback data record 197

You can read the feedback data record 197 from the ET 200SP with the RDREC instruction. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

Further information and examples

Specific examples of configuration control can be found in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

Further information on ET 200SP can be found in the manuals for IM 155-6 PN (http://support.automation.siemens.com/WW/view/en/73184046) and IM 155-6 DP (http://support.automation.siemens.com/WW/view/en/73098660)

Further information on ET 200AL is available here (http://support.automation.siemens.com/WW/view/en/89254863).

Expanding ET 200SP with ET 200AL modules

Introduction

The ET 200SP is a distributed I/O system for installation in a control cabinet.

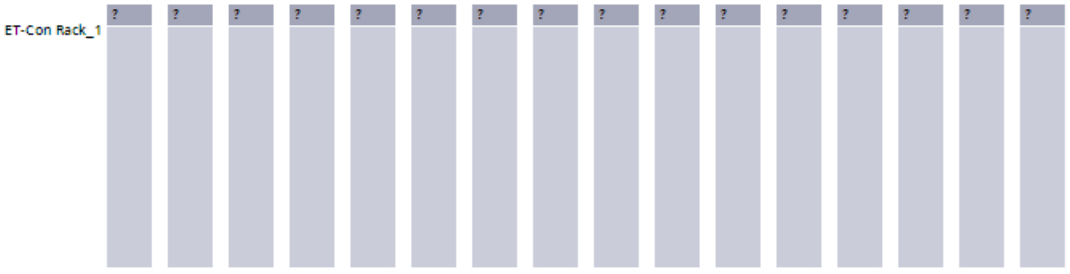
The system can be expanded with modules of the ET 200AL series with IP65/67 degree of protection. ET 200AL modules can be mounted on site, for example on a machine.

Slot rules

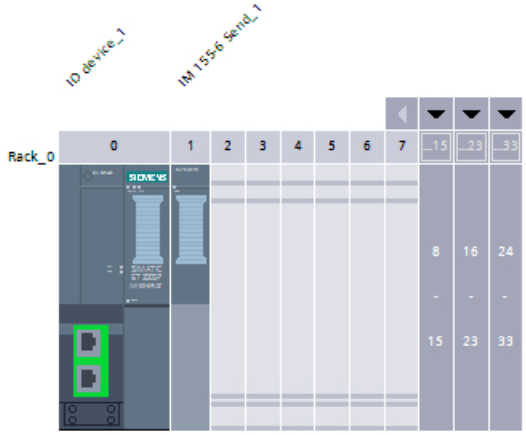
The following rules apply to the use of ET 200AL modules in an ET 200SP with interface module:

- The "BA-Send 1xFC" module must be inserted in slot 1 of the ET 200SP if the ET 200SP is to be expanded with ET 200AL modules.
- The ET 200AL modules must be configured with no gaps.

The procedure detailed further on covers the use of ET 200AL modules in an ET 200SP with interface module.

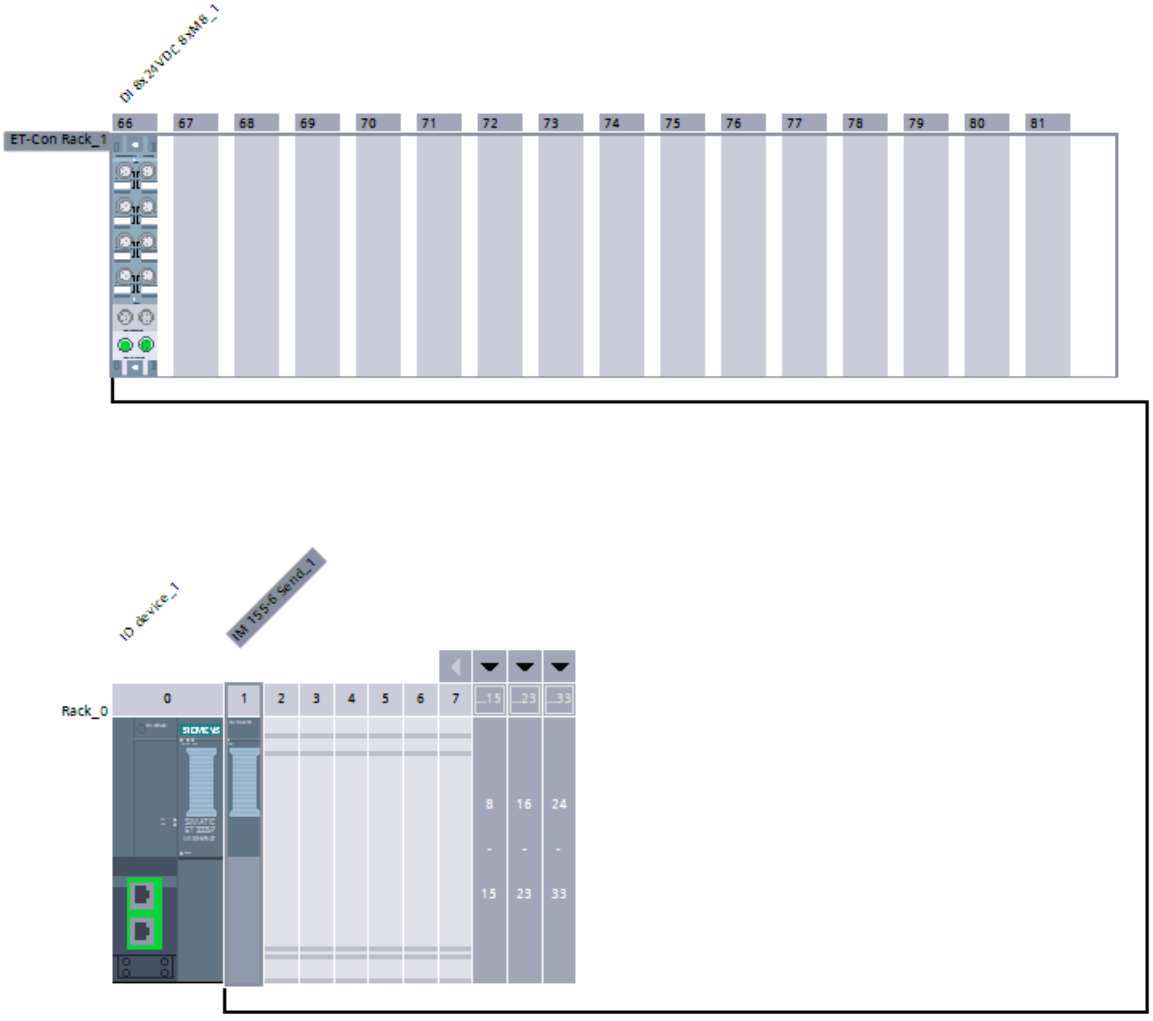


The following, different, rules apply to the use of ET 200AL modules in an ET 200SP with CPU:



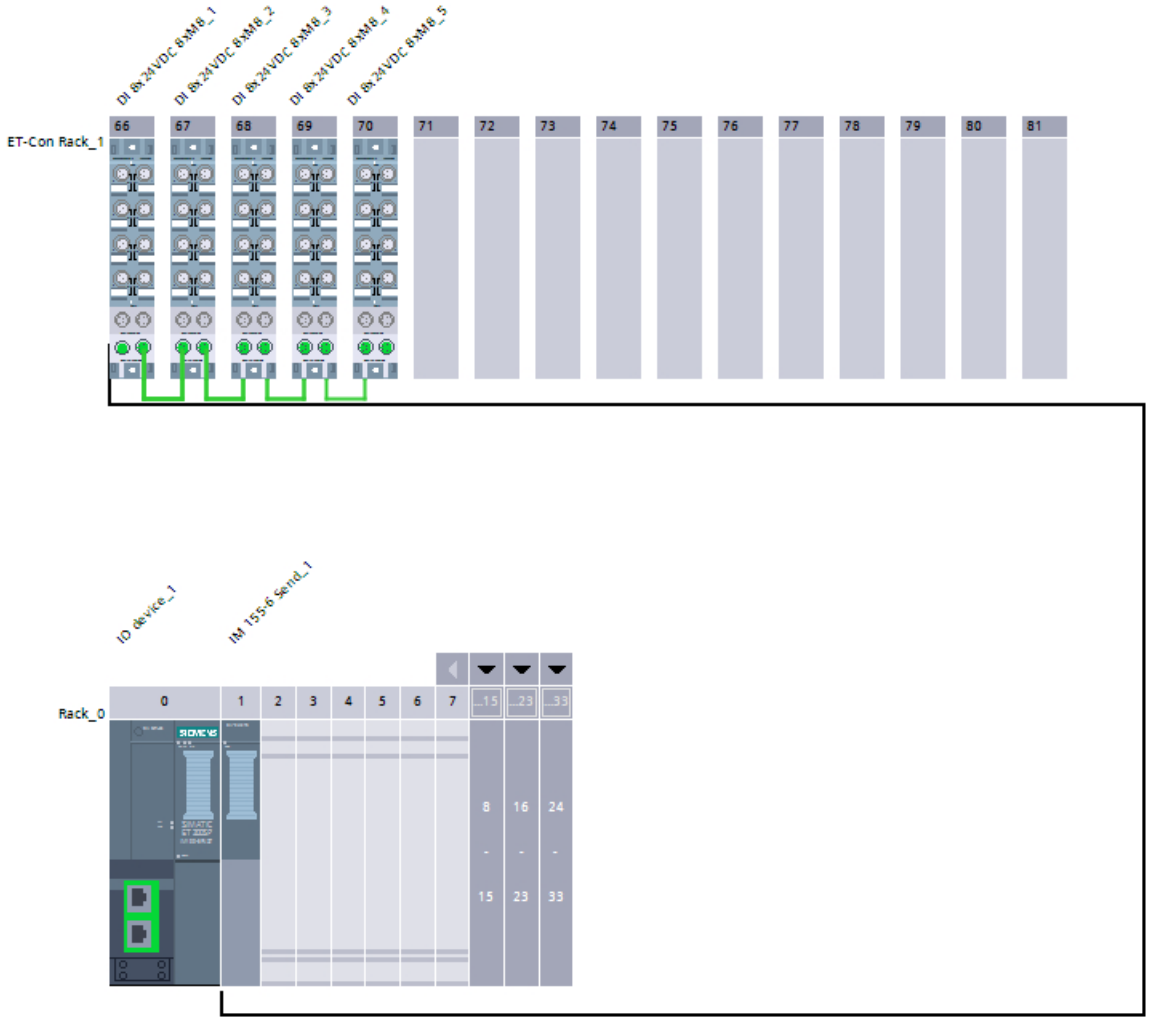
- The "BA-Send 1xFC" module can be located in slots 2 to 4 of the ET 200SP CPU.
- A CM DP communication module can be inserted as CPU submodule, but then occupies slot 2.

Procedure



Follow the steps below to configure an ET 200SP with interface module with ET 200AL modules:

1. Drag an interface module (PROFINET or PROFIBUS) from the ET 200SP series to the network view.
2. Go to the device view. You do this by clicking twice on the icon of the module you have just inserted.
3. Insert the module "BA Send 1xFC" into slot 1 of the ET 200SP.
   STEP 7 now generates an ET-Connection rack with 16 slots for ET 200AL modules (figure below).
   An ET-Connection rack is a virtual rack that sets the order of the connected ET 200AL modules.
   Question marks are displayed above the slots as an ET 200AL module has yet to be connected to BA-Send.



4. From the hardware catalog (subfolder ET 200AL in the ET 200SP folder), select the first ET 200AL module to be connected to the ET 200SP: Drag and drop this module to the 1st slot in the ET connection rack.
   From this module, STEP 7 generates a line to the "BA-Send 1xFC" module and allocates the slot numbers 66 to 81 (figure below).
   If you configure the ET 200SP with a DP interface module, STEP 7 assigns the slot numbers 34 to 49 for the ET 200AL modules.

5. Now drag all other ET 200AL modules into the free slots in the ET-Connection rack.
   STEP 7 automatically inserts the ET-Connection between the individual ET 200AL modules (green loops).
   In the configuration below, five ET 200AL modules are connected in series.

6. Complete the configuration of the ET 200SP: Drag all ET 200SP modules from the hardware catalog to the slots in the ET 200SP.
   Five ET 200SP modules are plugged in the configuration example below: The PN interface module in slot 0, the module "BA-Send 1xFC" in slot 1, one input module each in slots 2 and 3, and a server module in slot 4:

ET 200AL distributed I/O system (Page 1974)

Output module parameters

Substitute value reaction

Substitute value reaction

In the ET 200SP, the substitute value reaction is executed by the IO controller per slot.

The respective output reacts according to its set substitute value reaction:

- "Turn off"
- "Output substitute value"
- "Keep last value"

This substitute value reaction is triggered in the following cases:

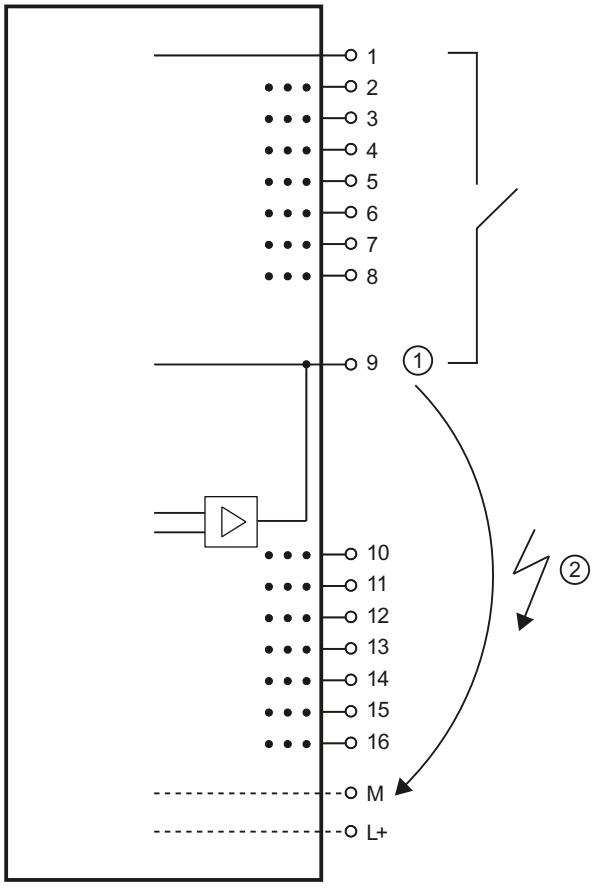
- IO controller in STOP
- Controller failure (connection interruption)
- Firmware update
- Reset to factory settings
- More than one I/O module withdrawn simultaneously
- Disable the IO device
- Station stop
  - Missing server module
  - More than one I/O module withdrawn simultaneously
  - At least one I/O module is inserted on the wrong BaseUnit

Note

Reducing a configuration

If you reduce the configuration of the ET 200SP and download the configuration to the CPU, the modules which are no longer configured but still present retain their original substitute value reaction. This applies until the supply voltage on the BaseUnit BU...D or on the interface module is turned off.

Input module parameters

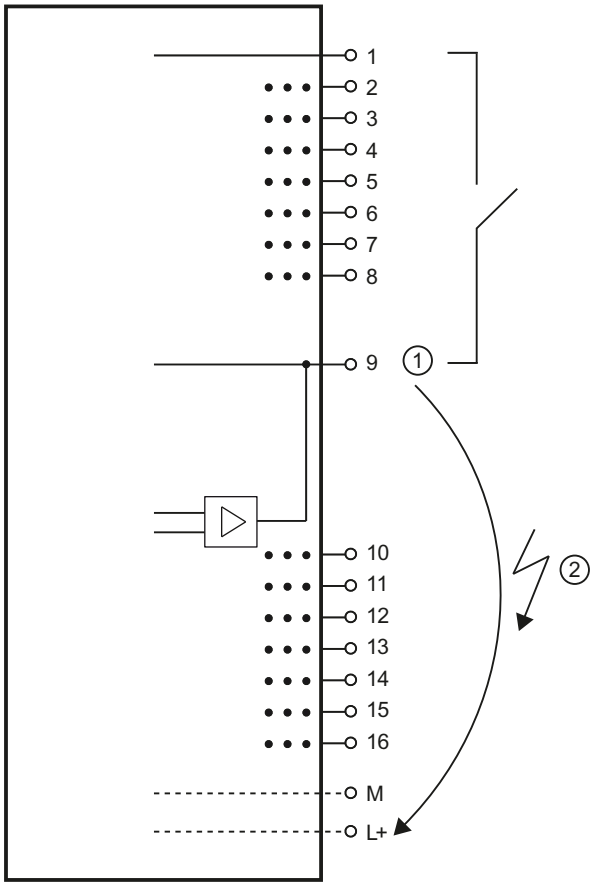


Parameters of the digital input modules

Diagnostics missing supply voltage L+

Enabling of the diagnostics for missing or insufficient supply voltage L+.

Diagnostics short-circuit to ground



Enabling of the diagnostics if a short-circuit of the actuator supply to ground occurs.

① Encoder supply
② Short-circuit

Diagnostics short-circuit to L+

Enabling of the diagnostics if a short-circuit of the encoder supply to L+ occurs.

① Encoder supply
② Short-circuit

Diagnostics wire break

Enabling diagnostics if the line to the encoder is interrupted.

Operating mode

Determines whether a channel is enabled or disabled.

Pulse extension (only High Feature modules)

Pulse extension is a function for changing a digital input signal. A pulse at a digital input is extended to at least the configured length. If the input pulse is already longer than the configured length, the pulse is not changed.

Pulse extension is started whenever the state of the input signal changes and no pulse extension is active for this channel.

Potential group of the left module / new potential group

Specifies whether the I/O module is located on a base unit with supply voltage feed (new potential group) or whether it is it located on a base unit without supply voltage feed (in which case it belongs to the potential group of the left module).

Parameters of the analog input modules

Missing supply voltage L+

Enabling of the diagnostics, with missing or too little supply voltage L+.

Reference junction (AI 4xRTD/TC 2-/3-/4-wire HF)

A BaseUnit with internal temperature sensor (BU..T) or the channel 0 of the I/O module can be used as reference junction, provided this has been configured as "Thermal resistor Pt100 climatic range Celsius".

A possible parameter assignment is shown below (see also Information about reference channel mode (Page 1957)):

Table 10-192 RTD channel

Setting	Description
No reference channel operation	Temperature value at channel 0 can be used as module-wide reference value if the parameters of the other channels are assigned accordingly.
Reference channel of Group x	The channel acts as sender for the reference junction temperature of Group x. Distribution is performed via the interface module.

Table 10-193 TC channel

Setting	Description
Reference channel of the module	The corresponding TC channel uses the channel 0 of the same module as reference junction temperature. This must be set as "Thermal resistor Pt 100 climatic range Celsius" and "No reference channel operation"; otherwise, reference junction diagnostics is triggered.
Internal reference junction	The reference junction temperature is read by an internal temperature sensor on the BaseUnit. Reference junction diagnostics is triggered if there is a wrong BaseUnit type.
Reference channel of Group x	With the setting "TC" (thermocouple...), the channel acts as receiver for the reference junction temperature of Group x.
Fixed reference temperature	No temperature compensation occurs. The linearization is executed with an assumed reference junction temperature of 0 °C.

Overflow

Enabling of the diagnostics if the measured value exceeds the overflow range.

Underflow

Enabling of the diagnostics if the measured value falls below the underflow range.

Wire break

Enabling of the diagnostics if the module has no current flow or too low a current flow for the measurement on the corresponding configured input.

Smoothing

The individual measurements are smoothed using digital filtering. The smoothing can be set in 4 stages, whereby the smoothing factor k multiplied by the cycle time of the I/O module corresponds to the time constant of the smoothing filter. The larger the smoothing, the larger the time constant of the filter.

The following figure shows the step response for the various smoothing factors depending on the number of module cycles.

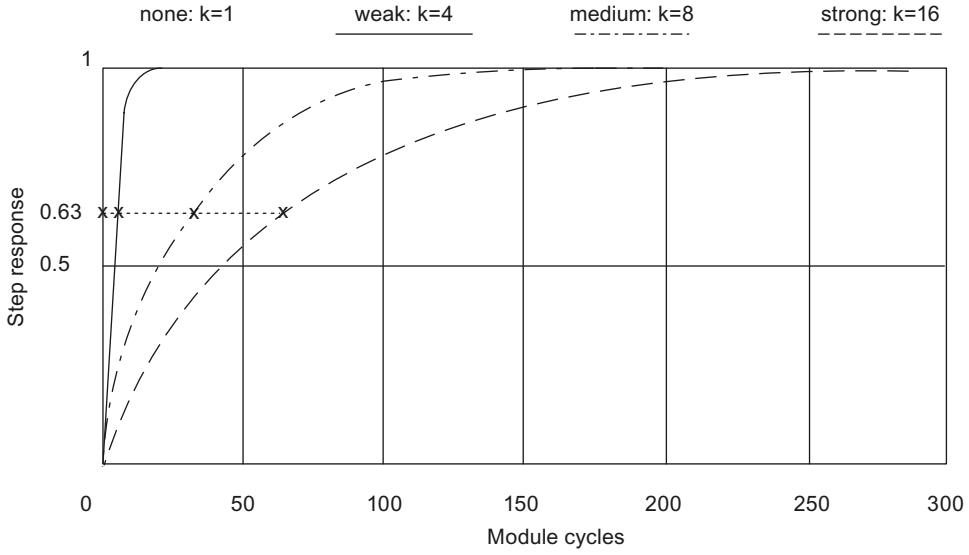


Figure 10-49 Smoothing with AI 4×RTD/TC 2-/3-/4-wire HF

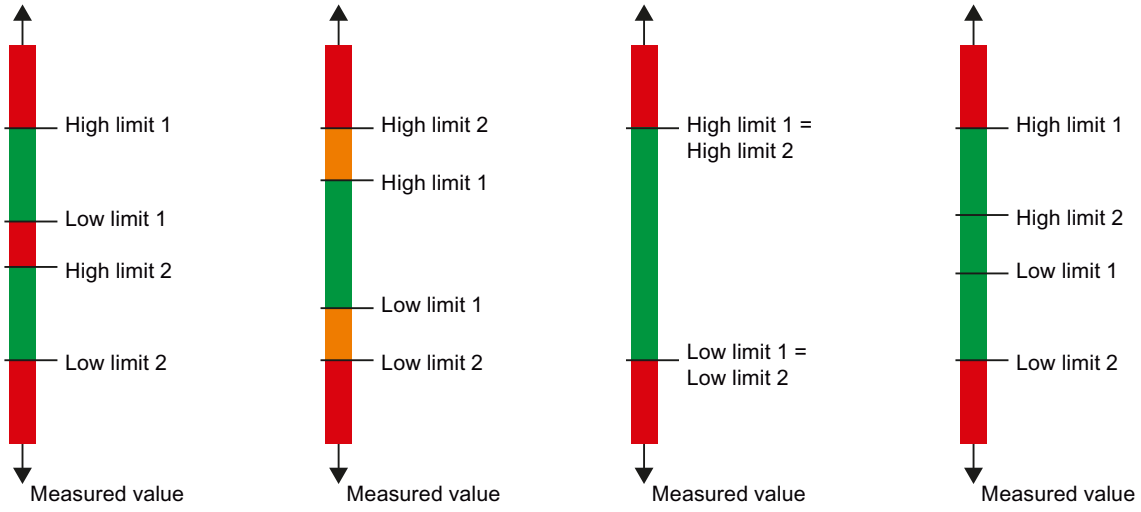
Interference frequency suppression



With analog input modules, suppresses the disturbance caused by the frequency of the AC network used.

The frequency of the AC network may interfere with measured values, particularly for measurements within low voltage ranges and when thermocouples are being used. This parameter is used to define the predominant power frequency of the system.

Hardware interrupt limits

If the high limit 1/2 or the low limit 1/2 is violated, the module triggers a hardware interrupt.

Below are some examples for the selection of the limits 1 and 2.

Low limit 1/2

Specify a threshold whose undershoot triggers a hardware interrupt.

High limit 1/2

Specify a threshold whose overrange triggers a hardware interrupt.

Potential group of the left module/New potential group

Specifies whether the I/O module is located on a BaseUnit with supply voltage infeed (new potential group) or on a BaseUnit without supply voltage feed (in which case, it belongs to the potential group of the left module).

Temperature coefficient (measurement type thermoresistor)

The correction factor for the temperature coefficient (α value) defines the relative rate of change of the resistance of a specific material at a temperature rise of 1 °C.

The temperature coefficient depends on the chemical composition of the material. In Europe, only one value is used per sensor type (default value).

The further values facilitate a sensor-specific setting of the temperature coefficient and enhance accuracy.

Special features of AI 4xRTD/TC 2-/3-/4-wire HF (Page 1965)

Information about reference channel mode

An RTD/TC module of the ET 200SP works in reference channel mode when a channel sends the reference temperature to other channels of the station. The receiving channels use the reference temperature for temperature compensation when measuring with thermocouples.

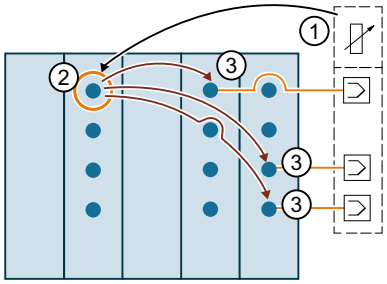
Structure and use of thermocouples

The thermocouple consists of two wires with different metals or alloys that are welded together at the end. The weld is called measuring point.

The other end of the two wires is open. This end is called reference junction.

A thermal voltage, which depends on the temperature at the measuring point, occurs between the two metals/alloys at the measuring point. Other thermal voltages also occur at the reference junction - with transition from thermocouple to copper lines, for example - that falsify the actual measured value and need to be compensated. No compensation is required for a reference junction temperature of 0 °C.

Different methods are used to compensate the reference junction temperature:



- Fixed reference temperature: The reference junction is permanently set to a specific temperature, for example, to 0 °C by an icewater bath (no compensation required).
- Internal reference junction: The reference junction is the terminal of the BaseUnit on which the analog module is plugged. If you select the "Internal reference junction" compensation type, you have to use BaseUnits with integrated temperature measurement to compensate the reference junction temperature. These BaseUnits have the designation "BU..T". The module records the temperature at the reference junction and uses this to determine the actual temperature at the measuring point.
- Reference channel of Group x: An external thermal resistor records the temperature at the reference junction for the Group x (group of channels within a station). The actual temperature at the respective measuring point can be determined as a result. One external thermal resistor is required for each group. The thermal resistors are each connected to one channel of an analog module. These channels are called senders (for the temperature at the reference junction).
  The mode of operation and settings are described in the section "Station-wide distribution of reference temperature".
- Reference channel of the module: The mode of operation is comparable with "Reference channel of Group x". You connect an external thermal resistor to channel 0 of the module to measure the temperature at the reference junction. Other channels of the same module use this reference temperature for temperature compensation.
  The mode of operation and settings are described in the section "Module-wide distribution of reference temperature".

You can find information about the structure and mode of operation of a thermocouple in the Analog value processing (http://support.automation.siemens.com/WW/view/en/67989094) manual.

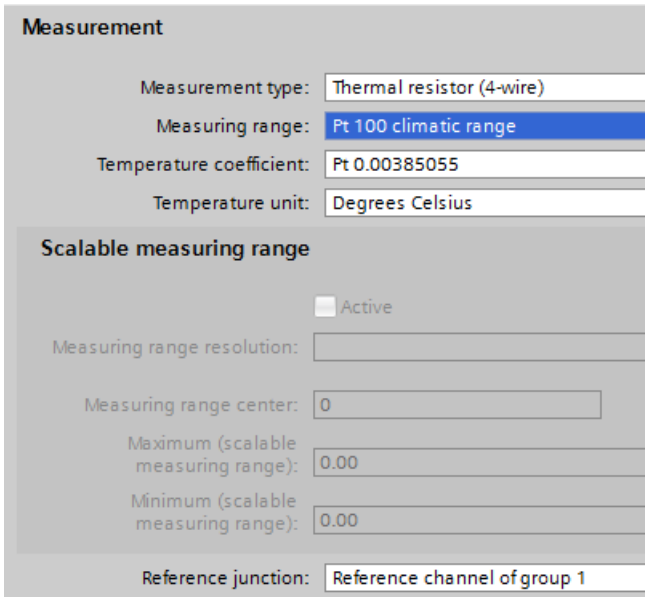
Station-wide distribution of the reference temperature

You can record the temperature at the reference junction x using a thermal resistor on a channel (sender of the reference temperature) and send it to other channels within a station (receivers). All channels that receive the temperature at a reference junction x form the Group x.

For each group, you assign parameters to exactly one channel as sender of the reference temperature.

① Thermal resistor at the reference junction

② Channel records temperature at the reference junction and sends it to the other channels within a station (sender of Group x). The temperature value is used for the compensation of the reference junction temperature.



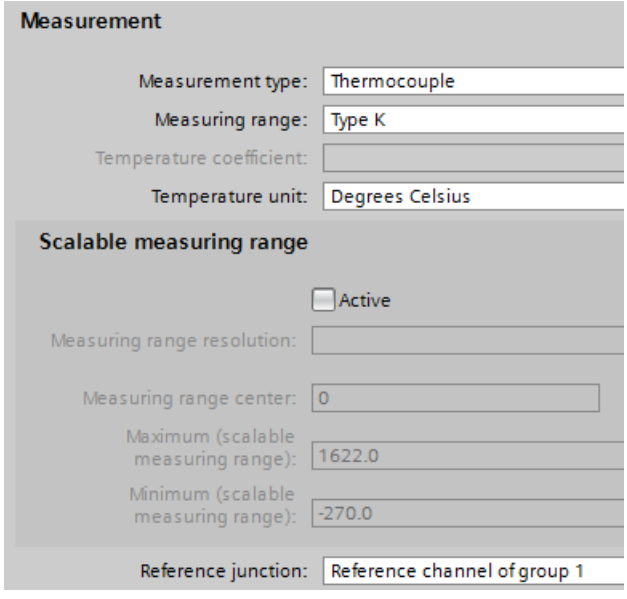
③ Channels of the Group x receive the temperature at the reference junction (receivers)

Parameter assignment of a channel as reference channel (sender for Group 1)

Parameter assignment is described below using Group 1 as example:

1. Open the project in STEP 7
2. Select the required analog module (RTD/TC) in the device view.
3. Then select a channel that is to work as sender of the reference junction temperature.
   The following settings are required:
   "Measurement type": "Thermal resistor", for example, "Thermal resistor (4-wire connection)"
   "Measuring range": "Pt 100 climatic range"
   "Temperature unit": "Degrees Celsius"
   "Reference junction": "Reference channel of Group 1"

The following figure shows the parameter assignment.

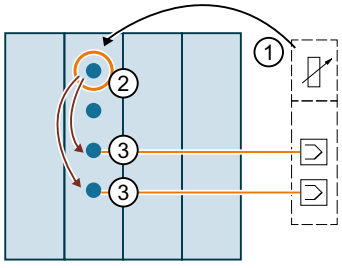


The channel configured in this way (thermal resistor measurement type) works as reference channel of Group 1 and sends the measured temperature to all channels (thermocouple measurement type) that are configured as receivers of Group 1.

In the next section, you will learn how to assign parameters for channels that are receivers of Group 1.

Parameter assignment of a channel as receiver of Group 1

The figure below shows the parameter assignment of a channel that receives the temperature at the reference junction of Group 1.

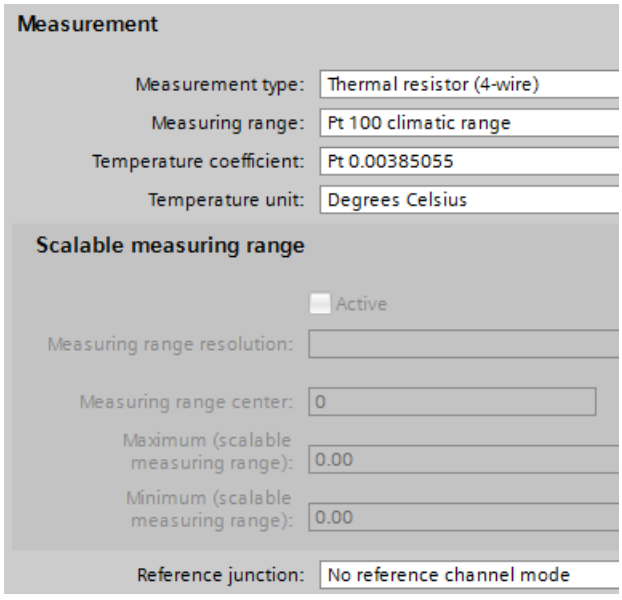


The following settings are required:

- "Measurement type": "Thermocouple"
- "Reference junction": "Reference channel of Group 1"

Module-wide distribution of the reference temperature

You can record the temperature on a reference junction using the channel 0 of the module and use the temperature value for the channels 1, 2, 3... of this module. The recorded temperature value is not sent to the channels of the other modules within the station (no reference channel mode).



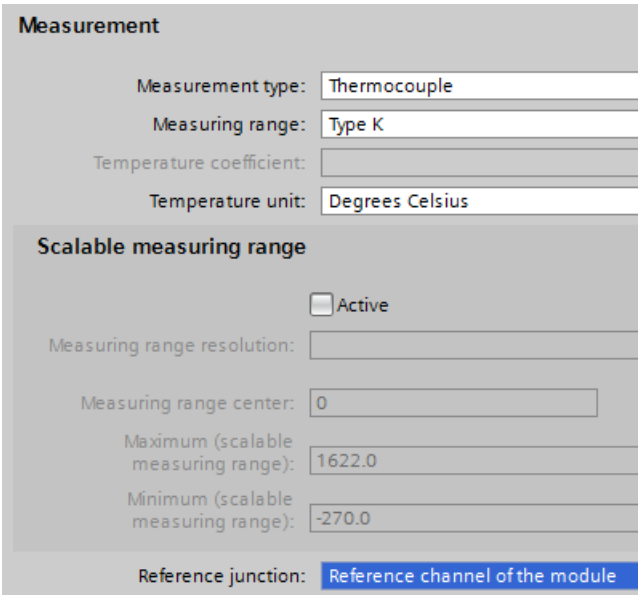
① Thermal resistor at the reference junction

② Channel records temperature at the reference junction, "Reference junction" parameter: "No reference channel mode"

③ Channels of the same module use the temperature value for the compensation of the reference junction temperature for the measurement with thermocouples, "Reference junction" parameter: "Reference channel of the module"

Parameter assignment of channel 0 as reference channel of the module

The figure below shows the parameter assignment of channel 0 of a module that is to be used for recording the temperature at the reference junction:



The following settings are required:

- "Measurement type": "Thermal resistor", for example, "Thermal resistor (4-wire connection)"
- "Measuring range": "Pt 100 climatic range"
- "Temperature unit": "Degrees Celsius"
- "Reference junction": "No reference channel mode"

Parameter assignment of a channel that uses channel 0 as reference channel

The figure below shows how parameters have to be assigned for a channel that uses the channel 0 of this module as reference channel for temperature compensation.

The settings below are required for the channels of the module that compensate the temperature of the reference junction using channel 0:

- "Measurement type": "Thermocouple"
- "Reference junction": "Reference channel of the module"

Parameters of the analog input modules (Page 1954)

Information about the Oversampling function

High-speed analog modules (HS) are available to meet high performance and speed requirements. The main characteristics of these HS analog modules compared to Standard analog modules (ST) is their shorter cycle times. To achieve this goal, the input and output modules are equipped with components with extremely short throughput and conversion times. In addition, the entire architecture of the modules is designed for faster signal processing.

HS analog modules convert the output of measured values and output values at the same time. Each channel within the module has its own A/D or D/A converter. This means the cycle time is basically the conversion time and independent of the number of activated channels. This is true for analog input modules as well as analog output modules. This means HS modules can be used in fast isochronous mode.

Apart from isochronous mode, the HS analog modules also provide benefits in non-isochronous (free-running) mode. Due to the fast processing of the process signals, HS analog modules are able to detect changes in the process values more quickly and to respond to

these events with the appropriate program blocks (for example, hardware interrupt or cyclic interrupt organization blocks).

Isochronous mode

Isochronous mode refers to synchronous coupling

- Of signal acquisition and output via the distributed I/O
- Of signal transmission via PROFIBUS or PROFINET
- Of program processing with the constant bus cycle time of the PROFIBUS or PROFINET.

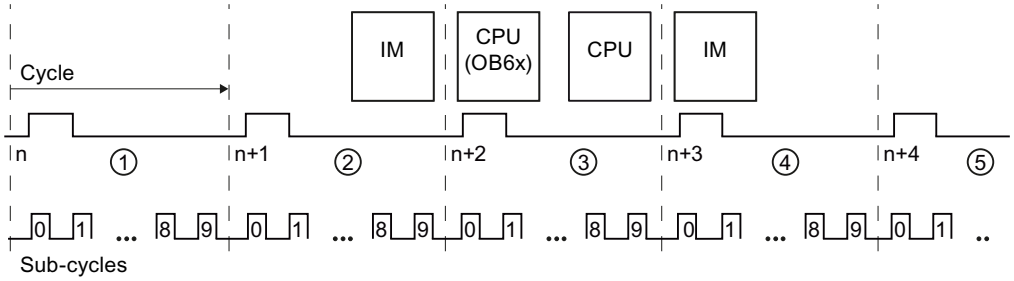
The result is a system that acquires its input signals in constant time intervals, processes them and outputs the output signals. Isochronous mode guarantees reproducible and defined process reaction times as well as equidistant and synchronous signal processing with distributed I/O.

The bus system and the I/O modules work synchronously with configured isochronous mode. The transmitted input and output data are linked to an "isochronous task" in the CPU. As a result, the data of a cycle are always consistent. All data of a process image belong together logically and in time. Jitter in the user program caused by the acquisition of outdated values is therefore almost impossible.

Even fast processes can be perfectly controlled by the exact timely reproducibility of all processes. Isochronous mode thus contributes to high control quality and hence to greater manufacturing precision. While possible fluctuations of the process reaction times are drastically reduced. The time-assured processing can be utilized to improve machine cycle times. Shorter cycle times increase the processing speed and help to lower production costs.

Oversampling

The use of the oversampling function in analog input or analog output modules requires an isochronous configuration.



With analog input modules, the set send clock is divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle reads in a measured value. The read-in measured values of a data cycle are copied to the interface module (IM) in the next send clock and are then available to the processing CPU one clock later.

With analog output modules, the set send clock is also divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle returns an output value. The output values are copied to the interface module by the CPU within the same send clock and are written to the process one send clock later.

The read-in and output values are transmitted in the user data of the analog module. In this way, the address space of the module is extended from 2 bytes of user data per channel to 16 x 2 bytes of user data per channel (with 16 sub-cycles). If you subdivide the send clock into fewer than 16 sub-cycles, the unused addresses are assigned the error value 0x7FFF during input. For output, the values of the unused addresses are ignored.

Because the sub-cycles have to be within a send clock, oversampling needs an additional clock to copy the data to the interface module, unlike the 3-cycle model of isochronous mode. The result is a 5-cycle model.

Isochronous mode

① Send clock is divided into sub-cycles which record the measured value (in this case: 10 sub-cycles)

② Measured values are copied to the IM

③ Measured values are processed and output values determined

④ Output values are copied by the CPU to the IM

⑤ Output values are written to the process

Higher sampling rates through oversampling

Due to the configured modules, the IO device has a minimum possible update time. Within this update period, the IO device/IO controller of the PROFINET IO system is supplied once with new data.

The following applies with respect to the channels of a single standard module in the I/O device: The shortest update time ("sampling rate") is exactly one send clock.

If you want to shorten the update time for the channels of a standard module, you have to shorten the send clock. Because of the properties of the involved components and the structure of the I/O system, this is only possible to a certain extent (e.g., down to 0.25 ms).

Modules with oversampling, however, offer the option of further reducing the update time ("sampling rate") for their channels without having to shorten the send clock for the entire IO device at the same time.

The subdivision of the send clock into time-equidistant sub-cycles enables the processing of faster processes through higher sampling rates.

Example

In practice, the use of oversampling makes sense when the isochronous system works with only one specific send clock (for example, 1 ms) due to the modules used and when faster sampling of the process values is required. By using oversampling and subdividing the send clock into 4 sub-cycles, for example, you can sample the process values in intervals of 250 µs.

Configuring oversampling

Enable the option "Isochronous mode" in the IO device used, and set the corresponding parameters ("Send clock", etc.).

With the distributed analog input modules (e.g. AI 2xU/I 2,4-wire HS), you specify the number of sub-cycles using the "Sampling rate" parameter.

With the distributed analog output modules (e.g. AQ 2xU/I HS), you specify the number of sub-cycles using the "Sampling rate" parameter.

If, for example, you configure a "Sampling rate" of 4 "Values/cycle" for a send clock of 1 ms, the send clock is subdivided into 4 sub-cycles and the process values are sampled at intervals of 250 µs.

Reference

You can find additional information in the manuals on the high-speed analog modules and in the Analog value processing (http://support.automation.siemens.com/WW/view/en/67989094) function manual.

Special features of AI 4xRTD/TC 2-/3-/4-wire HF

Use of Cu10 sensors

- Select "3-wire thermal resistor" and "Cu10" in the parameter assignment.
- Wire the Cu10 sensor using 3-wire connection technology.
- An automatic, internal compensation of the line resistance of the missing measuring line takes place during operation.

Note

To ensure optimum line compensation for Cu10, please note the following:

- The sum of cable resistance and measuring resistance must not exceed 31 Ω.
- Cable resistance should not exceed 8 Ω if you want to use the temperature range up to over 312 °C.
  Example: A 200 m long copper cable with 0.5 mm^2 core cross-section has approx. 7 Ω.
  A lower cross-section reduces the permissible cable length accordingly.

Use of PTC resistors

PTCs are suitable for temperature monitoring of or as thermal protective equipment for complex drives or transformer windings.

- Select "2-wire resistor" and "PTC" in the parameter assignment.
- Connect the PTC using 2-wire technology.
- Use type A PTC resistors (PTC thermistors) in accordance with DIN/VDE 0660, Part 302.
- If the "Over-/underflow" diagnostics is enabled, a "low limit violation" diagnostics which shows a short circuit is generated for resistance values < 18 Ω.
- Sensor data on PTC resistance:

Table 10-194 Use of PTC resistors

Property	Technical specifications	Note
Switching points	**Reaction to rising temperature**	
	< 550 Ω	**Normal range:** • SIMATIC S7: bit 0 = "0", bit 2 = "0" (in the PII)
	550 Ω to 1650 Ω	**Prewarning range:** • SIMATIC S7: bit 0 = "0", bit 2 = "1" (in the PII)
	< 1650 Ω	**Response range:** • SIMATIC S7: bit 0 = "1", bit 2 = "0" (in the PII)

- Assignment in the process image inputs (PII) with SIMATIC S7

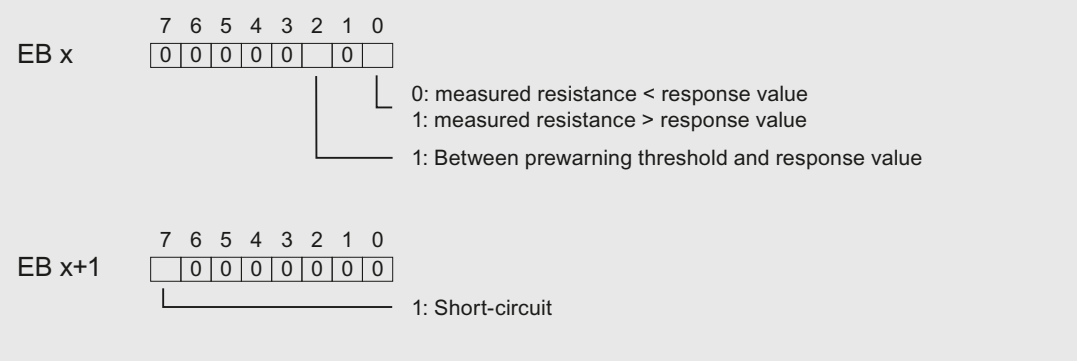

Figure 10-50 Assignment in the process image inputs (PII)

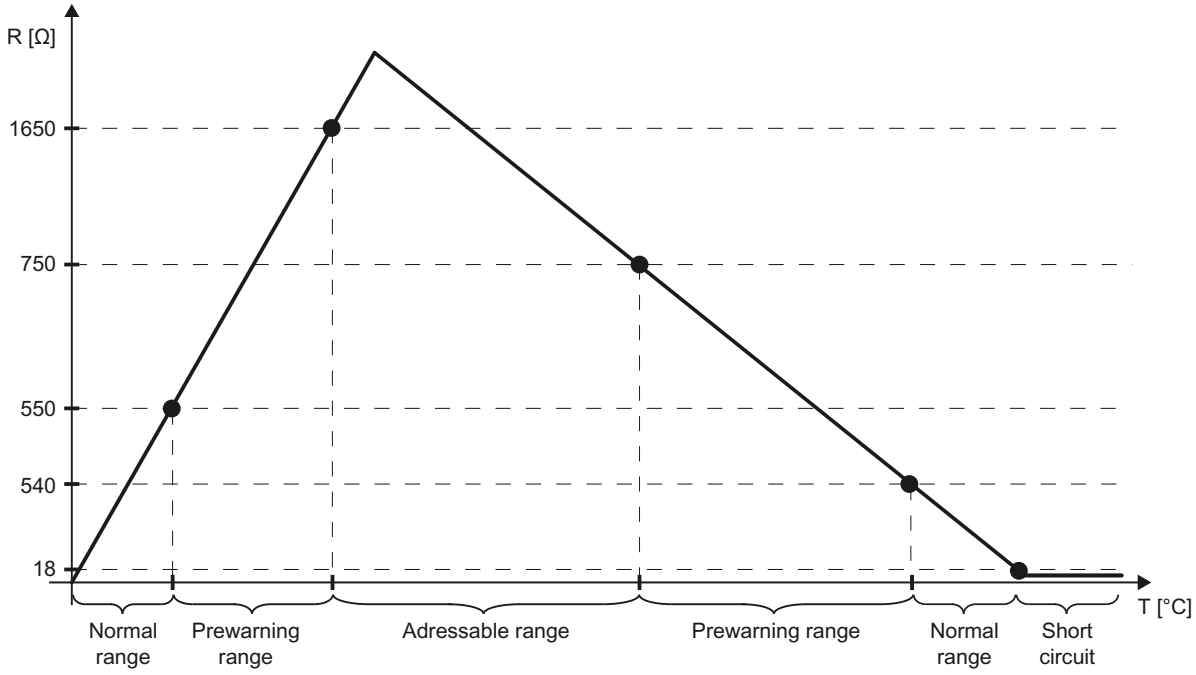
- Notes on programming

Note

Only the bits 0+2 are relevant for the evaluation in the process image inputs. You can use the bits 0+2 to monitor the temperature, for example, of a motor.



The bits 0+2 in the process image inputs have no latching function. When you are assigning parameters, take into consideration that a motor, for example, starts up in a controlled manner (via an acknowledgment).

Bits 0+2 can never be set simultaneously, but are instead set consecutively.

For safety reasons, always evaluate the diagnostic entries of the AI 4×RTD/TC 2-/3-/4-wire HF, as no measurement is possible if I/O modules are unplugged, if the supply voltage of the I/O module has failed, or if there is a wire break or short circuit of the measuring lines.

Example

The following diagram shows the temperature variation and the associated switching points.

Parameters of the analog input modules (Page 1954)

What you should know about the scalable measuring range (Page 1968)

What you should know about the scalable measuring range

The scalable measuring range

The scalable measuring range is a section from the temperature measuring range of an analog input module (for example, the ET 200SP module "AI 8xRTD/TC 2-wire HF").

In this section, a higher resolution of the measured values is possible, comparable with a magnifier that allows a subsection to be viewed in greater detail.

The scalable measuring range is supported for the following measurement types:

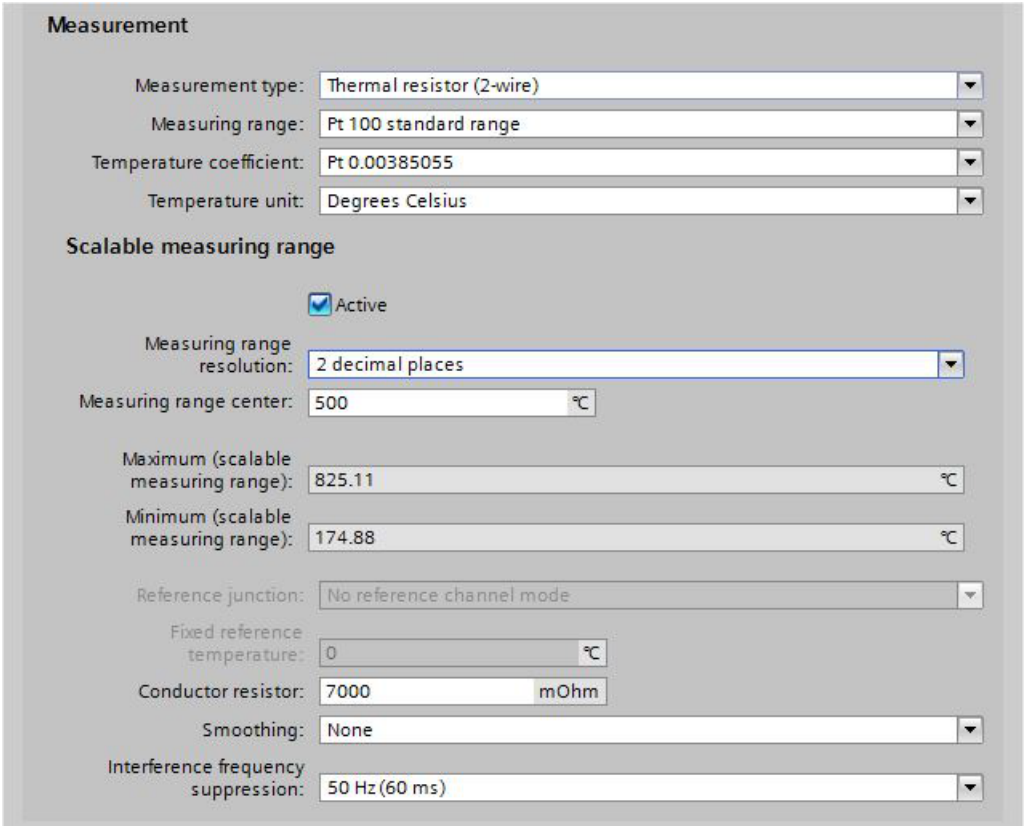
- Thermal resistor (RTD) standard
- Thermocouple

The scalable measuring range is not available with the following measurement types:

- Voltage
- Resistance
- Thermal resistor climatic

Position and resolution of the scalable measuring range

The position and resolution of the scalable measuring range can be set (scaled):



- **Position:** The scalable measuring range can be moved over the entire standard measuring range. This allows you to select the temperature range for which your application requires a higher resolution.
  Exception: The scalable measuring range cannot be moved to the extent that it enters the overflow or underflow of the standard measuring range (Clipping).
  You select the position of the scalable measuring range with the "Measuring range center" parameter (see figure below).
- **Resolution:** The following values can be set:
  - 2 decimal places (0.01 °C)
  - 3 decimal places (0.001 °C)

  You set the resolution with the "Measuring range resolution" parameter (figure below).

Example of a parameter assignment

The following figure shows a parameter assignment for the ET 200SP module "AI 8xRTD/TC 2-,3-,4-wire HF".

In STEP 7, you can find parameters in the properties box via General > AI 4 > Inputs > Channel 0 to channel 3.

Conductor resistor:

The "Conductor resistor" parameter in the parameter assignment above is enabled only if the "Thermal resistor (2-wire terminal)" measurement type was selected.

Here, enter the value for the resistance of the connecting cable of the thermal resistor: A 200 m long copper cable with 0.5 mm^2 wire cross-section, for example, has a resistance value of seven ohms.

Measuring range resolution:

In the parameter assignment above, a resolution of 0.01 °C was selected (measuring range resolution "2 decimal places").

Measuring range center:

The measuring range center is set to 500 °C.

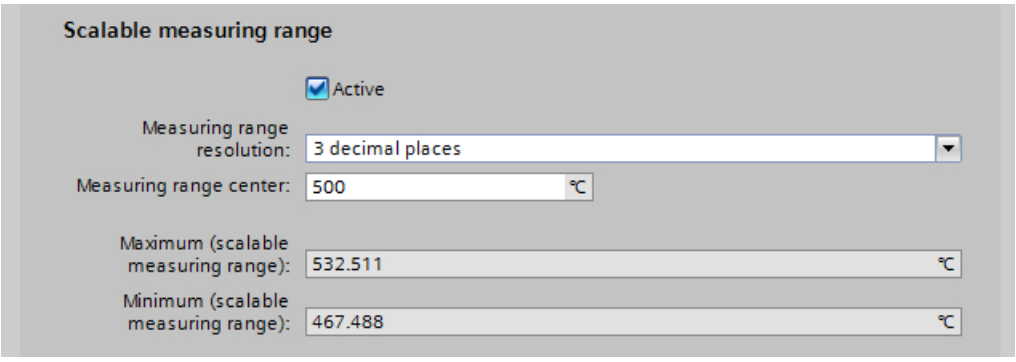
With a resolution of 0.01 °C, this results in a scalable measuring range from 174.88 °C to 825.11 °C.

At a resolution of 0.01 °C, the scalable measuring range covers 650.23 °C.

Maximum (scalable measuring range):

This value represents the high limit of the scalable measuring range. In the example above, 825.11 °C.

The value is calculated by STEP 7 (at a resolution of 0.001 °C, the high limit is at 532.511 °C, see figure below).



Minimum (scalable measuring range):

This value represents the low limit of the scalable measuring range. In the example above, 174.88 °C.

The value is calculated by STEP 7 (at a resolution of 0.001 °C, the low limit is at 467.488 °C; see figure below).

Higher resolution:

The following figure shows a parameter assignment with a resolution of 0.001 °C (otherwise the same example as in the figure above):

At a resolution of 0.001 °C, the scalable measuring range is between 467.488 and 532.511 °C and covers 65.023 °C (a tenth of the measuring range at a resolution of 0.01 °C).

Standard measuring range with 0.1 °C resolution

The following table shows the standard measuring range for thermal resistors of the type "Pt 100", values in degrees Celsius.

Pt 100 standard in °C (1 digit = 0.1 °C)	Decimal values	Hexadecimal values	Ranges
> 1000.0	32767	7FFF	Overflow
1000.0 : 850.1	10000 : 8501	2710 : 2135	Over range
850.0 : -200.0	8500 : -2000	2134 : F830	Nominal range
-200.1 : -243.0	-2001 : -2430	F82F : F682	Under range
< -243.0	-32768	8000	Underflow

The standard measuring range is the basis for the scalable measuring range.

You can set the measuring range center within the nominal range (-200 °C to 850 °C, see table above).

For temperatures below and above the set measuring range center, you then obtain measured values with a higher resolution.

The width of this range around the measured value center depends on the selected resolution.

Scalable measuring range 0.01 °C and 0.001 °C resolution

The scalable measuring range is identified by the following value ranges:

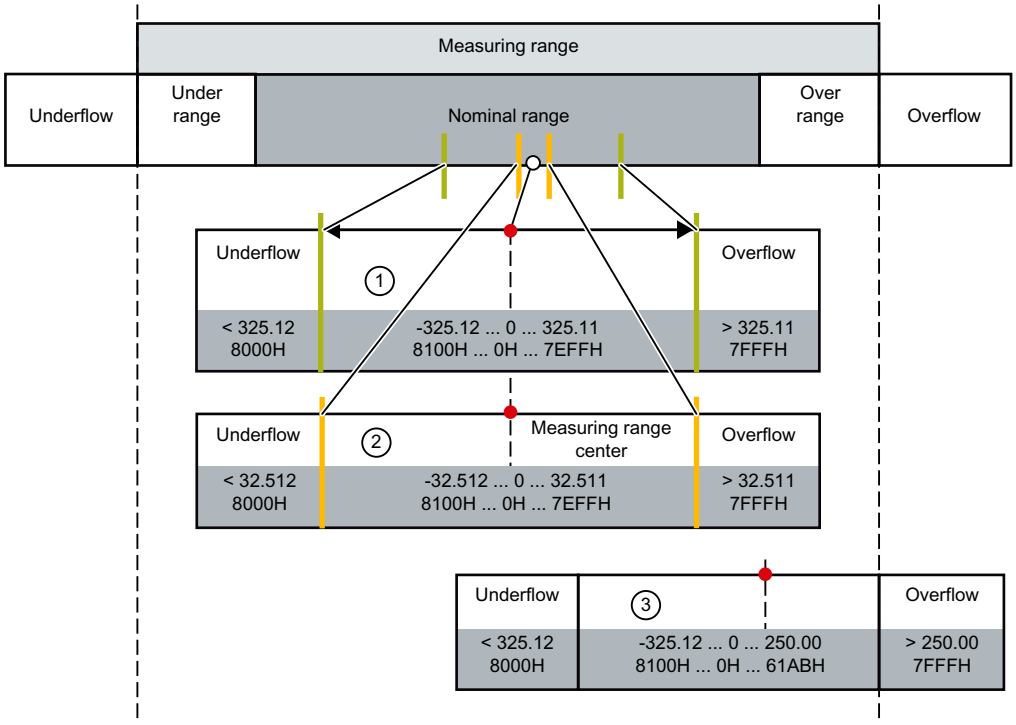
Scalable measuring range	Measuring range resolution (values in °C)		Hexadecimal values
	2 decimal places	3 decimal places	
Overflow	> 325.11	> 32.511	7FFF
High limit	325.11	32.511	7EFF
Measuring range center	0	0	0
Low limit	325.11	-32.511	8100
Underflow	< -325.11	< -32.511	8000

The maximum and minimum of the scalable measuring range depend on the selected resolution:

- 2 decimal places, resolution of 0.01 °C:
  The high limit is 325.11 °C above the measuring range center you have set.
  The low limit is 325.11 °C below the measuring range center you have set.
  This means that the scalable measuring range is 650.22 °C around the measuring range center.
- 3 decimal places, resolution of 0.001 °C:
  The high limit is 32.511 °C above the measuring range center you have set.
  The low limit is 32.511 °C below the measuring range center you have set.
  This means that the scalable measuring range is 65.022 °C around the measuring range center.

Calculation of the temperature

You calculate the temperature value by adding the value you receive from the module to the measuring range center.



Example:

- You have set the measuring range center 500 °C (see example in the section "Example of a parameter assignment"). For the resolution, you selected "2 decimal places".
- From the module, you receive the hexadecimal value "0100" in S7 format:

Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

- The hexadecimal value "0100" corresponds to the decimal value 256.
- Since you have selected a resolution of 0.**01** °C, the number 256 corresponds to the temperature value "2.**56** °C".
- You now add 500 °C and 2.56 °C and obtain the measured value 502.56 °C.

Scalable measuring range in the standard measuring range

① Scalable measuring range with 2 decimal places, temperature values in S7 format.

② Scalable measuring range with 3 decimal places, temperature values in S7 format.

③ Scalable measuring range cut off at the overflow of the standard measuring range ("Clipping").

The sum of the measuring range center (for example 750 °C) and the measured value returned by the module must not extend into the overflow of the standard measuring range. For this reason, in the example above, the maximum value that the module can return is limited to 250 °C

Clipping

STEP 7 limits the maximum of the scalable measuring range so that the sum of the measured value center and the maximum measured value that the module can return is not located in the overflow of the standard measuring range. In the same way, STEP 7 restricts the minimum of the scalable measuring range.

ET 200AL

ET 200AL distributed I/O system

SIMATIC ET 200AL

The SIMATIC ET 200AL distributed I/O system is a scalable and highly flexible, distributed I/O system for connecting process signals to a superordinate control with a field bus.

Properties

- Connection to PROFINET or PROFIBUS or integration into ET 200SP / ET 200SP CPU
- Up to 32 modules on an ET 200AL
- Integration into ET 200SP / ET 200SP CPU: Up to 16 AT modules can be connected to an ET 200AL
- Connection of modules via ET-Connection
- Spatially separated mounting possible
- Module widths of 30 and 45 millimeters
- Degree of protection IP65/IP67
- Suitable for temperatures from -25 to +55 °C and accelerations up to 5 g.
- Installation in all positions
- Color coding of the cables and connections
- CA-compliant labeling of the interfaces
- PROFIenergy integrated
- Configuration control
- Connection of sensors and actuators using M8 and M12 connection system

Area of application

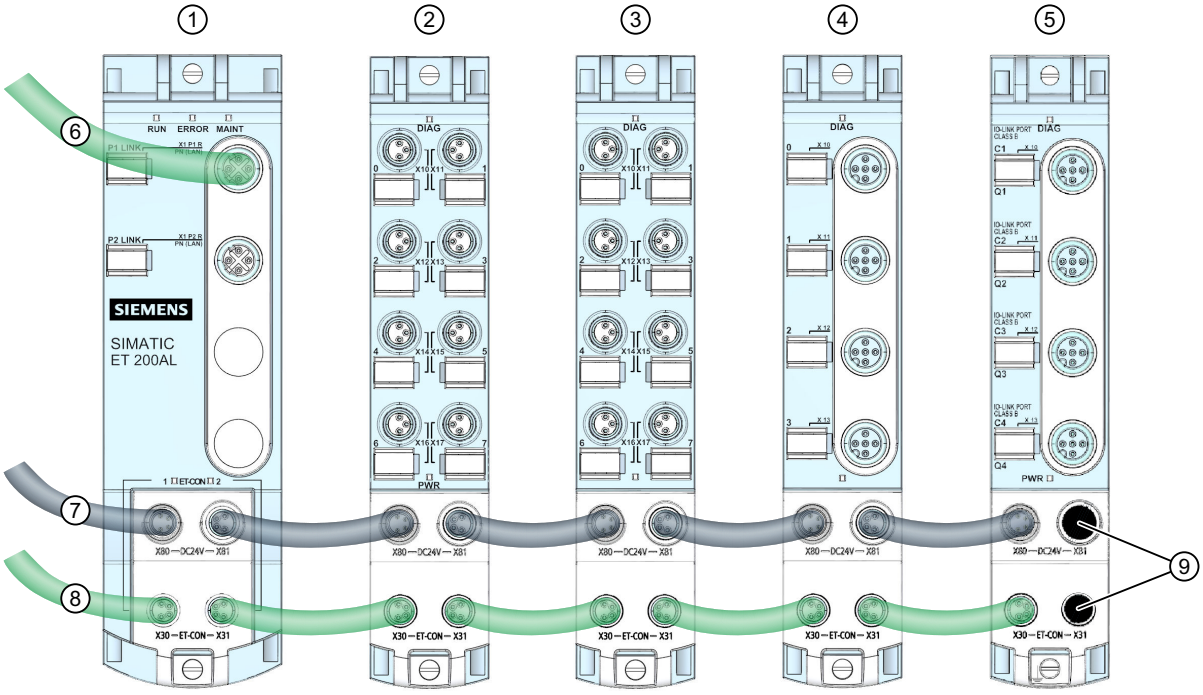
The SIMATIC ET 200AL distributed I/O system is especially well suited for use in tight spaces, moving applications and for assembly and handling technique. Thanks to its scalable construction, you have the option precisely customize its configuration to your on site needs.

The SIMATIC ET 200AL distributed I/O system features protection type IP65/IP67 and is suited for distributed use on a machine or assembly line.

Structure

The SIMATIC ET 200AL distributed I/O system is made up of the following components:

- Interface modules (PROFINET/PROFIBUS)
- Digital and analog I/O modules
- Communications module



After an interface module you can configure 2 lines (ET-Connection), each with 16 modules.

Alternatively, you can configure a line with 16 I/O modules on the SIMATIC ET 200SP distributed I/O system with BusAdapter BA-Send 1xFC.

The ET-Connection backplane bus is designed as a cable. This allows you to create spatial distances of up to 10 m between the modules.

Configuration example

The figure below shows a configuration example of the SIMATIC ET 200AL distributed I/O system with a PROFINET interface module.

① Interface module (PROFINET)
② Digital input/Digital output module
③ Digital input module
④ Analog input module
⑤ Communications module
⑥ PROFINET cable
⑦ Power supply cable
⑧ ET-Connection line
⑨ Sealing caps

Figure 10-51 Example configuration of the ET 200AL

Expanding ET 200SP with ET 200AL modules (Page 1946)

Configuring ET 200AL

Introduction

ET 200AL is a distributed I/O system with an IP65/67 degree of protection. It is therefore designed for use on site, for example right beside a machine (no control cabinet required).

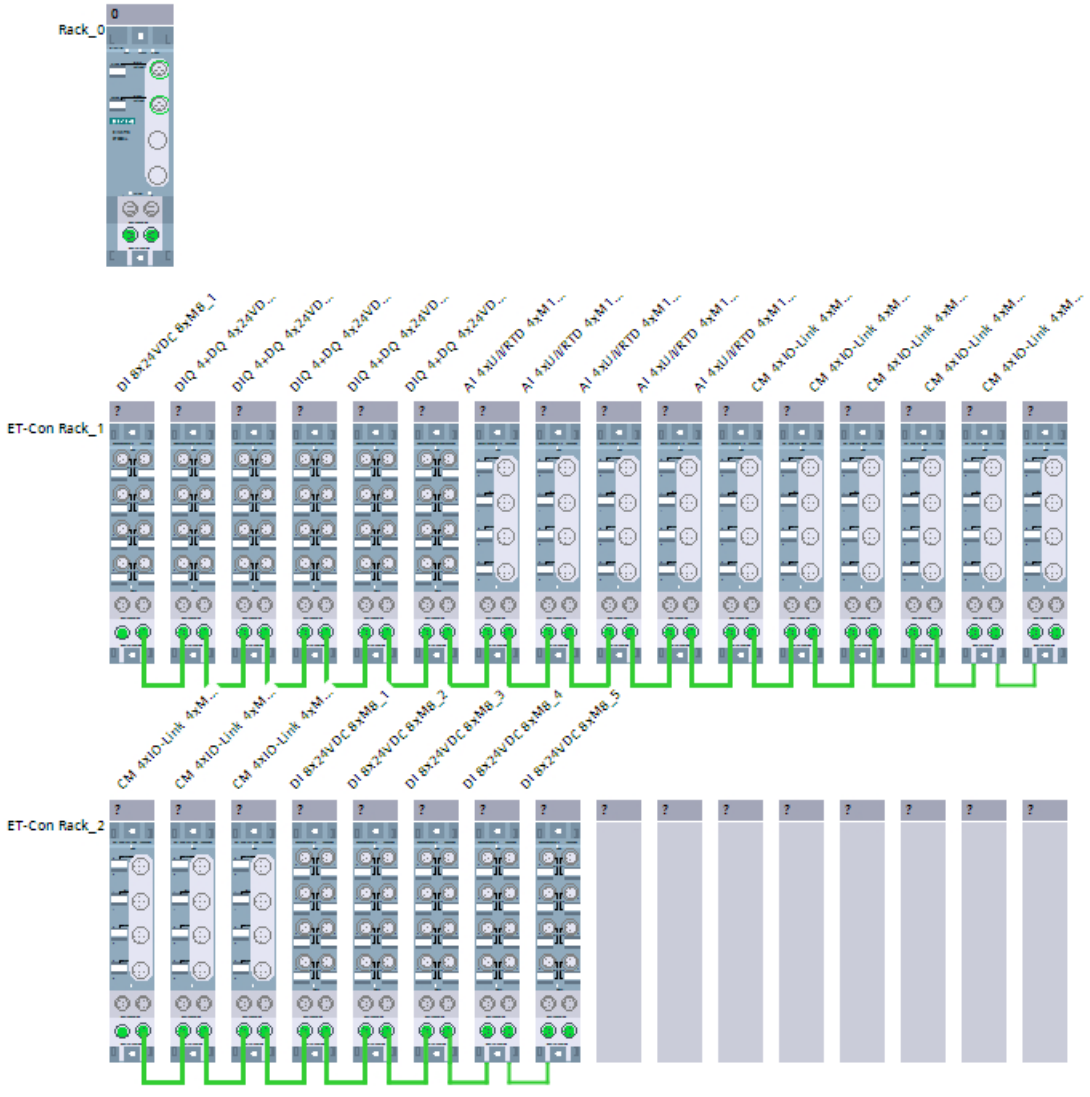
The system includes interface and communications modules as well as input and output modules.

There are two use cases for the ET 200AL:

1. As I/O device or DP slave: The system interface module is connected to a field bus (PROFINET or PROFIBUS) and connected to the PN or DP interface of a CPU.
2. As an ET 200SP expansion: The ET 200AL modules are connected to the ET 200SP over the "BA Send 1xFC" module ("mixed mode").

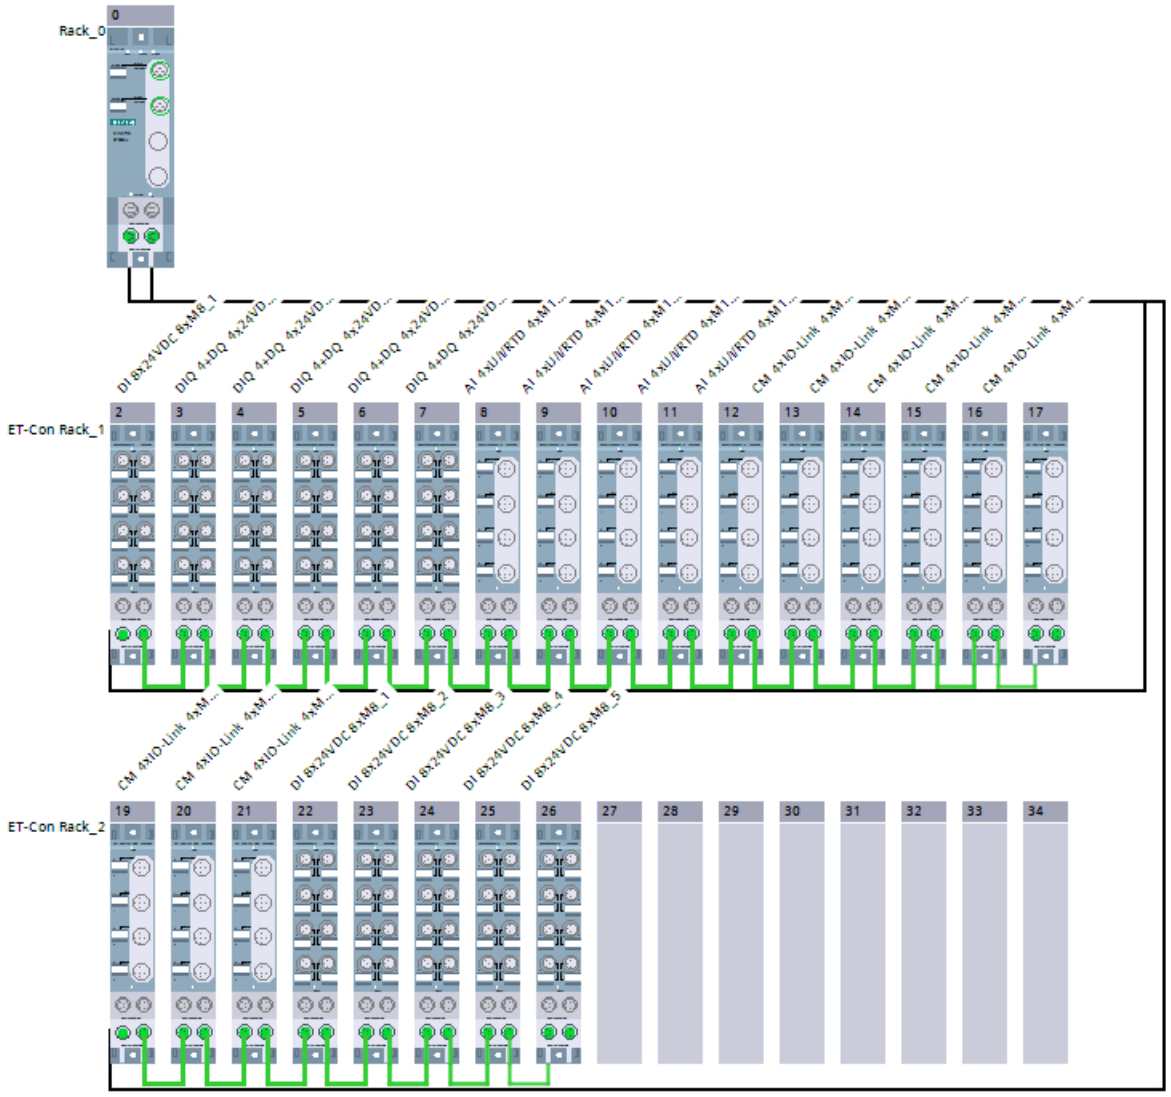
The following sections describe how to configure an ET 200AL as I/O device or DP slave (use case 1).

For use case 2, see the link under "See also".



Procedure

Follow the steps below to configure an ET 200AL in STEP 7:



1. Copy an interface module (PROFINET or PROFIBUS) from the ET 200SP series to the network view (drag-and-drop operation from the hardware catalog).
2. Go to the device view. Double-click on the interface module you have just inserted.
   The interface module and two ET-Connection racks are displayed in the device view (figure below).
   There are no slot numbers assigned yet, which is why question marks are displayed above the slots.

3. Now select the modules (input, output and communication modules) from the hardware catalog (ET 200AL folder) and drag them to the free slots (outlined in blue; not shown). You can place up to 16 ET 200AL modules in each ET-Connection rack (figure below). An ET-Connection rack is a virtual rack that sets the order of the connected ET 200AL modules.

4. Now connect the interface module to the two ET-Connection racks.
   First click on an ET-Connection interface of the interface module, then hold and drag a line to the left-hand ET connection of the first module in one of the two ET-Connection racks.
   Repeat this step for the second ET-Connection interface of the interface module and the second ET-Connection rack (if used).

5. Double-click on a module to access the module properties and set the module parameters.

Rules

- The ET 200AL modules must be configured with no gaps.
- The first module in an ET-Connection rack must be connected to the interface module.

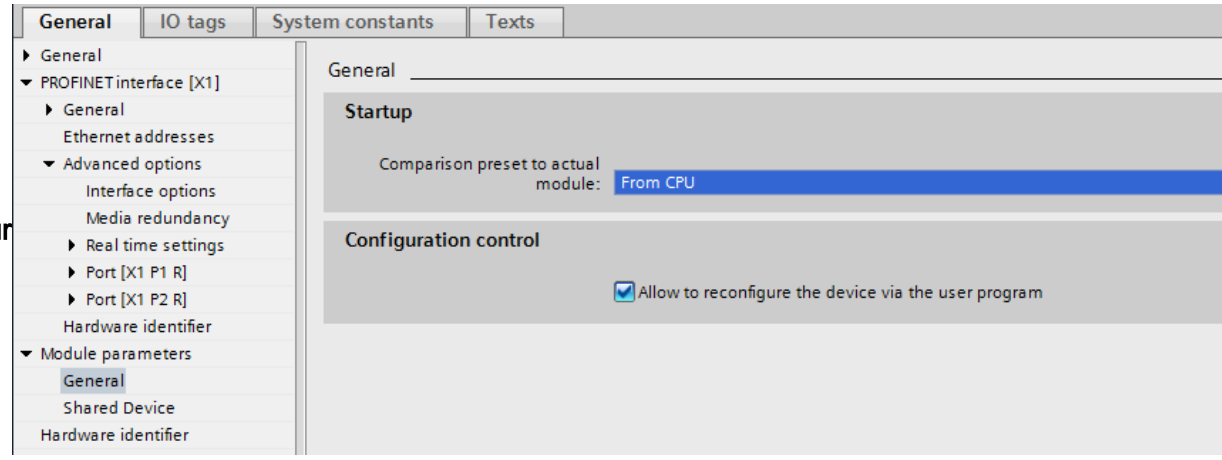
ET 200AL distributed I/O system (Page 1974)

Configuration control with ET 200AL

Operating principle

With configuration control, you can change the original configuration of an ET 200AL (created by configuring with STEP 7) with a user program and operate the ET 200AL in this modified configuration. STEP 7 is no longer required for this configuration: You use your user program to signal to the ET 200AL the slot in which a configured module is actually inserted.

In this case, use control data record 196. In this data record, you code which modules are missing or located in different slots in the real configuration compared to the configuration with STEP 7. The configuration control has no effect on the parameter assignment of the modules (for example, the enabling of diagnostic alarms).



You then call the "WRREC" instruction and use it to write the data record to the interface module of the ET 200AL.

Configuration control gives you the flexibility to vary the configuration of an ET 200AL as long as the real configuration can be derived from a preset maximum configuration (originally created with STEP 7).

The following sections describe how to enable configuration control and how to structure the required data record 196 for the ET 200AL.

Requirement

Enabling configur

Structure of control data record 196

The configuration of the data block corresponds to the original configuration of the ET 200AL with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record codes a module in the original configuration with STEP 7.

- Bytes 4 and 5 in the data record correspond to the module in slot 1 in the original configuration.
- Bytes 6 and 7 in the data record correspond to the module in slot 2 in the original configuration.
- Bytes 8 and 9 in the data record correspond to the module in slot 3 in the original configuration.
- etc.

The current (real) slot is coded by the number that is assigned to the "Slot_x" byte (by its value): Examples:

- The value "2" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration.
- The value "3" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration.
- The value "4" in byte 6 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration.
- etc.

Creating control data record 196

The figure below shows part of control data record 196 for configuration of an ET 200AL.

This configuration is given as an example:

- ET-Con1 is inserted in "slot_1" (fixed setting). The two ET-Connection submodules "ET-Con1" and "ET-Con2" are submodules of the interface module of the ET 200AL. They are integrated as fixed modules in the IM module. They cannot be inserted individually.
- ET-Con2 is inserted in "slot_18" (fixed setting).
- In this configuration, 16 AL modules are connected to ET-Con1 ("slot_2" to "slot_17" in the following data record). This is the maximum configuration.
- In this configuration, one AL module is connected to ET-Con2 ("slot_19"). However, a total of 16 AL electronic modules could be connected to ET-Con2 (as to ET-Con1).

The ET 200AL originally configured with STEP 7 is now to be reconfigured from the user program.

The new configuration has the following properties:

- ET-Con1 is inserted in "slot_1" (fixed setting).
- Module 2 is also operated in slot 2 in the modified configuration.
- Module 3 is not used.
- Module 4 is now inserted in slot 3.
- Module 5 is now inserted in slot 4.
- No other modules at ET-Con1 are used.

- ET-Con2 is inserted in "slot_18" (fixed setting)
- The module at ET-Con2 is used.

The components of control data record 196 (definition in section "Control data record 196" below):

- block_length: Note the length of the control data record here; in the example: 42 (bytes). The length of the control data block is calculated using the following formula: 2 x "number of modules" + 4.
- block_ID: Enter the figure 196 here. This number identifies the data record as the data record for configuration control.
- version: The ET 200AL uses version 2 of control data record 196.
- subversion: The ET 200AL uses subversion 1 of control data record 196.
- slot_1: The ET-Connection 1 submodule is always inserted in slot 1 of the ET 200AL.
- reserve_1: This byte is not used (value "0").
- slot_2: The configured module 2 is inserted in slot 2 (value "2").
- reserve_2: This byte is not used (value "0").
- slot_3: The configured module 3 is not present in the current configuration (value "0").
- reserve_3: This byte is not used (value "0").
- slot_4: The configured module 4 is inserted in slot 3 in the current configuration (value "3").
- reserve_4: This byte is not used (value "0").
- slot_5: The configured module 5 is inserted in slot 4 in the current configuration (value "4").
- reserve_5: This byte is not used (value "0").
- slot_6: The configured module 6 is not present in the current configuration (value "0").
- reserve_6: This byte is not used (value "0").
- slot_7: The configured module 7 is not present in the current configuration (value "0").
- reserve_7: This byte is not used (value "0").
- etc.
- slot_18: The ET-Connection 2 submodule is always inserted in slot 18 of the ET 200AL (value "18").
- reserve_18: This byte is not used (value "0").
- slot_19: The configured module 19 is inserted in slot 19 in the current configuration (value "19").
- reserve_19: This byte is not used. (value "0")

Control data record 196 for ET 200AL

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Element	Value	Description	
0	Block length in bytes	e.g. 14 for ET 200AL with 5 modules	The length of the data record is calculated using the formula: 4 + (number of modules x 2) bytes	Header
1	Block ID	196	ID for control data record 196	
2	Version	2	Version 2 of control data record 196	
3	Subversion	1	Subversion 1 of control data record 196	
4	Configured module 1 (ET-Connection 1)	1	ET-Connection 1 is always assigned to slot 1 (fixed). The value "1" must therefore always be entered in byte 4.	Assignment for configured module 1 (ET-Connection 1) to real slot 1
5	Reserve for configured module 1	0	Not used	
6	Configured module 2	Real slot of module 2 Possible values: 2 up to the number of modules (except 18) 0 (if the configured module 2 is not present)	The configured module 2 can be inserted in any slot from 2 to slot 34. Slot 18 is reserved for ET-Con 2. If the configured module is not used, this byte contains the value "0".	Assignment for the configured module 2 to a real slot
7	Reserve for configured module 2	0	Not used	
8	Configured module 3	Real slot of module 3 Possible values: 2 up to the number of modules (except 18) 0 (if the configured module 2 is not present)	The configured module 3 can be inserted in any slot from 2 to slot 34. Slot 18 is reserved for ET-Connection 2. If the configured module is not used, this byte contains the value "0".	Assignment for the configured module 3 to a real slot
9	Reserve for configured module 3	0	Not used	
:	:	:	:	:
39	Configured module 18 (ET-Connection 2)	18	ET-Connection 2 is always assigned to slot 18 if AT modules are connected at this submodule.	Assignment for configured module 18 (ET-Connection 2) to real slot 18
40	Reserve for configured module 18	0	Not used	
:	:	:	:	:

(Bytes 4 to 70, not byte 39)	Configured module x	Real slot of module x Possible values: 2 up to the number of modules (except 18) 0 (if there is no configured module x)	The configured module x can be inserted in any real slot from 2 to slot 34. Slot 18 is reserved for ET-Con 2 (bytes 39 and 40 in the control data record)	Assignment for configured module x to a real slot y
(Bytes 5 to 71, not byte 40)	Reserve for configured module x	0	Not used	

Rules

- The ET-Connection 1 and ET-Connection 2 submodules must be treated like real modules in configuration control. Restriction: ET-Connection 1 is always placed in slot 1 and ET-Connection 2 is always placed in slot 18 (fixed assignment).
- There are no reserve modules for the ET 200AL (unlike for the ET 200S or with BU cover modules for the ET 200SP). For this reason, bit 7 of "slot_x" must not be set (i.e. only the values 0 to 127 may be used).
- The value "0" of "slot_x" indicates that this module is not inserted in the current configuration.
- Gaps must not be left between the AL modules when configuring with STEP 7.
- If no modules are connected to ET-Con2 when STEP 7 is configured, ET-Con2 is not configured: This shortens data record 196.
- If fewer than 16 modules are connected to ET-Con1 during configuration with STEP 7 and there are also modules connected to ET-Con2, control data record 196 must contain all unassigned slots for ET-Con 1. They are assigned zero as the value for the real slot.

Writing a data record

Transfer the control data record to the ET 200AL module.

To do so, call the extended WRREC (Write data record) instruction, and transfer the control data record created.

If you do not transfer a control data record, the interface module uses the original configuration with STEP 7. Here, the following applies: Configured module x is inserted in real slot x.

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-195 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2 Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Feedback data record 197 for ET 200AL

The feedback data record 197 is used to read the actual configuration of a station (in this case of an ET 200AL).

This data record allows you to check the real configuration of the ET 200AL (actual configuration). The feedback data record for each configured module specifies whether or not it is actually present.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other possibilities (wrong module, empty slot, BU cover).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200AL with STEP 7.

There are two bytes in the data record for each module. The position of these two bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_1_ET_Con1" and "reserve_slot_1_ET-Con1" (bytes 4 and 5 in the data record) correspond to the module in slot 1 in the configuration,
- "status_slot_2" and "reserve_slot_2" (bytes 6 and 7) correspond to the module in slot 2 in the configuration
- "status_slot_3" and "reserve_slot_3" (bytes 8 and 9) correspond to the module in slot 3 in the configuration,
- etc.

Example

The following feedback data record 197 is returned by the ET 200AL that was reconfigured with control data record 196 in the example above (section "Creating control data record 196").

Record_197_ET_200AL

	Name	Data type	Default value
1	block_length	USInt	42
2	block_ID	USInt	197
3	version	USInt	2
4	subversion	USInt	1
5	status_slot_1_ET_Con1	USInt	1
6	reserve_1_ET_Con1	USInt	0
7	status_slot_2	USInt	1
8	reserve_2	USInt	0
9	status_slot_3	USInt	0
10	reserve_3	USInt	0
11	status_slot_4	USInt	1
12	reserve_4	USInt	0
13	status_slot_5	USInt	1
14	reserve_5	USInt	0
15	status_slot_6	USInt	0
16	reserve_6	USInt	0
17	status_slot_7	USInt	0
18	reserve_7	USInt	0
19	status_slot_8	USInt	0
20	reserve_8	USInt	0
21	status_slot_9	USInt	0
22	reserve_9	USInt	0
23	status_slot_10	USInt	0
24	reserve_10	USInt	0
25	status_slot_11	USInt	0
26	reserve_11	USInt	0
27	status_slot_12	USInt	0
28	reserve_12	USInt	0
29	status_slot_13	USInt	0
30	reserve_13	USInt	0
31	status_slot_14	USInt	0
32	reserve_14	USInt	0
33	status_slot_15	USInt	0
34	reserve_15	USInt	0
35	status_slot_16	USInt	0
36	reserve_16	USInt	0
37	status_slot_17	USInt	0
38	reserve_17	USInt	0
39	status_slot_18 ET_Con2	USInt	1
40	reserve_18_ET_Con2	USInt	0
41	status_slot_19	USInt	1
42	reserve_19	USInt	0

Modules 2, 4 and 5 are actually connected to ET-Con1.

None of the other modules that were connected to ET-Con1 in the configuration with STEP 7 are present in the current configuration (in line with the control data record 196 settings from the example above).

A module is really connected to ET-Con2 as in the original configuration with STEP 7.

Reading feedback data record 197

You can read the feedback data record 197 from the ET 200AL with the RDREC instruction. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Additional information and examples

Further information on ET 200AL is available here (http://support.automation.siemens.com/WW/view/en/89254863).

Specific examples of configuration control can be found here in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

You will find a library of the data records and other application examples here: Templates for the data records (http://support.automation.siemens.com/WW/view/en/29430270)

ET 200MP

ET 200MP distributed I/O system

Definition

The ET 200MP distributed I/O system is a scalable and flexible distributed I/O system for connection of process signals to a central controller via a field bus.

Application area

The ET 200MP is a multi-functional distributed I/O system for various fields of application. The scalable design allows you to configure the system exactly to the specific requirements on location.

The ET 200MP complies with IP 20 degree of protection and is intended for installation in a control cabinet.

Structure

The ET 200MP is installed on a mounting rail and comprises:

- An interface module that communicates with all IO controllers conforming to the PROFINET standard IEC 61158
- Up to 30 modules (power supply modules and I/O modules from the S7-1500 I/O range) can be inserted to the right of the interface module.
- If you insert a power supply module to the left of the interface module, this yields a possible maximum configuration of 32 modules in total.
- The number of insertable I/O modules is limited by their power requirements.

Slot rules

- Slot 0: Power supply module (optional)
- Slot 1: Interface module
- Slot 2 to 31: I/O modules or power supply modules

Interface module parameters

Supply voltage L+ connected

Parameter "Supply voltage L+ connected"

This parameter influences the diagnostics and the checking of the power budget.

- Diagnostics of the ET 200MP:
  If the actual configuration does not match the preset configuration with regard to the supply voltage of the interface module, the interface module generates a diagnostic alarm.
  Example: You have deactivated the "Supply voltage L+ connected" option, but you have connected the supply voltage in the actual configuration.
- Power budget check during configuration:
  The power budget changes in accordance with the parameter setting: Either the interface module feeds power into the backplane bus or it draws power from the backplane bus.

The default ("Supply voltage L+ connected" option is **activated**) means that the front of the interface module is supplied with 24 V DC and the power is stored in the backplane bus.

If the "Supply voltage L+ connected" option is **deactivated**, the interface module may not be supplied with 24 V DC on the front.

In this case, insert a power supply unit (PS) on the left next to the interface module that supplies the interface module and the modules to the right of the interface module.

Note

We recommend that you always supply the interface module on the front side with 24 V DC. If a system power supply unit (PS) is inserted and connected additionally **before** or on the left next to the interface module, both the power from the system power supply unit (PS) as well as the power from the integrated power supply of the interface module are then available to the configuration.

In this case, you do not have to change the default setting of the parameter.

Configuration control (handling options) with ET 200MP

Operating principle

Configuration control allows you to operate various real configurations (options) with a single configuration of the distributed I/O device ET 200MP.

Configuration control provides you with the option of configuring the ET 200MP distributed I/O device with its maximum configuration and still operating it with modules missing. If missing modules are retrofitted later, no new configuration is required and the hardware configuration does not have to be reloaded either.

Using control data record 196, which is transferred to the interface module in the user program, you define a current configuration. You transfer the control data record with the instruction WRREC.

Readback data record 197 is used to read the actual configuration of an ET 200MP.

Requirements

The CPU startup parameter "Compare preset to actual configuration" is set to Startup even if mismatch (default setting). This setting is also selected for the startup parameters of the individual modules of the ET 200MP.

Enabling configuration control

In the properties of the interface module under Module parameters > General > Configuration control, select "Enable reconfiguration of device via user program". This activates configuration control.

Control data record 196 for ET 200MP

The figure below shows the start of control data record 196 for the configuration control of an ET 200MP.

The data block is 36 bytes long (maximum configuration with 32 modules). The value "36" therefore appears in the "block_length" element of the data record.

If you configure an ET 200MP in STEP 7 with fewer modules, the data block will be shorter: If there are only five modules, for example, the data record is reduced to 9 bytes (4 bytes for the header plus one byte for each module).

There is one byte in the data record for each module. The position of this byte in the data record codes a module in the original configuration with STEP 7:

- "slot_0 power supply" (byte 4 in the data record below) corresponds to the power supply module in slot 0 in the configuration with STEP 7.
- "slot_2" (byte 5 in the data record) corresponds to the module in slot 2 in the configuration.
- "slot_3" (byte 6 in the data record) corresponds to the module in slot 3 in the configuration.
- "slot_4" (byte 7) corresponds to the module in slot 4 in the configuration.
- etc.

Note

Interface module in slot 1

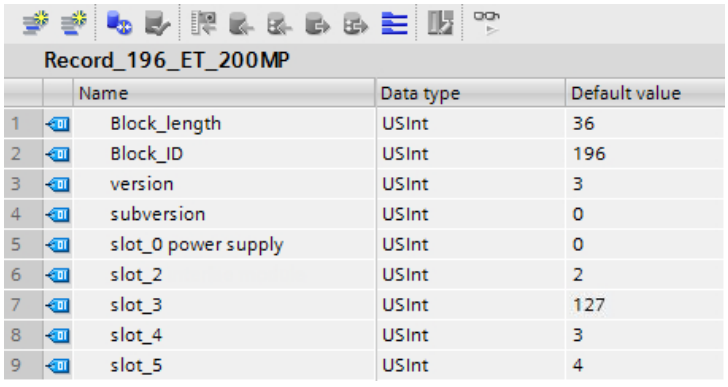
Configuration control is controlled by the interface module (slot 1/submodule 1). The interface module in slot 1 is therefore not an element of the configuration control and is not included in the data record.

Value in slot_x

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "2" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- The value "4" in slot_2 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration (slot_2 = 4).
- etc.

Example for data record 196



The following data record was created for a configuration that changes the original configuration with STEP 7.

The modified configuration has the following properties:

- The module inserted in slot 0 in the configuration (power supply module) is also inserted in slot 0 in the current configuration (specification).
- The module inserted in slot 2 in the configuration (module 2) is also inserted in slot 2 in the current configuration.
- The module inserted in slot 3 in the configuration (module 3) does not exist in the current configuration.
- The module inserted in slot 4 in the configuration (module 4) is inserted in slot 3 in the current configuration.

- The module inserted in slot 5 in the configuration (module 5) is inserted in slot 4 in the current configuration.
- etc.

The bytes "slot_6" to "slot_31" are not shown in the figure below.

Record_196_ET_200MP

	Name	Data type	Default value
1	Block_length	USInt	36
2	Block_ID	USInt	196
3	version	USInt	3
4	subversion	USInt	0
5	slot_0 power supply	USInt	0
6	slot_2	USInt	2
7	slot_3	USInt	127
8	slot_4	USInt	3
9	slot_5	USInt	4

Rules

- If a module dos not exist in the current configuration, this is indicated by the value 127: "slot_x" = 127.
- The power supply module is always in slot 0 ("slot_0 power supply" = 0).
- The interface module in slot 1 is not included in the control data record.

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Readback data record 197 for ET 200MP

Readback data record 197 is used to read the actual configuration of a station (in this case, of an ET 200MP).

This data record allows you to check the real configuration of the ET 200MP (actual configuration). The readback data record for each configured module specifies whether or not it is actually available.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot, reserve module).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200MP with STEP 7.

There is a byte in the data record for each module. The position of this bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_0 power supply" (byte 4 in the data record below) corresponds to the power supply module in slot 0 in the configuration with STEP 7.
- "status_slot_2" (byte 5) corresponds to the module in slot 2 in the configuration.
- "status_slot_3" (byte 6) corresponds to the module in slot 3 in the configuration,
- etc.

You can choose any name for the components (for example "status_slot_2").

Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is in the correct slot.
- The value "0" in status_slot_x codes all other possibilities (wrong module, module does not exist).

Example:

The figure below shows readback data record 197 for the configuration of an ET 200MP in which there is no module 3 (the module in slot 3 in the configuration).

All other modules are available and correctly plugged.

The bytes "status_slot_6" to "status_slot_31" are not shown in the figure below.

Record_197_ET_200MP

	Name	Data type	Default value
1	Block_length	USInt	36
2	Block_ID	USInt	197
3	version	USInt	3
4	subversion	USInt	0
5	status_slot_0 power supply	USInt	1
6	status_slot_2	USInt	1
7	status_slot_3	USInt	0
8	status_slot_4	USInt	1
9	status_slot_5	USInt	1

Reading readback data record 197

You can read readback data record 197 from the ET 200MP with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Additional information and examples

Further information on ET 200MP can be found in the manual for IM 155-5 PN (http://support.automation.siemens.com/WW/view/en/89261636).

Specific examples of configuration control can be found in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

You will find a library of the data records and other application examples here: Templates for the data records (http://support.automation.siemens.com/WW/view/en/29430270)

See also

Documentation on configuration control (http://support.automation.siemens.com/WW/view/en/67295970)

Input module parameters

Parameters of the analog input modules

Missing supply voltage L+

Enabling of the diagnostics for missing or insufficient supply voltage L+.

Wire break

Enabling of the diagnostics if the module has no current flow or the current is too weak for the measurement at the corresponding configured input or the applied voltage is too low.

Current limit for wire break diagnostics

Threshold at which a wire break is reported. The value can be set to 1.185 mA or 3.6 mA, depending on the sensor used.

Overflow

Enabling of the diagnostics if the measured value exceeds the overrange.

Underflow

Enabling of the diagnostics if the measured value undershoots the underrange.

Common mode error

Enable diagnostics if the valid common mode voltage is exceeded.

Reference channel error (only for AI 8xU/I/RTD/TC ST)

- Enable diagnostics on error at the temperature compensation channel, e.g. wire break.
- Dynamic reference temperature compensation type is configured and no reference temperature has been transferred to the module yet.

Temperature coefficient

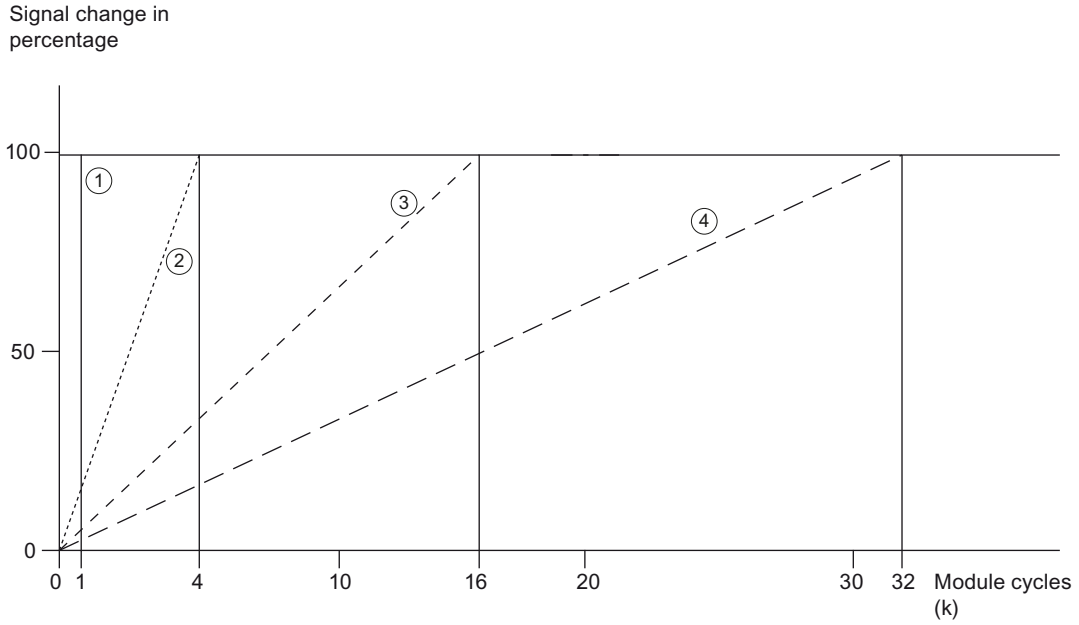
The temperature coefficient depends on the chemical composition of the material. In Europe, only one value is used per sensor type (default value).

The correction factor for the temperature coefficient (α value) specifies how much the resistance of a certain material changes when the temperature is raised by 1 °C.

The further values facilitate a sensor-specific setting of the temperature coefficient and enhance accuracy.

Interference frequency suppression

At analog input modules, this suppresses interference caused by the frequency of AC mains.



The frequency of the AC network may interfere with measured values, particularly for measurements within low voltage ranges and when thermocouples are being used. With this parameter, you define the mains frequency in your system.

Smoothing

The individual measured values are smoothed using filtering. Smoothing can be set in 4 stages for the analog input modules AI 8xU/I/RTD/TC ST and AI 8xU/I HS.

Smoothing time = number of module cycles (k) x cycle time of the module.

The figure below shows the number of module cycles after which the smoothed analog value is almost 100%, depending on the set smoothing. Is valid for each signal change at the analog input.

① None (k = 1)
② Weak (k = 4)
③ Medium (k = 16)
④ Strong (k = 32)

Reference junction (only for AI 8xU/I/RTD/TC ST)

The following settings can be configured for the reference junction parameter:

Table 10-196 Possible parameter assignments for the reference junction parameter

Setting	Description
Fixed reference temperature	The reference junction temperature is configured and stored in the module as a fixed value.
Dynamic reference temperature	The reference junction temperature is transferred in the user program from the CPU to the module by data records 192 to 199 using the WRREC (SFB 53) instruction.
Internal reference junction	The reference junction temperature is determined using an integrated sensor of the module.
Reference channel of the module	The reference junction temperature is determined using an external resistance thermometer (RTD) at the reference channel (COMP) of the module.

Note

Fixed reference temperature

During parameter assignment of a thermocouple Type B, only the setting "Fixed reference temperature" with a temperature of 0 °C is possible.

Enable hardware interrupt 1 or 2

Enable a hardware interrupt if high limit 1 or 2 is exceeded, or low limit 1 or 2 is violated.

Low limit 1 or 2

Specifies the low limit threshold that triggers hardware interrupt 1 or 2.

High limit 1 or 2

Specifies the high limit threshold that triggers hardware interrupt 1 or 2.

Temperature compensation for thermocouples

Introduction

You have several options of measuring the reference junction temperature in order to obtain an absolute temperature value as a function of the temperature difference between the reference junction and the measuring point.

You can use various compensation options depending on the required location of the reference junction.

Note

During parameter assignment of a thermocouple Type B, only the setting "Fixed reference temperature" with a temperature of 0 °C is possible.

Options of compensating for the reference junction temperature

Compensation options	Explanation	Application case
Internal reference junction	With this compensation, the reference junction temperature is determined using an integrated sensor of the module. **Procedure** Connect the thermocouple to the I/O module directly or with compensating lines.	• For the connection, you use compensating lines matching the thermocouple material. • If the reference junction temperature and the module temperature are identical in your system, you may also use lines made from a different material.
Reference channel of the module	The reference junction temperature is determined using an external resistance thermometer (RTD). **Procedure** Connect the thermocouple to the supply lines at the reference junction, either directly or with compensating lines. You connect the supply lines to the appropriate terminals of the module. Connect the resistance thermometer (RTD) to the reference channel of the module. The resistance thermometer (RTD) must be placed in the area of the reference junction.	• You want to measure the temperature directly at the reference junction. • The measured temperatures of all channels that you have configured for this compensation type is corrected automatically by the temperature value of the reference junction. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.
Dynamic reference temperature	The temperature of the reference junction is determined via a module. This temperature value is transferred to other modules via a data record in the user program. **Procedure** Connect the resistance thermometer (RTD) for the reference junction to any channel. The reference junction temperature is communicated from the CPU to the module by data records 192 to 199 using the WRREC instruction.	• You use multiple modules at the reference junction and can therefore compensate all channels using a common temperature value. • You require only one resistance thermometer (RTD) to acquire the temperature value. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.
Fixed reference temperature	The reference junction temperature is stored in the module as a fixed value. **Procedure** Connect the thermocouple to the supply lines at the reference junction, either directly or with compensating lines. You connect the supply lines to the appropriate terminals of the module. When configuring the module, specify a fixed temperature value for the reference junction (e.g. 20 °C).	• You keep the reference junction temperature constant and know the temperature value. • You can use inexpensive lines, e.g., copper lines, from the reference junction to the module.

Output module parameters

Parameters of the analog output modules

Missing supply voltage L+

Enabling of the diagnostics, with missing or too little supply voltage L+.

Short-circuit to ground

Enabling of the diagnostics if a short-circuit of the actuator supply to ground occurs.

Wire break

Enabling diagnostics if the line to the encoder is interrupted.

Overflow

Enabling of the diagnostics if the measured value exceeds the overflow range.

Underflow

Enabling of the diagnostics if the measured value falls below the underflow range.

Reaction to CPU STOP

Determines the reaction of the output to the CPU going into STOP state.

Substitute value

The substitute values are values that the outputs (the output) issue in the event of a CPU STOP.

Pulse-width modulation (PWM)

The channels of some modules support the pulse width modulation (PWM) function. You can use the pulse width modulation function to easily generate periodic pulses with a constant rated voltage and a variable pulse duration for the above-mentioned channels.

Configuration

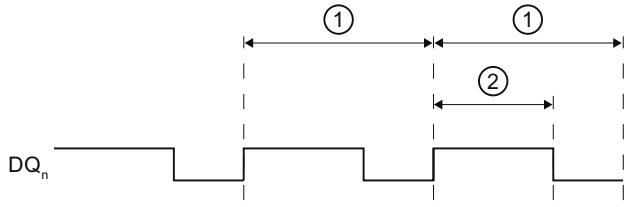
You configure the pulse width modulation with the following parameters:

- Enable PWM function on module
- Set PWM operating mode for the corresponding channel
- Set period

How it works

In the pulse width modulation mode, the correspondingly configured outputs provide a pulse width modulated output signal.

Pulse width modulation is characterized by its time period (frequency) and its duty factor. The duty factor describes the relation between pulse duration and time period.



The pulse duration is derived from the time period and the duty factor: Pulse duration = duty factor x time period.

Example for duty factor of 50% and time period of 10 ms:

Pulse duration 0.5 x 10 ms = 5 ms

You define the duty factor of the channels in the user program using the output value (0 ... 1000) in the process image output.

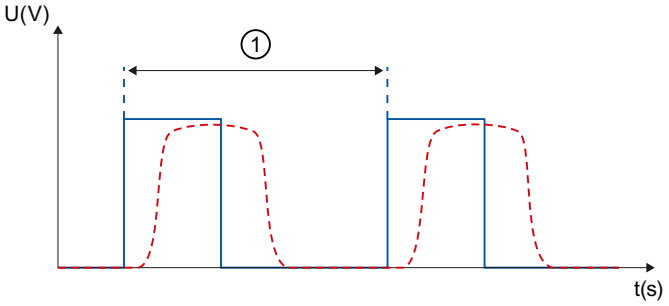
The output signal is a square wave signal (pulse sequence of on and off pulses).

① Time period T (2 to 100 ms); Frequency of the pulse width modulation: f = 1/T (10 to 500 Hz)

② Pulse duration (duty factor x time period)

Figure 10-52 How pulse width modulation works

Minimum pulse duration



The minimum pulse duration is 300 µs due to the hardware. The duty factor can be adjusted from 0.0 to 100.0%. The time period can be adjusted from 2 to 100 ms.

Example: If you configure a time period of 2 ms and set a duty factor of 0.1% for the output, this would result in a pulse duration of 200 µs. In fact, the output works with a minimum pulse duration of 300 µs.

Pulse waveform

The pulse duration of the actual signal profile is slightly longer than the specified, ideal pulse duration.

The figure below shows the reaction of the output to control by PWM. The blue line shows the specified, ideal signal profile (square wave signal), with which the output is controlled. The red dashed line show the actual signal profile on the output graph, caused by the externally connected load.

① Time period
② Pulse duration (duty factor x time period)

ET 200M

Configuring an ET 200M

Introduction

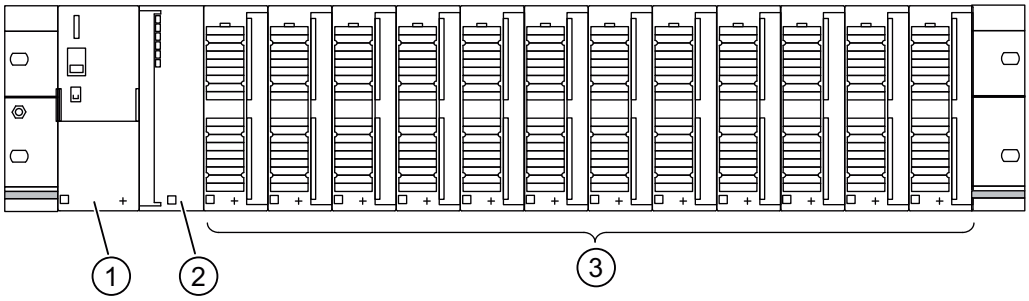
For the ET 200M series, you can find a wide range of modules in the hardware catalog under "Distributed I/O".

Configuration and parameter assignment

Information on configuration and parameter assignment can be found in the following sections.

ET 200M configuration

Definition



The distributed IO device, ET 200M, is a modular DP slave with an IP 20 degree of protection.

The ET 200M has the configuration technology of the S7-300 automation system and consists of an IM 153-x and I/O modules of the S7-300.

ET 200M supports communication with:

- all DP masters compliant with IEC 61784-1:2002 Ed1 CP 3/1
- all IO controllers compliant with IEC 61158

Configuration of the ET 200M (example)

① Power supply module PS 307
② Interface module IM 153-x
③ up to 12 I/O modules (SM / FM / CP)

Configuration of the 'Module replacement during operation' function

Introduction

The ET 200M supports the "Replace modules during operation" function and the associated pull/plug interrupt.

The "Replace modules during operation" function makes it possible for you to pull modules from or plug modules into the ET 200M rack during operation.

Requirement

You have configured an interface module that supports replacing modules during operation. (as of IM 153-1, article no. 153-1AA02-0XB0).

In addition, the configured CPU must also support the function, e.g. for PROFIBUS an S7-400 with DP interface.

You must use the active backplane bus (bus rail with slots) for the hardware configuration. The conventional profile rail with bus connectors between the modules does not support this function.

Configuring

If the configuration requirements have been met, the "Replace modules during operation" parameter is available for selection in the inspector window's "Module parameters" area. Below this parameter, a table for the configured modules is displayed, which shows the required active bus modules for the hardware configuration.

For a PROFIBUS configuration, the "Startup if preset configuration does not match actual configuration" option is displayed. This option is automatically enabled if "Replace modules during operation" is enabled.

Signal modules for process automation

Fundamentals

Introduction

Signal modules for the process automation are S7-300 models, such as SM 321; DI 16xNAMUR or SM 322; DO 16x24VDC/0.5A.

They are being operated in a DP slave (IM 153-2).

Unlike standard modules, they offer the following additional technical functions, such as pulse extension and chatter monitoring.

See also

Changeover contact (Page 2004)

Technological parameters (Page 2005)

Changeover contact

"Changeover contact" sensor type

If the digital inputs of a channel group are configured as "changeover contacts", the module runs diagnostics for the changeover contact sensor type for this channel group.

Changeover contact

A changeover contact is an auxiliary switch with only one moving switch element with one close setting each for closed and open switching device.

Remember the following rule:

- Always connect a normally open contact to the "even" channel
- Always connect a normally closed contact to the "odd" channel.

The tolerated switchover time between the two channels is fixed at 300 ms.

If the result of the check is negative, then

- the module identifies the value status of the normally open channel as "invalid"
- the module generates a diagnostic entry for the normally open channel
- triggers a diagnostic interrupt (if diagnostic interrupts have been enabled)

The digital input signal and the value status are updated only for the normally open channel. For the normally closed channel, the digital input signal is set permanently to "zero" and the value status to "invalid" since this channel is used only to check the sensor.

Diagnostics depends on the "Selection" parameter (of the sensor). You should also note the special features of diagnostics with the changeover contact sensor type in the "Signal Modules for Process Automation" manual.

Documentation on modules for process automation (http://support.automation.siemens.com/WW/view/de/7215812/0/en)

Technological parameters

Pulse extension and flutter monitoring

Pulse extension is a function for changing a digital input signal. A pulse at a digital input is extended to at least the length set in the parameters. If the input pulse is already longer than the specified length, it is not changed.

If you want the pulse to be extended, click in the box to select the time. If you do not want the pulses to be extended, select the "---" entry.

Flutter monitoring is a process control function for digital input signals. It detects and reports signal changes that are unexpected in process control, for example when an input signal fluctuates too often between "0" and "1".

Flutter monitoring is possible only when group diagnostics has also been enabled for this input.

Monitoring window and number of signal changes

Flutter monitoring works with aid of the two parameters Monitoring window and Number of signal changes.

The first time the signal changes, the time set as the monitoring window is started. If the signal changes more often during this time than allowed by the number of signal changes parameter, this is signaled as a flutter error. If no flutter error is detected during the monitoring window time, the monitoring window can be restarted at the next signal change.

Note

If you set pulse extension for an input channel, this also affects the flutter monitoring enabled for this channel. The "extended pulse" signal is the input signal for the flutter monitoring. You should therefore make sure that the values set for pulse extension and flutter monitoring are compatible with each other.

IQ Sense module

Properties of 8 IQ-SENSE

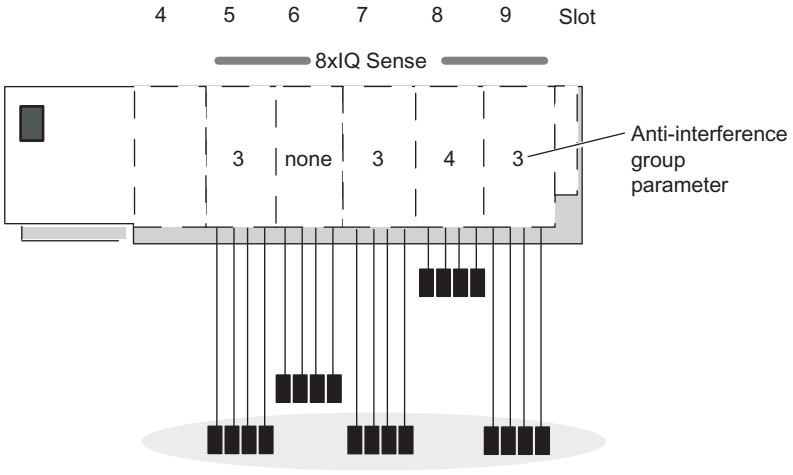
Properties

The 8 IQ-SENSE module has the following properties:

- Connection of sensors with IQ-SENSE®, photoelectric proximity switches: for example, reflex sensors, diffuse sensors, and laser sensors.
- It can be used centrally in an S7-300 or distributed in an ET 200M.
- You can connect up to 8 sensors to every module. Each sensor requires a two-wire cable.
- Function reserve that can be assigned parameters.
- Time functions, switching hysteresis, synchronous mode that can be assigned parameters
- Sensitivity and distance values can be specified (*IntelliTeach* using the "IQ-SENSE Opto" FB)
- Teach-in
- Sensors can be removed and inserted during operation (automatic reassignment of parameters)

Anti-interference group

Only for optical IQ Sense devices (IQ profile ID 1).



For IQ Sense devices with IQ profile ID 128 (ultrasound), see "Multiplex/synchronous mode" under the channel-specific parameters.

Prevention of interference (e.g., scattered light) by assigning an anti-interference group. This means:

- Anti-interference group: None (= default)
  Optical sensors on one or more modules can mutually influence each other when unfavorably arranged.
- Anti-interference group: 3 or 4
  Optical sensors on the same module with anti-interference group 3 or 4 cannot mutually influence each other. Similarly, optical sensors on different modules with anti-interference group 3 or 4 cannot mutually influence each other. You need not maintain minimum clearance between the IQ Sense devices and can, for example, align two retroreflective sensors on a single reflector.

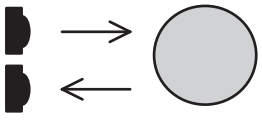
Operating principle

The diagram below explains the functioning of the anti-interference group parameter:

Mutual interference is only possible between the optical sensors of the modules in slot 5, 6, 7 and 9 because they are in the same anti-interference group 3 or "None" is set.

Note

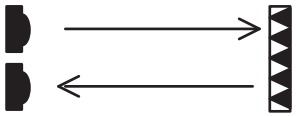
Sensors in the same anti-interference group must be installed to maintain the minimum clearance (see sensor package insert) and to prevent mutual interference.

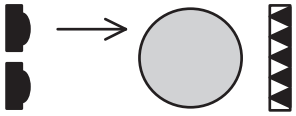


Encoder type

This parameter is used to set the sensor type per channel:

- Reflex sensor or
- Diffuse sensor or
- Disabled





Diffuse sensor

Table 10-197 Diffuse sensor

Diffuse sensor	Object	
Transmitter Receiver		Circuit state 0: No object detected, which means the object is not in the beam. The receiver does not see any light.
Transmitter Receiver		Circuit state 1: Object detected, which means the object is in the beam. The receiver does not see any light.

Reflex sensor

Table 10-198 Reflex sensor

Reflex sensor	Object	
Transmitter Receiver		Circuit state 0: No object detected, which means the object is not in the beam. The receiver sees light.
Transmitter Receiver		Circuit state 1: Object detected, which means the object is in the beam. The receiver does not see any light.

Switching hysteresis

Faults with the diffuse sensor or in the production process can result in signal wobbles. The measured value then changes the switching threshold by 100 % (object detected - object not detected). You can prevent this switching threshold wobble using the switching hysteresis parameter. This will ensure a stable output signal on the sensor.

You can assigned parameters to 5 %/10 %/20 %/50 % for switching hysteresis.

Requirements

You can only set the switching hysteresis parameter for diffuse sensors with background fadeout.

Operating principle

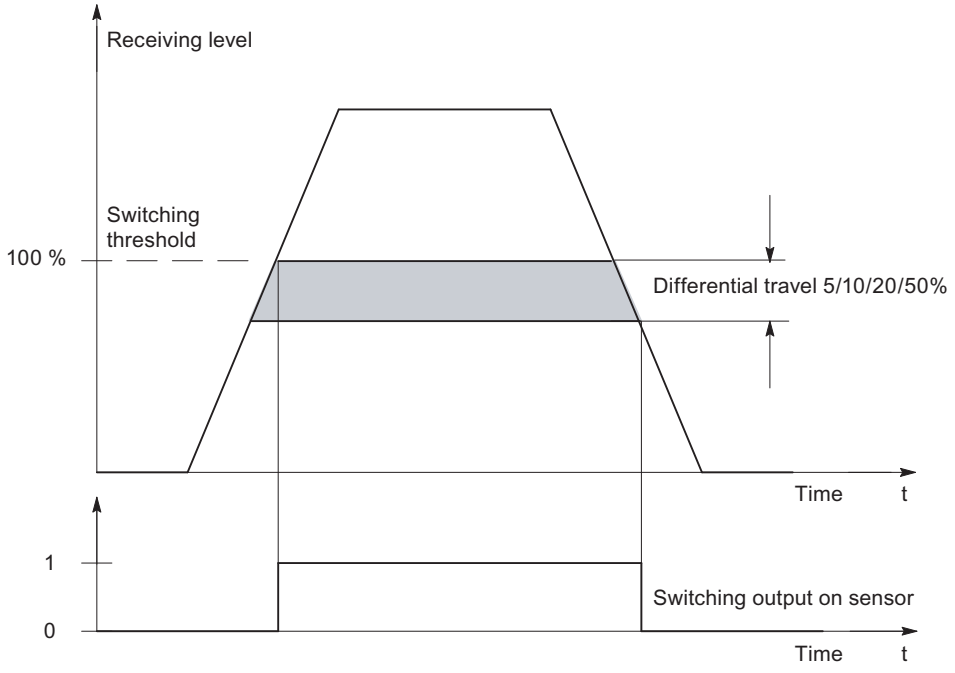


Figure 10-54 Switching hysteresis parameter

Time function,time value

These parameters can be used to set the electronic module for its specific application.

Operating principle

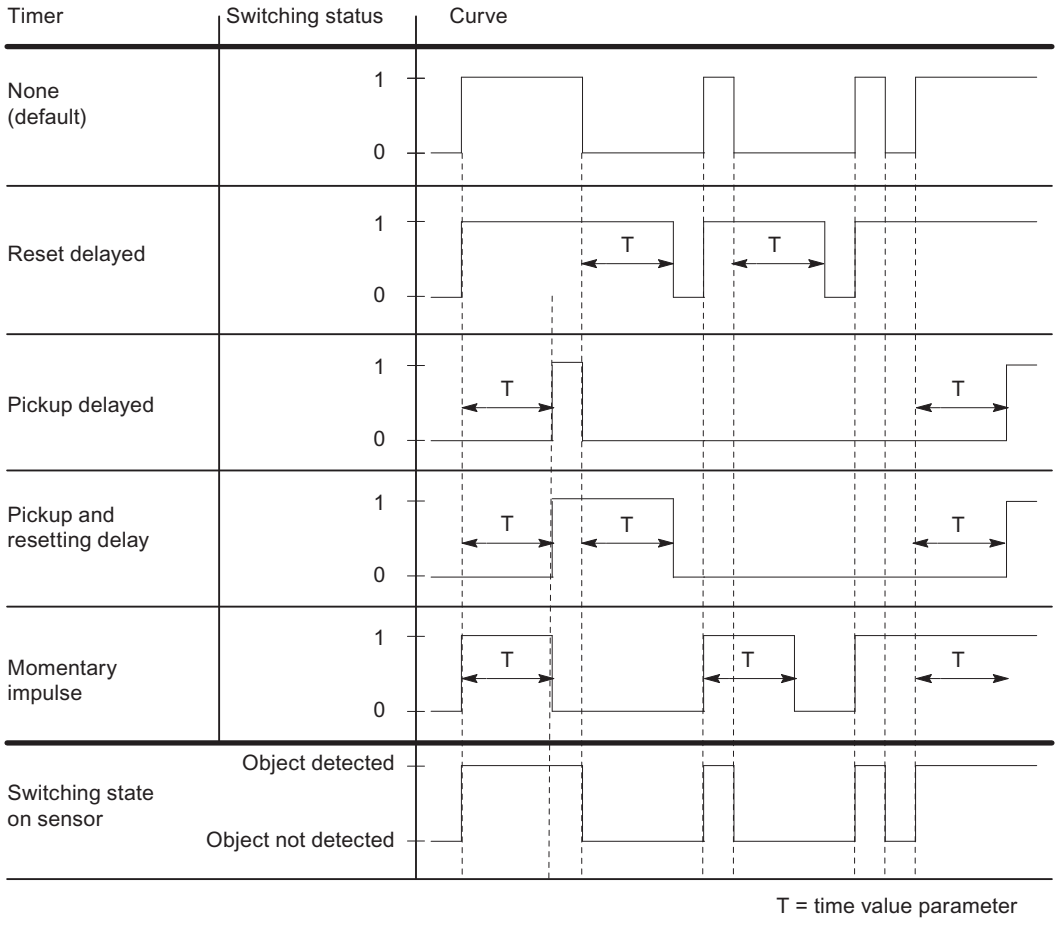

Figure 10-55 Time functions, time values parameters

Multiplex/synchronous mode

For the prevention of mutual influence between IQ Sense ultrasound devices in spatial proximity (devices with IQ profile ID 128), use the "Multiplex/synchronous operation" parameter.

Settings for the multiplex/synchronous mode parameter

Disabled: Mutual influence between IQ Sense ultrasound sensors in spatial proximity is possible (default). The cycle time is determined by the IQ Sense ultrasound sensor.

Multiplex: The IQ Sense ultrasound sensors determine the process value (distance) one after another, preventing them from affecting one another. The cycle time here is the sum of the configured synchronous cycle times of the IQ Sense ultrasound sensors that are to be multiplexed.

Synchronization: The IQ Sense ultrasound sensors determine the process value (distance) at exactly the same time, preventing them from affecting one another. The cycle time here corresponds to the greatest configured synchronous cycle time from among the IQ Sense ultrasound sensors that are to be synchronized.

You can, for example, use synchronous operation for a curtain function in which several IQ Sense ultrasound sensors aligned in parallel share a single extended detection area. The sensors simultaneously emit an ultrasound impulse. When an object enters the detection area, the sensor nearest to the object receives the echo most quickly. The object can therefore not only be detected, it can be located as well.

AFI value

Using the AFI value (application series identifier, as defined in the ISO 15693-3 international standard), transponders can be selected for different applications. Only transponders whose AFI value coincides with the value set on the sensor are processed. If a transponder has the AFI value "0", it can be identified and processed regardless of the AFI value of the sensor.

This parameter is only important if it is supported by the ident system, otherwise any value (normally "0") may be assigned.

Transponder type

Depending on the type of the transponder, you must configure whether it is an ISO transponder or a vendor-specific type.

For transponders in accordance with international standard ISO 15693, the value "1" should be selected; for all other types "0" is set. Based on this setting, one of the two possible air interface drivers is selected in the sensor.

This parameter is only important if it is supported by the ID system, otherwise any value (normally "0") may be assigned.

ET 200S

Configuring an ET 200S

Introduction

For the ET 200S series, you can find a wide range of modules in the hardware catalog under "Distributed I/O".

Assigning parameters

For information on configuration and parameter assignment, refer to "See also".

Frequency converters

Use of the frequency converter

Frequency converters

The frequency converter ICU24 and ICU24F (as fail-safe version) are modular design frequency converters that are completely embedded in the distributed I/O system ET 200S. For parameterization of both modules, please see the following.

Message frame

The message frame number and the operating mode of the module are only displayed and cannot be modified.

Application ID

You indicate the saved parameters in the frequency converter as a whole with the application ID. Enter an application ID from the value range 0 to 65535. During startup (or pull/plug), this ID is compared with the application ID stored on the converter.

Converters that work with identical applications are usually also identically parameterized and should be identified with the same application ID. Converters with the same application ID may be exchanged between each other. Copying of the complete parameterization of a converter to another converter, for example, via an MMC, is only accepted, if both have the same application ID.

Converters that work with different applications and are parameterized differently must be identified by different application IDs. This prevents a converter with unsuitable parameterization from starting on an incorrect slot, i.e. on the wrong application. This also prevents the parameterization that is saved in the converter from being accidently overwritten with any parameteriation that is stored on an MMC.

Enable diagnostic interrupt

You can enable the diagnostic interrupt for the frequency converter. If diagnostic interrupt is enabled, an OB 82 must be available in a CPU to process the diagnostic events.

Documentation for the frequency converter (http://support.automation.siemens.com/WW/view/en/26291825/0/en)

ET 200pro

ET 200pro with own CPU module

ET 200pro with own CPU

The ET 200pro can be equipped with its own CPU, for example with the CPU 1516pro.

In this regard, note the following rules.

Expansion rules with the CPU 1516pro:

- You can expand the CPU 1516pro with up to 16 modules.
- The total width can be a maximum of one meter.

Expansion with wide modules

If the maximum width of one meter is exceeded in a configuration with large modules (for example frequency converters or motor starters), the configuration cannot be compiled. In this case, reduce the configuration.

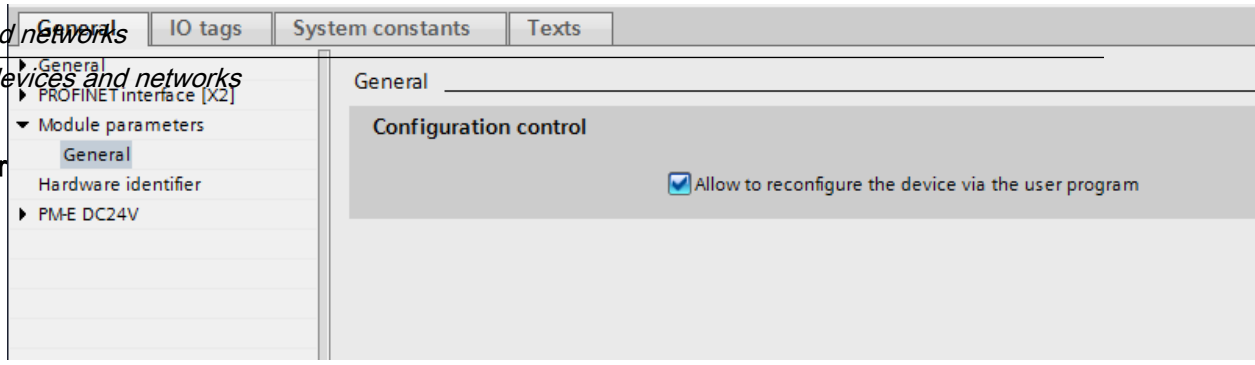
Configuration control with ET 200pro

Operating principle

Through the configuration control, it is possible to change the original configuration of an ET 200pro (created by configuring with STEP 7) and to operate the ET 200pro in this modified configuration. STEP 7 is no longer required for this configuration: You communicate to the ET 200pro the slot in which a configured module is actually inserted by means of your user program.

In this case, use control data record 196. In this data record, you code which modules are missing or located in different slots in the real configuration compared to the configuration. The configuration control has no effect on the parameter assignment of the modules (for example, the enabling of diagnostic alarms).

You then call the "WRREC" instruction and use it to write the data record to the interface module of the ET 200pro.



Configuration control gives you the flexibility to vary the configuration of an ET 200pro as long as the real configuration can be derived from a preset maximum configuration (originally created with STEP 7).

The following sections describe how to enable configuration control. They also outline how control data record 196 and readback data record 197 are structured.

Requirements

The CPU startup parameter "Compare preset to actual configuration" is set to Startup even if mismatch (default setting). This setting is also selected for the startup parameters of the individual modules of the ET 200pro.

Enabling configur

Configuration of control data record 196 for the ET 200pro

There is a byte in control data record 196 for each module.

The position of this byte in the data record codes one module in the original configuration with STEP 7:

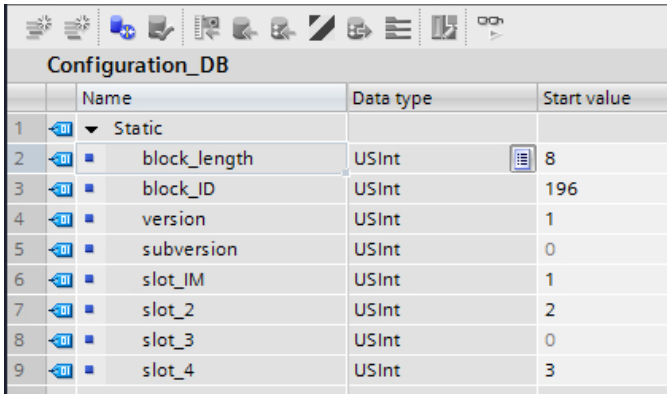
- "slot_IM" (byte 4 in the data record, figure below) corresponds to the module in slot 1 in the configuration
- "slot_2" (byte 5) corresponds to the module in slot 2 in the configuration.
- "slot_3" (byte 6) corresponds to the module in slot 3 in the configuration.
- etc.

"slot_x" byte

The current slot is coded by the figure that is assigned to "slot_x" (by its value). Examples:

- The value "2" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 2 in the current configuration (slot_2 = 2).
- The value "3" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 3 in the current configuration (slot_2 = 3).
- The value "4" in byte 5 means you are assigning the module originally inserted in slot 2 to slot 4 in the current configuration (slot_2 = 4).
- etc.

There are no reserve modules for the ET 200pro (unlike for the ET 200S or with BU cover modules for the ET 200SP). For this reason, bit 7 of "slot_x" must not be set.



The value "0" in "slot_x" indicates that this module is not inserted in the current configuration.

Example of control data record 196

The figure below shows control data record 196 for a configuration of an ET 200pro with four modules.

This configuration is given as an example:

- The module originally configured with STEP 7 in slot 1 is also inserted in slot 1 in the current configuration.
- The module in slot 2 is in slot 2 in the current configuration.
- The module in slot 3 does not exist in the current configuration.
- The module in slot 4 is actually inserted in slot 3 in the current configuration.

Configuration_DB

	Name	Data type	Start value
1	Static		
2	block_length	USInt	8
3	block_ID	USInt	196
4	version	USInt	1
5	subversion	USInt	0
6	slot_IM	USInt	1
7	slot_2	USInt	2
8	slot_3	USInt	0
9	slot_4	USInt	3

The components of control data record 196 (figure above):

- block_length: Note here the length of the control data record; in the example: 8 (bytes). The length is calculated using the following formula: "Number of assigned slots" + 4.
- block_ID: Enter the figure 196 here.
- version: The ET 200pro uses Version 1 of control data record 196.
- subversion: The ET 200pro uses Subversion 0 of control data record 196.
- slot_IM: The IM module is always inserted in slot 0 of the ET 200pro. Slot 1 always contains the virtual power module that is integrated as a fixed module in the IM module. The "slot_IM" (name can be changed) can contain any values. This byte is not interpreted in the configuration control of the ET 200pro.
- slot_2: The configured module 2 is inserted in slot 2 (value "2").
- slot_3: The configured module 3 is not present in the current configuration (value "0").
- slot_4: The configured module 4 is inserted in slot 3 in the current configuration (value "3").

Definition of control data record 196

A control data record 196 containing a slot assignment is defined for configuration control.

Byte	Element	Value	Description
0	Block length	e.g., 8 for ET 200pro with four modules	The length of the data record is calculated using the formula: 4 + Number of modules in bytes
1	Block ID	196	ID for control data record 196
2	Version	1	Version 1 of control data record 196
3	Subversion	0	Subversion 0 of control data record 196
4	Slot_1	Any values are possible: For example "1"	This byte is not interpreted for the ET 200pro because the power module that is integrated as a fixed module in the IM module of the ET 200pro is always inserted in slot 1.

5	Slot_2	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 5 indicates where the module originally configured with STEP 7 in slot 2 is actually inserted in the current configuration. Example: 2 The module originally configured with STEP 7 in slot 2 is also actually located in slot 2 in the current configuration (value "2").
6	Slot_3	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 6 indicates where the module originally configured with STEP 7 in slot 3 is actually inserted in the current configuration. Example: 0 The module originally configured with STEP 7 in slot 3 is not present in the current configuration (value "0").
7	Slot_4	Coding of the actual slot: 2 = Slot 2 3 = Slot 3 4 = Slot 4 etc. Coding for missing module: 0 = No slot, module not present	Byte 7 indicates where the module originally configured with STEP 7 in slot 4 is actually inserted in the current configuration. Example: 3 The module originally configured with STEP 7 in slot 4 is actually located in slot 3 in the current configuration (value "3").
:	:	:	:

Writing a data record

Transfer the control data record to the ET 200pro module.

To do so, call the extended WRREC (Write data record) instruction, and transfer the control data record created.

If you do not transfer a control data record, the interface module uses the original configuration with STEP 7. Here, the following applies: Configured module x is inserted in real slot x.

Addressing the interface module using the HW identifier

To transfer data record 196 with the instruction WRREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Error messages

The following error messages are returned if an error occurs when writing control data record 196:

Table 10-199 Error messages

Error code	Meaning
16#80A2	DP protocol error on layer 2 Indicates that a data record has not been acknowledged due to the system.
16#80B1	Invalid length; the length information in data record 196 is not correct.
16#80B5	Configuration control parameters not assigned.
16#80B2	Invalid slot: The configured slot is not assigned.
16#80B8	Parameter error; module signals invalid parameters.
16#80C5	DP slave or module not available. Indicates that a data record has not been acknowledged due to the system.

Readback data record 197 for ET 200pro

Readback data record 197 is used to read the actual configuration of a station (in this case of an ET 200pro).

This data record allows you to check the real configuration of the ET 200pro (actual configuration). The feedback data record for each configured module specifies whether or not it is actually present.

- The value "1" means that the correct module is inserted in the correct slot.
- The value "0" codes all other options (wrong module, empty slot).

Example:

A module has been configured with STEP 7 for slot 4.

This module has then been moved to slot 3 in the current configuration using data record 196.

If this module is also really in slot 3, this is coded by the value "1" (status_slot_4 = 1).

Configuration details:

The configuration of the data block corresponds to the original configuration of the ET 200pro with STEP 7.

There is a byte in the data record for each module. The position of this bytes in the data record corresponds to the position of a module in the original configuration with STEP 7.

Sequence of bytes:

- "status_slot_IM" (byte 4 in the data record) corresponds to the module in slot 1 in the configuration,
- "status_slot_2" (byte 5) corresponds to the module in slot 2 in the configuration
- "status_slot_3" (byte 6) corresponds to the module in slot 3 in the configuration,
- etc.

The following example is for a configuration with 4 modules. The value "8" therefore appears in the "block_length" element of the data record.

If you configure an ET 200pro in STEP 7 with fewer modules, the data block will be shorter.

You can choose any name for the components of the control data record (for example "status_slot_2").

Meaning of "status_slot_x":

- The value "1" in status_slot_x means that module x is inserted in the correct slot
- The value "0" in status_slot_x codes all other options (wrong module, module does not exist).

Example:

The figure below shows readback data record 197 for an ET 200pro with four modules.

- There is no module 3 (this was assigned in control data record 196, see section "Example of control data record 196" above)
- The three other modules are actually inserted in the ET 200pro.

Record_197_ET_200pro

	Name	Datentyp	Defaultwert
1	block_length	USInt	8
2	block_ID	USInt	197
3	version	USInt	1
4	subversion	USInt	0
5	status_slot_IM	USInt	1
6	status_slot_2	USInt	1
7	status_slot_3	USInt	0
8	status_slot_4	USInt	1

Reading readback data record 197

You can read readback data record 197 from the ET 200pro with the instruction RDREC. RDREC operates asynchronously. If you call RDREC in the startup OB, you must call the instruction multiple times using a loop until the "BUSY" or "DONE" output parameter indicates that the data record has been read.

To read data record 197 with the instruction RDREC, you must enter the HW identifier of the IM submodule with the extension "~Head" as the input parameter for the instruction. The system constant of this HW identifier is, for example, "IO-Device_2~Head". The system constants of a selected device are, for example, displayed in the network view in the "System constants" tab. Use the corresponding value for addressing.

Additional information and examples

Further information on the PN interface module of the ET 200pro is available here (http://support.automation.siemens.com/WW/view/en/98099372).

Specific examples of configuration control can be found here in this application description (http://support.automation.siemens.com/WW/view/en/29430270).

You will find a library of the data records and other application examples here:

Templates for the data records (http://support.automation.siemens.com/WW/view/en/29430270)

See also

Configuration control with ET 200SP (Page 1934)

Use of the frequency converter

Frequency converters

The frequency converters ET 200pro FC and ET 200pro F-FC (as fail-safe version) are modularly design frequency converters that are completely embedded in the distributed I/O system ET 200pro. The following section describes how to configure the two modules.

Message frame

The message frame number and the operating mode of the module are only displayed and cannot be modified.

Application ID

You indicate the saved parameters in the frequency converter as a whole with the application ID. Enter an application ID from the value range 0 to 65535. During startup (or pull/plug), this ID is compared with the application ID stored on the converter.

Converters that work with identical applications are usually also identically configured and should be identified with the same application ID. Converters with the same application ID may be exchanged between each other. Copying of the complete configuration of a converter to another converter, for example, via an MMC, is only applied, if both have the same application ID.

Converters that work with different applications and are configured differently must be identified by different application IDs. This prevents a converter with unsuitable configuration from starting on an incorrect slot, in other words on the wrong application. This also prevents the configuration that is saved in the converter from being accidently overwritten with any configuration that is stored on an MMC.

Enable diagnostic interrupt

You can enable the diagnostic interrupt for the frequency converter. If diagnostic interrupt is enabled, an OB 82 must be available in a CPU to process the diagnostic events.

10.1.5.3 IPv4 routing with CP 1543-1 / CM 1542-1

IPv4 routing with CP 1543-1 / CM 1542-1

The following restrictions apply to the "IPv4 routing over the backplane bus" function of the CM/CP.

- IPv4 routing over the CM / CP to the CPU of the station is not possible.
- IP configuration with CM 1542-1 as PROFINET IO controller
  If the CM with enabled IPv4 routing over the backplane bus is used as PROFINET IO controller, please note the following points for IP configuration of the subordinate IO devices:
  If IP address configuration for the subordinate IO devices is fixed ("Set IP address in the project" option), IPv4 routing over the CM to the IO devices is not possible.
  The following settings are required in the IP configuration of the subordinate IO devices to allow IPv4 routing over the CM to those IO devices:
  - First select the "Use router" option for the IO device.
    Copy the IP address of the IO controller (CM) to the router address field.
  - Activate the "IP address is set directly at the device" option for the IO device.

10.1.5.4 IPv6 configuration

IPv6 protocol

The Internet Protocol version 6 - called IPv6 below - extends the Internet Protocol version 4 (IPv4) that is used predominantly at the current time.

Address format IPv6: Notation

IPv6 addresses consist of 8 fields each with four-character hexadecimal numbers (128 bits in total). The fields are separated by a colon.

Example: fd00:0000:0000:0000:0db8:002f:0000:0000

Rules / simplifications:

- Leading zeros within a field can be omitted.
  Example: fd00:0000:0000:0000:0db8:002f:0000:0000, abbreviated fd00:0:0:0:db8:2f:0:0
- If one or more blocks have the value 0, a shortened notation is possible with two successive colons. To ensure uniqueness, this shortened form can only be used once within the entire address. With two or more such abbreviations, it may not be possible to determine how many blocks were shortened.
  Valid example: fd00::db8:2f:0:0 or fd00:0:0:0:db8:2f:: (both clearly recognizable as fd00:0:0:0:db8:2f:0:0)
  Invalid example: fd00::db8:2f:: (not clear, can be interpreted as fd00:0:0:0:db8:2f:0:0 or fd00:0:0:db8:2f:0:0:0 etc.)
- The last 2 fields or 4 bytes can be written in the normal decimal notation with periods.
  Example: The IPv6 address fd00::db8:fd01:2f is equivalent to fd00::db8.253.1.0.47

Entry and appearance

The entry of IPv6 addresses is possible in the notations described above. IPv6 addresses are always shown in the same notation in which they were entered.

IPv6 with the CP 1543-1 (Page 2021)

IPv6 with the CP 1543-1

Use of IPv6 with the CP 1543-1

For all IP services, the CP supports the Internet protocol version 4 (IPv4)

The additional specification of addresses in IPv6 format can be used with the CP for the following services and applications:

- FETCH/WRITE: Direct write/read access by PC stations, SIMATIC S5 or third-party devices
- FTP client: FTP access from the S7-1500 CPU to an FTP server with program block FTP_CMD
- FTP server: FTP access from an FTP client to data areas of the S7-1500 CPU
- SNMP: Data query using MIB objects according to SNMP
- E-mail: Data transfer from the S7-1500 CPU using the program block T_Mail

10.2 Device and network diagnostics

10.2.1 Hardware diagnostics

10.2.1.1 Overview of hardware diagnostics

Principal methods of hardware diagnostics

Principal methods of hardware diagnostics

Hardware diagnostics can be performed as follows:

- Using the Online and Diagnostics view
- Using the "Online Tools" task card
- Using the "Diagnostics > Device Info" area of the Inspector window
- Using diagnostics icons, for example, in the device view and the project tree

Structure of the Online and Diagnostics view

The Online and Diagnostics view consists of two windows alongside each other:

- The left window shows a tree structure with folders and - when you open the folder - groups.
- The right window contains detailed information on the selected folder or selected group.

The "Online access" group and the "Diagnostics" and "Functions" folders are located here:

- "Online access" group: Displays whether or not there is currently an online connection with the associated target. In addition, you can establish or disconnect the online connection.
- "Diagnostics": Contains several diagnostics groups for the selected module.
- "Functions": Contains several groups, in which you can make settings for the selected module or issue commands to the module.

Function and structure of the "Online Tools" task card

For modules with their own operating mode (such as CPUs), the "Online tools" task card allows you to read current diagnostics information and commands to the module.

If you selected a module without its own operating mode or if you selected several modules before activation of the "Online Tools" task card, the task card relates to the relevant CPU.

The "Online Tools" task card consists of the following panes:

- CPU control panel
- Cycle time
- Memory

Note

A pane is filled with content only if the module controls the associated functions and an online connection exists.

If there is no online connection to the respective module, the display "No online connection" appears in blue in each pane. If an existing online connection was disconnected, then "This target is not available" will be displayed.

Structure or the "Diagnostics" tab of the Inspector window

The "Diagnostics" tab of the Inspector window itself consists of several tabs. Of these tabs, the following is relevant for the hardware diagnostics.

- Device information
  This tab relates to all online devices (e.g. CPUs) to which an online connection has been established and to the devices that are assigned to these online devices (such as PROFINET devices and PROFIBUS slaves). Alarms related to the faulty online devices and the faulty devices are output here.

Note

What is displayed when a module is faulty?

If a module within a device is faulty, only the associated device or its proxy (e.g. head module) are shown, but not the module itself.

The faulty devices are displayed "at the top level" and not in a hierarchical view below their online device (as is the case in the project tree).

Basics on task cards (Page 257)

Inspector window (Page 255)

Determination of which of the devices that are connected online are defective

Overview of the defective devices

In the "Diagnostics > Device Info" area of the Inspector window you will obtain an overview of the defective devices that are or were connected online.

The "Diagnostics> Device Info" area of the Inspector window consists of the following elements:

- Header line with the number of defective devices
- Table with detailed information on each defective device

If you originate the establishment of an online connection to a device which is not reachable or reports one or more faults or is not in RUN mode, it will rank as defective.

Structure of the table with detailed information on the defective devices

The table consists of the following columns:

- Online status: Contains the online status as a diagnostic symbol and in words
- Operating mode: Contains the operating mode as a symbol and in words
- Device / module: Name of the affected device or the affected module
- Message: explains the entry of the previous column
- Details: The link opens the online and diagnostics view for the device, and places it in the foreground. If an online connection does not exist any longer, the link will open the connection establishment dialog.
- Help: The link supplies further information on the defect that has occurred.

Displaying diagnostics status and comparison status using icons (Page 2024)

Displaying diagnostics status and comparison status using icons

Determining diagnostics status online and displaying using icons

When the online connection to a device is established, the diagnostics status of the device and, if applicable, its lower-level components is determined. The operating state of the device is also determined, where applicable.

The following is a description of which icons are displayed in specific views.

- Device view
  - The associated diagnostic icon is displayed for every hardware component (except the signal board on the CPU).
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - For hardware components with their own operating state, the operating state icon is also displayed to the left of or above the diagnostic icon.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: No diagnostic icons are displayed (due to the configuration as GSDML device).

  Note

  Diagnostics status of SCALANCE-XM-400 and SCALANCE-XR-500-managed modules

  Incorrect or no diagnostic icons are displayed in case of an existing online connection to the SCALANCE-XM-400 and SCALANCE-XR-500-managed modules.

  The correct diagnostic icons will be displayed when you establish the online connection to an associated CPU.

- Device overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: For modules assigned to the CPU, the associated diagnostic icon is displayed (modules that are not assigned do not receive a diagnostic icon). The associated diagnostic icon is displayed for plug-in submodules of an assigned module (submodules that are not pluggable are not visible and therefore do not receive a diagnostic icon).
- Network view
  - The associated diagnostic icon is displayed for every device.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.

- Network overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.
- Topology view
  - The associated diagnostic icon is displayed for every device.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The associated diagnostic icon is displayed for every port. The meaning of the individual colors is described further below.
  - Each cable between two online ports is assigned the color associated with its diagnostics status.
    The color of the cable between two ports depends on the status of the individual ports:

Color of the first port	Color of the second port	Color of the connecting cable
light green	light green	light green
light green	dark green	dark green
green	gray	gray
green	red	red
gray	red	red

  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.
- Topology overview
  - The associated diagnostic icon is displayed for every hardware component.
    To start the Online and Diagnostics view (if available), double-click the diagnostic icon.
  - For a hardware component with lower-level components, if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: A diagnostic icon is displayed. It belongs to that part of the station that is assigned to the CPU.

- Project tree
  - The associated diagnostic icon is displayed behind every hardware component.
  - For a hardware component with lower-level components (e.g., distributed I/O, Slave_1), if there is a hardware error in at least one lower-level component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Hardware error in lower-level component" is also shown in the lower right corner.
  - For hardware components with their own operating state, the operating state icon is also displayed in the top right corner of the diagnostic icon.
  - If forcing is active on a CPU, a red F is displayed at the left margin of the diagnostic icon.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the "Local modules" folder when there is a hardware error in at least one of the associated modules.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the "Distributed I/O" folder when there is a hardware error in at least one of the associated modules.
  - The diagnostic icon "Hardware error in lower-level component" is displayed behind the project folder when the "Hardware error in lower-level component" diagnostic icon is displayed behind at least one of the "Local modules" or "Distributed I/O" folders.
  - The following applies to modules or submodules of a shared device with an S7-1500 CPU: The associated diagnostic icon is displayed for modules assigned to the CPU (modules that are not assigned are grayed out and do not receive a diagnostic icon). The associated diagnostic icon is displayed for plug-in submodules of an assigned module (submodules that are not pluggable are not visible and therefore do not receive a diagnostic icon).

Note

If the diagnostic for a hardware component is "not reachable from the CPU", the diagnostic icon "Hardware error in lower-level component" is not additionally shown.

Diagnostic icons for modules and devices

The following table shows the available icons and their meaning.

Icon	Meaning
	The connection with a CPU is currently being established.
	The CPU is not reachable at the set address.
	The configured CPU and the CPU actually present are of incompatible types.
	On establishment of the online connection to a protected CPU, the password dialog was terminated without specification of the correct password.
	No fault

Icon	Meaning
	Maintenance required
	Maintenance demanded
	Error
	The module or device is deactivated.
	The module or the device cannot be reached from the CPU (valid for modules and devices below a CPU).
	No input or output data are available, because the (sub)module has blocked its input or output channels.
	Diagnostics data are not available because the current online configuration data differ from the offline configuration data.
	The configured module or device and the module or device actually present are incompatible (valid for modules or devices under a CPU).
	The connection is established, but the module status has not yet been determined or is unknown.
	The configured module does not support display of the diagnostics status.
	Hardware error in lower-level component: A hardware fault has occurred in at least one lower-level hardware component (occurs as a separate icon only in the project tree)

Note

Some modules, for example, the FM 450-1, are only indicated as having a problem in the case of an error if you have enabled the diagnostic interrupt when assigning the module property parameters.

Icons for the comparison status

The diagnostic icons can be combined at the bottom right with additional smaller icons that indicate the result of the online/offline comparison. The following table shows the available comparison icons and their meaning.

Icon	Meaning
	Hardware error in lower-level component: The online and offline versions differ (only in the project tree) in at least one lower-level hardware component.
	Software error in lower-level component: The online and offline versions differ (only in the project tree) in at least one lower-level software component.
	Online and offline versions of the object are different
	Object only exists online
	Object only exists offline
	Online and offline versions of the object are the same

Note

If both a comparison icon and the "Error in lower-level component" diagnostic icon are to be displayed at the bottom right in the device view, the following rule applies: The diagnostic icon for the lower-level hardware component has a higher priority than the comparison icon. This means that a comparison icon is only displayed if the lower-level hardware components have no errors.

Display of software errors in the project tree

- The associated comparison icon is shown behind each block.
- Behind each folder, under which exclusively blocks are contained, the diagnostic icon "Software error in lower-level component" is displayed when there is a software error in at least one of the associated blocks.
- For a hardware component with lower-level software components, if there is no hardware error and there is an error in at least one lower-level software component, the diagnostic icon appears as follows: The hardware component's diagnostic icon has a pale appearance and the diagnostic icon "Software error in lower-level component" is also shown in the lower right corner.

Combined diagnostics and comparison icons

The following table shows examples of icons that are displayed in the diagnostics icon.

Icon	Meaning
	Folder contains objects whose online and offline versions differ (only in the project tree)
	Object only exists online

Operating state icons for CPUs and CPs

The following table shows the available icons and their respective operating states.

Icon	Operating state
	RUN
	STOP
	STARTUP
	HOLD
	DEFECTIVE

Icon	Operating state
	Unknown operating state
	The configured module does not support display of the operating state.

Note

If forcing is active on a CPU, a red F is displayed on a pink background at the bottom right of the operating state icon.

Color marking of ports and Ethernet cables

The following table shows the available colors and their respective meaning.

Color	Meaning
	No fault or maintenance required
	Offline
	Maintenance demanded
	Communication error or topological error
	no diagnostic capability

Start online and diagnostics view

Overview of possible ways of starting the Online and Diagnostics view

You can start the Online and Diagnostics view of a module to be diagnosed at the following locations:

- Overview
- Project tree
- Device view
- Device overview
- Network view
- Network overview
- Topology view
- Topological overview

In the following, examples are used to show how to proceed.

Requirement

The project with the module to be diagnosed is open.

Note

This requirement does not apply if you call the online and diagnostics view from the project tree after you have identified the accessible devices.

Procedure

To start the online and diagnostics view of a module, follow these steps:

1. In the project tree, open the respective device folder.
2. Double click on "Online & Diagnostics".

Or:

1. In the project tree, select the respective device folder.
2. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. In the project tree, open the "Online access" folder.
2. Open the folder for the interface with which you want to establish the online connection.
3. Double click on "Show/Update accessible devices".
4. Select the module to be diagnosed.
5. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. In the project tree, open the "Local modules" folder.
2. Select the respective device or the module that is to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the main menu.

Or:

1. Open the device view in the device configuration.
2. Select the module to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. Open the device view in the device configuration.
2. Establish an online connection to the module to be diagnosed.
3. Double-click on the diagnostics icon above the module.

Or:

1. Open the network view in the device configuration.
2. Select the station with the module to be diagnosed.
3. Select the "Online & Diagnostics" command in the shortcut menu or the "Online" main menu.

Or:

1. Open the topology view in the device configuration.
2. Establish an online connection to the module to be diagnosed.
3. In the topology view, double-click the diagnostic icon associated with the module.

Result

The online and diagnostics view of the module to be diagnosed will be started. If an online connection to the associated CPU had previously been created, the header bar of the Online and Diagnostics view will now have an orange background.

Note

If no online connection exists when the online and diagnostics view is started, no online information is displayed and the display fields remain empty.

Activation of the "Online Tools" task card

Activation of the "Online Tools" task card

You can activate this task card as follows:

1. Start the online and diagnostics view.
2. Click on the "Online Tools" task card.

Or:

1. Start the device view.
2. Click on the "Online Tools" task card.

Or:

1. Start the network view.
2. Click on the "Online Tools" task card.

10.2.1.2 Showing non-editable and current values of configurable module properties

Showing general properties and system-relevant information for a module

Where do I find the information I need?

The general properties and system-relevant information for a module can be found in the "General" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed.

Structure of the "General" group

The "General" group consists of the following areas:

- Module
- Module information
- Vendor information

"Module" area

This area shows the following data of the module:

- Short designation, for example, CPU 1214C DC/DC/DC
- Article no.
- Hardware
- Firmware
- TIA Portal version

  Note

  TIA Portal version

  The displayed TIA Portal version is the minimum version that is required to open the blocks loaded to the device or to load the blocks to the ES. This means it does not necessarily have to be the version with which you have loaded the blocks to the device.

  Fictitious example: You have installed the TIA Portal in version V14.0 SP1 on your ES and are creating a new project. This project is assigned project version V14.0. You download this project (along with its project version) to the CPU. The project version, which means V14.0, is displayed.

- Racks
- Slot

"Module information" area

This area shows the following data of the module that you configured during hardware configuration:

- Module name
- Installation date (not displayed for all modules)
- Additional information (not displayed for all modules)

"Manufacturer information" area

This area shows the following data of the module:

- Manufacturer
- Serial number
- Profile: Profile ID as hexadecimal number

  Note

  You will find the corresponding profile name in the profile ID table for PROFIBUS International (see "www.profibus.com").

- Profile details: Profile-specific type as hexadecimal number

  Note

  You will find the corresponding profile-specific type name in the profile-specific type table for PROFIBUS International (see "www.profibus.com").

Display configured cycle times

Where do I find the information I need?

The required information can be found in the following places:

- In the "Cycle time" group of the "Diagnostics" folder in the Online and Diagnostics view of the module to be diagnosed.
- In the "Cycle time" pane of the "Online Tools" task card

Structure of the "Cycle time" group in the "Diagnostics" folder of the Online and Diagnostics view

The "Cycle time" group consists of the following areas:

- Cycle time diagram (graphical display of the assigned and measured cycle times)
- Cycle time configured (display of the assigned cycle times as absolute values)
- Cycle times measured (display of the measured cycle times as absolute values)

Structure of the "Cycle time" pane of the "Online Tools" task card

The "Cycle time" pane displays the cycle time diagram and below it the measured cycle times as absolute values.

Assigned cycle times

The following assigned cycle times are displayed in the cycle time diagram and in the "Cycle time configured" area.

- Minimum cycle time
- Maximum cycle time

In the cycle time diagram, the minimum cycle time and the maximum cycle time correspond to the two markings on the time axis.

In the "Cycle time configured" area, the assigned cycle times are displayed as absolute values.

Show interfaces and interface properties of a module

Where do I find the information I need?

The interfaces and interface properties of a module can be found in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed in the following group:

- PROFINET interface

"PROFINET interface" group

This group is divided into the following areas:

- "Ethernet address" with the "Network connection" and "IP Parameters" subareas
- "Ports"

"Network connection" subarea of the "Ethernet address" area

This subarea shows the following data for the module:

- MAC Address:
  MAC address of the interface.
  The MAC address consists of two parts. The first part ("Basic MAC address") identifies the manufacturer (Siemens, 3COM, ...). The second part of the MAC address differentiates between the various Ethernet devices. Each Ethernet module is assigned a unique MAC address.

"IP Parameters" subarea of the "Ethernet address" area

This subarea shows the following data for the module:

- IP address:
  Internet protocol address of the device on the bus (TCP/IP)
- Subnet mask:
  The subnet mask shows which part of the IP address determines the membership of a particular sub-network.
- Default router:
  If the subnet is connected via a router to other subnets, the IP address of the default router must be known. This is the only way a datagram can be forwarded with a non-matching subnet address.
- IP settings:
  Identifier for the path by which the device has obtained its IP settings (IP address, subnet mask, default router).

Identifier	Meaning
0	IP address is not initialized
1	By configuration (i.e., by the configuration loaded to the device from the device or network view)
2	Via the "Assign IP address" group of the online and diagnostics view
3	Via the DHCP server (i.e., the IP parameters are obtained by a special service from a DHCP server (Dynamic Host Configuration Protocol) and assigned for a limited time)
4	IP address is set by a user program
5	Source of IP address unknown

- IP setting time:
  Time stamp of the last change to the IP address directly through the Ethernet connection of the module

"Ports" area

This area shows the following data for the module:

- Ethernet ports
  Physical properties of the PROFINET interface

Properties of the PROFINET interface	Meaning
Port no.	Port number The short description of interface (X + interface no.) and port (P + port no.) is specified in parentheses. An "R" in the short description of a port means that it is a ring port.
Status	Displays the status of the port LINK LED. • Status "OK" means another device (such as a switch) is connected to the port and the physical connection is available. • Status "disconnected" means no other device is connected to the port. • Status "deactivated" means that access to the port is blocked.
Settings	• "Automatic" for automatic network settings of the device • Network settings for speed and transmission method for manual network settings of the device
Operating mode	Network settings for speed and transmission method

If you select a line in the port table, additional help information will be provided for the corresponding port.

Displaying IO controllers that access modules of a Shared Device (S7-1500)

Where do I find the information I need?

The display of those IO controllers that access the modules of a Shared Device can be found in the Online and Diagnostics view of the interface module of the Shared Device in the "Diagnostics" folder in the following area of the "PROFINET interface" group:

- IO controller

Displaying sync domain properties of a PROFINET device

Where do I find the information I need?

The sync domain properties of a PROFINET device can be found in the following area of the "PROFINET interface" group in the "Diagnostics" folder of the Online and Diagnostics view of the device to be diagnosed:

- Domain

"Domain" area

This area is divided into the following subareas:

- Sync domain
- MRP domain

What is a sync domain?

A sync domain is a group of PROFINET devices that are synchronized to a common clock. Exactly one device has the role of the sync master (clock generator); all other devices assume the role of a sync slave. The sync master is usually an IO controller or a switch.

Non-synchronized PROFINET devices are not part of a sync domain.

"Sync domain" subarea of the "Domain" area

This subarea shows the following properties of the sync domain:

- Name:
  Name of sync domain
- Role:
  Role of the PROFINET device in the sync domain. The following roles are possible:
  - Sync master
  - Sync slave
- Synchronization interval:
  Interval at which the synchronization is performed
- Send clock
  Smallest possible send interval for the data exchange
- Jitter accuracy of the send clock
- Reserved bandwidth for cyclic communication

Displaying MRP domain properties of a PROFINET device

Where do I find the information I need?

The MRP domain properties of a PROFINET device can be found in the following area of the "PROFINET interface" group in the "Diagnostics" folder of the Online and Diagnostics view of the device to be diagnosed:

- Domain

"Domain" area

This area is divided into the following subareas:

- Sync domain
- MRP domain

What is an MRP domain?

The Media Redundancy Protocol (MRP) enables redundant networks to be structured. Redundant transmission paths (ring topology) ensure that, if one transmission path fails, an alternative communication path is available. The PROFINET devices that are part of this redundant network form an MRP domain.

"MRP domain" subarea of the "Domain" area

This subarea shows the following properties of the MRP domain:

- Name:
  Name of MRP domain
- Role:
  Role of the PROFINET device in the MRP domain. The following roles are possible:
  - Manager
  - Manager (Auto)
  - Client
  - Not a device of the ring
- Ring port 1:
  The port of the PROFINET device that has the "Ring port 1" property
- Ring port 2:
  The port of the PROFINET device that has the "Ring port 2" property
- Status of the MRP ring:
  Indicates whether the ring is interrupted ("open" status) or not ("closed" status).

Displaying current firmware of a module (S7-300, S7-400, S7-1500)

Displaying firmware

You can display the currently installed firmware of a module.

Requirements

- The module supports a firmware update.
- The module is connected online.

Procedure

To display the current firmware, follow these steps:

1. Open the module in the Online and Diagnostics view.
2. Select the "Firmware update" group in the "Functions" folder.
3. You read off the current firmware in the "Online data" area under "Firmware".

10.2.1.3 Showing the current values of dynamic modules properties

Display measured cycle times

Where do I find the information I need?

The measured cycle times can be found at each of the following places:

- In the "Cycle time" group of the "Diagnostics" folder in the Online and Diagnostics view of the module to be diagnosed.
- In the "Cycle time" pane of the "Online Tools" task card

Structure of the "Cycle time" group in the "Diagnostics" folder of the Online and Diagnostics view

The "Cycle time" group consists of the following areas:

- Cycle time diagram (graphical display of the assigned and measured cycle times)
- Cycle time configured (display of the assigned cycle times as absolute values)
- Cycle times measured (display of the measured cycle times as absolute values)

Structure of the "Cycle time" pane of the "Online Tools" task card

The "Cycle time" pane displays the cycle time diagram and below it the measured cycle times as absolute values.

Graphical display of the measured cycle times

The following measured cycle times are displayed in the cycle time diagram:

- Shortest cycle time: Duration of the shortest cycle since the last transition from STOP to RUN
  This corresponds to the dashed gray arrow on the left in the diagram.
- Current / last cycle time: Duration of the last cycle
  This corresponds to the green arrow in the diagram. If the current / last cycle time exceeds the maximum cycle time, the arrow will turn red.

  Note

  If the duration of the last cycle comes close to the maximum cycle time, it may be possible that it will be exceeded. Depending on the CPU type, parameter assignment and your user program, the CPU can switch to STOP mode. If for instance you are monitoring the tags in your program, this will increase the cycle time.

  If the cycle lasts longer than double the maximum cycle time, and you do not restart the maximum cycle time in the user program (by calling the extended RE_TRIGR) instruction, the CPU will switch to STOP mode.

- Longest cycle time: Duration of the longest cycle since the last transition from STOP to RUN.
  This corresponds to the dashed blue arrow on the right in the diagram.

A blue band extends between the two dashed lines; this band corresponds to the entire range of the measured cycle times. If a measured cycle time is greater than the maximum cycle time, the portion of the band that lies outside the assigned limits will be colored red.

Display of the measured cycle times as absolute values

The following measured times are displayed in the "Cycle times measured" area and in the "Cycle time" pane.

- Shortest cycle time since the last transition from STOP to RUN.
- Current/last cycle time:
- Longest cycle time since the last transition from STOP to RUN.

Showing the current status of the LEDs of a CPU

Where do I find the information I need?

The current status of the LEDs of a CPU can be found in the display area of the "CPU control panel" pane of the "Online tools" task card.

Display area of the "CPU control panel" pane of the "Online Tools" task card

This area contains the following displays:

- Station name and CPU type (short designation)
- RUN / STOP (corresponds to the "RUN / STOP" LED of the CPU)
- ERROR (corresponds to the "ERROR" LED on the CPU)
- MAINT (corresponds to the "MAINT" LED on the CPU)

Showing fill levels of all types of memory on a CPU

Where do I find the information I need?

The fill levels of all types of memory on a CPU can be found on the following two pages:

- In the display area of the "Memory" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed
- In the display area of the "Memory" pane on the "Online Tools" task card

Display area of the "Memory" group in the "Diagnostics" folder of the online and diagnostics view

This area contains the current memory utilization of the associated module and details of the individual memory areas.

The memory utilization is shown both as a bar diagram and as a numerical value (percentage).

The following memory utilizations are shown:

- Load memory
  If no memory card is inserted, the internal load memory is displayed.
  If a memory card is inserted, the operating system only uses the inserted load memory as the load memory. This is displayed here.
- Work memory
- Retentive memory

Display area of the "Memory" pane of the "Online Tools" task card

This area contains the current memory utilization of the associated module. The available memory is shown both as a bar diagram and as a numerical value (percentage). The numerical value is rounded to an integer value.

Note

If less than 1% of a memory area is utilized, the available portion of this memory area is shown as "99%".

The following memory utilizations are shown:

- Load memory
  If no memory card is inserted, the internal load memory is displayed.
  If a memory card is inserted, the operating system only uses the inserted load memory as the load memory. This is displayed here.
- Work memory
- Retentive memory

Displaying fill level of all types of memory of an S7-1500 CPU (S7-1500)

Where do I find the information I need?

The fill levels of all types of memory of an S7-1500 CPU can be found at the following two places:

- In the display area of the "Memory" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed
- In the display area of the "Memory" pane on the "Online Tools" task card

Display area of the "Memory" group in the "Diagnostics" folder of the online and diagnostics view

This area contains the current memory utilization of the associated module and details of the individual memory areas.

The memory utilization is shown both as a bar diagram and as a numerical value (percentage).

The following memory utilizations are shown:

- Load memory

  Note

  The load memory is located on the SIMATIC memory card.

- Code work memory: work memory for program code
- Data work memory: work memory for data blocks
- Retentive memory

Display area of the "Memory" pane of the "Online Tools" task card

This area contains the current memory utilization of the associated module. The available memory is shown both as a bar diagram and as a numerical value (percentage). The numerical value is rounded to an integer value.

Note

If less than 1% of a memory area is utilized, the available portion of this memory area is shown as "99%".

The following memory utilizations are shown:

- Load memory

  Note

  The load memory is located on the SIMATIC memory card.

- Code work memory: work memory for program code
- Data work memory: work memory for data blocks
- Retentive memory

10.2.1.4 Checking a module for defects

Determining the diagnostic status of a module

Where is the diagnostics status of a module displayed?

The diagnostic status of a module is displayed in the "Diagnostic status" group in the "Diagnostics" folder in the online and diagnostics view of the module to be diagnosed.

The "Diagnostics status" group consists of the following areas:

- Status
- Standard diagnostics (for S7-300 and S7-400 only for non-CPU modules)

"Status" area

The following status information is displayed in this area:

- Status of the module as viewed by the CPU, for example:
  - Module available and OK.
  - Module defective.
    If the module experiences a fault and you have enabled the diagnostic error interrupt during configuration, the "Module defective" status is displayed.
  - Module configured, but not available.
    Example: Diagnostics data is not available because the current online configuration differs from the offline configuration.
- Detected differences between the configured and the inserted module. Provided it can be ascertained, the article number will be displayed for the set and actual type.

The scope of the displayed information depends on the selected module.

"Standard diagnostics" area

The following diagnostics information for non-CPU modules is displayed in this area:

- Internal and external faults that relate to the overall module
- Associated diagnostics events

Examples of such diagnostics information are:

- Entire backup failed
- Module defective

Note

Diagnostic interrupts

A diagnostic interrupt can be reported to the CPU only if the module has diagnostic interrupt capability and the diagnostic interrupt has been enabled.

The display of the diagnostic interrupt is a snapshot. Sporadic module defects can be identified in the diagnostics buffer of the respective CPU.

Performing communication diagnostics of PROFINET ports

Where are port-specific errors of PROFINET ports displayed?

The port-specific errors of PROFINET ports are displayed in the "Communication diagnostics" group of the "Diagnostics" folder in the Online and Diagnostics view of the module to be diagnosed.

Structure of the "Communication diagnostics" group

The "Communication diagnostics" group consists of the following areas:

- Table containing the port-specific errors
- "Details of the event" text field
- "Help on event" text field

Structure of the table containing the port-specific errors

Each line of the error table corresponds to one error.

The table consists of the following columns:

- Name: port no. and port designation, as well as diagnostics icon
- Error: description of the error that occurred on this port

"Details" text field

If you select a line in the error table, the "Detail" text field will contain detailed information (if available) on the corresponding error.

"Help on selected diagnostic line" text field

If you select a line in the error table, the "Help on selected diagnostic line" text field will contain help information (if available) on the corresponding error.

PROFINET IO component diagnostics

Where do I perform PROFINET IO component diagnostics?

You perform the PROFINET IO component diagnostics in the "PROFINET IO diagnostics" group under "PROFINET interface" in the "Diagnostics" folder of the Online and Diagnostics view.

"PROFINET IO diagnostics" group

Manufacturer-related diagnostics texts for the IO device or the selected module of the IO device are displayed in this area.

If the diagnostics can be read by the IO controller, then communication errors and configuration errors (online/offline discrepancies) are displayed here.

Reading out the diagnostics buffer of a CPU

Where do you read out the diagnostics buffer of a CPU?

You read out the diagnostics buffer of a CPU in the "Diagnostics buffer" group in the "Diagnostics" folder in the Online and Diagnostics view.

Structure of the "Diagnostics buffer" group

The "Diagnostics buffer" group consists of the following areas:

- "Events"
- "Settings"

Diagnostics buffer

The diagnostics buffer is used as a log file for the diagnostics events that occurred on the CPU and the modules assigned to it. These are entered in the order of their occurrence, with the latest event shown at the top.

"Events" area

The "Events" area consists of the following elements:

- Check box "CPU time stamp takes into account local PG/PC time"
- Event table
- "Freeze display" or "Cancel freeze" button
- Details of the event: Event no., event ID, module and possibly station or device name, rack/slot, description, help on the event, plant designation, location identifier, coming/going information, event type
- "Open in editor", "Save as" buttons

Check box "CPU time stamp takes into account local PG/PC time"

If you have not activated the check box, the diagnostics buffer entries are shown with the module time.

If you have activated the check box, the diagnostics buffer entries are shown with the time given by the following formula:

Displayed time = module time + time zone offset on your programming device / PC

This requires the module time to be identical to UTC.

You should use this setting if you wish to see the times of the diagnostics buffer entries for the module expressed in the local time of your programming device / PC.

Selecting or clearing the check box immediately changes the times displayed for the diagnostics buffer entries.

Note

If you use the "WR_SYS_T" instruction in your program or if you set the real-time clock of the CPU using an HMI device instead of using UTC, we recommend that you clear the "CPU time stamp takes into account local PG/PC time" check box. In this case, the module time is the sole time of concern.

Event table

The following information is displayed in the table for each diagnostics event:

- Sequential number of the entry
  The first entry contains the latest event.
- Date and time of the diagnostics event
  If no date and time are shown, the module has no integrated clock.
- Short name of the event and, if applicable, the reaction of the CPU

  Note

  If an individual parameter of a text cannot be determined, the character string "###" is shown in its place.

  If no display text is yet available for new modules or new events, the numbers of the events and the individual parameters are stated as hexadecimal values.

- Only for S7-1200 and S7-1500 CPUs: Icon for the event type
  The following table shows the available icons and their meaning.

Icon	Meaning
	OK (no maintenance and/or no fault)
	Maintenance required
	Maintenance demanded
	Error

- Icon for information related to incoming/outgoing status
  The following table shows the available icons and their meaning.

Icon	Meaning
	Incoming event
	Outgoing event
	Incoming event to which there is no independent outgoing event
	User-defined diagnostics event

You can change the order of the columns, adjust the column widths and remove and add individual columns in the event table. In addition, you can sort as follows: by sequential number, by "Date and time" and by "Event".

"Freeze display" or "Cancel freeze" button

The "Freeze display" or "Cancel freeze" button is only enabled when there is an online connection to the CPU.

The default setting is "Freeze display".

The following happens when you click the "Freeze display" button:

- The current display of the diagnostics buffer entries is frozen.
- The labeling of the button changes to "Cancel freeze".

If an error has occurred in your system, diagnostics events can occur very quickly in succession. This produces a high update rate on the display. Freezing the display allows you to calmly examine the situation in more detail.

If the display is frozen and you click the "Cancel freeze" button, the following happens:

- The display of the diagnostics buffer entries is updated again.
- The labeling of the button changes to "Freeze display".

Note

If you freeze the diagnostics buffer display, the CPU continues to enter events in the diagnostics buffer.

Details of the event

If you select a line in the list of events, you obtain detailed information on the respective event:

- Sequential number of the event in the diagnostics buffer
- Event ID
- Module and, if applicable, station or device name
- Rack/slot
- Description of the event with event-specific additional information. Examples of this additional information:
  - Command that caused the event
  - Operating mode switch caused by the diagnostics event
- Help on the event: The selected event is explained in more detail and possible solutions may be specified. With outgoing events, the text "Outgoing event: "No user action required" is displayed.
- Only for S7-1200 and S7-1500 CPUs: Plant designation, location identifier

- Information on whether the event is an incoming or outgoing event
- Type of event. The following types of event are possible:
  - OK (no maintenance and/or no fault)
  - Maintenance required
  - Maintenance demanded
  - Error

"Open in editor" button

The following table shows if the "Open block" button is active and which function it conceals.

When is the "Open in editor" button enabled?	What happens when you click this button?
If the diagnostics event references the relative address of a block. This is the address of the command that caused the event.	The "Open in editor" function opens the referenced block in the offline view at the programming instruction that causes the error. This allows you to check and, if necessary, change the source code of the block at the specified place and then download it again to the CPU.
If the diagnostics event was triggered by a module.	The "Open in editor" function opens the Device view of the module involved.

"Save as ..." button

If you click this button, the content of the diagnostics buffer is saved in a text file. "Diagnostics", depending on the language, with the extension ".txt" is suggested as the file name. You can however change this name.

"Settings" area

The "Settings" area consists of the following elements:

- "Display events" list
- "Apply settings as default" button
- "Output event information in hexadecimal format" check box

List "Display events:"

There is an check box in this list for every event class (default setting: all check boxes are selected). If you clear a check box, the events of that event class is no longer displayed in the "Events" area. Reselecting the check box displays the associated events once again.

"Apply settings as default" button

If you click this button, the settings are also applied to future occasions when the "Events" tab is opened.

"Output event information in hexadecimal format" check box

If you select the check box, the event IDs in the Events list of the "Events" area is displayed in hexadecimal format. If you clear the check box, the event information is given in text form.

Basic information on the diagnostics buffer (Page 2070)

Saving service data (S7-1500)

Purpose

In the event of servicing it may be possible that the SIEMENS Customer Support requires very special information about the state of a module of your system for diagnostic purposes.

If such a case occurs in your system, you will be asked by Customer Support to save the service data of the module and send the resulting file to them.

Where do you carry out the saving of service data of a module?

You carry out the saving of service data of a module in its online and diagnostics view at the following points: In the "Functions" folder in the "Save service data" group"

The "Save service data" group consists of the following areas:

- Online data
- Saving service data

"Online data" area

This area shows the following data of the module:

- Article number
- Firmware version
- Module name (you configured this while configuring the hardware.)
- Rack
- Slot

"Save service data" area

Proceed as follows to create and save a file with special service data:

1. Select the point in the file system at which you want to save the file:
   - You use the path preset in the "Path" field.
   - Click the three-dot (browse) button. In the dialog that opens specify the desired path and enter the file name.
2. Click the "Save data" button.

10.2.1.5 Changing the properties of a module or the programming device/PC

Changing the mode of a CPU

Requirement

There is an online connection to the CPU whose mode you want to change.

Procedure

To change the mode of the CPU, follow these steps:

1. Enable the "Online tools" task card of the CPU.
2. Click the "RUN" button in the "CPU control panel" pane if you want to change the CPU to RUN mode or the "STOP" button if you want to change the CPU to STOP mode.

   Note

   The only button active is the one that can be selected in the current operating mode of the CPU.

3. Acknowledge the confirmation prompt with "OK".

Or:

1. Open the "Online" menu.
2. Choose the "Start CPU" menu command if you want to set the CPU to RUN mode and "Stop CPU" if you want to set the CPU to STOP mode.

   Note

   The only button that is active is the one that can be chosen in the current operating mode of the CPU.

3. Acknowledge the confirmation prompt with "OK".

Or:

1. Click the "Start CPU" button in the toolbar if you want to set the CPU to RUN mode and the "Stop CPU" button if you want to set the CPU to STOP mode.

   Note

   The only button that is active is the one that can be chosen in the current operating mode of the CPU.

2. Acknowledge the confirmation prompt with "OK".

Result

The CPU will be switched to the required operating mode.

Performing a memory reset

Requirement

- There is an online connection to the CPU on which the memory reset is to be performed.
- The CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the memory reset, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To perform a memory reset on a CPU, follow these steps:

1. Enable the "Online Tools" task card of the CPU.
2. Click the "MRES" button in the "CPU control panel" pane.
3. Acknowledge the confirmation prompt with "OK".

Result

The CPU is switched to STOP mode, if necessary, and the memory reset is performed on the CPU.

Determining and setting the time of day on a CPU

Where do I find the functions I need?

You determine and change the time of day on a CPU in the "Set time of day" group in the "Functions" folder of the Online and Diagnostics view. This requires an online connection.

Structure of the "Set time of day" group

The "Set time of day" group consists of the following areas:

- Area for reading out and setting the time of day
- Time system (This area does not exist for S7-1200 and will not be examined here.)

Structure of the area for reading out and setting the time of day

This area consists of the following parts:

- Programming device / PC time
  Here the time zone setting, the current date and the current time setting of your programming device / PC are displayed.
- Module time
  Here the date and time values currently read from the module (for example the CPU), are converted to local time and date and displayed.
  If the "Take from PG/PC" check box is selected, when you click the "Apply" button, the date and the PG/PC time converted to UTC are transferred to the module.
  If the "Take from PG/PC" check box is not selected, you can assign the date and time for the integrated clock of the module. After clicking the "Apply" button, the date and the time recalculated to UTC time are transferred to the module.

Resetting an S7-1200 CPU to factory settings (S7-1200)

Requirement

- There is no memory card inserted in the CPU.
- There is an online connection to the CPU that you want to reset to the factory settings.
- The CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the reset operation, you can place it in STOP mode by answering the security prompt with yes.

Procedure

To reset an S7-1200 CPU to factory settings, follow these steps:

1. Open the Online and Diagnostics view of the CPU.
2. Select the "Reset to factory settings" group in the "Functions" folder.
3. Select the "Keep IP address" check box if you want to keep the IP address or the "Delete IP address" check box if you want to delete the IP address.

   Note

   The two check boxes mentioned are only available if the module to be reset is able to choose whether to retain or delete the IP address.

4. Click the "Reset" button.
5. Acknowledge the confirmation prompt with "OK".

Result

The module is switched to STOP mode if necessary and the settings are then reset to factory settings. This means:

- The work memory and the internal load memory and all operand areas are cleared.
- All parameters are reset to their defaults.
- The diagnostic buffer is cleared.
- The time is reset.
- The IP address is kept or deleted depending on which setting you made.

Resetting an S7-1500 CPU to factory settings (S7-1500)

Requirement

- If you start a reset to factory settings from the project context, an online connection to the relevant CPU must exist.
- The relevant CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start the reset operation, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To reset an S7-1500 CPU to factory settings, follow these steps:

1. Open the Online and Diagnostics view of the CPU (either from the project context or via "Accessible devices").
2. Select the "Reset to factory settings" group in the "Functions" folder.
3. Select the "Keep IP address" check box if you want to keep the IP address or the "Delete IP address" check box if you want to delete the IP address.

   Note

   With "Delete IP address", all IP addresses are deleted. This applies regardless of how you created the online connection.

   If a memory card is inserted, selecting the "Delete IP address" option causes the following: The IP addresses are deleted and the CPU is reset to factory settings. Then, the configuration (including IP addresses) that is stored on the memory card is transferred into the CPU (see below). If the memory card was formatted before resetting to factory settings or if it is empty, no IP address is transferred into the CPU.

4. Click the "Reset" button.
5. Acknowledge the confirmation prompt with "OK".

Result

The module is switched to STOP mode if necessary and the settings are then reset to factory settings. This means:

- The work memory and the internal retentive system memory and all operand areas are cleared.
- All parameters are reset to their defaults.
- The diagnostic buffer is cleared.
- The time of day is reset.
- The I&M data are deleted except for I&M0 data.
- The runtime meters are reset.
- The IP address is kept or deleted depending on which setting you made.
- If a memory card was inserted prior to the reset to factory settings, the configuration contained on the memory card (hardware and software) is downloaded to the CPU.

Resetting a PROFINET IO device to factory settings (S7-1500)

Requirements

- There must be an online connection to the PROFINET IO device that is to be reset.

Procedure

To reset a PROFINET IO device to factory settings, follow these steps:

1. Open the Online and Diagnostics view of the device (either from the project context or via "Accessible devices").
2. In the "Functions" folder, select the "Reset to factory settings" group.
3. Select the "Retain identification and maintenance data" option button or the "Delete identification and maintenance data" option button, depending on whether you want to retain or delete the identification and maintenance data IM0 to IM3 on the device.
4. Click the "Reset" button.

5. Click "OK" in response to the confirmation prompt.
   If the PROFINET IO device to be reset supports the Reset-to-Factory command according to PROFINET V2.3, its PROFINET device name, its IP address and the SNMP parameters (SNMP: Simple Network Management Protocol) are reset. Your selection in step 3 determines whether the identification and maintenance data is retained or deleted.
   The reset process is now complete.
6. If the PROFINET IO device to be reset does not support the Reset-to-Factory command according to PROFINET V2.3, however, you will see a message informing you that all data on the module will be lost during a reset to factory settings.
   Confirm the security prompt. The reset process will be conducted.
   If you have selected "Delete identification and maintenance data" in step 3, the identification and maintenance data IM0 to IM3 is deleted during the reset.
   However, if you have selected "Retain identification and maintenance data" in step 3, it can still happen that the identification and maintenance data IM0 to IM3 is deleted during the reset: The reset behavior depends on the module in this case.

Result

The PROFINET IO device is reset. The data deleted in the process depends on the factors described above.

Formatting an S7-1500 memory card (S7-1500)

Requirement

- If you start the formatting of the memory card from the project context, an online connection to the relevant CPU must exist.
- The relevant CPU is in STOP mode.

Note

If the CPU is still in RUN mode and you start a formatting operation, you can place it in STOP mode after acknowledging a confirmation prompt.

Procedure

To format an S7-1500 memory card, follow these steps:

1. Open the Online and Diagnostics view of the CPU (either from the project context or via "Accessible devices").
2. Select the "Format memory card" group in the "Functions" folder.
3. Click the "Format" button.
4. Answer the safety prompt with "Yes".

Result

- The memory card is formatted.
- The CPU is temporarily unavailable.
- The project data on the CPU are deleted with the exception of the IP address.
- If you start the formatting of the memory card from the project context, the Online and Diagnostics view remains open. If formatting is started via "Accessible devices", the Online and Diagnostics view will close.

Updating the firmware of a module

Basic information on the firmware update of a module

Performing a firmware update

Using firmware files, you can update the firmware of a module.

Requirements

- The module is connected online.
- The module supports a firmware update.
- For those modules that require supply voltage to perform the firmware update correctly: The supply voltage of the module is ensured. For details, see the documentation of the module.

Procedure

You can call up the firmware update of a module from the project tree or from the project context.

⚠ WARNING

Impermissible system states possible

An S7-1500 CPU immediately goes to STOP mode when you start the firmware update, which can have an effect on the operation of an online process or a machine.
Unexpected operation of a process or a machine can result in severe or fatal injuries and/or damage to property.

Note

After you have run a firmware update, you will need to replace the affected module with the same module with the current firmware version in the hardware configuration of your project. The engineering configuration then matches the actual physical configuration again.

"Run firmware after update" check box

If you have not selected the "Run firmware after update" check box, the previous firmware remains active until the module is reset (for example by power cycling). The new firmware only becomes active after the module has been reset.

If you have selected the check box, the module is automatically reset after the firmware has been downloaded and it then runs with the new firmware.

Activating the firmware following the update has the following consequences:

- A station executes a restart. All modules in the station become unavailable as a result.
- If the corresponding CPU is in RUN, activating the firmware can lead to access errors or other problems in the user program and might even mean that the CPU remains permanently in STOP.

Note

For some CPUs, the "Run firmware after update" check box is grayed out and cleared. In this case, you must restart the CPU manually.

For S7-1500 CPUs, the "Run firmware after update" check box is grayed out and selected. In this case, the new firmware is activated immediately after the download operation.

Calling the firmware update from the project tree

Requirement

- The module is located in the first hierarchical level behind the head module (IM or CPU of the module family S7-1500 or ET200SP).
- The head module is connected to the engineering system via PROFINET.

Procedure

Follow these steps:

1. Select the relevant head module in the project tree.
2. Open the online and diagnostics view of the head module using the shortcut menu.
3. Select the "Firmware update" group in the "Functions" folder.
4. Select "Local modules".
   In the "Online data" area, a table lists modules of the first hierarchy level behind the head module. With Siemens modules, these are the modules that support a firmware update. With GSDML-based devices, this is all modules.
5. Select the module whose firmware you want to update.
6. Click the "Browse" button in the "Firmware loader" area in order to select the path to the firmware update files.
7. Select one of these files. The table then lists all modules for which an update is possible with the selected firmware file.

8. Optional: Select the "Run firmware after update" check box to reset the module after the load operation and to start the new firmware.
9. Click the "Start update" button. If the selected file can be interpreted by the module, it is downloaded to the module. If the operating mode of the CPU needs to be changed for this purpose, you will be prompted to do this by means of dialogs.

Starting the firmware update from the project context

Procedure

To perform a firmware update, follow these steps:

1. Open the module in the Online and Diagnostics view.
2. Select the "Firmware update" group in the "Functions" folder.

   Note

   For S7-1500-CPUs, this group is subdivided into "PLC" and "Display".

3. Click the "Browse" button in the "Firmware loader" area in order to select the path to the firmware update files.
4. Select one of these files. The table then lists all modules for which an update is possible with the selected firmware file.
5. Optional: Select the "Run firmware after update" check box to reset the module after the load operation and to start the new firmware.
6. Click the "Start update" button. If the selected file can be interpreted by the module, it is downloaded to the module. If the operating mode of the CPU needs to be changed for this purpose, you will be prompted to do this by means of dialogs.

Assigning an IP address to a PROFINET IO device

Basic information on assigning an IP address to a PROFINET IO device

Overview

All PROFINET IO devices work with the TCP/IP protocol and therefore require an IP address for operation on Industrial Ethernet. Once an IP address has been assigned to an IO device, it can be accessed via this address. You can then download configuration data or perform diagnostics, for example.

Requirement

- The Ethernet LAN connection must already be established.
- The Ethernet interface of your programming device or PC must be accessible.
- The IO device that is to be assigned an IP address must be in the same IP band as the programming device or PC.

Starting the address assignment via "Accessible devices"

Requirement

- The devices accessible via the associated interface of the PG/PC are displayed in the project tree (to display these, either double-click "Update accessible devices" in the project tree or select the "Accessible devices..." command in the "Online" menu.).
- You have double-clicked "Online access" -> <Selected interface> -> <PROFINET IO device> -> "Online & Diagnostics" in the project tree to open the Online and Diagnostics view.

Procedure

1. Open the "Functions" folder and the "Assign IP address" group inside this folder. The "MAC address" field displays the MAC address of the PROFINET IO device. The "Accessible devices" button is grayed out.
2. Enter the desired IP address.
3. Enter the subnet mask.
4. If a router is to be used, select the "Use router" check box and enter its IP address.
5. Click the "Assign IP address" button.

Result

The IP address is permanently assigned to the IO device or to the relevant PROFINET interface of the IO device. It is retained even through a startup or a power failure.

Note

For an S7-1500 CPU, you can also use the above-described method to change the IP address of a PROFINET interface, if a project has already been downloaded to the CPU via this interface. This overwrites the IP address downloaded via the project.

Starting the address assignment from the project context

Requirement

- An online connection to the PROFINET IO device exists.
- You have opened the Online and Diagnostics view of the PROFINET IO device from the project context.
- The PROFINET IO device is not assigned to any IO controller.

Procedure

1. Open the "Functions" folder and the "Assign IP address" group inside this folder.
2. Click the "Accessible devices" button in order to identify the devices that can be accessed. Note: For an S7-1500 CPU, there are two entries here because it has two PROFINET interfaces.
3. Select the IO device. The "IP address" field, "Subnet mask" field, "Use router" check box and "Router address" field are grayed out and contain the node properties you used to establish the current online access.
4. Click the "Assign IP address" button.

Result

The IP address is permanently assigned to the IO device or to the relevant PROFINET interface of the IO device. It is retained even through a startup or a power failure.

Assigning a PROFINET device name

Basic information on assigning a name to a PROFINET IO device

Device name

Before an IO device can be addressed by an IO controller, it must have a device name. This procedure was chosen for PROFINET because names are easier to handle than complex IP addresses.

Assigning a device name to a PROFINET IO device is comparable to setting the PROFIBUS address for a DP slave.

An IO device has no device name in its delivery state. For an IO controller to address an IO device, it must first be assigned a device name using the programming device or PC. It is now ready to transfer the configuration information including the IP address during startup or exchange user data in cyclic operation.

Rules for the device name

The device name is subject to the following limitations:

- Restricted to a total of 240 characters (lower case letters, numbers, dash, or dot)
- A name component within the device name, which is a character string between two dots, must not exceed 63 characters.
- No special characters such as umlauts, brackets, underscore, slash, blank space, etc. The only special character permitted is the dash.
- The device name must not begin or end with the "-" character.
- The device name must not begin with a number.
- The device name form n.n.n.n (n = 0, ... 999) is not permitted.
- The device name must not begin with the string "port-xyz" or "port-xyz-abcde" (a, b, c, d, e, x, y, z = 0, ... 9).

Where do I find the function I am seeking?

You can assign the name of a PROFINET IO device at the following places:

- In the online and diagnostics view of the device in the "Assign name" group of the "Functions" folder. The user interface for this group differs depending on how you open the online and diagnostics view:
  - Open via "Accessible devices"
  - Open from the project context
- In the "Assign PROFINET device name" dialog

See also

Assigning a name in the online and diagnostics view opened via "Accessible devices" (Page 2062)

Assigning a name in the online and diagnostics view opened from the project context (Page 2063)

Assigning a name in the "Assign PROFINET device name" dialog (Page 2064)

Assigning a name in the online and diagnostics view opened via "Accessible devices"

Requirement

- You have opened the online and diagnostics view of the PROFINET IO device using "Update accessible devices" (in the project tree) or "Accessible devices..." ("Online" menu).

Procedure

1. Open the "Functions" folder and the "Assign name" group inside this folder. The "Type" field displays the module type of the PROFINET IO device.
2. Enter the required device name in the "PROFINET device name" input box.
3. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box or by closing the online and diagnostics view.
4. Click "Assign name".

Result

The entered name is assigned to the PROFINET IO device.

Assigning a name in the online and diagnostics view opened from the project context

Requirement

- You have opened the online and diagnostics view of the PROFINET IO device from the project context.
- The PROFINET IO device can be accessed using at least one PG/PC interface.

Procedure

1. Open the "Functions" folder and the "Assign name" group inside this folder. The "PROFINET device name" drop-down list displays the current name in the offline project, and the "Type" box shows the module type of the PROFINET IO device.

   Note

   For CPUs with several PROFINET interfaces, the names of all existing PROFINET interfaces are displayed in the offline project.

2. Choose a different name from the drop-down list, if necessary.

   Note

   In steps 3 to 5, you determine the IO devices that are present in the PROFINET subnet.

3. In the "PG/PC interface for assignment" drop-down list, select the PG/PC interface you want to use to establish the online connection.
4. Optional: Use the three check boxes to make a selection from all IO devices available online.

5. Click the icon for determining the IO devices present in the PROFINET subnet. The table is then updated.
6. Select the desired IO device in the table.
7. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box, by selecting another IO device in the table, or by closing the online and diagnostics view.
8. Click "Assign name".

Result

The selected name is assigned to the PROFINET IO device or one of its PROFINET interfaces.

Assigning a name in the "Assign PROFINET device name" dialog

Requirement

- You have opened the "Assign PROFINET device name" dialog from the network view (from the shortcut menu of a PN/IE connection).
- The PROFINET IO device can be accessed using at least one PG/PC interface.

Procedure

1. The following is displayed in the "PROFINET device name" drop-down list:
   – the name of the interface that was used to open the project in the current offline project
   – the names of those IO devices that are connected by means of this interface

   The "Type" field displays the module type of the PROFINET IO device.
   Choose a different name from the drop-down list, if necessary.

   Note

   In steps 2 to 4, you determine the IO devices that are present in the PROFINET subnet.
2. In the "PG/PC interface for assignment" drop-down list, select the PG/PC interface you want to use to establish the online connection.
3. Optional: Use the three check boxes to make a selection from all IO devices available online.
4. Click the icon for determining the IO devices present in the PROFINET subnet. The table is then updated.
5. Select the desired IO device in the table.

6. Optional: Select the "Flash LED" check box in order to run an LED flash test on the PROFINET IO device. In this way, you verify that you are naming the desired IO device.

   Note

   The LED flash test is not supported by all PROFINET IO devices.

   The LED flash test runs until you cancel it. This is done, for example, by clearing the "Flash LED" check box or by selecting another IO device in the table.

7. Click "Assign name".

Result

The selected name is assigned to the PROFINET IO device or the interface that was used to open the dialog.

Calibrating an S7-1500 analog module (S7-1500)

Calibrating an S7-1500 analog module - Overview (S7-1500)

Where do you calibrate an S7-1500 analog module?

You calibrate an S7-1500 analog module in its Online and Diagnostics view in the "Calibrate" group of the "Functions" folder.

Overview of the function scope of the calibrating function

You can perform the following functions for an S7-1500 analog module in the "Calibrate" group:

- Specifying the current calibration of all channels
- Calibrating a channel
- Canceling a running calibration
- Resetting the calibration of a channel to the factory settings

Requirement for the calibrating function described below

The following is required for the calibrating function described below:

- You have opened the Online and Diagnostics view from the project context (thus not from the project tree or via the "Online" menu).
- There is an online connection to the analog module that is to be calibrated.
- Offline and online configuration are identical.

Calibrating an S7-1500 analog module (S7-1500)

Overview of the calibration of a channel of an S7-1500 analog module

The calibration of a channel of an S7-1500 analog module consists of the following steps:

1. Start calibration
2. Perform the second step up to the next to last step of the calibration
3. Complete calibration

These steps are described in more detail in the following section.

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.
- No calibration is currently running on the analog module (if you want to start the calibration) or the last step initiated has been performed successfully (if you want to resume or complete the calibration).

Procedure for starting the calibration

To start the calibration, follow these steps:

1. In the overview table, select the line that belongs to the channel to be calibrated.
2. Click the "Start manual calibration" button.

The user interface then changes as follows:

- The overview table and the "Start manual calibration" button and "Set to factory settings" buttons become inactive.
- The step display is activated and displays the numbers of the current and last steps.
- The "Command" field becomes active and indicates what the user must do in the next calibration step.
- The "Status" field becomes active and shows the current status of the calibration, e.g., "Calibration successfully started".
- The "Measured value" field becomes active. For an input module a value is displayed here; you must enter a value here for an output module.
- The "Cancel" button becomes active.
- With certain analog modules (AI Energy Meter) the "Skip" button becomes active. This button can be used to skip to the next step of the calibration.
- The "Next" button becomes active. This button can be used to advance to the next step of the calibration.

Procedure for the second to the next to last step of the calibration

Follow these steps:

1. Click the "Next" button.

The fields of the user interface described above are then updated.

With certain analog modules (AI Energy Meter), you can skip the next calibration step as long as the next step is not the last step of the calibration procedure. To do this, follow these steps:

1. Click the "Skip" button.

The fields of the user interface described above are then updated.

Procedure for the last step of the calibration

Follow these steps:

1. Click the "Next" button.

The user interface then changes as follows:

- The overview table becomes active.
- The calibration display of the calibrated channel is updated.
- The "Start manual calibration" button and "Set to factory settings" buttons become active.
- The step display is deactivated and the numbers of the current step and last steps are empty.
- The "Command" field becomes inactive and is empty.
- The "Status" field becomes inactive and shows the last status of the calibration, e.g., "Calibration successfully finished".
- The "Measured value" field becomes inactive and is empty.
- The "Cancel" button becomes inactive.
- The "Skip" button becomes inactive.
- The "Next" button becomes inactive.

Error occurrence

If an error occurs during the calibration, the module cancels the calibration. Afterwards, the channel that was to be calibrated has the same settings as before the start of the calibration.

Except for the "Status" field, the user interface appears the same after the occurrence of an error as before the calibration. The "Status" field displays the error that the module detected during the calibration.

Canceling a running calibration of an S7-1500 analog module (S7-1500)

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.
- A calibration is currently running on the analog module.

Procedure

To cancel a running calibration, follow these steps:

1. Click the "Cancel" button.

Result

The running calibration is canceled, and afterwards the channel to be calibrated has the same settings as before the calibration.

All operator controls in the user interface are deactivated until the cancelation is complete. Except for the "Status" field, the user interface appears the same afterwards as before the calibration. The "Status" field displays the result of the cancelation.

Resetting an S7-1500 analog module to factory settings (S7-1500)

Requirement

- You have opened the Online and Diagnostic view of the S7-1500 analog module from the project context and are in the "Calibrate" group of the "Functions" folder.
- The associated CPU is online.

Procedure

To reset a channel of an S7-1500 analog module to factory settings, follow these steps:

1. Select the line associated with the channel to be reset in the overview table.
2. Click the "Set to factory settings" button.

Result

All operator controls in the user interface are deactivated until the reset operation is complete. Except for the "Status" field, the user interface appears the same afterwards as before the reset operation. The "Status" field displays the result of the reset operation.

Loading I&M data to PROFINET IO devices and your modules

Which I&M data can be loaded to PROFINET IO devices and your modules?

You can load I&M 1 data (plant designation and location identifier) and/or I&M 2 data (installation date) and/or I&M 3 data (additional information) to the actual hardware.

Requirements

- In the project settings (Options > Settings, Hardware configuration > Compiling and downloading), the option "Download I&M data" must be enabled.
- There is an online connection to the PROFINET IO devices and the modules to which you want to load I&M data.
- You have entered the I&M data you want to download in the properties of the respective PROFINET IO devices and your modules (Inspector window: "Properties" tab > "General" tab, Settings > Identification & Maintenance).

Where do I specify which I&M data is downloaded to which PROFINET IO devices?

You specify which I&M data you want to download to which PROFINET IO devices in the "Load preview" dialog. You will find the following alternatives in the drop-down list of the "Identification and maintenance data (I&M)" row:

- Load nothing
  The check boxes for all PROFINET IO devices as well as the check boxes for the loadable I&M data are cleared.
  No I&M data is transferred to the actual hardware during loading with this setting.
- Load data
  The check boxes for all PROFINET IO devices as well as the check boxes for the loadable I&M data are selected.
  The respective I&M 1, I&M 2 and I&M 3 data is transferred to all PROFINET IO devices during loading with this setting.
- Load selected
  You select the check boxes of those PROFINET IO devices to which you want to load I&M data. You also select the check boxes of the identification data you want to load.
  With this setting, you transfer the selected I&M data to the selected PROFINET IO devices during loading.

Note

Language dependency of the I&M data to be loaded

The I&M data are loaded to the real hardware in the form that you specified in the properties of the relevant PROFINET IO devices and your modules. There is no language dependency.

10.2.1.6 Diagnostics in STOP mode

Basic information on the diagnostics buffer

Function

The operating system of the CPU enters the errors detected by the CPU and the diagnostics-capable modules into the diagnostics buffer in the order in which they occurred. This includes the following events:

- Every mode change of the CPU (POWER UP, change to STOP mode, change to RUN mode)
- Every hardware and diagnostic error interrupt

The top entry contains the most recent event. The entries in the diagnostics buffer are stored permanently. They are retained even if the power supply fails and can only be deleted by resetting the CPU to factory settings.

A diagnostics buffer entry contains the following elements:

- Time stamp
- Error ID
- Additional information specific to the error ID

Advantages of the diagnostics buffer

The diagnostics buffer offers the following advantages:

- After the CPU has changed to STOP mode, you can evaluate the last events prior to the STOP so that you can locate and identify the cause of the STOP.
- You can detect and eliminate the causes of errors more quickly and thus increase the availability of the system.
- You can evaluate and optimize the dynamic system response.

Organization of the diagnostics buffer

The diagnostics buffer is a ring buffer. With the S7-1200 CPUs, the maximum number of entries is 50. When the diagnostics buffer is full and a further entry needs to be made, all existing entries are shifted one position (which means that the oldest entry is deleted) and the new entry is made at the first position that is now free (FIFO principle: first in, first out).

Evaluation of the diagnostics buffer

The contents of the diagnostics buffer can be accessed as follows:

- Using the Online and Diagnostics view

The evaluation of events occurring prior to the error event (e.g., transition to STOP mode) allows you to obtain a picture of the possible causes or to zero in more closely or specify in more detail the possible causes (depending on the error type).

Read the detailed information about the events carefully and use the "Help on event" text box to obtain additional information and possible causes of individual entries.

Note

To make the best use of the time stamp information on the diagnostics buffer entries in time-critical systems, it is advisable to check and correct the date and time of day on the CPU occasionally.

Alternatively, it is possible to perform a time-of-day synchronization using an NTP time server.

See also

Resetting an S7-1200 CPU to factory settings (Page 2053)

Determining the cause of a STOP of a CPU (Page 2071)

Determining and setting the time of day on a CPU (Page 2052)

Determining the cause of a STOP of a CPU

Requirement

The CPU you want to analyze is in STOP mode.

Procedure

To find out the reason why a CPU changed to STOP, follow these steps:

1. Open the online and diagnostics view of the CPU.
2. Select the "Diagnostics buffer" group from the "Diagnostics" folder.
3. Evaluate the events occurring prior to the transition to STOP mode. Use this to obtain a picture of the possible causes or to zero in on or specify in more detail the possible causes (depending on the error type).
   Read the detailed information about the events carefully and use the "Help on event" button to obtain additional information and possible causes of individual entries.

Result

You were able to zero in on or determine in more detail the cause of the CPU STOP.

Note

If the analysis does not enable you to overcome the problem, contact Customer Support. In this case, use the "Save as" button to back up the content of the diagnostics data to a text file and submit it to Customer Support.

See also

Reading out the diagnostics buffer of a CPU (Page 2046)

10.2.1.7 Online accesses in the Online and Diagnostics view

Displaying status of the online connection

Requirement

- The associated device can be accessed using at least one PG/PC interface.

Procedure

1. Open the online and diagnostics view for the device whose online connection status you want to display.
2. Select the "Online access" group.

Note

The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

Result

The status of the online connection is displayed in the "Status" area both graphically and in text form.

Specifying a PG/PC interface, going online

Requirement

- The associated device can be accessed using at least one PG/PC interface.
- There is currently no online connection to the relevant device.

Procedure

1. Open the Online and Diagnostics view of the device to which you want to establish an online connection.
2. Choose the "Online access" group and the "Online access" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. If you have opened the Online and Diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. If an online connection was established previously for the device, the associated data for this online connection is preset in the drop-down lists. In this case, you can immediately continue with the last step of this operating instruction, provided you have not changed the IP address in the meantime using the Online and Diagnostics view.
4. Choose the interface type in the "Type of PG/PC interface" drop-down list.
   The "PG/PC interface for online access" drop-down list then shows only the interfaces of the programming device or PC that match the selected interface type.
5. In the "PG/PC interface for online access" drop-down list, select the programming device or PC interface via which you want to establish the online connection.
6. Optional: Click the "Properties" button to change the properties of the associated CP.
7. In the "Connection to subnet" drop-down list, select the subnet via which the device is connected to the PG/PC interface.

   Note

   The PG/PC interface is connected to an interface of a device.

   If you only want to access this device, select the setting "Directly at slot <interface name>" in the drop-down list.

   If, however, you want to access another device by means of routing, create a subnet at this interface in the device configuration and then select this subnet in the drop-down list.

8. If the device is accessible via a gateway, select the gateway that connects the two subnets involved in the "1st gateway" drop-down list.
9. In the "Device address" entry field, enter the IP address of the device to which you want to establish an online connection, if necessary.

   Note

   For CPUs with multiple IP addresses, select the IP address of the PROFINET interface you want to use to establish an online connection from the "Device address" drop-down list.

10. Alternatively: Click the "Show accessible devices" button and choose the device from the list of accessible devices to which you want to establish an online connection.
11. Click the "Go online" button.

Result

The online connection to the desired device is established.

Going offline

Requirement

- There is currently an online connection to the relevant device.

Procedure

1. Open the online and diagnostics view of the device for which you want to disconnect the online connection.
2. Choose the "Online access" group and the "Online access" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. Click the "Go offline" button.

Result

The online connection to the desired device will be disconnected.

Performing the flash test for a device with an online connection

Requirement

- There is currently an online connection to the relevant device.
- The FORCE function is not active.

Procedure

1. Open the online and diagnostics view of the device for which you want to perform a flash test.
2. Choose the "Online access" group and the "Status" area within this group.

   Note

   The "Online access" group exists only for CPUs and some CPs. However, if you have opened the online and diagnostics view using the "Show/update accessible devices" function, it is not displayed.

3. Select the "LED flash test" check box.

Result

- On an S7-1200 CPU, the RUN/STOP, ERROR and MAINT LEDs flash.
- On an S7-1500 CPU, the RUN/STOP, ERROR, and MAINT LEDs flash.
- On an S7-300 or S7-400 CPU, the FRCE LED flashes.

The LEDs flash until you cancel the flash test. This is done, for example, by clearing the "LED flash test" check box, by changing to another group of the online and diagnostics view, or by changing settings in the "Online access" area.

10.2.1.8 Checking PROFIBUS DP subnets for faults

Basic information on the diagnostic repeater

What is the diagnostic repeater?

The diagnostic repeater is a repeater that can monitor a segment of an RS 485 PROFIBUS subnet (copper cable) during operation and signal line errors to the DP master via a diagnostics message frame.

The diagnostic repeater detects, localizes and visualizes line errors during operation at an early stage. As a result, problems in the system are identified early and production downtimes will be minimized.

Function of the diagnostic repeater

The diagnostic repeater can perform line diagnostics on the DP2 and DP3 segments because it has a measuring circuit for these segments.

The line diagnostics run in two steps:

- Step 1: Topology determination
  You start the topology determination by calling the "DP_TOPOL" instruction in your program. The diagnostic repeater then determines the PROFIBUS addresses and the distance of the devices and creates a topology table.
- Step 2: Error localization
  The diagnostic repeater checks the lines during operation. It determines the distance to the point of the error and the reason for the error; it then issues a diagnostics alarm with relative information on the error location.

Display of detailed information on the determined error location

You receive detailed information on the determined error location in the Online and Diagnostics view of the diagnostic repeater.

- By means of icons
- By means of a display with graphics and text

See also

Displaying the status of the segment diagnostics using icons (Page 2076)

Displaying the status of the segment diagnostics using graphics and text (Page 2076)

Displaying the status of the segment diagnostics using icons

Where do I find the information I need?

The icons for the status of the segment diagnostics are available:

- In the expanded "Segment diagnostics" folder in the navigation pane of the Online and Diagnostics view of the relevant diagnostic repeater.

The diagnostics icon associated with the segment will be displayed behind the segment designation. It must be noted here that line errors will be displayed for the DP2 and DP3 segments only. The DP1 and programming device segments do not display errors in the form of a diagnostics icon; rather, they signal only a few bus errors.

Diagnostics icons

The following table shows the available icons and their meaning.

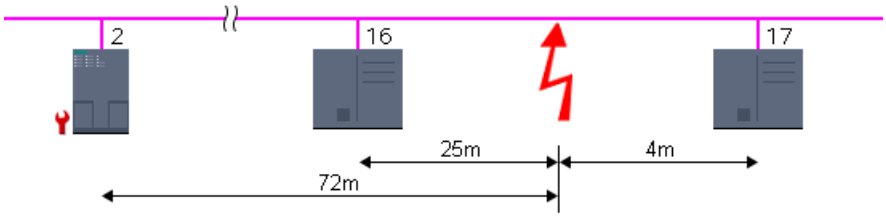
Icon	Meaning
	Segment is error-free
	Segment contains errors
	Segment is deactivated

Displaying the status of the segment diagnostics using graphics and text

Where is the status of the segment diagnostics displayed with graphics and text?

The status of the segment diagnostics will be displayed using graphics and text in the "DP1", "DP2", "DP3", and "PG" groups of the "Segment diagnostics" folder in the Online and Diagnostics view of the relevant diagnostic repeater.

Structure of the "DP1", "DP2" "DP3", and "PG" groups



The "DP1", "DP2", "DP3", and "PG" groups consist of the following elements:

- "Error location" field
- "Error" field
- "Resolution" field
- "Help on event" button
- "Freeze display" or "Cancel freeze" button

"Error location" field

This field displays the error location graphically, provided the diagnostic repeater can determine the location.

The following picture shows an example for a line error occurring in the DP2 segment.

In this example, the diagnostic repeater has the PROFIBUS address 2, and a line error has occurred between the devices with PROFIBUS addresses 16 and 17. This line error is located 25 m from device 16, 4 m from device 17, and 72 m from the diagnostic repeater.

"Error" field

The error is explained in plain text in this field.

"Resolution" field

Here, you will find actions for resolving the error.

"Help on event" button

Click this button to obtain a more detailed explanation of the error and additional details on resolving the error, if applicable.

"Freeze display" or "Cancel freeze" button

The "Freeze display" or "Cancel freeze" button is only enabled when there is an online connection to the diagnostic repeater.

The default setting is "Freeze display".

The following happens when you click the "Freeze display" button:

- The current display of the segment diagnostics is frozen.
- The labeling of the button changes to "Cancel freeze".

If the display is frozen and you click the "Cancel freeze" button, the following happens:

- The display of the segment diagnostics is updated again.
- The labeling of the button changes to "Freeze display".

10.2.2 Connection diagnostics

10.2.2.1 Overview of connection diagnostics

Basics

Connection diagnostics, as described below, refers to the diagnostics of communication connections.

The connection diagnostics is started each time an online connection is established to a module (CPU or CP) that participates in one or more communication services. The connection status is updated automatically in the background.

In the case of one-way connections, an online connection must exist to the communication partner that has established the communication connection.

On connections configured at both ends, a distinction between the following two situations must be made:

- If there is an online connection to only one connection endpoint, only the part of the connection belonging to this connection endpoint can be diagnosed.
- If there is an online connection to both connection endpoints, both parts of the connection (and therefore the entire connection) can be diagnosed.

Basic connections diagnostics options

Connection diagnostics can be performed as follows:

- Using icons on the connection status display
  This display is generated in the connection table.
- Through detailed connection diagnostics
  This step is available in the "Diagnostics > Connection information" area of the Inspector window.

Requirement for the connection diagnostics described below

The connection diagnostics is only possible if the devices participating in the connection make the corresponding diagnostics data available.

You can display the details of either all the communication connections created in the project (default) or selected communication connections in the connection table.

The connection diagnostics described in the following assume that you display the details of selected communication connections. To do this, clear the "Show all connections" option in the shortcut menu.

10.2.2.2 Displaying the connection status using icons

Content of connection table without an online connection

- For a CPU or CP, the connection table lists the communication connections (including properties) configured offline, if an online connection is not established.

Content of connection table with an online connection

After the online connection has been established, the properties of the communication connections listed offline will be expanded to include diagnostics icons for the connection status ("Online status" column).

In addition, entries for all communication connections that exist online only (e.g., connections for the instructions for Open User Communication, programming device and OP connections, connections for web server access) will now be added to the connection table.

For connections that exist online or offline only, the diagnostics icon at the bottom right is combined with a smaller additional comparison status icon.

Diagnostics icons for communication connections

The following table shows the diagnostics icons for communication connections.

Icon	Meaning
	Connection setup
	Connection not setup / is being setup
	Connection not available

Diagnostics icons for the comparison status

The diagnostic icons for communication connections can be combined at the bottom right with additional smaller icons that indicate the result of the online/offline comparison. The following table shows the available comparison icons and their meaning.

Icon	Meaning
	Connection exists online only
	Connection exists offline only

10.2.2.3 Detailed connection diagnostics

Detailed connection diagnostics - overview

Where do I perform detailed connection diagnostics?

To perform detailed connection diagnostics, go to the "Diagnostics > Connection" information of the Inspector window.

How do I open the "Diagnostics > Connection information" area of the Inspector window?

The following options are available for opening the "Connection information" tab of the Inspector window.

- Select the line of the relevant connection in the connection table. Click the "Diagnostics" and "Connection information" tabs one after the other in the Inspector window.
- Double-click the diagnostics icon of the relevant connection in the connection table.
- This step takes you to the programming editor for a S7 communication instruction or open user communication instruction. Double-click the diagnostic icon of the instruction (stethoscope).

Structure or the "Diagnostics > Connection information" area of the Inspector window

Requirements: the content of the "Connection information" tab has been filled, and an online connection to at least one end point of the relevant connection has been established.

If a module has been selected (network view), the tab will contain the following group:

- Connection resources (for S7-1200 and S7-1500)

If a connection has been selected (connection table), it will contain the following groups:

- Connection details
- Address details of the connection (for S7-1200 and S7-1500)

Determining online connection resources for S7-1200 (S7-1200)

Where do you determine the online connection resources?

The online connection resources are obtained in the "Connection resources" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window. It is displayed only if you have selected a module in the network view to which an online connection exists.

Number of connection resources

- Maximum number: Specifies the maximum number of available connection resources of the module.
- Not assigned: Indicates how many connection resources are not yet assigned. If connection resources are already reserved for certain types of communication, then the unreserved connection resources cannot always be used for the various connection types.

Reserved and currently assigned connection resources

For the communication types indicated below, the connection resources that are reserved and currently assigned by the module will be displayed.

Communication type	Meaning
PG communication	Resources for connections between the module and programming devices (for example, for the establishment of a connection from the project tree, for online diagnostics, etc.)
HMI communication	Resources for connections between the module and HMI devices
Open User Communication	Resources for connection of open user communication instructions
S7 communication	Resources for configured S7 connections, through which data can be exchanged by calling instructions in the user program.
Other communication	Specifies other assigned connection resources for which connection resources are not reserved.

Determining online connection resources for S7-1500 (S7-1500)

Where do you determine the online connection resources?

The online connection resources are obtained in the "Connection resources" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window. It is displayed only if you have selected a module in the network view to which an online connection exists.

Description of the detailed display of the connection resources

The detailed display of the connection resources includes:

- Number of available connection resources
- Number of configured connection resources
- Number of connection resources still available

For a description of these, go to here .

Determining connection details

Where do I determine the connection details?

The connection details are obtained in the "Connection details" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window.

When is the "Connection details" group filled in?

The following requirements must be met to fill in the "Connection details" group on the "Connection information" tab:

- An online connection to the end point of the relevant connection must exist.
- You have selected a line in the connection table.

Structure of the "Connection details" group

The "Connection details" group consists of the following elements:

- Local ID (hex)
- Connection type (for S7-1200 and S7-1500)
- Protocol
- Connection status: icon and description
- Details
- Last status change (for S7-300 and S7-400 only)

Determining the address details of a connection (S7-1200, S7-1500)

Where do I determine the address details of a connection?

The address details of a connection are obtained in the "Connection address details" group. This group is located in the "Diagnostics > Connection information" area of the Inspector window.

For which CPUs is the "Connection address details" group available?

The "Connection address details" group of the "Connection information" tab is available for S7-1200 and S7-1500 CPUs.

When is the "Connection address details" group filled in?

The following requirements must be met to fill in the "Connection address details" group on the "Connection information" tab:

- An online connection to the end points of the relevant connection must exist.
- You have selected a line in the connection table.

Structure of the "Connection address details" group

The address details relevant to the connection type are specified for the two communication partners.

Programming the PLC 11

11.1 Programming basics

11.1.1 Operating system and user program

11.1.1.1 Operating system

Function

The operating system is contained in every CPU and organizes all CPU functions and sequences that are not associated with a specific control task.

The tasks of the operating system, for example, include the following:

- Processing a warm restart
- Updating the process image of the inputs and outputs
- Calling the user program
- Detecting interrupts and calling interrupt OBs
- Detecting and handling errors
- Managing memory areas

The operating system is a component of the CPU and is already installed there upon delivery.

See also

User program (Page 2085)

11.1.1.2 User program

Function

The user program contains all functions that are necessary for processing your specific automation task.

The tasks of the user program include:

- Checking the requirements for a (warm) restart using startup OBs, for example, limit switch in correct position or safety relay active.
- Processing process data, e.g. linking binary signals, reading in and evaluating analog values, defining binary signals for output, and outputting analog values

- Reaction to interrupts, for example, diagnostic error interrupt if the limit value of an analog expansion module is overshot.
- Error handling in normal program execution

You write the user program and load it into the CPU.

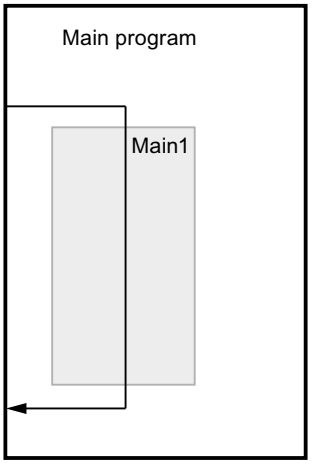
Operating system (Page 2085)



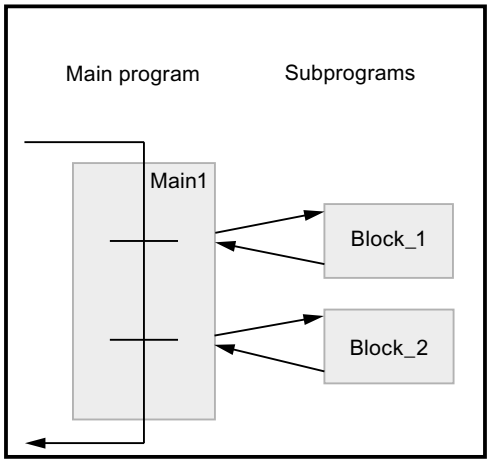
11.1.2 Blocks in the user program

11.1.2.1 Linear and structured programming

Linear programming

Solutions for small automation tasks can be programmed linearly in a program cycle OB. This is only recommended for simple programs.

The following figure shows a linear program schematically: The "Main1" program cycle OB contains the complete user program.



Structured programming

Complex automation tasks can be more easily handled and managed by dividing them into smaller sub-tasks that correspond to the technological functions of the process or that can be reused. These sub-tasks are represented in the user program by blocks. Each block is then an independent section of the user program.

Structuring the program offers the following advantages:

- Extensive programs are easier to program through the structure.
- Individual program sections can be standardized and used repeatedly with changing parameters.
- Program organization is simplified.
- Changes to the program can be made more easily.
- Debugging is simplified since separate sections can be tested.
- Commissioning is simplified.

The following figure shows a structured program schematically: The "Main1" program cycle OB calls subprograms one after the other that execute defined subtasks.

Nesting depth for blocks

The permissible nesting depth for blocks depends on the CPU that is used.

The following table shows the guide values for the maximum nesting depth. For detailed information on the CPU you are using, refer to the technical specifications in the hardware documentation. To call the hardware documentation on the Internet, click the links in the table.

CPU family	Nesting depth (guide value)	Link to hardware documentation
S7-1500	24 blocks per priority class	SIMATIC S7-1500 / ET 200MP Manual Collection (https://support.industry.siemens.com/cs/ww/en/view/86140384)
S7-1200	16 blocks from cycle or startup OB, 6 additional blocks within any interrupt event OB	SIMATIC S7-1200 Automation System (https://support.industry.siemens.com/cs/ww/en/view/91696622)
S7-400	24 blocks per priority class, 1-2 additional blocks within an error OB	SIMATIC S7-400 automation system S7-400 CPU data (https://support.industry.siemens.com/cs/de/en/view/53385241)

CPU family	Nesting depth (guide value)	Link to hardware documentation
S7-300	16 blocks per priority class, 4 additional blocks within an error OB	SIMATIC S7-300 CPU 31xC and CPU 31x: Technical specifications (https://support.industry.siemens.com/cs/de/de/view/12996906/en)
ET 200SP	24 blocks	SIMATIC ET 200SP Manual Collection (https://support.industry.siemens.com/cs/ww/en/view/84133942)

Nesting depth for structures

Structures (STRUCT) and PLC data types (UDT) can be nested to a depth of 8. This nesting depth is independent of the CPU used.

11.1.2.2 Overview of the block types

Block types

Different BLOCK types are available to perform tasks within an automation system. The following table shows the available block types:

Block type	Brief description
Organization blocks (Page 2088) (OB)	Organization blocks define the structure of the user program.
Functions (Page 2089) (FC)	Functions contain program routines for recurring tasks. They have no "memory".
Function blocks (Page 2090) (FB)	Function blocks are code blocks that store their values permanently in instance data blocks, so that they remain available even after the block has been executed.
Instance data blocks (Page 2100)	Instance data blocks are assigned to a function block when it is is called for the purpose of storing program data.
Global data blocks (Page 2091)	Global data blocks are data areas for storing data that can be used by any blocks.

11.1.2.3 Organization blocks (OB)

Definition

Organization blocks (OBs) form the interface between the operating system and the user program. They are called by the operating system and control, for example, the following operations:

- Startup characteristics of the automation system
- Cyclic program processing
- Interrupt-driven program execution
- Error handling

You can program the organization blocks and at the same time determine the behavior of the CPU. Various organization blocks are available to you depending on the CPU used.

For more information on organization blocks, refer to the descriptions of the modes of operation of CPUs in the "Additional information on configurations" chapter in "Configuring Hardware and Networks".

Start information of organization blocks

When certain organization blocks are started, the operating system provides information that can be evaluated in the user program. Refer to the descriptions of the organization blocks to find out which information is provided, if any.

See also

Creating organization blocks (Page 4715)

11.1.2.4 Functions (FCs)

Definition

Functions (FCs) are code blocks without memory. You have no data memory in which values of block parameters can be stored. Therefore, when a function is called, all formal parameters must be assigned actual parameters.
Functions can use global data blocks to store data permanently.

Application

A function contains a program that is executed when the function is called by another code block. Functions can be used, for example, for the following purposes:

- To return function values to the calling block, e.g. for mathematical functions
- To execute technological functions, e.g. individual controls using bit logic operations

A function can also be called several times at different points in a program. As a result, they simplify programming of frequently recurring functions.

Note

Parameter transfer when calling functions

To avoid errors when working with functions, observe the information in chapter "AUTOHOTSPOT".

See also

Creating functions and function blocks (Page 4716)

11.1.2.5 Function blocks (FB)

Definition

Function blocks are code blocks that store their input, output and in-out parameters permanently in instance data blocks, so that they remain available even after the block has been executed. Therefore they are also referred to as blocks "with memory".

Function blocks can also operate with temporary tags. Temporary tags are will not be stored in the instance DB, but are available for one cycle only.

Application

Function blocks contain subroutines that are always executed when a function block is called by another code block. A function block can also be called several times at different points in a program. As a result, they simplify programming of frequently recurring functions.

Instances of function blocks

A call of a function block is referred to as an instance. An instance data block is required for each instance of a function block; it contains instance-specific values for the formal parameters declared in the function block.

The function block can store its instance-specific data in its own instance data block or in the instance data block of the calling block.

Access modes

S7-1200 and S7-1500 offer two different access options for the instance data blocks, which can be assigned to a function block when this is called:

- Data blocks with optimized access
  Data blocks with optimized access have no firmly defined memory structure. The data elements contain only a symbolic name in the declaration, no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed memory structure. The declaration elements contain both a symbolic name in the declaration and a fixed address within the block.

Note

To avoid errors when working with function blocks, refer to the section "AUTOHOTSPOT".

Multi-instances (Page 2112)

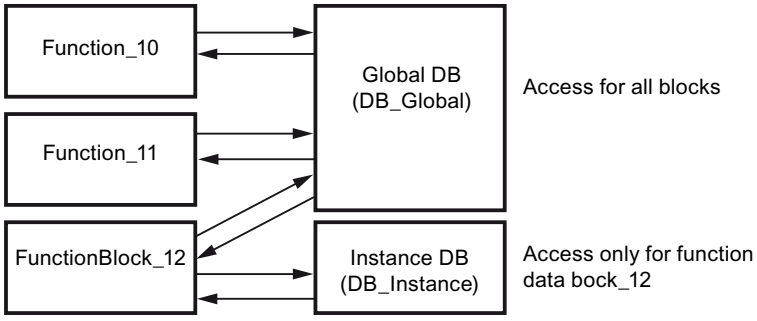
Instance data blocks (Page 2100)

Basics of block access (Page 2102)

11.1.2.6 Global data blocks (DB)

Definition

Data blocks are used to store program data. Data blocks thus contain variable data that is used by the user program. Global data blocks store data that can be used by all other blocks.



The maximum size of data blocks varies depending on the CPU. You can define the structure of global data blocks anyway you please.

You also have the option of using PLC data types (UDT) as a template for creating global data blocks.

Global data blocks in the user program

Every function block, function, or organization block can read the data from a global data block or can itself write data to a global data block. This data remains in the data block even after the data block is exited. A global data block and an instance data block can be open at the same time.

The following figure shows the different accesses to data blocks:

Access modes

S7-1200 and S7-1500 offer two different access options for global data blocks:

- Data blocks with optimized access
  Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block.

Creating data blocks (Page 4798)

Basics of block access (Page 2102)

11.1.2.7 Global ARRAY data blocks (DB)

ARRAY data blocks (S7-1500)

ARRAY data blocks are a particular type of global data block. These consist of an ARRAY of any data type. For example, an ARRAY of a PLC data type (UDT) is possible. The DB contains no other elements besides the ARRAY. Because of their flat structure, ARRAY data blocks facilitate access to the ARRAY elements and their transfer to called blocks.

The "Optimized block access" attribute is always enabled for ARRAY data blocks. ARRAY data blocks with standard access are not possible.

The "Instructions > Basic instructions" task card in the "Move > ARRAY DB" section offers extended options for addressing ARRAY DBs. These instructions give you the option, for example, to address the DB name indirectly:

- ReadFromArrayDB: Read from array data block
- WriteToArrayDB: Write to ARRAY data block
- ReadFromArrayDBL: Read from ARRAY data block in load memory
- WriteToArrayDBL: Write to array data block in load memory

Example of the use of ARRAY data blocks (Page 2092)

Addressing ARRAY DB (Page 2153)

Creating data blocks (Page 4798)

11.1.2.8 Example of the use of ARRAY data blocks

Using an ARRAY data block (S7-1500)

ARRAY data blocks are global data blocks that consist exclusively of an ARRAY. A data block with a tag of the ARRAY data type is sufficient for most applications because access can be programmed intuitively with a tag of the ARRAY data type (for example, #myArray[#index]) and offer a better runtime performance than ARRAY data blocks. In certain scenarios, however, it is necessary to process ARRAYs with different lengths. The ARRAY data block is particularly suitable for these scenarios.

The following example shows how you can use an ARRAY data block.

Programming example

Individual pieces of material are transported on a conveyor belt. These pieces of material pass a scanner which can read out the information that a piece of material carries with it. The information is read out and transmitted to a panel. Because the scanner and the panel have different clock cycles/speeds, the material information must be cached in each case.

In the following programming example, we show you how to program the program code for passing on material information. For this purpose, you use an ARRAY data block.

The example is set up to be flexible, so that you do not have to know at the time the program code is created which ARRAY data block will be read or written or how large it is. You can thus use ARRAYs of different length. Use of data type DB_ANY gives you this flexibility.

The data type VARIANT is used so that you also have flexibility when specifying the value that is to be read or written.

Not until runtime is the ARRAY data block transferred in order to then access the values in the program block. The data type of the ARRAY elements and the data type of the value that is to be read or written are determined.

You can determine the number of objects and the fill level of the ARRAY data block using special instructions.

Procedure

Create the PLC data type "UDT_Queue". This PLC data type is used by both functions ("FC_Enqueue" and "FC_Dequeue"). This is important, for example, for accessing the tag #Queue.Used, as the function "FC_Enqueue" increments the tag by one and the function "FC_Dequeue" decrements the tag by one.

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare the following lines within the PLC data type:
   DB > Data type: DB_ANY
   Size > Data type: DINT
   Used > Data type: DINT
   ReadPos > Data type: DINT
   WritePos > Data type: DINT

UDT_Queue

	Name	Data type	Default value	Comment
1	DB	DB_ANY	0	
2	Size	DInt	0	
3	Used	DInt	0	
4	ReadPos	DInt	0	Pointer Reading Position
5	WritePos	DInt	0	Pointer Writing Position

Program the "FC_Enqueue" function, which writes the values of the material information to an ARRAY data block. The specific ARRAY data block and the data type of the value do not have

to known at this time, because the interfaces are being programmed with the VARIANT and DB_ANY data types.

1. Create an SCL function and name it "FC_Enqueue".
2. Declare the block interface as follows:

FC_Enqueue

	Name	Data type	Comment
1	Input		
2	Value	Variant	
3	Output		
4	InOut		
5	Queue	"UDT_Queue"	
6	DB	DB_ANY	
7	Size	DInt	
8	Used	DInt	
9	ReadPos	DInt	Pointer Reading Position
10	WritePos	DInt	Pointer Writing Position
11	Temp		
12	Error	Int	
13	<Add new>		
14	Constant		
15	Return		
16	FC_Enqueue	Int	

3. Write the following program code:

```
IF #Queue.Used < #Queue.Size THEN // As long as there is enough space in the DB
                                  // the function keeps on writing.

    #Error := WriteToArrayDB(db := #Queue.DB, index := #Queue.WritePos, value := #Value);

    IF #Error = 0 THEN

        #Queue.Used := #Queue.Used + 1;
        #Queue.WritePos := #Queue.WritePos + 1;

        IF #Queue.WritePos >= #Queue.Size THEN // If this condition is fullfilled
                                               // the end of the DB is reached.
                                               // End of writing pointer.

            #Queue.WritePos := 0;

        END_IF;

    END_IF;

ELSE

    #Error := 4711; // The queue is full.

END_IF;
```

With this function, you check whether there is still space free in the data block. If so, write the value that is specified at the parameter value into the data block at the parameter db. With each new item of material information that is written, the tag #Queue.Used and the pointer tag #Queue.WritePos are incremented by one. As soon as the cursor reaches the end of the data block, it is reset to 0. If the data block is full, the error code #4711 is returned.

Program the "FC_Dequeue" function, which reads the material information from an ARRAY data block and writes it to the panel. The specific ARRAY data block and the data type of the value do not have to known at this time, because the interfaces are being programmed with

the VARIANT and DB_ANY data types. The material information can then be displayed on a panel, for example:

1. Create an SCL function and name it "FC_Dequeue".
2. Declare the block interface as follows:

FC_Dequeue

		Name	Data type	Comment
1		Input		
2		Output		
3		InOut		
4		Value	Variant	
5		Queue	"UDT_Queue"	
6		DB	DB_ANY	
7		Size	DInt	
8		Used	DInt	
9		ReadPos	DInt	Pointer Reading Position
10		WritePos	DInt	Pointer Writing Position
11		Temp		
12		Error	Int	
13		Constant		
14		Return		
15		FC_Dequeue	Int	

3. Write the following program code:

```
IF #Queue.Used > 0 THEN // As long as there is some information in the DB
                        // the function keeps on reading.

    #Error := ReadFromArrayDB(db := #Queue.DB, index := #Queue.ReadPos, value => #Value);

    IF #Error = 0 THEN

        #Queue.Used := #Queue.Used - 1;
        #Queue.ReadPos := #Queue.ReadPos + 1;

        IF #Queue.ReadPos >= #Queue.Size THEN // If this condition is fullfilled
                                              // the end of the DB is reached.
                                              // End of reading pointer.

            #Queue.ReadPos := 0;

        END_IF;

    END_IF;

ELSE

    #Error := 4712; // The queue is empty.

END_IF;
```

With this function, you check whether material information is available in the data block. If so, read the value to which the pointer #Queue.ReadPos points, and write it to the tag #Value. With each item of material information that is read, the tag #Queue.Used is decremented by one and the pointer tag #Queue.ReadPos is incremented by one. As soon as the cursor reaches the end of the data block, it is reset to 0. If the data block is empty, the error code #4712 is returned.

To save the material data, create an ARRAY data block. Use the PLC data type "UDT_Material" as the data type of the ARRAY data block.

First, create the PLC data type "UDT_Material". This PLC data type contains a structure for the material information supplied by the scanner.

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare the following lines within the PLC data type:
   ArticleNumber > Data type: DINT
   ArticleName > Data type: STRING
   Amount > Data type: REAL
   Unit > Data type: STRING

UDT_Material

	Name	Data type
1	ArticleNumber	DInt
2	ArticleName	String
3	Amount	Real
4	Unit	String

Create the ARRAY data block "DB_MaterialBuffer". The ARRAY data block is to contain data records with material information of data type "UDT_Material". The material information is written to the ARRAY data block using the "FC_Enqueue" function.

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_MaterialBuffer".
4. Select the type of the data block "ARRAY DB".
5. Select the PLC data type "UDT_Material" as ARRAY data type.
6. Specify "1000" as high ARRAY limit.
7. Click "OK".

DB_MaterialBuffer

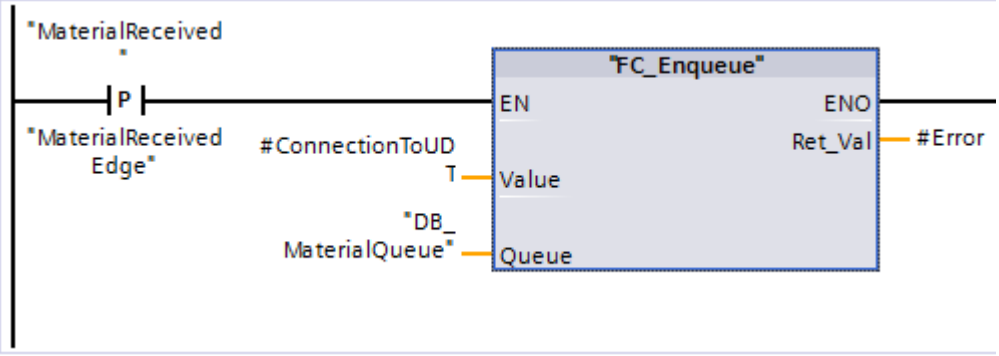
	Name	Data type
1	DB_MaterialBuffer	Array[0..1000] of "UDT_Material"
2	DB_MaterialBuffer[0]	"UDT_Material"
3	ArticleNumber	DInt
4	ArticleName	String
5	Amount	Real
6	Unit	String
7	DB_MaterialBuffer[1]	"UDT_Material"
8	DB_MaterialBuffer[2]	"UDT_Material"
9	DB_MaterialBuffer[3]	"UDT_Material"
10	DB_MaterialBuffer[4]	"UDT_Material"
11	DB_MaterialBuffer[5]	"UDT_Material"

Create the startup organization block (OB) "OB_MaterialQueue". In this organization block, you initialize the tags DB and Size.

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Organization block (OB)" button.
3. Specify the name "OB_MaterialQueue".
4. Select the type "Startup".
5. Select SCL as the language of the organization block.
6. Click "OK".
7. Write the following program code:

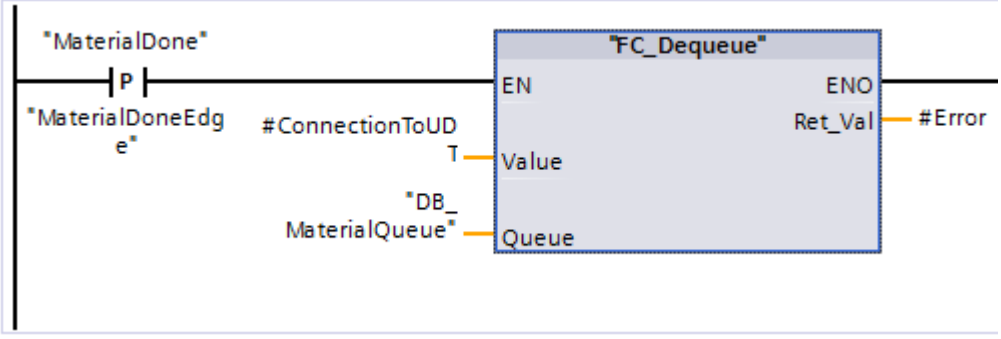
```
1  "DB_MaterialQueue".DB := "DB_MaterialBuffer";
2  "DB_MaterialQueue".Size := 1000;
3  "DB_MaterialQueue".Used := 0;
4  "DB_MaterialQueue".ReadPos := 0;
5  "DB_MaterialQueue".WritePos := 0;
```

   By assigning the data block, you connect the ARRAY data block "DB_MaterialBuffer" with the SCL functions "FC_Enqueue" and "FC_Dequeue". Enter the size of the ARRAY data block at the Size parameter. The start value of the Used parameter is "0". The first item of material information is thus written to the ARRAY element "0".



1. Declare the following tags in the "Default tag table":

	Name	Data type	Address
	MaterialReceived	Bool	%I0.0
	MaterialReceivedEdge	Bool	%M0.0
	MaterialDone	Bool	%I1.0
	MaterialDoneEdge	Bool	%M0.1



2. Call the SCL function "FC_Enqueue" within the function block in which the scanner reads out the material information.
3. Declare the tag "ConnectionToUDT" in the section "Temp" in the block interface and link this tag with the PLC data type "UDT_Material":

Temp	
ConnectionToUDT	"UDT_Material"
ArticleNumber	DInt
ArticleName	String
Amount	Real
Unit	String

4. Link the function call with the following tags and, at the enable input EN, create the signal edge "P: Scan operand for positive signal edge". Link the signal edge with the global tags from the standard tag table:

5. Call the SCL function "FC_Dequeue"
6. Link the function call with the following tags and, at the enable input EN, create the signal edge "P: Scan operand for positive signal edge". Link the signal edge with the global tags from the standard tag table:

Result

As soon as a positive signal edge occurs, material information is written to an ARRAY data block with the help of the instruction "WriteToArrayDB" and sent to the panel with the help of the instruction "ReadFromArrayDB".

Addressing ARRAY DB (Page 2153)

11.1.2.9 Instance data blocks

Definition

The call of a function block is referred to as an instance. The data with which the instance works is stored in an instance data block.

The maximum size of instance data blocks varies depending on the CPU. The tags declared in the function block determine the structure of the instance data block.

Access modes

S7-1200 and S7-1500 offer two different access options for the instance data blocks, which can be assigned to a function block when this is called:

- Data blocks with optimized access
  Data blocks with optimized access have no firmly defined structure. The declaration elements contain only one symbolic name in the declaration, and no fixed address within the block.
- Data blocks with standard access (compatible with S7-300/400)
  Data blocks with standard access have a fixed structure. The declaration elements contain both a symbolic name in the declaration and a fixed address within the block.

11.1.2.10 CPU data blocks

Definition

CPU data blocks are generated by the CPU at runtime. To this purpose, insert the "CREATE_DB" instruction into your user program. You can use the data block that is generated at runtime to save your data.

CPU data blocks are indicated by means of a small CPU icon in the "Program blocks" folder of an available node. You can monitor the values of the variables of a CPU data block in online mode, similar to those of a different data block type.

You cannot create CPU data blocks in your offline project.

Loading CPU data blocks

The CPU data block that the user program has generated by means of the "CREATE_DB" instruction is initially only available on the device in online mode. All CPU data blocks will be included with the other blocks the next time you perform a complete download from the device to the project. The CPU data blocks are marked with a small CPU icon in the process. However, you cannot upload these CPU data blocks to your device again.

Restrictions on CPU data blocks in the project

Once the CPU data blocks have been loaded into your offline project, you can open and view their content. However, note that the CPU data blocks in the project are write-protected. The CPU data blocks in the project are therefore subject to the following restrictions:

- You cannot edit CPU data blocks, or convert these into a different data block type.
- CPU data blocks cannot be assigned a know-how protection.
- You cannot change the programming language of a CPU data block.
- CPU data blocks cannot be compiled or downloaded to a device.

Comparing CPU data blocks

Once the CPU data blocks have been loaded into your offline project, you can run an online/offline comparison for the CPU DBs loaded. The comparison editor provides you with a corresponding overview of the differences. It is possible to synchronize the online and off-line version of CPU data blocks if differences are found, but not by downloading the offline version to the device.

Deleting CPU data blocks

You can delete CPU data blocks both from the project and from the CPU.

See also

Deleting CPU data blocks (Page 4737)

11.1.2.11 Blocks with optimized access

Basics of block access

Introduction

STEP 7 offers data blocks with different access options:

- Data blocks with optimized access (S7-1200/S7-1500)
- Data blocks with standard access (S7-300 / S7-400 / S7-1200 / S7-1500)

Within one program you can combine the two types of blocks.

Data blocks with optimized access

Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block. The elements are saved automatically in the available memory area of the block so that there are no gaps in the memory. This makes for optimal use of the memory capacity.

Tags are identified by their symbolic names in these data blocks. To address the tag, enter its symbolic name. For example, you access the "Fill Level" tag in the "Data" DB as follows:
`"Data".Fill Level`

Blocks with optimized access offers the following advantages:

- You can create data blocks with any structure without paying attention to the physical arrangement of the individual data elements.
- Quick access to the optimized data is always available because the data storage is optimized and managed by the system.
- Access errors, as with indirect addressing or from the HMI, for example, are not possible.
- You can define specific individual tags as retentive.
- Optimized blocks are equipped with a memory reserve by default which lets you expand the interfaces of function blocks or data blocks during operation. You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

Note

The "Optimized block access" attribute is always enabled for the following blocks and cannot be deselected.

- GRAPH blocks
- ARRAY data blocks

Data blocks with standard access

Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block. The address is shown in the "Offset" column.

Tags in these data blocks can be addressed in both symbolic and absolute form.
`"Data".Fill Level`
`DB1.DBW2`

Setting Retentivity for Optimized Access or Standard Access

If you define data as retentive, its values are retained even after a power failure or a network off. A retentive tag is not initialized after the hot restart but retains the value it had prior to the power failure. If a DB tag is defined as retentive, it is stored in the retentive memory area of the data block.

The options for setting the retentivity depend on the access type of the block.

- In data blocks with standard access, you cannot set the retentive behavior of individual tags. The retentivity setting is valid for all tags of the data block.
- In data blocks with optimized access you can define the retentive behavior of individual tags.
  For structured data type tags, the retentivity setting always applies to the entire structure. You cannot make any individual retentivity setting for separate elements within the data type.

Setting Addressing Options for Optimized Access or Standard Access

Blocks with optimized access permit only "type-safe" access. Type-safe access addresses tags by their symbolic name only. This means even changes to the block or the block interface will not result in inconsistencies in the program or access errors.

The following table shows the permitted addressing options for optimized data:

Addressing	Block with standard access	Block with optimized access
Symbolic addressing	x	x
Indexed addressing of ARRAYs		x
Slice access	x	x
Overlapping with AT	x	-
Absolute addressing	x	-
Indirect addressing via ANY	x	-
Indirect addressing via POINTER and VARIANT	x	with symbolic notation only

Creating blocks (Page 4714)

Setting up block access

Introduction

Block access is set up automatically when you create a block:

- Blocks created on CPUs of the S7-1200/1500 product range provide optimized access by means of a default setting.
- New blocks created on CPUs of the S7-300/S7-400 product range provide standard access by means of a default setting.

Access to a block that you copy or migrate to a CPU of a different product range is not converted automatically. However, in certain situations it may be useful to change block access in manual mode, e.g., in order to utilize the full functional scope of the CPU.

In most cases, you will have to recompile and load the program after block access has been converted.

NOTICE
Optimized block access for GRAPH blocks The "Optimized block access" attribute is always enabled for GRAPH blocks in S7-1500 and cannot be deselected.

Procedure

To set the block access, proceed as follows:

1. Open the "Program blocks" folder in the project tree.
2. Right-click on the block whose block access you want to change.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.
4. Click "Attributes" in the area navigation.
5. Enable or disable the "Optimized block access" option.
6. Confirm your entries with "OK".

Restrictions and special features

As a matter of principle, you can only convert block access on CPUs of the S7-1200/1500 product range, as only these support the "optimized" access mode.

The following restrictions or special features apply in this context:

- Instance data blocks
  The block access of instance data blocks is always determined by the assigned function block and cannot be changed in manual mode. If you change the access mode on a function block, you also need to update the assigned instance data blocks. This update procedure adapts the access mode of the instance data block.
- System blocks and know-how protected blocks
  You cannot manually edit the block access for system blocks and know-how protected blocks.
- Organization blocks
  The start information of an OB with standard access is always stored in the first 20 bytes of the "Temp" section in the block interface. By contrast, the start information of an OB with optimized access is always written to the "Input" section. For this reason, the block interface of OBs will also change whenever you convert block access. Additional information is provided in the following sections.

Converting block access from "standard" to "optimized".

A block copied from the CPU of the S7-300/400 product range to a CPU of the S7-1200/1500 product range will initially retain the "standard" access mode. However, you can significantly increase the performance of program execution by using blocks with optimized access, which is why it may be useful to modify the access mode manually.

The blocks are adapted as follows in the course of conversion:

- Function blocks
  All interface parameters are assigned the "Non-retain" retentivity setting.
- Global data blocks
  The retentivity setting that was assigned centrally to the entire data block is transferred to the individual interface parameters. It is now possible to manipulate the retentivity setting of the various parameters.
  However, the following rule will still apply: For structured data type tags, the retentivity setting always applies to the entire structure. You cannot assign separate retentivity settings to the various elements within a structured data type. It therefore follows that you cannot assign individual retentivity settings to the tags of data blocks that are based on PLC data types.
- Organization blocks
  All interface parameters that are stored in the first 20 bytes of the "Temp" section will be deleted. New CPU-specific start information is entered in the "Input" section. Naming conflicts with user-defined interface parameters occurring in the process are resolved by renaming the user-defined interface parameters.

CAUTION

The conversion of the block access has the following consequences:

- Absolute addressing of the interface parameters of the block is no longer possible after conversion of block access to the "optimized mode.
  Example: `#L0.1` is no longer valid.
- Since conversion to the "optimized" block access mode of organization blocks also modifies the OB interface,

you may possibly have to adapt, recompile and load the program again due to these changes.

Converting block access from "optimized" to "standard".

If you want to copy or move a block from the CPU of the S7-300/400 product range to a CPU of the S7-1200/1500 product range, you first need to set the "standard" access mode.

The blocks are adapted as follows in the course of conversion:

- Function blocks and global data blocks.
  You can no longer set a retentivity in the function block. The corresponding setting is made in the instance data block.
  All interface parameters in the instance DB or global DB are assigned the same retentivity setting. The conversion is subject to the following rule:
  - If all interface parameters in the original block were retentive, the entire block will be retentive after conversion.
  - If all interface parameters in the original block were non-retentive, the entire block will be non-retentive after conversion.
  - If the interface parameters in the original block had different retentivity settings, the entire block will be non-retentive after conversion.
- Organization blocks
  All interface parameters stored in the "Input" section will be deleted. New CPU-specific start information is entered in the "Temp" section. This data is written to the first 20 bytes. Naming conflicts with user-defined interface parameters occurring in the process are resolved by renaming the user-defined interface parameters.

CAUTION

The conversion of the block access has the following consequences:

Since a conversion to "standard" block access mode might change the retentivity settings of the interface parameters, you may possibly have to adapt, recompile and load the program again due to these changes.

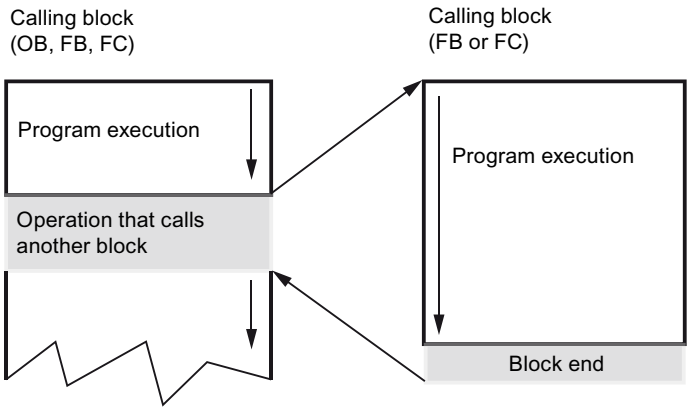
11.1.3 Block calls



11.1.3.1 Principles of block calls

Function of block calls

For your blocks to be executed in the user program, they need to be called from another block.

When one block calls another block, the instructions of the called block are executed. Only when execution of the called block has been completed does execution of the calling block resume. The execution is continued with the instruction that follows on the block call.

The following figure shows the sequence of a block call within a user program:

Parameter transfer

When a block is called, you must assign values to the parameters in the block interface. By providing input parameters you specify the data with which the block is executed. By providing the output parameters you specify where the execution results are saved.

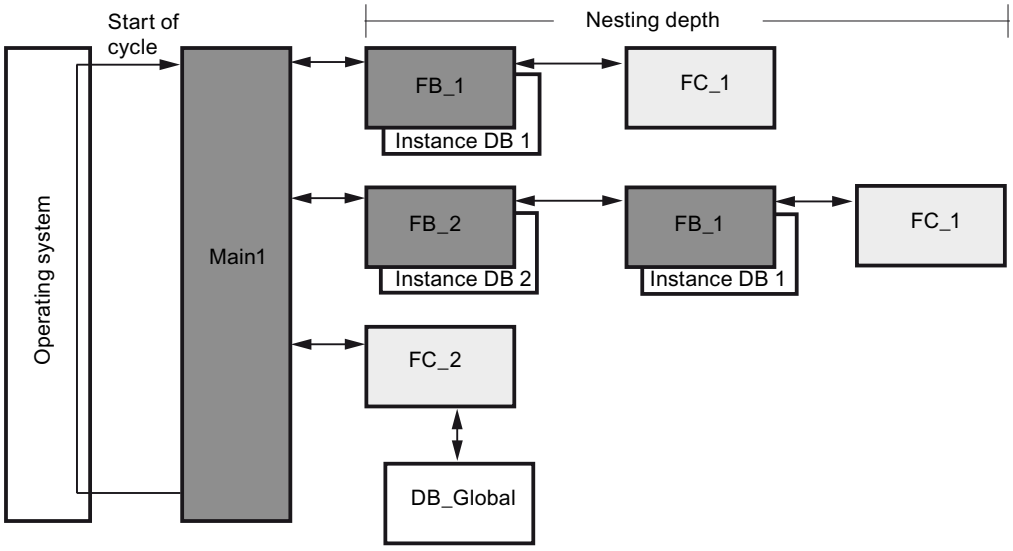
Call hierarchy (Page 2108)



Basics of instances (Page 2110)

11.1.3.2 Call hierarchy

Definition

The order and nesting of block calls is referred to as the call hierarchy.

The following figure shows an example of the order and nesting of block calls within an execution cycle:

Nesting depth for blocks

The permissible nesting depth for blocks depends on the CPU that is used.

The following table shows the guide values for the maximum nesting depth. For detailed information on the CPU you are using, refer to the technical specifications in the hardware documentation. To call the hardware documentation on the Internet, click the links in the table.

CPU family	Nesting depth (guide value)	Link to hardware documentation
S7-1500	24 blocks per priority class	SIMATIC S7-1500 / ET 200MP Manual Collection (https://support.industry.siemens.com/cs/ww/en/view/86140384)
S7-1200	16 blocks from cycle or startup OB, 6 additional blocks within any interrupt event OB	SIMATIC S7-1200 Automation System (https://support.industry.siemens.com/cs/ww/en/view/91696622)
S7-400	24 blocks per priority class, 1-2 additional blocks within an error OB	SIMATIC S7-400 automation system S7-400 CPU data (https://support.industry.siemens.com/cs/de/en/view/53385241)
S7-300	16 blocks per priority class, 4 additional blocks within an error OB	SIMATIC S7-300 CPU 31xC and CPU 31x: Technical specifications (https://support.industry.siemens.com/cs/de/de/view/12996906/en)
ET 200SP	24 blocks	SIMATIC ET 200SP Manual Collection (https://support.industry.siemens.com/cs/ww/en/view/84133942)

Nesting depth for structures

Structures (STRUCT) and PLC data types (UDT) can be nested to a depth of 8. This nesting depth is independent of the CPU used.

Basics of instances (Page 2110)

Principles of block calls (Page 2107)

11.1.3.3 Instances

Basics of instances

Definition

The call of a function block is referred to as an instance. The data with which the instance works is stored in an instance data block.

Instance data blocks have the following properties:

- Instance data blocks are always assigned to an FB.
- The structure of the instance data block is derived from the interface of the corresponding FB and can only be changed there.
- Instance data blocks are created automatically when a function block is called.

Assignment of instances

You have the following options for assigning instance data blocks:

- Single instance:
  The called function block saves its data in an instance data block of its own.
  See also: Single instances (Page 2111)
- Multi-instance:
  The called function block does not save its data in its own instance data block, but in the instance data block of the calling function block.
  See also: Multi-instances (Page 2112)
- Parameter instance:
  You transfer the instance of the block to be called as an in/out parameter to the calling block.
  See also: Parameter instances (Page 2114)

Note

Parameter type "Block_DB" for entry of the instance DB

In LAD and FBD, you cannot enter the instance DB of a function block using an input of the data type "BLOCK_DB". Use a parameter instance instead.

See also

Overview of the block interface (Page 4764)

Addressing instance data (Page 2152)

Principles of block calls (Page 2107)

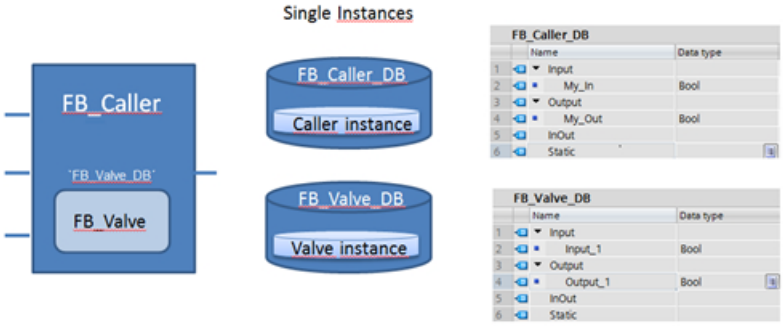
Call hierarchy (Page 2108)

Single instances

Definition

The call of a function block (FB) that is assigned its own instance data block is referred to as a single instance.

By assigning the instance data block, you specify where the instance data of the FB will be saved.



Advantages

The use of single instances provides the following advantages:

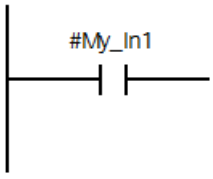
- Reusability of the function blocks
- Good structuring options for simple programs

How single instances work

The following figure shows an FB that uses a further FB ("FB_Valve"). "FB_Valve" is called as a single instance; in other words, it saves its data in its own instance DB.

The structure of the instance data block is defined by the interface of the corresponding FB and can only be changed there. The instance DB contains the following data:

- Block parameters
  The block parameters in the sections Input, Output and InOut form the block interface for the call in the program.
- Static local data
  Static local data in the section Static is used to permanently store intermediate results beyond the current program cycle.



Creating single instances

Instance DBs are created when a function block is called. When you call an FB, a dialog appears in which you can specify whether the FB will be called as a single instance, multi-instance or parameter instance.

Addressing data in single instances

To address a tag from the instance DB of the current block, enter the character # followed by the symbolic tag name:

#<tag name>

See also

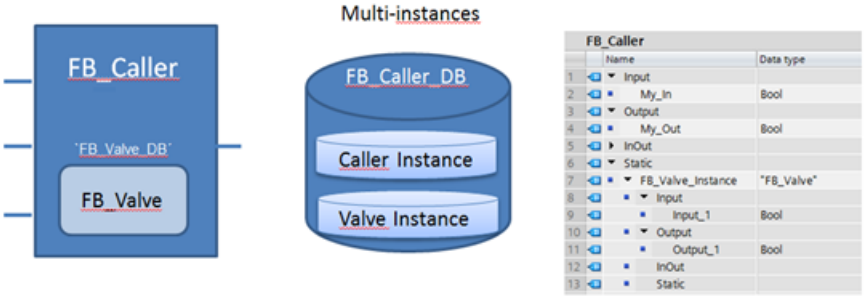
Basics of instances (Page 2110)

Multi-instances (Page 2112)

Multi-instances

Definition

When a function block (FB) calls a further FB, you do not need to create a separate instance DB for the called block. The called FB can also save its instance data in the instance DB of the calling FB. This type of block call is referred to as a multi-instance.



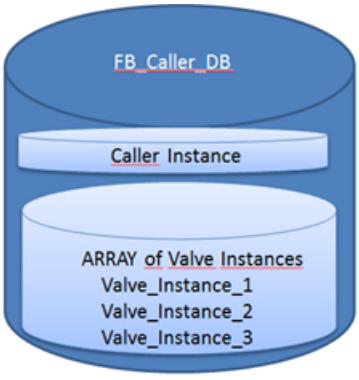
Advantages

The use of multi-instances provides the following advantages:

- Good structuring options for complex blocks
- Lower number of instance DBs
- Simple programming of local sub-programs.

How multi-instances work

The following figure shows an FB that uses a further FB ("FB_Valve"). "FB_Valve" is called as a multi-instance; in other words, it saves its data in the instance DB of the calling FB. Multi-instance data is located in the "Static" section of the calling block.



Creating multi-instances

Multi-instances are defined when a function block is called. When you call an FB, a dialog appears in which you can specify whether the FB will be called as a single instance, multi-instance or parameter instance.

ARRAYs of multi-instances

Multi-instances can also be created as an ARRAY. You can address the individual ARRAY elements via a variable index, e.g. when processing program loops.

You do not declare ARRAYS of multi-instances in the dialog that appears when you call the block, but directly in the block interface.

See also: Declaring multi-instances

Addressing data in multi-instances

Both the calling and the called FB can access the multi-instance data.

Within the called FB, you address the data with the # character followed by the tag name. From the calling block, you access the data with #<multi-instance name>.<tag name>.

Syntax	Meaning
`#<tag name>`	`//Access within the called FB`
`#<multi-instance name>.<tag name>`	`//Access from the calling FB`

See also

Basics of instances (Page 2110)

Single instances (Page 2111)

Example of the use of parameter instances (Page 2117)

Parameter instances

Definition

The parameter instance provides a special option for instantiation:

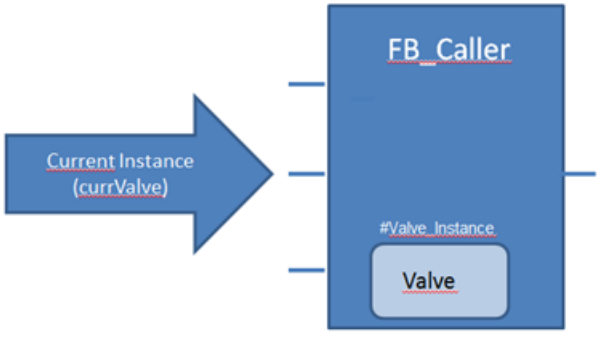
Here, at the time of creating the program, you do not specify a fixed instance for saving the block data. Instead, at runtime, you transfer the instance of the block to be called as an in/out parameter to the calling block.

Advantages

The use of parameter instances provides the following advantages:

- At runtime, you can define which instance is currently being used.
- You can process different instances iteratively in program loops.

Note



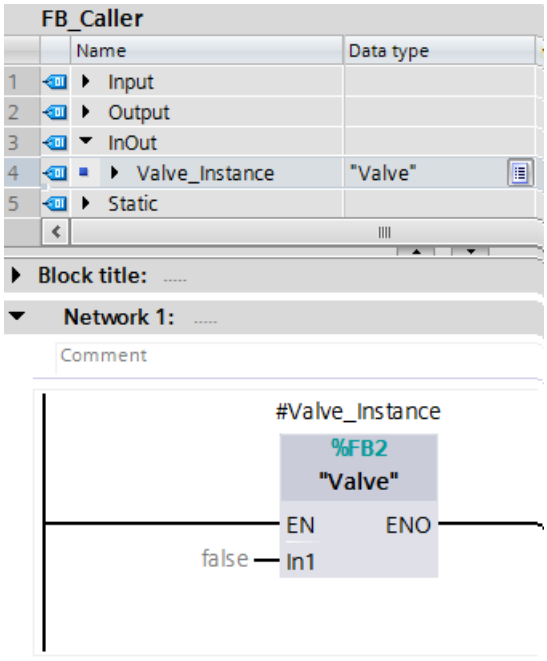
ARRAYs of multi-instances

To simplify the iterative processing of instances in program loops, define an ARRAY of multi-instances.

See also: Multi-instances (Page 2112)

How parameter instances work

The following figure shows the "FB_Caller" that uses a further FB ("Valve"). "Valve" is called as a parameter instance. Therefore, when calling "Valve", do not specify a concrete instance. Instead, define an in/out parameter ("#Valve_Instance") with which the concrete instance is transferred at runtime.

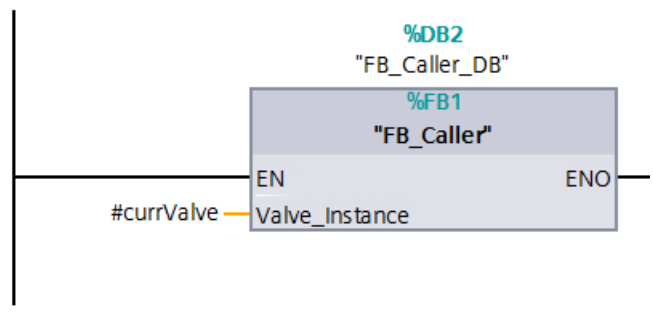


Creating parameter instances

Parameter instances are defined when a function block is called: When you call an FB, a dialog appears in which you can specify whether the FB will be called as a single instance, multi-instance or parameter instance. As an alternative, you also have the option of entering parameter instances manually directly in the block interface.

See also: Declaring parameter instances (Page 4781)

The following figure shows the call of a parameter instance for the FB "Valve":



Transferring the instance as a parameter

Each time the higher-level FB is called ("FB_Caller" in the example) transfer an instance for the called FB (in the example "Valve"). You can transfer the following types of instances:

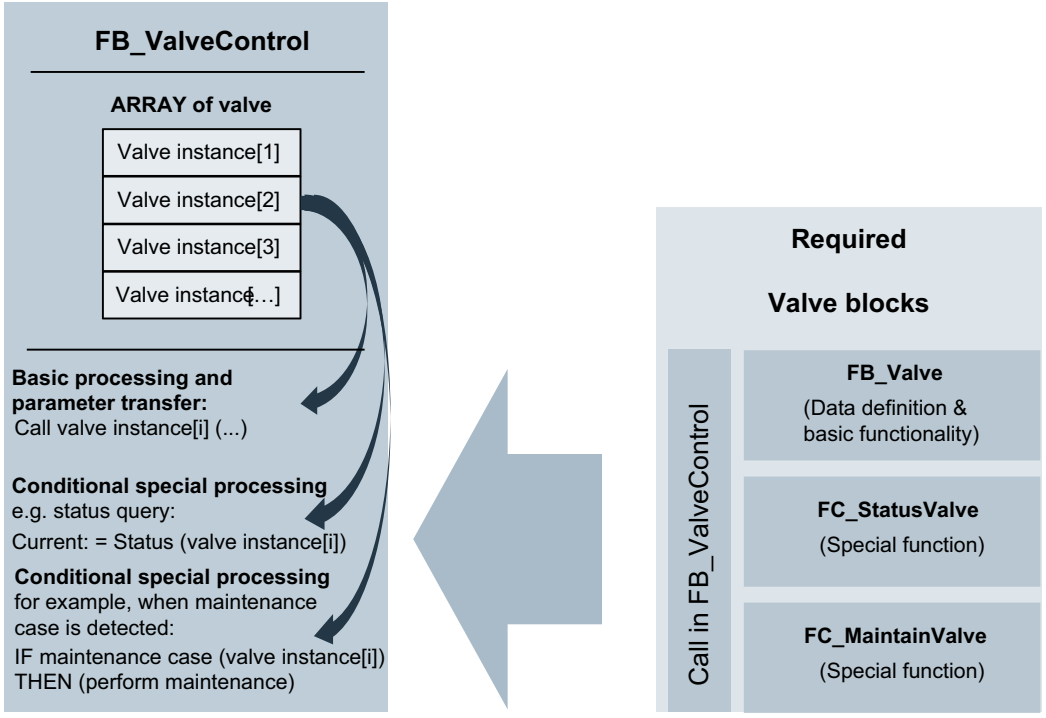
- Single instance
  Transfer an existing instance DB of the called FB (the FB "Valve" in the example).
- Multi-instance
  Transfer an existing multi-instance of the called FB.
- Individual element of an ARRAY of multi-instances
  Transfer an element of an existing ARRAY of multi-instances.

The following figure shows the call of "FB _Caller". With the "Valve_Instance" parameter, the instance "#currValve" is transferred. This instance, which is pending at the #currValve parameter during runtime, is used to call "Valve".

See also

Example of the use of parameter instances (Page 2117)

Example of the use of parameter instances



Description

The use of parameter instances allows you to transfer the instance of a function block to another block (FB or FC) for further processing, for example, a data query or an error analysis, or even have the function block executed with the passed instance.

The ARRAY multi-instances can be used to combine objects of the same type and process their instances indexed in a program loop. Indexed ARRAY elements can also be passed to another block as a parameter instance.

To illustrate this, the object "Valve" (FB_Valve) was selected in the following example. On this basis, you are provided with all required information on valve processing in a program block, "FB_ValveControl" in this case.

The figure below illustrates the features needed and how they can be used:

- The two functions "FC_StatusValve" and "FC_MaintainValve" process a parameter instance of the "FB_Valve" program block which they received in the call.
- In the "FB_ValveControl" program block, you use the ARRAY multi-instances on the one hand to declare the number of existing valves and, on the other hand, to manage all of the valves in a loop by means of various functions.

Note

Completeness

This solution is only an example to illustrate how this task can be approached. Keep in mind that you need to adjust the program code to your actual task.

The following program blocks are required to implement this example:

Block	Description	Programming language
FB_ValveControl	This function block is used as a control block, where you can process all the valves using an ARRAY of multi-instances.	SCL
FB_Valve	This function block contains the definition of the valve data and the program code for processing a valve.	SCL (The three program blocks are used by the "FB_ValveControl" program block.)
FC_StatusValve	The function returns the status of the currently processed valve.	
FC_MaintainValve	This function checks if maintenance is required on the valve. If required, the maintenance is performed and the function value TRUE is returned when everything is completed.	

Procedure: Create "FB_Valve"

To create the SCL function block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog opens.
2. Click on the "Function block (FB)" button.
3. Enter the name "FB_Valve".
4. Select "SCL" as the language.
5. Click "OK".

6. The declaration of the block interface is based on a valve which can open and close, and could look like this, for example:

FB_Valve

		Name	Data type	Comment
1		Input		
2		R_max_A_Valve	Real	Maximum valve performance in mA
3		period_duration_factor	Int	Duration = "period_duration_factor" x 0.1 x configured duration
4		MANUAL_DO	Bool	Check output manually
5		SET_DO	Bool	Set output
6		Output		
7		I_actual_A	Real	Actual valve performance in mA
8		Current_Limit	Bool	Maximum valve performance exceeded (< 4A)
9		InOut		
10		SW_ENABLE	Bool	When this tag has the signal state TRUE, maintenance is required.
11		Static		
12		I_actual_mil	Int	The actual value of the program block "ValveControl", that is queried every millisecond.
13		control_byte	Byte	Control Byte: Bit0=SW_ENABLE; Bit1=MANUAL_DO; Bit2=SET_DO

7. The program code for controlling the valves could look like this, for example:

```
1  #I_actual_mil := #period_duration_factor;
2  #SW_ENABLE := #control_byte.%X4;
```

Procedure: Create "FC_StatusValve"

To create the SCL function "FC_StatusValve", follow these steps:

1. Double-click on the "Add new block" command.
   The "Add new block" dialog opens.
2. Click on the "Function (FC)" button.
3. Enter the name "FC_StatusValve".
4. Select "SCL" as the language.
5. Click "OK".
6. The declaration of the block interface with integration of the parameter instance "FB_Valve" could look like this, for example:

FC_StatusValve

		Name	Data type	Comment
1		Input		
2		Output		
3		InOut		
4		CurrentValve	"FB_Valve"	The function block "FB_Valve" is used as a parameter instance to exchange its data with the "FB_Valve".
5		<Add new>		
6		Temp		
7		Constant		
8		Return		
9		FC_StatusValve	Byte	Return value of the function

7. Write the following program code, for example:

```
1  #FC_StatusValve := #CurrentValve.control_byte;
```

Procedure: Create "FC_MaintainValve"

To create the SCL function "FC_MaintainValve", follow these steps:

1. Double-click on the "Add new block" command.
   The "Add new block" dialog opens.
2. Click on the "Function (FC)" button.
3. Enter the name "FC_MaintainValve".
4. Select "SCL" as the language.
5. Click "OK".
6. The declaration of the block interface with integration of the parameter instance "FB_Valve" could look like this, for example:

FC_MaintainValve

	Name	Data type	Comment
1	Input		
2	NewValue	Int	Specifies a new value for the duration of the current valve.
3	Output		
4	InOut		
5	CurrentValve	"FB_Valve"	The function block "FB_Valve" is used as a parameter instance to exchange its data with the "FB_Valve".
6	Temp		
7	Constant		
8	Return		
9	FC_MaintainValve	Bool	Return value of the function

7. Write the following program code, for example:

```
IF #CurrentValve.SW_ENABLE THEN // Valve control enabled
    // Do some tuning and maintenance
    #CurrentValve.period_duration_factor := #NewValue;
    #CurrentValve.control_byte.%X0 := true;
    #FC_MaintainValve := true;
ELSE
    // Tuning currently not allowed
    #FC_MaintainValve := false;
    ;
END_IF;
```

Procedure: Create "FB_ValveControl"

To create the SCL function block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog opens.
2. Click on the "Function block (FB)" button.
3. Enter the name "FB_ValveControl".
4. Select "SCL" as the language.
5. Click "OK".

6. Define the user constant:

		Name	Data type	Value	Comment
1		vmax	Int	99	Number of the valves

The user constant "vmax" is used in this example in order to easily adapt the program to a different number of valves.

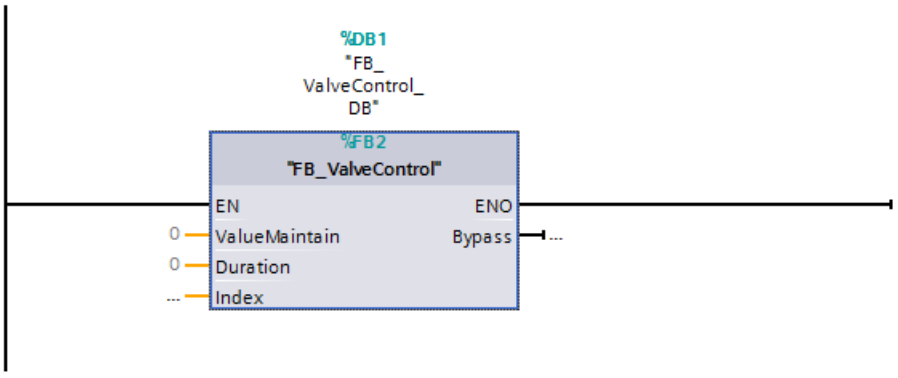
7. The declaration of the block interface with integration of the valve instances from "FB_Valve" could look like this, for example:

FB_ValveControl

		Name	Data type	Comment
1		Input		
2		ValueMaintain	Int	Maintenance
3		Duration	Int	Duration of the valve control
4		Output		
5		Bypass	Bool	True or false
6		InOut		
7		Index	Int	Number index
8		Static		
9		ValveInstances	Array[0.."vmax"] of "FB_Valve"	Multiple instances of the valve
10		ValveStatus	Array[0.."vmax"] of Byte	Status of the valve
11		CurrentAmpere	Real	Current number of amperes

8. Write the following program code, for example:

```
// Set #Index, given from outside, to a value that adresses an existing valve.
#Index := (#Index + 1) MOD ("vmax" + 1);



// Indirect call of a valve that is addressed via an ARRAY index.
#ValveInstances[#Index](R_max_A_Valve := 1.0,
                        period_duration_factor := #Duration,
                        MANUAL_DO := 0,
                        SET_DO := 0,
                        I_actual_A => #CurrentAmpere,
                        Current_Limit => #Bypass);

// Do some checks and tuning on the valve.
// FC_MaintainValve sets some values of the passed valve.
// FC_StatusValve returns the current status that is stored as internal value in the Instance.
IF "FC_MaintainValve"(CurrentValve := #ValveInstances[#Index],
                      NewValue := #ValueMaintain) THEN
    #ValveStatus[#Index] := #ValveStatus[#Index] XOR "FC_StatusValve"(CurrentValve := #ValveInstances[#Index]);
END_IF;
```

Procedure: Call of "FB_ValveControl" in OB 1

To call the "FB_ValveControl" function block in OB 1, follow these steps:

1. Open the "Main [OB1]" block with a double-click.
2. Use a drag-and-drop operation to add the "FB_ValveControl" function block to OB1.

Result

One valve is processed in each program cycle. The respective valve selected by index is processed, its status queried and maintenance is performed, if needed.

In this example, one valve per cycle has been processed. Of course, it is also possible to process all valves in one program loop, but then the cycle time increases accordingly. If you need a short program cycle, we recommend that you avoid working with a program loop.

Multi-instances (Page 2112)

11.1.3.4 Parameter transfer at block call

Rules for supplying block parameters

Block parameters

The calling block gives the called block the values with which it is to work. These values are referred to as block parameters. The input parameters provide the called block with the values that it has to process. The block returns the results via the output parameters.

Block parameters therefore form the interface between the calling and the called block.

You use input parameters when you want to only query or read values, and output parameters when you want to set or write these values. If block parameters are read and written you have to create these as in-out parameters.

The following rules apply to the use of block parameters within the block:

- Input parameters may only be read.
- Output parameters may only be written.
- In/out parameters may be read and written.

Formal and actual parameters

The block parameters are defined in the interface of the called block. These parameters are referred to as formal parameters. They are placeholders for the parameters that are transferred to the block when it is called. The parameters transferred to the block when it is called are referred to as actual parameters.

The data types of actual and formal parameters must be identical or convertible according to the rules of data type conversion.

Note

S7-1200/1500: Transferring peripheral inputs or outputs as block parameters

If you supply an input parameter with a peripheral input or output, it is possible that I/O access errors will occur during runtime when the block is called, e.g. a read error when an input module is accessed directly.

The system response of the CPUs of the S7-1200/1500 series is as follows:

The block is not called as a result of the I/O access error. Program execution is continued after the block call. If OB 122 exists or local error handling is enabled, these are executed.

To prevent the situation that the block is not called as a result of an I/O access error, first copy the peripheral input or output to a local tag (Temp) and transfer it as a block parameter to the called block.

Using tags within the program (Page 2140)

Parameter assignment to function blocks (Page 2126)

Parameter assignment to functions (Page 2123)

Rules for declaring the block interface (Page 4765)

PLC data types (UDT) (Page 2277)

Parameter assignment to functions

Parameters of functions (FC)

Functions have no data memory in which values of block parameters can be stored. Therefore, when a function is called, all formal parameters must be assigned actual parameters.

Input parameters (Input)

Input parameters are only read once before each block call. Therefore, the rule is that writing an input parameter within the block does not affect the actual parameter. Only the formal parameter is written.

Output parameters (Output)

Output parameters are only read once after each block call. Therefore, the rule is that output parameters should not be read within the block. If you nevertheless read an output parameter, please note that only the value of the formal parameter is read. The value of the actual parameter cannot be read within the block.

If an output parameter of a function is not written in this function, the value that is predefined for the specified data type is used. For example, the value "false" is predefined for BOOL. However, structured output parameters are not pre-assigned with a value.

To prevent unintentional further processing of the predefined value or an undefined value, note the following when programming the block:

- Make sure that the output parameters are written with values for all possible program paths within the block. In doing so, note that jump commands may skip instruction sequences in which outputs are set, for example.
- Note that the set and reset commands are dependent on the result of the logic operation. If the value of an output parameter is determined with these commands and RLO = 0, a value will not be generated.
- If possible, assign a default value for the output parameters of functions.

In/out parameters (InOut)

In/out parameters are read before the block call and written after the block call. If you read or write the parameter within the block, you only access its formal parameter.

An exception is in/out parameters with a structured data type. Structured data types consist of several data elements, for example ARRAY or STRUCT. These are transferred to the called block by a pointer. You therefore always access the actual parameter when you read or write a structured in/out parameter within a block.

When an in/out parameter of a function is not written to this function, the old output value or the input value is used as a value. Nevertheless, you should observe the information provided above for output parameters so that old values are not inadvertently processed further.

Temporary local data (Temp)

Temporary local data is only available during block processing. It is treated differently depending on the optimization setting of the block:

- Standard access
  The following rule applies to code blocks with standard access as well as to all tags with retentivity setting "Set in IDB":
  If you are using temporary local data, you must ensure that the values are initialized prior to use. Otherwise, the values will be random. Temporary data of the STRING of WSTRING data type is an exception: It is automatically pre-assigned the actual length 0.
- Optimized access
  The following rules apply to code blocks with optimized access:
  - If a temporary tag is not written within a function, the value that is predefined for the specified data type is used.
    The following table shows some examples of pre-defined values:

Data type	Pre-defined value
Bool	False
Int	0
REAL	0.0
Char	' '
Wchar	WCHAR#' '
DTL	DTL#1970-01-01-00:00:00
DATE_AND_TIME	DT#1990-01-01-00:00:00
Date	D#1990-01-01

  - Elements of the PLC data types are pre-assigned with the default value that is specified in the declaration of the PLC data type (UDT).
  - STRINGs and WSTRINGs are pre-assigned with the actual value "0", even if they are used within a PLC data type.
  - Elements of the data type ARRAY are pre-assigned with the value "0", even if they are used within a PLC data type.

Function value (Return)

Functions normally calculate a function value. This function value can be returned to the calling block via the RET_VAL output parameter. For this, the RET_VAL output parameter must be declared in the interface of the function. RET_VAL is always the first output parameter of a function. All data types are permitted for the RET_VAL parameter except ARRAY and STRUCT, as well as parameter types TIMER and COUNTER.

In the SCL programming language functions can be call directly in an expression. The result of the expression is then formed with the calculated function value. Therefore, the data type ANY is not permitted in SCL for the function value.

Parameter assignment to function blocks

Supplying parameters of function blocks (FB)

In the case of function blocks the parameter values will be stored in the instance data.

If the input, output, or in-out parameters of a function block were not assigned with values, the stored values are used.

In some cases, it is mandatory to specify an actual parameter.

The following table shows which parameters of a function block must be assigned actual parameters:

Parameter	Elementary data type	Structured data type	Parameter type
Input (Input)	optional	optional	required
Output (Output)	optional	optional	required
In-out (InOut)	optional	required	Permitted with S7-1200 only, parameter assignment required
Temporary (Temp)	required S7-1500: Optional with optimized block access	required S7-1500: Optional with optimized block access	required

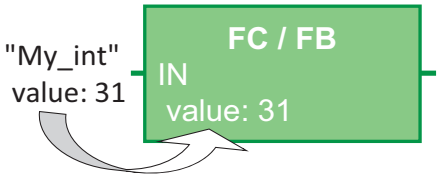
Parameter types (Page 2325)

Transfer parameter as copy or as pointer

Introduction

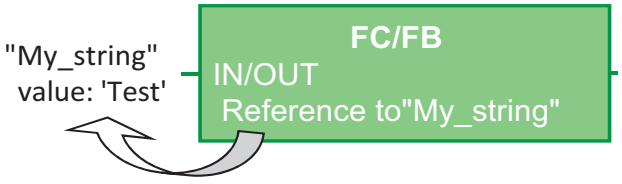


When a block is called, you transfer data to the parameters in the block interface. At the input parameters, you transfer the data with which the block is to work. At the output parameters, you specify where the results of the processing are saved. In/out parameters are used to transfer data to the called block as well as to return results.

Internally, STEP 7 recognizes two different methods of parameter transfer: The data is transferred either as pointer or as copy, depending on the transfer range and data type of the parameter.

Transfer as copy (Call by value)

During a block call, the value of the operand is copied to the input parameter of the called block. With function blocks, the copy is stored in the instance DB; with functions, it is stored in the block stack. Additional storage space is required for the copy.

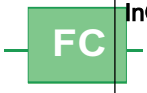


This means that the called block always works with the value that the specified operand had at the time of the block call. It cannot access the operand directly. Write access modifies only the copy, but not the actual value of the specified operand. Read access reads only the copy that was created at the time of the block call.

Transfer as pointer (Call by reference)

The parameters are referenced via a pointer during the block call.

This means that the called block can directly access the memory address of the operand that is specified as parameter: Write access directly results in the changing of the specified operand. Read access reads the value of the operand directly at the time of access. As no copy is created, no additional memory is required.



Note

Declare structured data types in the "InOut" area

If possible, use the "InOut" area in the block interface for structured tags (e.g., of data type ARRAY, STRUCT, STRING, …). Because structured in/out parameters by default are transferred as pointers, the required data memory is not increased unnecessarily.

Parameter transfer with S7-1200/1500

The following table shows how block parameters with elementary or structured data type are transferred in S7-1200/1500. Elementary data types are, for example, BOOL, INT or BYTE. Structured data types are, for example, ARRAY, STRUCT or STRING.

		Elementary data types	Structured data types
	**Input**	Copy	Pointer
	Output	Copy	Pointer
	InOut	Copy	Pointer
	**Input**	Copy	Copy
	Output	Copy	Copy
	InOut	Copy	Pointer

Note

Parameter transfer between blocks with optimized access and blocks with standard access

If structures are transferred to the called block as in/out parameters during a block call, they are transferred by default as pointers (Call by reference).

However, this does not apply if the two blocks have different optimization settings: If one of the blocks has the property "Optimized access" and the other block has the property "Standard access", all parameters are always transferred as copies (Call by value).

If the block contains numerous structured parameters, this can quickly lead to the temporary memory area (local data stack) overflowing.

Problems can also occur if the original operands are changed by asynchronous processes, such as by HMI access or interrupt OBs. If the copies are copied back to the original operands after the block processing, the changes carried out asynchronously since the creation of the copy during the block call are hereby overwritten at the original operands.

You can avoid this by setting the same access type for both blocks or by having the asynchronous access written first to a separate memory area and then copying this area synchronously at a suitable time.

Blocks with optimized access

FAQ 109478253: How can it happen that data of the HMI system or of the Web server is overwritten in the S7-1500? (https://support.industry.siemens.com/cs/de/en/view/109478253)

Parameter transfer with S7-300/400

The following table shows how block parameters with elementary or structured data type are transferred in S7-300/400.

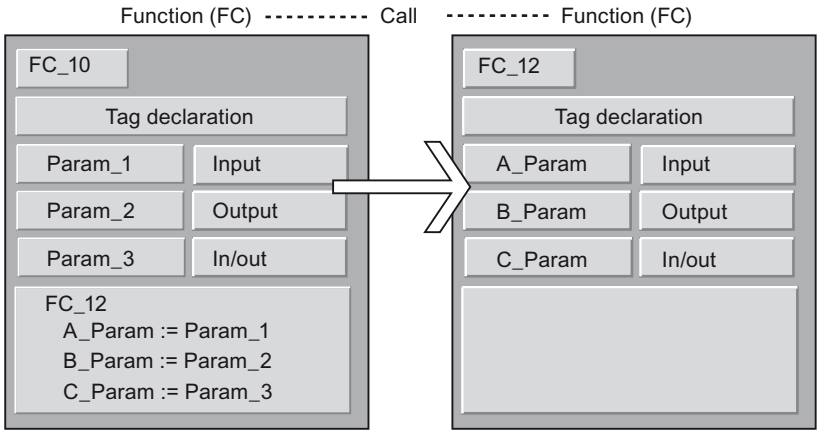
		Elementary data types	Structured data types
FC	Input	Copy*	Pointer
	Output	Copy*	Pointer
	InOut	Copy*	Pointer
FB	Input	Copy	Copy
	Output	Copy	Copy
	InOut	Copy	Pointer

* Exception: Operands from the memory areas I, Q, M, P, L and partly qualified DB addresses (for example, "DW 2") are transferred as pointer.

Note

Special aspects of transfer as pointer in S7-300/400

In cases in which the parameters are transferred via a pointer, it is not possible to forward output parameters or in/out parameters from the calling block to the input parameters of the called block.



Forwarding of block parameters

Basic information on forwarding block parameters

Definition

The "Forwarding" of block parameters is a special type of parameter use. In this case the block parameters of the calling block are forwarded to the parameters of the called block. The called block uses the values that are currently present at the block parameters of the calling block as the actual parameters.

The following figure shows how the parameters of the function FC_10 are forwarded to the function FC_12:

Rules for LAD/FBD

The following general rules apply in LAD and FBD:

- Input parameters can only be forwarded to input parameters.
- Output parameters can only be forwarded to output parameters.
- In/out parameters can be forwarded to all parameter types.
- In S7-300/400, the two block parameters must have the same data type.
- In S7-1200/1500, the parameters can also be converted according to the rules of implicit conversion.

Rules for STL

The following general rules apply in STL:

- Input parameters can only be forwarded to input parameters.
- Output parameters can only be forwarded to output parameters.
- In/out parameters can be forwarded to all parameter types.
- Both block parameters must have the same data type. In STL, this rule applies to all CPU families.

Rules for SCL

The rules for SCL are less stringent. So that programs from previous SCL versions can be taken over more easily, additional parameter transfer options are permissible. You can, for example, forward a structured in/out parameter to an input parameter. However, in this case you must ensure that the actual parameter is not located in the temporary local data or in a global data block.

Additional rules are described in detail in the following chapters.

11.1.4 Using and addressing operands

11.1.4.1 Basic information about operands

Introduction

When you program instructions you must specify which data values the instruction should process. These values are referred to as operands. You can, for example, use the following elements as operands:

- PLC tags
- Constants
- Tags in instance data blocks
- Tags in global data blocks

Absolute address and symbolic name

Operands are identified by means of an absolute address and a symbolic name. You define the names and addresses in the PLC tag table or in the tag declaration of the blocks.

Data blocks with optimized access (S7-1200, S7-1500)

Data elements in data blocks with optimized access only receive a symbolic name and no absolute address in the declaration.

Displaying symbolic and absolute addresses (Page 4696)

Basics of block access (Page 2102)

11.1.4.2 Keywords

SIMATIC recognizes a range of key words whose definitions are fixed and which have a certain meaning in the program. You should not use these keywords as names for tags or constants.

Table of keywords

The following table shows all keywords.

Keywords German mnemonics	Keywords English mnemonics	Description
&	&	And logical operation of logical expressions
A	Q	Output, bit
A1	CC1	Condition code bit
A0	CC0	Condition code bit
AB	QB	Output, byte
AD	QD	Output, double word
AND	AND	And logical operation of logical expressions
ANY	ANY	Data type, pointer
AR1	AR1	Address Register 1
AR2	AR2	Address Register 2
ARRAY	ARRAY	Introduces the specification of an array and is followed by the index list between "[" and "]"
AT	AT	Overlaying tag declaration
AUTHOR	AUTHOR	Name of the author, company name, department name, or other name (max. 8 characters, no spaces)
AW	QW	Output, word
B	B	Byte
BEGIN	BEGIN	Introduces the instruction part for code blocks or initialization part for a data block
BIE	BR	Binary result
BLOCK_FB	BLOCK_FB	Parameter type for specification of an FB
BLOCK_FC	BLOCK_FC	Parameter type for specification of an FC
BLOCK_SDB	BLOCK_SDB	Parameter type for specification of an SDB
BOOL	BOOL	Data type
BY	BY	Increment of the FOR loop
BYTE	BYTE	Data type
CALL	CALL	Call

Keywords German mnemonics	Keywords English mnemonics	Description
CASE	CASE	Introduction to the CASE statement
CHAR	CHAR	Elementary data type
CODE_VERSION1	CODE_VERSION1	Label, whether an FB is multiple instance capable or not. If you want to declare multiple instances, the FB must not have this characteristic.
CONST	CONST	Start of the constant declaration
CONTINUE	CONTINUE	Instruction to exit a loop in SCL
COUNTER	COUNTER	Parameter type for specification of a counter
DATA_BLOCK	DATA_BLOCK	Introduces the data block
DATE	DATE	Data type
DATE_AND_TIME	DATE_AND_TIME	Data type
DB	DB	Data block
DB_ANY	DB_ANY	Data type
DBB	DBB	Data block, data byte
DBD	DBD	Data block, data double word
DBLG	DBLG	Data block length
DBNO	DBNO	Data block number
DBW	DBW	Data block, data word
DBX	DBX	Data block, data bit
DI	DI	Instance data block
DIB	DIB	Instance data block, data byte
DID	DID	Instance data block, data double word
DILG	DILG	Instance data block length
DINO	DINO	Instance data block number
DINT	DINT	Data type
DIW	DIW	Instance data block, data word
DIX	DIX	Instance data block, data bit
DO	DO	Introduction of the instruction part in FOR and WHILE instruction
DT	DT	Data type
DTL	DTL	Data type
DWORD	DWORD	Data type
E	I	Input (via process image), bit
EB	IB	Input (via process image), byte
ED	ID	Input (via process image), double word
ELSE	ELSE	Alternative branch in IF and CASE statement

Keywords German mnemonics	Keywords English mnemonics	Description
ELSIF	ELSIF	Alternative condition of the IF instruction
EN	EN	System operand of the EN/ENO mechanism
ENO	ENO	System operand of the EN/ENO mechanism
END_CASE	END_CASE	End of the CASE statement
END_DATA_BLOCK	END_DATA_BLOCK	Ends the data block
END_FOR	END_FOR	End of the FOR statement
END_FUNCTION	END_FUNCTION	Ends the function
END_FUNCTION_BLOCK	END_FUNCTION_BLOCK	Ends the function block
END_IF	END_IF	End of the IF instruction
END_ORGANIZATION_BLOCK	END_ORGANIZATION_BLOCK	Ends the organization block
END_REGION	END_REGION	End of a block
END_REPEAT	END_REPEAT	End of the REPEAT statement
END_STRUCT	END_STRUCT	Ends the specification of a structure
END_SYSTEM_FUNCTION	END_SYSTEM_FUNCTION	Ends the system function
END_SYSTEM_FUNCTION_BLOCK	END_SYSTEM_FUNCTION_BLOCK	Ends the system function block
END_TYPE	END_TYPE	Ends the PLC data type
END_VAR	END_VAR	Ends a declaration block
END_WHILE	END_WHILE	End of the WHILE instruction
EW	IW	Input (via process image), word
EXIT	EXIT	Instruction to exit a loop in SCL
FALSE	FALSE	Predefined Boolean constant: Logical condition false, value equal to 0
FAMILY	FAMILY	Block family name: e.g. controller
FB	FB	Function block
FC	FC	Function
FOR	FOR	Introduction of the FOR statement
FUNCTION	FUNCTION	Introduces the function
FUNCTION_BLOCK	FUNCTION_BLOCK	Introduces the function block
GOTO	GOTO	Introduction of the GOTO statement
IF	IF	Introduction of the IF instruction
INSTANCE	INSTANCE	Data type
INT	INT	Data type
KNOW_HOW_PROTECT	KNOW_HOW_PROTECT	Block protection
L	L	Local data bit
LB	LB	Local data byte
LD	LD	Local data double word

Keywords German mnemonics	Keywords English mnemonics	Description
LDT	LDT	Data type
LINT	LINT	Data type
LTIME	LTIME	Data type
LTOD	LTOD	Data type
LW	LW	Local data word
LWORD	LWORD	Data type
M	M	Memory bit
MB	MB	Memory byte
MD	MD	Memory double word
MOD	MOD	Modulo operator
MW	MW	Memory word
NAME	NAME	Block name
NETWORK	NETWORK	Network
NOT	NOT	Logic inversion
NULL	NULL	Zero pointer
OB	OB	Organization block
OF	OF	Introduction of the data type specification / Introduction of the instruction part of the CASE statement
OR	OR	Or logical operation of logical expressions
ORGANIZATION_BLOCK	ORGANIZATION_BLOCK	Introduces the organization block
OS	OS	Save overflow
OV	OV	Overflow
PA	PQ	Output (direct peripherals), bit
PAB	PQB	Output (direct peripherals), byte
PAD	PQD	Output (direct peripherals), double word
PAW	PQW	Output (direct peripherals), word
PE	PI	Input (direct peripherals), bit
PEB	PIB	Input (direct peripherals), byte
PED	PID	Input (direct peripherals), double word
PEW	PIW	Input (direct peripherals), word
POINTER	POINTER	Data type
PRAGMA_BEGIN	PRAGMA_BEGIN	Introduction of a Pragma
PRAGMA_END	PRAGMA_END	End of a Pragma
READ_ONLY	READ_ONLY	Write protection for data blocks
REAL	REAL	Data type
REGION	REGION	Introduction of a block
REPEAT	REPEAT	Introduction of the REPEAT statement

Keywords German mnemonics	Keywords English mnemonics	Description
RET_VAL	RET_VAL	Return value
RETURN	RETURN	RETURN statement in SCL
S5T	S5T	Syntax for data type S5TIME
S5TIME	S5TIME	Data type
S7_	S7_	Keywords for system attributes
SDB	SDB	System data block
SFB	SFB	System function block
SFC	SFC	System function
SINT	SINT	Data type
STRING	STRING	Data type
STRUCT	STRUCT	Introduces the specification of a structure and is followed by a list of components
STW	STW	Status word
SYSTEM_FUNCTION	SYSTEM_FUNCTION	System function
SYSTEM_FUNCTION_BLOCK	SYSTEM_FUNCTION_BLOCK	System function block
T	T	Time element (timer)
THEN	THEN	Introduction of the instruction part of an IF instruction
THIS	THIS	Syntax for access to an ARRAY data block
TIME	TIME	Elementary data type for time information
TIME_OF_DAY	TIME_OF_DAY	Data type
TIMER	TIMER	Parameter type for specification of a timer
TITLE	TITLE	Optional block title or network title
TO	TO	Definition of the full-scale value of a FOR statement
TOD	TOD	Data type
TRUE	TRUE	Predefined Boolean constant: Logical condition true, value not equal to 0
TYPE	TYPE	Introduction of the PLC data type
UDT	UDT	Global or PLC data type
UDINT	UDINT	Data type
UINT	UINT	Data type
ULINT	ULINT	Data type
UNLINKED	UNLINKED	Marking 'non runtime-related'
UNTIL	UNTIL	End of the instruction part of a REPEAT statement
USINT	USINT	Data type
UO	UO	Query after (Q1=1) AND (Q0=1)

Keywords German mnemonics	Keywords English mnemonics	Description
VAR	VAR	Introduces a declaration block
VAR_IN_OUT	VAR_IN_OUT	Introduces a declaration block
VAR_INPUT	VAR_INPUT	Introduces a declaration block
VAR_OUTPUT	VAR_OUTPUT	Introduces a declaration block
VAR_TEMP	VAR_TEMP	Introduces a declaration block
VARIANT	VARIANT	Data type
VERSION	VERSION	Version number of the block
VOID	VOID	Function has no return value
WCHAR	WCHAR	Data type
WSTRING	WSTRING	Data type
WHILE	WHILE	Introduction of a WHILE instruction
WORD	WORD	Data type
XOR	XOR	Logic operation
Z	C	Counter

11.1.4.3 Using tags within the program

Definition

A variable is a placeholder for a data value that can be changed in the program. The format of the data value is defined. The use of variables makes your program more flexible. For example, you can assign different values to variables that you have declared in the block interface for each block call. As a result, you can reuse a block you have already programmed for various purposes.

A variable consists of the following elements:

- Name
- Data type
- Absolute address
  - PLC tags and DB tags in blocks with standard access have an absolute address.
  - DB variables in blocks with optimized access have no absolute address.
- Value (optional)

Declaring Variables

You can define variables with different scopes for your program:

- PLC tags that apply in all areas of the CPU
- DB variables in global data block that can be used by all blocks throughout the CPU.
- DB tags in instance data blocks that are predominantly used within the block in which they are declared.

The following table shows the difference between the variable types:

	PLC tags	Variables in instance DBs	Variables in global DBs
Range of application	• Are valid throughout the entire CPU. • Can be used by all blocks on the CPU. • The name is unique within the CPU.	• Are predominantly used in the block in which they are defined. • The name is unique within the instance DB.	• Can be used by all blocks on the CPU. • The name is unique within the global DB.
Permissible characters	• Letters, numbers, special characters • Quotation marks are not permitted. • Reserved keywords are not permitted.	• Letters, numbers, special characters • Reserved keywords are not permitted.	• Letters, numbers, special characters • Reserved keywords are not permitted.
Use	• I/O signals (I, IB, IW, ID, Q, QB, QW, QD) • Bit memory (M, MB, MW, MD)	• Block parameters (input, output and in-out parameters), • Static data of a block	• Static data
Location of definition	PLC tag table	Block interface	Declaration table of the global DB

Note

You can find more information on permissible characters in tag names in the Siemens Industry Online Support in the following entries:

When should identifiers and operands be used in "quotation marks" in STEP 7 (TIA Portal)?

https://support.industry.siemens.com/cs/ww/en/view/109477857 (https://support.industry.siemens.com/cs/ww/en/view/109477857)

11.1.4.4 Constants

Basics of constants

Definition

Constants are data with a fixed value that you cannot change during program runtime. Constants can be read by various program elements during the execution of the program but cannot be overwritten. There are defined notations for the value of a constant, depending on the data type and data format. A distinction is made between the typed and non-typed notation.

Non-typed constants

In the non-typed notation, you only enter the value of the constant without a data type. Non-typed constants do not receive their data type until the first arithmetic or logical operation in which they are used.

The example below shows the non-typed notation:

```
SCL
#My_Int1 := #My_Int2 + 12345        (*The data type of the constant "12345"
                                    results from the addition with My_Int. 2. "12345"
                                    receives the data type INT.*)
#My_Real1 := #My_Real2 + 12345      (*The data type of the constant "12345" results
                                    from the addition with My_Real2. "12345" re-
                                    ceives the data type REAL.*)
```

Typed constants

In the typed notation, you specify a data type in addition to the value of the constant.

The example below shows the typed notation:

```
SCL
#My_Int1 :=  INT#12345                    (*The data type of the constant is always
                                          INT.*)
```

Note

Constants of BOOL type in LAD/FBD

Constants of the BOOL type may not be used as inputs of instructions in S7-300/400.

Constants of the BOOL type may be used as inputs of instructions which are a system-internal function block (FB) in S7-1200/1500. These instructions are identified by the fact that the "Call options" dialog opens when you insert the instruction into a network. Boolean constants may not be used as inputs for all other instructions.

Declaration of symbolic names for constants

Symbolic constants

You have the option of declaring symbolic names for constants and thus making constant values available under a name in the program. This makes a program more readable and easier to maintain when changing constant values.

A symbolic constant consists of the following elements:

- Name
- Data type
  Symbolic constants always have a data type; non-typed notation is not possible for symbolic constants.
- Constant value
  You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

Declaration of constants

You can define constants with different scopes of validity:

- Global constants that apply to all areas of the CPU
- Local constants that only apply within a block

The table below shows the difference between the constant types:

	Global constants	Local constants
Scope of validity	• Are valid throughout the entire CPU • The name is unique within the CPU.	• Are valid only in the block in which they were declared. • The name is unique within the block.
Permitted characters	• The permitted characters in constant names are letters, digits and special characters.	• The permitted characters in constant names are letters, digits and special characters.
Location of definition	"Constants" tab from the PLC tag table	Block interface
Representation	In quotation marks, for example.: `"Glob_Const"`	Prefixed with a number sign, for example: `#Loc_Const`

Name conflicts can occur if you have declared a local and a global constant with the same symbolic name and have used this doubly specified name as the default value of a tag. In this case, the local constant is automatically used.

Note

Downloading constant declarations (S7-300/400)

Local and global constant declarations are not downloaded into the CPU. If you download a program from a device, the constant declarations may no longer be available.

Note

You can find more information on permissible characters in constant names in the Siemens Industry Online Support in the following entries:

When should identifiers and operands be used in "quotation marks" in STEP 7 (TIA Portal)?

https://support.industry.siemens.com/cs/ww/en/view/109477857 (https://support.industry.siemens.com/cs/ww/en/view/109477857)

Declaring the block interface (Page 4771)

Data types of constants

Permitted data types

For constants, all basic data types as well as all derived data types are permitted:

- Binary numbers
- Bit strings
- Integers
- Floating-point numbers
- Timers
- Date and time
- Character strings

All general rules for explicit and implicit type conversion apply.

Data types of non-typed constants

Non-typed constants do not contain an explicit type specification. They do not receive their data type until the first arithmetic or logical operation in which they are used.

The example below shows how non-typed constants are used:

```
SCL
#My_Int1 := #My_Int2 + 12345        (*The data type of the constant "12345"
                                    results from the addition with My_Int. 2. "12345"
                                    receives the data type INT.*)
#My_Real1 := #My_Real2 + 12345      (*The data type of the constant "12345" results
                                    from the addition with My_Real2. "12345" re-
                                    ceives the data type REAL.*)
```

Note

STEP 7 always uses the data type with the highest possible precision

Unless the data type of a constant can be clearly defined in an expression, the data type with the highest precision available on the current CPU is used.

Example:

```
#My_Real := #My_Int / 3.5
```

In this expression an integer tag is combined with a non-typed floating point constant. In S7-300/400 the right part of the assignment is calculated in the REAL format. In S7-1200/1500, calculation is performed using the highest possible precision, which in this case means LREAL. As a result, the assignment to a REAL tag is invalid or generates a warning.

To precisely define the data type of a constant, use the typed notation.

Example:

```
#My_Real := #My_Int / REAL#3.5
```

See also

Overview of the valid data types (Page 2239)

Calculating with constants in SCL (Page 5010)

Declaring global constants (Page 4852)

Declaring the block interface (Page 4771)

Examples of using constants

Use in instructions, assignments and expressions

Constants can be used in place of tags in instructions or assignments. You can also use constants in expressions in SCL. But because constants cannot be written, they may only be used as inputs.

The example below shows possible uses of constants:

```
SCL
#My_Int :=   3;
#My_Real1 := #My_Real2 * 3;
#My_Real1 := #My_Real2 * #My_local_const;
#My_Real1 := #My_Real2 * "My_global_const";
```

Use as a default value

You can use constants as the default value of a tag. To do so, enter either the value or the symbolic name of the constant in the "Default value" column of the block interface. The data type of the constant must match the data type of the tag or be convertible with it according to the implicit conversion with IEC check.

Use as maximum STRING length

You can use local or global constants of data type UINT, UDINT, ULINT, SINT, INT, DINT, LINT as maximum STRING length.

The example below shows the use of constants as maximum STRING length:

```
SCL
STRING[#My_local_const1]
STRING["My_global_const1"]
```

Use as an ARRAY limit

You can use local or global constants of data type UINT, UDINT, ULINT, SINT, INT, DINT, LINT as ARRAY limits.

The example below shows the use of constants as ARRAY limits:

```
SCL
Array[#My_local_const1..#My_local_const2] of REAL
Array["My_global_const1".."My_global_const1"] of REAL
```

Note

Constants as ARRAY limits or as maximum STRING length

- Constants which are used as ARRAY limits or maximum STRING length cannot be changed if the memory reserve of the block is activated. This applies to both local and global constants. To change these constants, you must first disable the memory reserve.
- Changes to global constants result in inconsistencies in the blocks which use them. The inconsistencies are marked in red in the block used. To remedy these inconsistencies, the data blocks have to be updated.

11.1.4.5 Addressing operands

Addressing global variables

Addressing global variables

To address a global PLC variable, you can use the absolute address or the symbolic name.

Note

The LWORD, LINT, ULINT, LREAL, LTIME, LTOD and LDT data types can only be addressed by means of their symbolic name.

Addressing global variables in symbolic form

When you use addressing in symbolic form, you enter the variable name from the PLC tag table. The symbolic name of global variables are automatically enclosed in quotation marks.

You address structured tags that are based on a PLC data type with the symbolic name of the PLC tag. You can also indicate the names of the individual components separated by a dot.

Addressing global variables in absolute form

When you use addressing in absolute form, you enter the address of the variables from the PLC tag table. The absolute address uses numerical addresses starting with zero for each operand range. The address identifier % is set automatically as prefix for the absolute address of global tags.

Examples

The following examples show applications of symbolic and absolute addressing:

Addressing	Explanation
%Q1.0	Absolute address: Output 1.0
%I16.4	Absolute address: Input 16.4
%IW4	Absolute address: Input word 4
"Motor"	Symbolic address "Motor"
"Value"	Symbolic address "Value"
"Structured_Tag"	Symbolic address of a tag that is based on a PLC data type
"Structured_Tag".Component	Symbolic address of the component of a structured tag.

See also

Displaying symbolic and absolute addresses (Page 4696)

Permissible addresses and data types of PLC tags (Page 4840)

Accessing I/O devices (Page 2148)

Accessing I/O devices

Description

The process image of the CPU is updated once in a cycle. In time-critical applications, however, it can be that the current state of a digital input or output has to be read or transferred more often than once per cycle. For this purpose you can use a suffix for I/O access identifiers on the operand to directly access the I/O.

If you want to read the input directly from the peripherals, use the peripheral inputs memory area (PI) instead of the process image input (I). The peripherals memory area can be read as a bit, byte, word, or double word.

If you want to write directly to the output, use the peripheral output (PQ) memory area instead of the process image output (Q). The peripheral output memory area can be written as a bit, byte, word, or double word.

To read or write a signal directly from a peripheral input, you can add the suffix for I/O access ":P", to the operand.

Components of structured PLC tags can also be addressed with ":P". However, access to the higher-level tag with ":P" is not possible.

WARNING

Direct writing of the I/O

Immediate writing to the I/O can lead to hazardous states, for example when writing multiple times to an output in one program cycle.

Note

S7-1200/1500: Transferring peripheral inputs or outputs as block parameters

If you supply an input parameter with a peripheral input or output, it is possible that I/O access errors will occur during runtime when the block is called, e.g. a read error when data of an input module is accessed directly.

The system response of the CPUs of the S7-1200/1500 series is as follows:

The block is not called as a result of the I/O access error. Program execution is continued after the block call. If OB 122 exists or local error handling is enabled, these are executed.

To prevent the situation that the block is not called as a result of an I/O access error, first copy the peripheral input or output to a local tag (Temp) and transfer it as a block parameter to the called block.

Syntax

```
<Operand>:P
```

Example

The following example shows applications of I/O access identifiers:

Addressing	Description
"Motor"	Addresses the "Motor" tag in the process image.
"Motor":P	Addresses the "Motor" tag in the I/O memory area (PI or PQ).
"Structured_Tag".Component	Addresses the component of a structured PLC tag in the process image.
"Structured_Tag".Component:P	Addresses the component of a structured PLC tag in the I/O memory area (PI or PQ).

Addressing global variables (Page 2147)

Addressing variables in data blocks

Addressing variables in global data blocks

Description

Tags in global data blocks can be addressed in symbolic or absolute form. For symbolic addressing, you use the name of the data block and the name of the tag, separated by a dot. The name of the data block is enclosed in quotation marks.

For absolute addressing, you use the number of the data block and the absolute address of the tags in the data block, separated by a dot. The address identifier % is set automatically as prefix for the absolute address.

The S7-1200/1500 provides you with an option of accessing a data block that is not yet known during programming. For this purpose, create a block parameter of data type DB_ANY in the block interface of the accessing block. The data block name or data block number is transferred to this parameter during runtime. In order to access the internal tags of the data block, use the name of the block parameter of data type DB_ANY and the absolute address of the tag, separated by a dot.

Note

Transfer DB with memory reserve to the parameter DB_ANY.

It is not possible to transfer a DB with memory reserve to a block parameter of data type "DB_ANY".

Note

Addressing DB tags in absolute form

Absolute addressing is not possible for the following tags:

- Tags in blocks with optimized access.
- Tags of data type LWORD, LINT, ULINT, LREAL, LTIME, LTOD and LDT.

Best practice is to use the more convenient symbolic addressing for these tags.

ARRAY data blocks

ARRAY data blocks are a particular type of global data block. These consist of an ARRAY of any data type. For example, an ARRAY of a PLC data type (UDT) is possible.

You address elements in ARRAY data blocks with the help of the keyword "THIS". The index is then specified in square brackets. The index can be a constant as well as a tag. Integers with a width of up to 32 bits are permitted as tags for the index.
Extended options for addressing ARRAY DBs are available in the "Move" section of the "Instructions" task card. These instructions give you the option, for example, to also address the DB name indirectly.

Syntax

```
"<DBname>".TagName
%<DBnumber>.absoluteAddress
#<DBAny_name>.%absoluteAddress
"<ArrayDBname".THIS[#i].<Component>.<ComponentElement>
```

SCL:

```
"<ArrayDBname"."THIS"[#i].<Component>.<ComponentElement>
```

The following table show the possible absolute addresses of tags in data blocks:

Data type	Absolute address	Example	Description
BOOL	%DBn.DBXx.y	%DB1.DBX1.0	Data bit 1.0 in DB1
BYTE, CHAR, SINT, USINT	%DBn.DBBy	%DB1.DBB1	Data bit 1 in DB1
WORD, INT, UINT	%DBn. DBWy	%DB1.DBW1	Data word 1 in DB1
DWORD, DINT, UDINT, REAL, TIME	%DBn.DBDy	%DB1.DBD1	Data double word 1 in DB1

Example

The following examples show the addressing of tags in global data blocks:

Addressing	Description
"Motor".Value	Symbolic addressing of the "Value" tag in the "Motor" global data block.
%DB1.DBX1.0	Absolute addressing of the "DBX1.0" tags in the "DB1" global data block.
#MyDBAny.%DBX30.0	Absolute addressing of the "DBX30.0" tag in the global data block that is transferred at runtime at the "MyDBany" parameter.
"MyARRAY_DB".THIS[#MyIndex].MyComponent.MyComponentElement	Addressing an ARRAY data block. The ARRAY index is specified with the "MyIndex" tag. The ARRAY element has two additional substructures: "MyComponent" and "MyComponentElement".

Addressing ARRAY components (Page 2292)

Addressing areas of a tag with slice access (Page 2154)

Basics of indirect addressing (Page 2158)

Addressing instance data (Page 2152)

Addressing instance data

Description

You can address data elements from the interface of the current block. These tags are stored in the instance data block.

Note

Tags in blocks with optimized access can only be addressed in symbolic form.

To address a tag from the interface of the current block, enter the character # followed by the symbolic tag name.

You can also access the tags of a multi-instance block. Within the multi-instance block, also use the character # followed by the tag name to address the data. You access the data of the multi-instance block from the calling block using #<Multi-instanceName.TagName>.

Syntax

Use the following syntax for addressing tags in instance data blocks:

```
#<tag name>
#<multi-instance name>.<tag name>
```

Examples

The following examples show the addressing of tags in instance data blocks:

Addressing	Description
#Value	Addressing the "Value" tag in the instance data block.
#On	Addressing the "On" tag within the multi-instance block
#Multi.On	Addressing the "On" tag of the multi-instance block from the calling block

See also

Addressing variables in global data blocks (Page 2150)

Addressing ARRAY components (Page 2292)

Addressing areas of a tag with slice access (Page 2154)

Basics of indirect addressing (Page 2158)

Addressing ARRAY DB (S7-1500)

Addressing ARRAY data blocks

ARRAY data blocks are a particular form of the ARRAY. ARRAY data blocks are global data blocks that consist of exactly one ARRAY. You address elements in ARRAY data blocks using the following syntax:

```
 "<GlobArrayDBname>".THIS[#i].<elementname>
```

SCL:

```
"<GlobArrayDBname>"."THIS"[#i].<elementname>
```

Examples

The following examples show the addressing of elements in an ARRAY DB:

Addressing in SCL	Explanation
"My_ARRAY_DB"."THIS"[0]	"My_ARRAY_DB" is an ARRAY DB, which contains components of the REAL data type. The first component within "My_ARRAY_DB" is addressed here.
"MY_UDT_ARRAY_DB"."THIS"[3].MyREAL	"MY_UDT_ARRAY_DB" is an ARRAY DB, which contains components of a PLC data type (UDT). The PLC data type contains elements of the BYTE data type. In the "MY_UDT_ARRAY_DB", the fourth ARRAY component and the "MyREAL" element in it are addressed here.

Instructions for addressing ARRAY DBs

The "Instructions > Basic instructions" task card in the "Move > ARRAY DB" section offers extended options for addressing ARRAY DBs. These instructions give you the option, for example, to address the DB name indirectly:

- ReadFromArrayDB: Read from array data block
- WriteToArrayDB: Write to array data block
- ReadFromArrayDBL: Read from array data block in load memory
- WriteToArrayDBL: Write to array data block in load memory

Example of the use of ARRAY data blocks (Page 2092)

Global ARRAY data blocks (DB) (Page 2092)

ARRAY (Page 2286)

Addressing areas of a tag with slice access (S7-1200, S7-1500)

Description

You have the option to specifically address areas within declared tags. You can access areas of the 1-bit, 8-bit, 16-bit, or 32-bit width. The division of a memory area (e.g. BYTE or WORD) into a smaller memory area (e.g. BOOL) is also referred to as a "slice".

Structures, constants and tags overlaying AT cannot be addressed with slice access.

Syntax

The following syntax is used for addressing:

```
<Tag>.X<Bit number>
<Tag>.B<BYTE number>
<Tag>.W<WORD number>
<Tag>.D<DWORD number>
```

The syntax has the following components:

Part	Description
<Tag>	Tag that you access. The tag must be of the "Bit string" or "Integer" data type. With SCL, you can only program slice access to tags of the "Integer" data type when the IEC check is disabled.
X B W D	ID for the access width "Bit (1Bit)" ID for the access width "Byte (8 Bit)" ID for the access width "Word (16 Bit)" ID for access width "DWord (32-bit)"
<BIT number>	Bit number within <tag> that is accessed. Number 0 accesses the least significant BIT.
<BYTE number>	Byte number within <tag> that is accessed. The number 0 accesses the least significant BYTE.
<WORD number>	Word number within <tag> that is accessed. The number 0 accesses the least significant WORD.
<DWORD number>	DWord number within <tag> that is accessed. The number 0 accesses the least significant DWORD.

Examples of slice access

The following examples show the addressing of slices in bit, byte, word and double word modes:

Addressing	Description
"Engine".Motor.X0 "Engine".Motor.X7	"Motor" is a tag of the BYTE, WORD, DWORD or LWORD data type in the global data block "Engine". X0 addresses the bit address 0, X7 the bit address 7 within "Motor".
"Engine".Speed.B0 "Engine".Speed.B1	"Speed" is a tag of the WORD, DWORD or LWORD data type in the global data block "Engine". B0 addresses the byte address 0, B1 the byte address 1 within "Speed".
"Engine".Fuel.W0 "Engine".Fuel.W1	"FUEL" is a tag of the DWORD or LWORD data type in the global data block "Engine". W0 addresses the word address 0, W1 the word address 1 within "Fuel".
"Engine".Data.D0 "Engine".Data.D1	"Data" is a tag of the LWORD data type in the global data block "Engine". D0 addresses the double word address 0, D1 the double word address 1 within "Data".

Programming example

You can find a detailed example in the Siemens Industry Online Support:

https://support.industry.siemens.com/cs/ww/de/view/57374718 (https://support.industry.siemens.com/cs/ww/en/view/57374718)

Overlaying tags with AT

Description

To access data areas within a declared tag, you can overlay the declared tags with an additional declaration. This provides you with the option of addressing an already declared tag with a different data type. You can, for example, address the individual bits of a tag of WORD data type with an ARRAY of BOOL.

Alternatively, you can also use the instructions "SCATTER" and "GATHER" to break down bit sequences into an ARRAY of BOOL or group together individual bits to form a bit sequence. You can find these instructions in the "Basic instructions" task card in the "Move" area.

Rules

The following general rules are valid for tag overlaying:

- Overlaying is possible in S7-1200 and S7-1500 in STL, LAD, FBD and GRAPH.
- SCL supports overlaying in all CPU families.

- Overlaying of tags is possible in the following blocks:
  - In code blocks with standard access
  - In code blocks with optimized access for tags with the retain setting "Set in IDB"
- The data width of the overlaying tag must be equal to or less than that of the overlaid tag.
- It is not possible to overlay tags of the VARIANT and INSTANCE data types.
- Blocks from libraries which are declared as parameters in the interface cannot be overlaid.
- Structured PLC tags that are declared as parameters in the interface cannot be overlaid.
- You cannot address overlaying tags with slice access.

Note

S7-1200/1500: Using AT in FCs

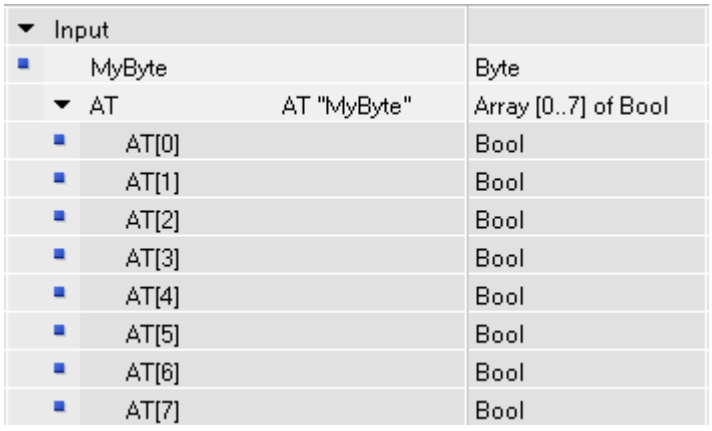
The data widths of the overlaying tag and the overlaid tag must be identical for FCs in S7-1200/1500. If this is not possible in your program, check to see if you can use slice access instead of the AT construct, or use the instructions "SCATTER" or "GATHER".

See also: Addressing areas of a tag with slice access (Page 2154)

The following combination rules are also valid:

		Overlaying tag	Overlaid tag			
Elementary	Structured *	Any/Pointer	DB_ANY			
FB	Input	Elementary	x	x		x
		Structured *	x	x	x	x
		Any/Pointer		x		
	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		
	Static, Output	Elementary	x	x		x
		Structured	x	x		x
		Any/Pointer				
	InOut	Elementary	x			x
		Structured		x		
		Any/Pointer				
FC	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		
	Input, Output, InOut	Elementary (both tags must have the same bit width)	x			x
		Structured		x		
		Any/Pointer				

		Overlaying tag	Overlaid tag			
OB	Temp	Elementary	x	x		
		Structured	x	x	x	
		Any/Pointer		x		



* Structured data types consist of several data elements, e.g. ARRAY or STRUCT.

Declaration

To overlay a tag, declare an additional tag directly after the tag that is to be overlaid and identify it with the keyword "AT".

Example

The following figure shows the declaration of an overlaid tag in the interface of a FB:

When a block is called with the shown tag declaration, the "MyByte" tag is assigned. Within the block there are now two options for interpreting the data:

- as a byte
- As one-dimensional ARRAY of BOOL

Setting retentivity (Page 4809)

Addressing operands indirectly (S7-1200, S7-1500)

Indirect addressing (S7-1200, S7-1500)

Basics of indirect addressing (S7-1200, S7-1500)

Introduction

Indirect addressing offers you the option of addressing operands whose address is not calculated until runtime. With indirect addressing, you can also have program sections run several times and use a different operand during each run. For example, you can use a different index in each run in program loops.

This gives you the following advantages:

- You have more flexibility within your program.
- Indirect addressing is available to you in all STEP 7 programming languages.
- The program code is more straightforward.
- The existing names of data blocks and tags are used (symbolic addressing). This improves readability of the program code.

⚠ WARNING

Risk of access errors

Since operands are only calculated at runtime with indirect addressing, there is a risk that access errors may occur and that the program will operate with incorrect values. In addition, memory areas may inadvertently be overwritten with incorrect values. The automation system can then react in an unexpected manner.

Therefore, indirect addressing should be used with caution.

General indirect addressing options in S7-1200 and S7-1500

The following indirect addressing options are available in all programming languages:

- Indirect addressing via pointer
- Indirect indexing of ARRAY components
- Indirect addressing of a data block via DB_ANY data type.

Language-specific options of indirect addressing

The following specific addressing options are also available in the various programming languages:

- In STL, you can address operands indirectly via the address register.
- In SCL, you can read or write a variable memory area with the following instructions:
  - POKE - Write memory address
  - POKE_BOOL - Write memory bit
  - PEEK - Read memory address
  - PEEK_BOOL - Read memory bit
  - POKE_BLK - Write memory area

Indirect indexing of ARRAY components (Page 2164)

Indirect addressing in STL (Page 2169)

Examples of indirect addressing (S7-1200, S7-1500)

1. Program example

In the example below, you use the index to access three tags from different memory areas.

Overview of the three tags that are assigned to one index each:

Index	Accessing tag	Memory area
1	Input_WORD_0	IW 0
2	"Processdata".Temperature	DB 1
3	Output_WORD_4	QW 4

Declare the following two tags in the "Default tag table":

Default tag table

		Name	Data type	Address
1		Input_WORD_0	Word	%IW0
2		Output_WORD_4	Word	%QW4

Create a global data block:

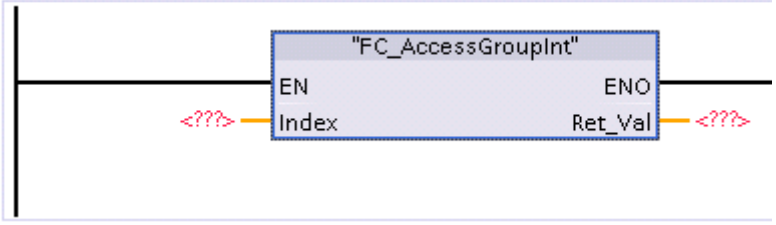
1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_Processdata".
4. Select "Global DB" as the type of the data block.
5. Click "OK".
6. Declare the data block element "Temperature":

DB_Processdata

		Name	Data type	Start value
1		Static		
2		Temperature	DInt	50

Declare indirect access using an index within a function.

1. Create an SCL function and name it "FB_AccessGroupInt".
2. Declare the block interface as follows:



FC_AccessGroupInt

		Name	Data type
1		Input	
2		Index	Int
3		Output	
4		InOut	
5		Temp	
6		Constant	
7		Return	
8		FC_AccessGroupInt	DInt

3. Write the following program code:

```
1
2  CASE #Index OF
3
4      1: // First case: "Input_WORD_0"
5          #FC_AccessGroupInt := "Input_WORD_0";
6      2: // Second case: "DB_Processdata".Temperature
7          #FC_AccessGroupInt := "DB_Processdata".Temperature;
8      3: // Third case: "Output_WORD_4"
9          #FC_AccessGroupInt := "Output_WORD_4";
10
11 END_CASE;
```

4. Call the "FC_AccessGroupInt" function in OB1:

Depending on which number (1, 2 or 3) you specify at the Index parameter, the first, second or third case of the "FC_AccessGroupInt" instruction is executed.

2. Program example

In the example below, you use the index to access three different optimized data blocks.

Since all data blocks should contain the same tags, you can use a PLC data type (UDT) in this case.

1. To create a PLC data type, double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Rename the PLC data type to "UDT_SiloContents".
3. Declare the following lines within the PLC data type:
   MyBool > Data type: BOOL
   MyInt > Data type: INT
   MyWord > Data type: WORD

UDT_SiloContents			
		Name	Data type
1	...	MyBool	Bool
2	...	MyInt	Int
3	...	MyWord	Word

Create three global data blocks.

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the names "DB_SiloWater", "DB_SiloSugar" and "DB_SiloMilk".
4. Select the data blocks "UDT_SiloContents" as the type of the data blocks.
5. Click "OK".

DB_SiloWater

	Name	Data type
1	Static	
2	MyBool	Bool
3	MyInt	Int
4	MyWord	Word

DB_SiloSugar

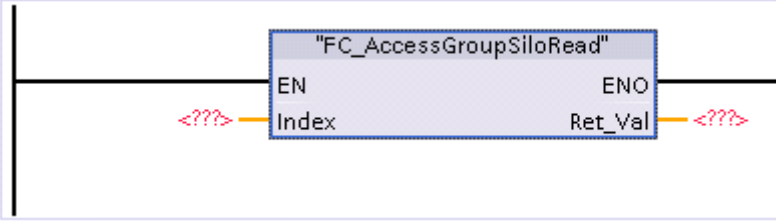
	Name	Data type
1	Static	
2	MyBool	Bool
3	MyInt	Int
4	MyWord	Word

DB_SiloMilk

	Name	Data type
1	Static	
2	MyBool	Bool
3	MyInt	Int
4	MyWord	Word

Create a function to read the values of the data block tags and to write these to a PLC data type.

1. Create an SCL function and name it "FC_AccessGroupSiloRead".
2. Declare the block interface as follows:



FC_AccessGroupSiloRead

		Name	Data type
1		Input	
2		Index	DInt
3		Output	
4		InOut	
5		Temp	
6		Constant	
7		Return	
8		FC_AccessGroupSiloRead	"UDT_SiloContents"

3. Write the following program code:

```
1
2  CASE #Index OF
3
4      1: // First case: "DB_SiloWater"
5          #FC_AccessGroupSiloRead := "DB_SiloWater";
6      2: // Second case: "DB_SiloSugar"
7          #FC_AccessGroupSiloRead := "DB_SiloSugar";
8      3: // Third case: "DB_SiloMilk"
9          #FC_AccessGroupSiloRead := "DB_SiloMilk";
10
11     ELSE // Optional case
12         #FC_AccessGroupSiloRead := "DB_SiloWater";
13
14 END_CASE;
```

4. Call the "FC_AccessGroupSiloRead" function in OB1:

Depending on which number (1, 2 or 3) you specify at the Index parameter, the first, second or third case of the "FC_AccessGroupSiloRead" instruction is executed.

Indirect addressing via pointer (S7-1200, S7-1500)

Description

For indirect addressing, a special data format is required that contains the address and possibly also the range and the data type of an operand. This data format is referred to as pointer. The following types of pointers are available to you:

- POINTER (S7-1500)
- ANY (S7-1500, only for blocks with standard access)
- VARIANT (S7-1200/1500)

For more information on the pointer data types, refer to "See also".

Note

In SCL the use of the POINTER is restricted. The only option available is to forward it to the called block.

Example

The following example shows an indirect addressing with an area-internal pointer:

Addressing in STL	Explanation
L P#10.0	// Load pointer (P#10.0) in accumulator 1
T MD20	// Transfer pointer to the operand MD20
L MW [MD20]	// Load MW10 in accumulator 1
....	// Any program
L MD [MD20]	// Load MD10 in accumulator 1
....	// Any program
= M [MD20]	// If RLO=1, set the memory bit M10.0

The pointer P#10.0 is transferred to the operand MD20. If the operand MD20 in square brackets is programmed, this will be replaced in runtime by the address that is contained in the pointer.

Pointer (Page 2302)

Indirect indexing of ARRAY components (S7-1200, S7-1500)

ARRAY access with variable index

For addressing ARRAY elements, you can specify either constants or tags of the integer data type as index. Integers with a length of up to 32 bits are allowed here.

With indirect addressing using a tag, the index is only calculated during program runtime. You can, for example, use a different index for each cycle in program loops.

Syntax

The following syntax is used for the indirect indexing of a ARRAY:

```
"MyDB".MyArray[#i]   // One-dimensional ARRAY
"MyDB".MyArray[#i].a // One-dimensional ARRAY of STRUCT
"MyDB".MyArray[#i,#j]// Multi-dimensional ARRAY
"MyDB".MyArray[#i].a // Multi-dimensional ARRAY of STRUCT
```

The syntax has the following components:

Part	Description
MyDB	Name of the data block in which the ARRAY is located
MyArray	Tag of the ARRAY data type
i, j	PLC tags of the integer data type that are used as pointers
a	Additional partial tag of the structure

Note

When you call a block and transfer an indirectly indexed ARRAY component ("MyDB".MyArray[#i]) to it as in/out parameter (InOut), you cannot change the value of the index tag [i] while the block is being executed. The value is therefore always written back to the same ARRAY component from which it was read.

Indexing ARRAY components using the "FieldRead" and "FieldWrite" instructions

You may also use the following instructions for indirect indexing of ARRAY components in LAD and FBD:

- FieldWrite - Write field
- FieldRead - Read field

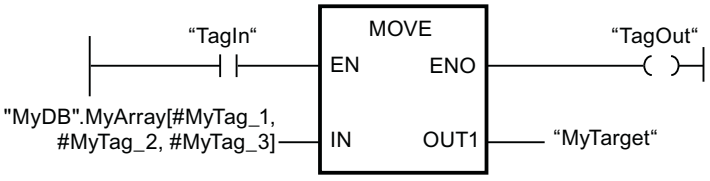
Examples of indirect indexing of ARRAYs (Page 2166)

Indirect addressing of ARRAY components (Page 2215)

Basics of indirect addressing (Page 2158)

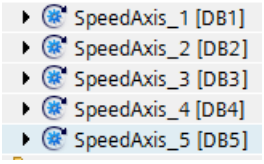


Addressing ARRAY components (Page 2292)

ARRAY (Page 2286)

Examples of indirect indexing of ARRAYs (S7-1200, S7-1500)

Example: ARRAY access with variable index in LAD



The following example shows the indirect indexing of an ARRAY component using LAD as example. "MyArray" is a three-dimensional ARRAY. #Tag_1, #Tag_2 and #Tag_3 are input parameters of the data type "Integer". Depending on their values, one of the MyArray components is copied to the "MyTarget" tag.

Example: ARRAY access with variable index in SCL

The following example shows you how to address multiple data blocks using a variable index. Five speed-controlled axes are used in the example. These axes are to be processed with SCL iteratively in a FOR loop.

1. First you create five speed-controlled axes. All five axes must be of the same type.
   A data block is created for each axis in the project navigator:

2. Next, generate a global data block and declare an ARRAY of the data type ANY with five components.

1		Static	
2		MyArray	Array[0..4] of DB_ANY
3		MyArray[0]	DB_ANY
4		MyArray[1]	DB_ANY
5		MyArray[2]	DB_ANY
6		MyArray[3]	DB_ANY
7		MyArray[4]	DB_ANY

3. For initialization, you assign the symbolic names of the five axes to the individual ARRAY elements in the startup OB.

```
"MyGlobalDB".MyArray[0] := "SpeedAxis_1";
"MyGlobalDB".MyArray[1] := "SpeedAxis_2";
"MyGlobalDB".MyArray[2] := "SpeedAxis_3";
"MyGlobalDB".MyArray[3] := "SpeedAxis_4";
"MyGlobalDB".MyArray[4] := "SpeedAxis_5";

```

4. In SCL, access to the individual axes takes place iteratively with the help of a FOR loop. The axes are transferred to the function "MaximumVelocity" for execution one after the other.

1	Input			☐	☐	☐	☐	
2	Output			☐	☐	☐	☐	
3	InOut			☐	☐	☐	☐	
4	CurrentMaximum	LReal	0.0	☑	☐	☑	☐	
5	Static			☐	☐	☐	☐	
6	Temp			☐	☐	☐	☐	
7	Index	DInt		☐	☐	☐	☐	
8	Constant			☐	☐	☐	☐	

IF... CASE... OF... FOR... TO DO... WHILE... DO... (*...*) REGION

```
FOR #Index := 0 TO 9 BY 1 DO
    #CurrentMaximum := "MaximumVelocity" (CurrentAxis:="MyGlobalDB".MyArray[#Index]);
END_FOR;

```

Example: ARRAY access with variable index in STL

An application example for ARRAY access with variable index in STL is available under "Addressing ARRAY elements indirectly". (Page 2215)

Addressing ARRAY components (Page 2292)

ARRAY (Page 2286)

Indirect addressing of individual characters of a STRING (S7-1200, S7-1500)

Description

For addressing the individual characters of a STRING or WSTRING, you can specify constants and also tags as the index. The tags must be of the Integer data type. When tags are used, the index is calculated during runtime. You can, for example, use a different index for each cycle in program loops.

If you transfer a STRING or WSTRING with variable index to an in/out parameter during a block call, please note that: The index tag [i] is read once at the start of the block call and cannot be changed by the called block while it is being executed.

Note

Monitoring STRING access in runtime

When a STRING or WSTRING that exceeds the defined length is written in runtime, unwanted reactions may occur in the program. Violation of the STRING or WSTRING length is monitored in S7-1200/1500. On read access to the STRING, you receive the character '$00' or '$0000'; write access to the STRING is not executed. If the instruction has the enable output ENO, ENO is set to the signal state FALSE. The CPU does not change to STOP.

Syntax

The following syntax is used for the indirect indexing of a STRING or WSTRING:

```
"<Data block>".<STRING>["i"]
"<Data block>".<WSTRING>["i"]
```

Example

The example below shows indirect indexing of a STRING using SCL as an example. "STRING", "WSTRING", "CHAR" and "WCHAR" are tags. "Tag_1" is a PLC tag of the "Integer" data type.

Addressing in SCL	Description
`STRING["Tag_1"] := CHAR;`	`(*Indirect addressing: Assignment of "CHAR" to the character of the STRING*) specified by "Tag_1"`
`WSTRING["Tag_1"] := WCHAR;`	`(*Indirect addressing: Assignment of "WCHAR" to the character of the WSTRING*) specified by "Tag_1"`
`WCHAR := WSTRING["Tag_1"];`	`(*Indirect addressing: Assignment of the WSTRING character specified by "Tag_1" to WCHAR*)`

WSTRING (Page 2273)

Indirect addressing in STL (S7-1500)

Basic information about address registers (S7-1500)

Introduction

Two address registers are available for the indirect addressing of operands: address register 1 (AR1), and address register 2 (AR2). The address registers are equal and are 32 bits in length. You can store area-internal and cross-area pointers in the address registers. To define the address of an operand, you can call the stored data in the program.

Data is exchanged between the registers and the other available memory areas with the assistance of load and transfer instructions.

Note

In S7-1500, special rules apply to data exchange via address register and data block register:

- The values in the registers do not remain in existence beyond the block limits.
- The registers are reset when the language is changed within a block.
- You can only reference data in blocks with optimized access if these have the retain setting "Set in IDB".
- It is not possible to reference local data in blocks with optimized access with the help of the address registers (across areas).

Indirect addressing in STL (Page 2169)

Addressing areas of a tag with slice access (Page 2154)

Setting retentivity (Page 4809)

Indirect addressing in STL (S7-1500)

In STL, the following options are available for indirect addressing:

- Memory-indirect addressing
- Register-indirect area-internal addressing
- Register-indirect cross-area addressing

Memory-indirect addressing

In the case of memory-indirect addressing, you store the address in a tag. The tag can be of WORD or DWORD data type. The tag can be located in the memory areas "Data" (DB or DI), "Bit memory" (M) or "Temporary local data" (L). In S7-1500, FB parameters can also be used to store the address. If the tag is located in a data block, it must be a data black with standard access.

The following example shows applications of memory-indirect addressing:

Addressing in STL	Explanation
`U E [MD 2]`	`// Execute an AND logic operation with a variable input bit. The address of the input bit is located in the memory double word MD2.`
`= DIX [DBD 2]`	`// Assign the RLO to a variable data bit. The address of the data bit is located in the data double word DBD2.`
`L EB [DID 4]`	`// Load a variable input byte to ACCU 1. The address of the input byte is located in the instance double word DID4.`
`AUF DB [LW 2]`	`// Open a variable data block. The number of the data block is located in the local data word LW2.`

Register-indirect area-internal addressing

Register-indirect addressing uses one of the address registers (AR1 or AR2) to pick up the address of the operand.

In the case of register-indirect, area-internal addressing, you index only the bit address and the byte address via the address register (e.g. `P#10.0`). You do not enter the memory area for which the address in the address register is to apply until during programming of the instruction. The address in the address register then moves to the memory area specified in the instruction.

Possible memory areas are "Inputs" (I), "Outputs" (Q), "I/O" (PI or PQ), "Bit memory" (M), "Temporary local data" (L) and "Data" (DB or DI). If the operand is located in a data block, it must be a data black with standard access.

When you enter register-indirect, area-internal addressing, specify an offset after the specification of the address register. This offset is added to the contents of the address register without changing the address register. This offset also has the format of a pointer. The specification of a pointer is mandatory and must be entered as constant (e.g. `P#0.0` or `P#2.0`).

The following example shows an application of register-indirect area-internal addressing:

STL	Explanation
`LAR1 P#10.0`	`// Load pointer (P#10.0) to address register 1`
`L IW [AR1, P#2.0]`	`// Increase contents of address register 1 (P#10.0) by offset P#2.0.`
	`// Load contents of input word IW12 into accumulator 1`
`L IW [AR1, P#0.0]`	`// Increase contents of address register 1 (P#10.0) by offset P#0.0.`
	`// Load contents of input word IW10 into accumulator 1`

Register-indirect cross-area addressing

In the case of register-indirect, cross-area addressing, use the address register to index the entire address of the operand, in other words, the bit address and byte address, as well as the memory area. Possible memory areas are "Inputs" (I), "Outputs" (Q), "I/O" (P), "Bit memory" (M), "Temporary local data" (L) and "Data" (DB or DI). If the operand is located in a data block, it must be a data black with standard access or the operand must have the retain setting "Set in IDB".

In the instruction, program only the operand width. Possible operand widths are bit, byte, word, and double word.

The following example shows an application of register-indirect cross-area addressing:

```
LAR1 P#M10.0          // Load cross-area pointer (P#M10.0) to address register 1
L W [AR1, P#2.0]      // Increase contents of address register 1 (P#M10.0) by offset
                      P#2.0.
                      // Load contents of memory word "MW12" into accumulator 1
LAR1 P#A10.0          // Load cross-area pointer (P#A10.0) to address register 1
L W [AR1, P#2.0]      // Add contents of address register 1 (P#A10.0) by offset P#2.0
                      // Load contents of output word QW12.0 into accumulator 1
```

Note

Special features in S7-1500

In S7-1500, special rules apply to data exchange via address register and data block register:

- The values in the registers do not remain in existence beyond the block limits. The registers are also reset when the language is changed within a block.
- If you access an operand of the BYTE, WORD or DWORD type using register-indirect addressing, the address must begin at a byte limit.
  Examples:
  LAR1 P#0.0
  L MW [AR1, P#0.0] // P#0.0 + P#0.0 = P#0.0 - The addressing is allowed, because P#0.0 points to a byte limit.
  L MW [AR1, P#2.1] // P#0.0 + P#2.1 = P#2.1 - The addressing is not allowed, because P#2.1 does not point to a byte limit.

11.1.5 Handling program execution errors

11.1.5.1 Causes of error

Introduction

There are different causes for various error qualities in TIA Portal to which you can respond with different mechanisms. These mechanisms with which you can react to an error are independent of the programming languages. Only the display of the individual mechanisms depends on the respective programming language.

The situation determines what counts as an error. The overflow in the case of an addition, for example, can be an error because it does not return the desired result. In some cases, however, the addition overflow is acceptable and defined behavior and therefore not an error.

When creating a program code, you must be aware that certain situations may arise. When you program communication, for example, you must be aware that this connection can be canceled at any time. To be prepared for this situation, you must install a corresponding fault reaction because any connection abort prevents the T_SEND program block from transmitting a message. This is why it is important that the connection abort is signaled to inform the operator that the message can no longer be transmitted. Because the instruction T_SEND cannot prevent the connection abort, the error output is the correct behavior for T_SEND. Ignoring this output can be interpreted as an error made by the programmer.

Below, we will always refer to an error even if it is defined behavior.

Different causes for an error

We can distinguish between the following causes for an error:

	Faulty parameter values	Faulty programming	Failure of resources
Description	Errors that are dealt with directly in the instruction.	Programming or access errors that result in the execution of an instruction being aborted.	Errors that are handled by the operating system and for which you can program a reaction in the program code.
Error quality	Handled error	Synchronous error	Asynchronous error
Example	Overflow of an arithmetic instruction	Faulty programming: • Querying a non-existent peripheral input • When accessing an ARRAY by means of a variable index, the value of the index is located outside the valid ARRAY limits	Occurrence of a specific event outside the program code.

	Faulty parameter values	Faulty programming	Failure of resources
Reaction of the program or operating system	Instructions that are linked with the enable output ENO are not executed.	If you have not programmed an error OB, the operating system response depends on the CPU.	1. If an organization block (OB) is not assigned to the event, the operating system executes the default system response when the event occurs. 2. If an organization block (OB) is assigned to the event, it is called.
Mechanisms for error handling in the program	Depending on the instruction, you have different local error handling options [2]: • EN/ENO mechanism • The output parameters: – RET_VAL – STATUS – ERROR	Global error handling [1]: • Program execution error OB • Programming error OB • I/O access error OB Local error handling [2] with the instructions: • GET_ERROR • GET_ERR_ID	Error organization blocks (OB): • Time error (OB 80) • Diagnostic interrupt (OB 82) • Insert/remove module interrupt (OB 83) • Rack error (OB 86) Possible system responses without assigned error OB: • The event is ignored by the operating system. • The CPU changes to STOP mode. • If possible, the error handling takes place locally. If an error OB has been assigned, it will be called in case of a corresponding event. An application example for diagnostics in the user program With evaluation of the errors in the error OBs (https://support.industry.siemens.com/cs/document/98210758?lc=en-WW)

[1] You implement global error handling with the help of organization blocks.

[2] You program local error handling within your program code.

Note

Asynchronous error handling

For a CPU of the S7-1500 series, the error OBs are called asynchronously. This means I/O access errors or programming error OBs may not be processed immediately when the error occurs, but delayed depending on the set priority. If additional errors occur before the I/O access error or the programming error OB was processed completely, no additional I/O access error or programming error OB is called. If you want to prevent I/O access or programming error OBs from being discarded, set the priority correspondingly high.

See also

Example of how to handle program execution errors (Page 2203)

11.1.5.2 Overview of mechanisms for error handling

Overview

There are different mechanisms by which you can track parameter, programming or access errors:

Mechanism	Task	Error handling
Enable input EN or IF instruction	Prevent execution of a program code	Local
Enable output ENO or binary result bit	Indicate an error	
Parameter outputs RET_VAL, STATUS and ERROR		
GET_ERROR and GET_ERR_ID instructions	Respond to an error	
Organization blocks		Global

Local error handling in the case of faulty parameter values

Not only does local error handling let you react to an error immediately after it has occurred, you can also get a specific reaction within your program code. You program the local error handling directly in a program block (OB, FB or FC). It only handles errors that occur within this individual program block.

Advantages of local error handling:

- You can use the error information to program a reaction to the error that occurred in the program block.
- Programmed error evaluation and error reactions do not interrupt the program cycle.
- System performance is not unnecessarily affected by local error handling. If no errors occur, programmed error analyses and reactions are not executed.

The following local error handling options are available:

Error handling method	Validity	Explanation
EN/ENO mechanism [1]	S7-300 / S7-400 / S7-1200 / S7-1500	You can detect and handle specific runtime errors with the help of the enable output ENO. Execution of subsequent instructions depends on the signal state of the enable output. You can avoid program crashes by using the EN/ENO mechanism. The block status is passed on in the form of a Boolean tag. For additional information on the EN/ENO mechanism, refer to: Basics of the EN/ENO mechanism (Page 2177)
Output parameters STATUS and ERROR	S7-300 / S7-400 / S7-1200 / S7-1500	Using the STATUS and ERROR parameters as return values of system function blocks (SFBs), you can query block-specific error information. The error information is output in a pre-defined structure. For further information on the output parameters, refer to the descriptions of the individual instructions in the information system.
Output parameter RET_VAL	S7-300 / S7-400 / S7-1200 / S7-1500	You can display general error codes or specific error codes with the help of the output parameter RET_VAL as return value of sequential functions (SFCs). The general error codes refer to any instruction and the specific error codes refer only to a specific instruction. A maximum of one tag of the data type INT or WORD can be output. Additional information on the output parameter RET_VAL is available here: Evaluating errors with output parameter RET_VAL (Page 2198)
[1] If the parameters of an instruction did not cause any memory access errors, the associated enable output ENO returns the signal state "1" and the outputs return valid values which you can query.		

Global and local error handling in the case of faulty programming

With the global and local error handling, you can react immediately to errors that have occurred without the CPU changing to "STOP" mode. The following options are available for handling programming and access errors:

Type of global error handling	Validity	Explanation
Program execution error OB (OB 85)	S7-300 / S7-400	If you are not using OB 85, the CPU changes from RUN mode to STOP mode in case of a program execution error and generates an entry in the diagnostics buffer. Additional information on OB 85 can be found here: AUTOHOTSPOT
CPU internal error handling in case of programming and access errors	S7-1200	In the event of an error, the CPU generates an entry in the diagnostics buffer and remains in RUN mode without additional programming effort.
Programming error OB (OB 121)	S7-300/ S7-400 / S7-1500	If you are not using OB 121, the CPU changes from RUN mode to STOP mode in the case of a programming error and generates an entry in the diagnostics buffer. Additional information on OB 121 can be found here: S7-300 / S7-400: AUTOHOTSPOT S7-1500: AUTOHOTSPOT

Type of global error handling	Validity	Explanation
I/O access error OB (OB 122)	S7-300/ S7-400 / S7-1500	S7-300 / S7-400: If you are not using OB 122, the CPU changes from RUN mode to STOP mode in the case of an access error. AUTOHOTSPOT S7-1500: In the case of an I/O access error, the CPU always remains in RUN mode and generates an entry in the diagnostics buffer, even if you have not used OB 122. Additional information on OB 122 can be found here: AUTOHOTSPOT
Additional information on reading out the diagnostics buffer can be found here:AUTOHOTSPOT		

You can integrate local error handling directly in your program code with the help of the GET_ERROR and GET_ERR_ID instructions. You also have the option of receiving detailed information on the error and evaluating it in your program close to the error location. You program the local error handling directly in a program block (OB, FB or FC). It only handles errors that occur within this individual program block.

Type of local error handling	Validity	Explanation
GET_ERROR and GET_ERR_ID instructions	S7-1200/ S7-1500	The instructions give you the opportunity to obtain an error ID or detailed error information and to program a direct response in the program code. When information about the first error is queried, the memory space of the error in the system memory is enabled again. Then, when additional errors occur, information about the next error is output. Additional information on the GET_ERROR and GET_ERR_ID instructions and an overview for prioritizing the errors that occur is available here: Use of the instructions GET_ERROR and GET_ERR_ID (Page 2202)

When using local error handling, query via the GET_ERROR instruction, the following default reactions exist:

- In the case of a write error: The error is ignored and processing of the program continues.
- In the case of a read error: Processing of the program continues with the substitute value "0" for arithmetic instructions.
- In the case of an execution error: Processing of the instruction is canceled and processing of the program continues with the next instruction.

Advantages of local error handling:

- Error information that you can query and evaluate is stored in the system memory (e. g. with the help of the GET_ERROR and GET_ERR_ID instructions).
- You can use the error information to program a reaction to the error that occurred in the program block.
- Programmed error evaluation and error reactions do not interrupt the program cycle.

- Local error handling has a lower effect than global error handling on the system performance. If no errors occur, programmed error analyses and reactions are not executed.
- If local error handling has been set for a program block, no global error handling is conducted in the case of errors.

Note

To prevent the CPU from switching to STOP mode in the case of an error, all programming and I/O access errors must be captured either by global or local error handling.

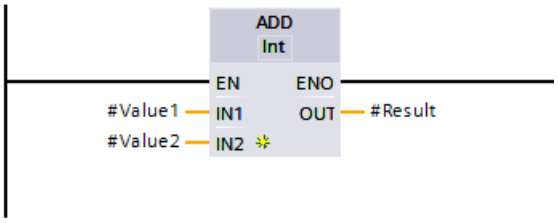
Example

A detailed example of local error handling that contains several of the above described options is available here: AUTOHOTSPOT

See also

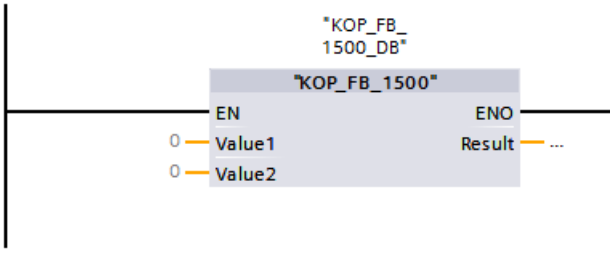
Example of how to handle program execution errors (Page 2203)

11.1.5.3 EN/ENO mechanism



Basics of the EN/ENO mechanism

Introduction



You can detect and handle certain runtime errors using the enable output ENO. Execution of subsequent instructions depends on the signal state of the enable output. You can avoid program crashes by using the EN/ENO mechanism. The block status is passed on in the form of a Boolean tag.

The EN/ENO mechanism can be used at two levels:

- For individual instructions (instruction ENO)

- For program block calls (block ENO)

The EN/ENO mechanism is already available in LAD and FBD for calling the simple and advanced instructions in the program code.

With the EN/ENO mechanism you can influence the calling of the following instructions and customize the jumping out from a program block using the instruction "RET: Return". At the same time you can also assign an individual value (0 or 1) to the enable output ENO of the program block. This behavior is generally used for LAD and FBD program blocks. You can also use this procedure for SCL program blocks. You do not necessarily have to use the instruction "RET" to influence the enable output ENO of the SCL program block.

At the network borders the enable output is repeatedly set to the signal state "1". In a LAD program block you can recognize this, for example, by the fact that the left busbar always supplies current, even when the enable output ENO of the last instruction of the previous network returns the signal state "0".

Function of the instruction "RET: Return" (LAD/FBD)

When the result of logic operation = 0 the instruction is not executed and the next network is processed.

When the result of logic operation = 1 the instruction is executed and a return to the calling program block takes place.

The signal state of the block ENO can be determined with four options:

- RLO: RLO = 1 is applied, i.e. the block ENO is set to TRUE.
- TRUE: The block ENO is set to TRUE.
- FALSE: The block ENO is set to FALSE.
- Operand: The signal state of the specified operand determines the block ENO.

Programming and I/O access errors

You cannot evaluate programming and I/O access errors with the EN/ENO mechanism. To do this, use either the global error handling via OBs or the local error handling using the "GET_ERROR" or "GET_ERR_ID" instructions (S7-1200/1500 only). If none of the errors occurred for an instruction, you can evaluate the associated enable output ENO.

Program block calls in all programming languages (S7-300/400)

The following applies to a CPU of the S7-300/400 series: When you call program blocks that do not include any instructions, neither the BR bit nor the ENO enable output are influenced. The signal state of the BR bit remains constant as a result. No statement can be made about the success of the program block call.

EN/ENO mechanism is LAD

Overview of the EN/ENO mechanism in LAD

To increase the performance, the EN/ENO mechanism is disabled by default for the instructions. It can be enabled at any time also for individual instructions. For additional information on the enabling and disabling of the EN/ENO mechanism, refer to: Enabling and disabling the EN/ENO mechanism in LAD and FBD (Page 2180)

For LAD/FBD program block the EN/ENO mechanism only works with an activated enable output ENO at the respective instructions.

EN/ENO mechanism within an instruction.

You can use the enable input EN to make the execution of the instruction dependent on conditions. The instruction is only executed if the signal state at the enable input EN is "1".

You can use the enable output ENO to query runtime errors in an instruction and react to these:

- The enable output ENO has the signal state "1" if no error occurred during the execution.
- Enable output ENO has the signal state "0" if one of the following conditions applies:
  - Enable input EN has the signal state "0".
  - An error occurred during processing.

EN/ENO mechanism with program block calls

All program block calls are provided with an enable input EN and an enable output ENO. This applies to all calling program blocks, regardless of the programming language in which they were created. This means that when you call an STL or SCL program block in which there is no default and pre-configured EN/ENO mechanism, the LAD or FBD program block call still has an EN/ENO mechanism.

You can use the enable input EN to call a program block depending on conditions. The program block is only executed if the signal state at the enable input EN is "1".

You can query the error status of the program block using the enable output ENO:

- The enable output ENO returns the signal state "1" when the program block is processed.
- If, in the case of error, you do not explicitly set the enable output ENO within the called program block to the signal state "0", it retains the signal state "1". Using the instruction "RET: Return" you can set the block ENO to the signal state "0".
  Additional information on using the RET instruction is available here: Influencing the block ENO of an LAD/FBD program block (Page 2181)

Enabling and disabling the EN/ENO mechanism in LAD and FBD

In LAD and FBD, certain instructions have an enable output ENO and thus use the EN/ENO mechanism. This allows you to query runtime errors in instructions and react to them. In order to increase the performance of the CPU, the EN/ENO mechanism is disabled in the default setting. This means that you are not initially able to react to runtime errors of the instruction using the ENO value. However, you can enable the EN/ENO mechanism again at any time, if required.

You can enable the EN/ENO mechanism individually for each instruction in order to generate the ENO. If you enable the EN/ENO mechanism for an instruction, other instructions that you subsequently add to your program are also inserted with the EN/ENO mechanism enabled. You can disable the EN/ENO mechanism again at any time if you do not want to use the evaluation of ENO for an instruction. Further instructions that you subsequently add to your program will then be inserted without the EN/ENO mechanism.

Runtime errors do not cause the CPU to go to STOP when the enable output ENO is enabled.

Activating the EN/ENO mechanism

Proceed as follows to activate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to activate the EN/ENO mechanism.
2. Select the "Generate ENO" command from the shortcut menu.
   The ENO value is again generated for the instruction. Additional instructions are then also inserted with the activated enable output.

Deactivating the EN/ENO mechanism

Proceed as follows to deactivate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to deactivate the EN/ENO mechanism.
2. Select the "Do not generate ENO" command from the shortcut menu.
   The ENO value is no longer generated for the instruction. Additional instructions are then also inserted without the activated enable output.

Basics of the EN/ENO mechanism (Page 2177)

Influencing the block ENO of an LAD/FBD program block

Description

Using the instruction "RET: Return" you jump out from a program block and hereby influence the signal state of the ENO block.

Procedure

To influence the signal state of the block ENO, follow these steps:

1. Enable the EN/ENO mechanism of an instruction (for example, the addition "ADD").
2. Then use a negation to program the instruction "RET: Return" with signal state FALSE at the enable output ENO.

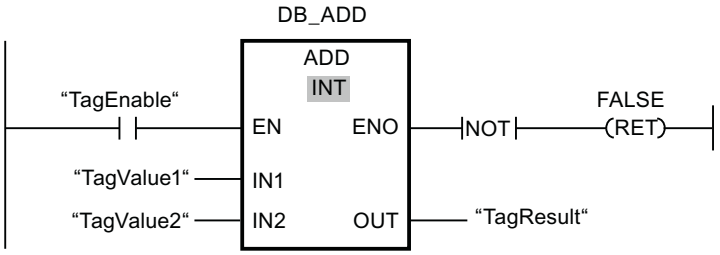
Result

In case of error (for example, an overflow in the result), the signal state "0" is first returned at the enable output ENO. This signal state "0" becomes signal state "1" using the negation and thus forms the RLO = 1 for executing the instruction "RET", which returns the value FALSE. The block ENO of the program block is hereby FALSE and a return takes place from the program block to the next instruction after the previous program block call. This procedure can be programmed in each network (for example, with multiple mathematical functions etc.).

However, it is not compulsory to program a jump out of the program block. Within a network you can also use the signal state "0" of the enable output ENO of a single instruction to determine that the subsequent instruction is not executed. The block ENO is not hereby influenced.

Note

Influencing of the block ENO



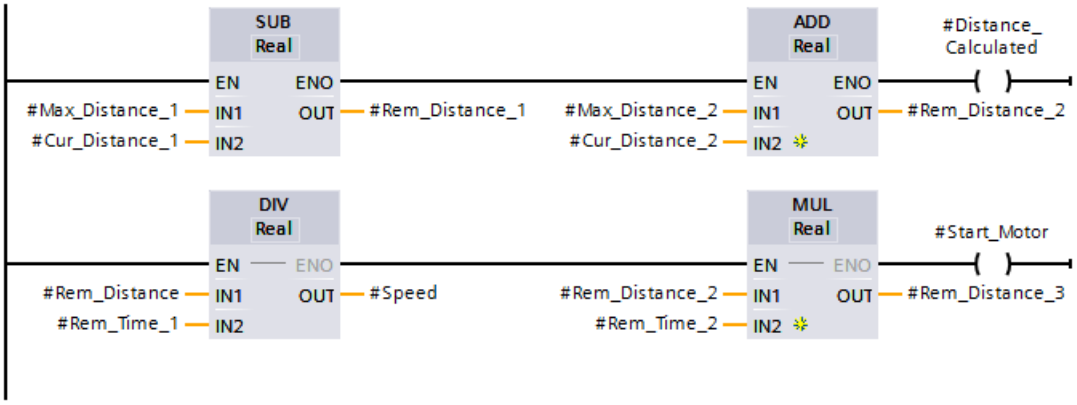
You can only influence the signal state of the block ENO by jumping out of the program block.

Even if the enable output ENO of the last instruction in the last network within a program block has the signal state "0", the block ENO is not influenced.

Example of the use of the EN/ENO mechanism in LAD

Example of an instruction with EN/ENO mechanism

The following example shows the "Add" instruction with EN/ENO circuit and a RET coil (Ret False):



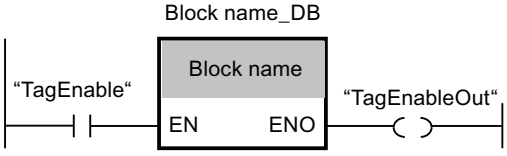
After the NO contact "TagEnable", the enable input EN contains the result of the preceding logic operation:

- If the operand "TagEnable" has the signal state "0", the "Add" instruction is not executed. The enable output ENO is set to signal state "0" and the called program block is exited. The enable output ENO of the calling program block then also has the signal state "0".
- If the operand "TagEnable" has the signal state "1", the enable input "EN has the signal state "1" and the instruction "Add" is executed. The instruction adds two values of the data type INT. If the expected result is outside the value range of INT (16 bits: -32768 to +32767), the instruction still returns a result but it is within the value range of INT. The reason for this is that the 16th bit for INT is the sign bit. This result does not indicate that there was an overflow. Which is why the following applies in case of an addition => ENO:= NOT(OV). If an error occurs during processing of the program block, the enable output ENO is set to signal state "0" and the called program block is exited. The enable output ENO of the calling program block then also has the signal state "0".
- If the operand "TagEnable" has the signal state "1", the enable input "EN has the signal state "1" and the instruction "Add" is executed. If the instruction is executed without errors, the enable output ENO also has the signal state "1" and the output "TagResult" the result.

A detailed description of the instruction "RET: Return" is available here: --(RET): Return (Page 2827)

Example of the effect of the enable output ENO

The following example shows you how to use instructions with the ENO enable output enabled and disabled:



If you have activated the ENO enable output, for example with the SUB instruction, all subsequent instructions are also applied with an activated ENO enable output. If an arithmetic error occurs during the execution of the SUB instruction, the ADD instruction is not executed.

The ENO enable output is disabled for the DIV instruction in the second branch. If a runtime error occurs during execution, the MUL instruction is executed anyway.

Example of a program block call with EN/ENO mechanism

The following example shows the call of the program block with EN/ENO circuit:

The program block is executed only if the operand "TagEnable" has the signal state "1":

- The enable output ENO has a signal state that depends on what was programmed within the program block.
- If the operand "TagEnable" has the signal state "0", the program block call is not executed. The enable input EN and the enable output ENO both have the signal state "0".

EN-/ENO mechanism in LAD

Overview of the EN/ENO mechanism in LAD

To increase the performance, the EN/ENO mechanism is disabled by default for the instructions. It can be enabled at any time also for individual instructions. For additional information on the enabling and disabling of the EN/ENO mechanism, refer to: Enabling and disabling the EN/ENO mechanism in LAD and FBD (Page 2185)

For LAD/FBD program block the EN/ENO mechanism only works with an activated enable output ENO at the respective instructions.

EN/ENO mechanism within an instruction.

You can use the enable input EN to make the execution of the instruction dependent on conditions. The instruction is only executed if the signal state at the enable input EN is "1".

You can use the enable output ENO to query runtime errors in an instruction and react to these:

- The enable output ENO has the signal state "1" if no error occurred during the execution.
- Enable output ENO has the signal state "0" if one of the following conditions applies:
  - Enable input EN has the signal state "0".
  - An error occurred during processing.

EN/ENO mechanism with program block calls

All program block calls are provided with an enable input EN and an enable output ENO. This applies to all calling program blocks, regardless of the programming language in which they were created. This means that when you call an STL or SCL program block in which there is no default and pre-configured EN/ENO mechanism, the LAD or FBD program block call still has an EN/ENO mechanism.

You can use the enable input EN to call a program block depending on conditions. The program block is only executed if the signal state at the enable input EN is "1".

You can query the error status of the program block using the enable output ENO:

- The enable output ENO returns the signal state "1" when the program block is processed.
- If, in the case of error, you do not explicitly set the enable output ENO within the called program block to the signal state "0", it retains the signal state "1". Using the instruction "RET: Return" you can set the block ENO to the signal state "0".
  Additional information on using the RET instruction is available here: Influencing the block ENO of an LAD/FBD program block (Page 2185)

Enabling and disabling the EN/ENO mechanism in LAD and FBD

In LAD and FBD, certain instructions have an enable output ENO and thus use the EN/ENO mechanism. This allows you to query runtime errors in instructions and react to them. In order to increase the performance of the CPU, the EN/ENO mechanism is disabled in the default setting. This means that you are not initially able to react to runtime errors of the instruction using the ENO value. However, you can enable the EN/ENO mechanism again at any time, if required.

You can enable the EN/ENO mechanism individually for each instruction in order to generate the ENO. If you enable the EN/ENO mechanism for an instruction, other instructions that you subsequently add to your program are also inserted with the EN/ENO mechanism enabled. You can disable the EN/ENO mechanism again at any time if you do not want to use the evaluation of ENO for an instruction. Further instructions that you subsequently add to your program will then be inserted without the EN/ENO mechanism.

Runtime errors do not cause the CPU to go to STOP when the enable output ENO is enabled.

Activating the EN/ENO mechanism

Proceed as follows to activate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to activate the EN/ENO mechanism.
2. Select the "Generate ENO" command from the shortcut menu.
   The ENO value is again generated for the instruction. Additional instructions are then also inserted with the activated enable output.

Deactivating the EN/ENO mechanism

Proceed as follows to deactivate the EN/ENO mechanism of an instruction:

1. In your program, right-click the instruction at which you want to deactivate the EN/ENO mechanism.
2. Select the "Do not generate ENO" command from the shortcut menu.
   The ENO value is no longer generated for the instruction. Additional instructions are then also inserted without the activated enable output.

Basics of the EN/ENO mechanism (Page 2177)

Influencing the block ENO of an LAD/FBD program block

Description

Using the instruction "RET: Return" you jump out from a program block and hereby influence the signal state of the ENO block.

Procedure

To influence the signal state of the block ENO, follow these steps:

1. Enable the EN/ENO mechanism of an instruction (for example, the addition "ADD").
2. Then use a negation to program the instruction "RET: Return" with signal state FALSE at the enable output ENO.

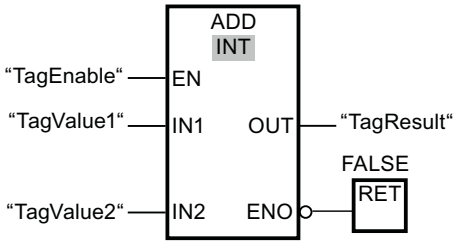
Result

In case of error (for example, an overflow in the result), the signal state "0" is first returned at the enable output ENO. This signal state "0" becomes signal state "1" using the negation and thus forms the RLO = 1 for executing the instruction "RET", which returns the value FALSE. The block ENO of the program block is hereby FALSE and a return takes place from the program block to the next instruction after the previous program block call. This procedure can be programmed in each network (for example, with multiple mathematical functions etc.).

However, it is not compulsory to program a jump out of the program block. Within a network you can also use the signal state "0" of the enable output ENO of a single instruction to determine that the subsequent instruction is not executed. The block ENO is not hereby influenced.

Note

Influencing of the block ENO



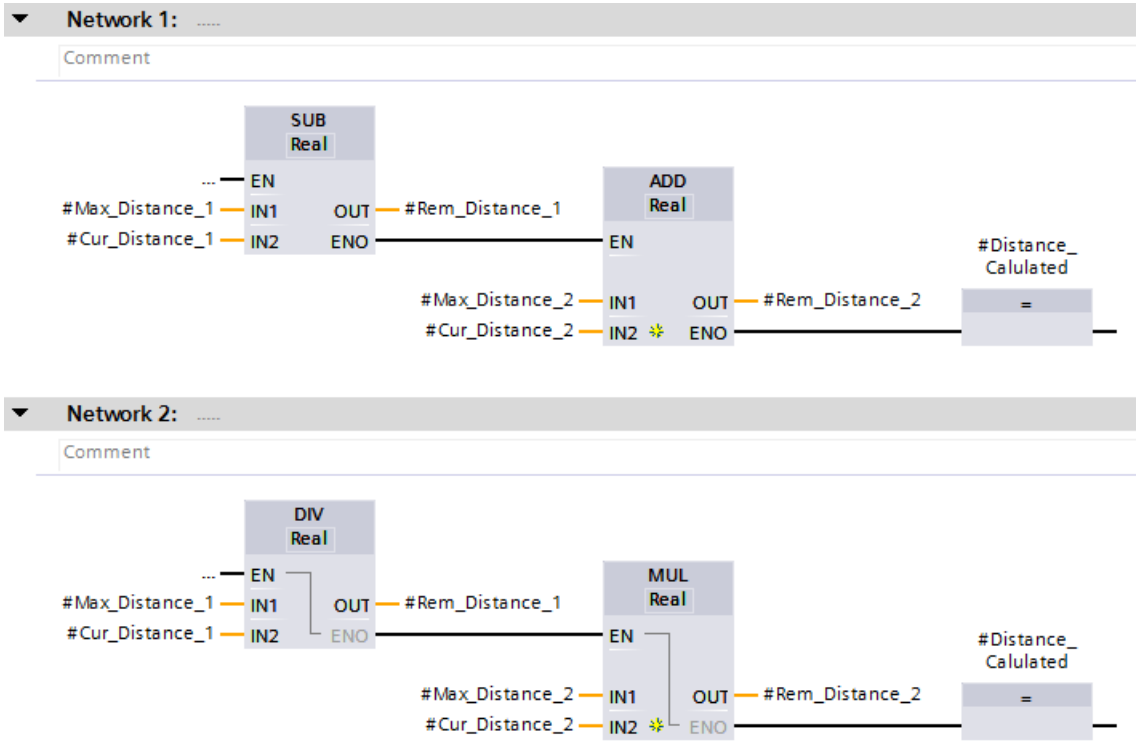
You can only influence the signal state of the block ENO by jumping out of the program block.

Even if the enable output ENO of the last instruction in the last network within a program block has the signal state "0", the block ENO is not influenced.

Example of the use of the EN/ENO mechanism in FBD

Example of an instruction with EN/ENO mechanism

The following example shows the "Add" instruction with EN/ENO circuit and a RET coil (Ret False):



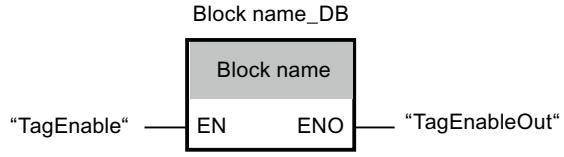
After the NO contact "TagEnable", the enable input EN contains the result of the preceding logic operation:

- If the operand "TagEnable" has the signal state "0", the "Add" instruction is not executed. The enable output ENO is set to signal state "0" and the called program block is exited. The enable output ENO of the calling program block then also has the signal state "0".
- If the operand "TagEnable" has the signal state "1", the enable input "EN has the signal state "1" and the instruction "Add" is executed. The instruction adds two values of the data type INT. If the expected result is outside the value range of INT (16 bits: -32768 to +32767), the instruction still returns a result but it is within the value range of INT. The reason for this is that the 16th bit for INT is the sign bit. This result does not indicate that there was an overflow. Which is why the following applies in case of an addition => ENO:= NOT(OV). If an error occurs during processing of the program block, the enable output ENO is set to signal state "0" and the called program block is exited. The enable output ENO of the calling program block then also has the signal state "0".
- If the operand "TagEnable" has the signal state "1", the enable input "EN has the signal state "1" and the instruction "Add" is executed. If the instruction is executed without errors, the enable output ENO also has the signal state "1" and the output "TagResult" the result.

A detailed description of the instruction "RET: Return" is available here: RET: Return (Page 3152)

Example of the effect of the enable output ENO

The following example shows you how to use instructions with the ENO enable output enabled and disabled:



If you have activated the ENO enable output, for example with the SUB instruction, all subsequent instructions are also applied with an activated ENO enable output. If an arithmetic error occurs during the execution of the SUB instruction, the ADD instruction is not executed.

The enable output ENO is disabled for the instruction DIV. If a runtime error occurs during execution, the MUL instruction is executed anyway.

Example of a program block call with EN/ENO mechanism

The following example shows the call of the program block with EN/ENO circuit:

The program block is executed only if the operand "TagEnable" has the signal state "1":

- The enable output ENO has a signal state that depends on what was programmed within the program block.
- If the operand "TagEnable" has the signal state "0", the program block call is not executed. The enable input EN and the enable output ENO both have the signal state "0".

Basics of the EN/ENO mechanism (Page 2177)

EN/ENO mechanism in STL (S7-1500)

Overview of the EN/ENO mechanism in STL (S7-1500)

EN/ENO mechanism within an instruction.

The EN/ENO mechanism is not available for individual instructions. It is mapped by language-specific instruction sequences and use of the status word (BR bit).

For additional information on the status word, refer to: AUTOHOTSPOT

Additional information is available here: Example of the simulation of the EN/ENO mechanism in STL (Page 2189)

EN/ENO mechanism with program block calls

A program block that you call from an STL program block is not provided with the EN and ENO parameters. Regardless of the programming language in which the program block was created, you can get an error statement to the calling STL program block by using the BR bit of the status word.

You can evaluate the error status of the called program block by linking the BR bit of the status word with the result of logic operation (RLO). The RLO has the signal state "1" as soon as the

program block execution of the called program block starts. If you do not explicitly reset the RLO to "0" after the execution of the actions, it retains the signal state "1". To signal an error statement back to the calling program block, you have to explicitly reset the RLO to the signal state "0". The error statement is set with the instructions "SAVE: Save RLO in BR bit" and "JNB: Jump if RLO = 0 and save RLO".

An error analysis of the BR bit is available in STL. The BR bit is the basis for generating the enable output ENO in the programming languages LAD, FBD and SCL.

The value "0" in the BR bit of the status word indicates that an error occurred during an STL program block call (calling program block is an STL program block).

CPU execution of the instruction	BR bit	Return value	Sign of the integer
With error(s)	0	Less than "0"	Negative (sign bit is "1")
Without error	1	Greater than or equal to "0"	Positive (sign bit is "0")

For additional information on the BR bit, refer to: Evaluating errors with output parameter RET_VAL (Page 2198)

Example of the simulation of the EN/ENO mechanism in STL (S7-1500)

Example of a program sequence with EN/ENO mechanism

The following example shows a program section for adding values with EN/ENO mechanism:

STL	Description
A "TagEnable"	// Query the signal state of the "TagEnable" operand for "1" and AND with the current RLO.
JNB MyLABEL	// Evaluation of the enable input EN
	// If RLO = "0", jump to jump label "MyLABEL" and save the current RLO in the BR bit. The following actions are not executed.
	// If the RLO = "1", execute the following actions.
L "Tag_Input_1"	// Load first value for addition.
L "Tag_Input_2"	// Load second value for addition.
+I	// Add values
T "Tag_Result"	// Transfer sum to the operand "Tag_Result".
AN OV	// Query whether an overflow has occurred.
SAVE	// Transfer signal state of the RLO to the BR bit.
CLR	/// Reset RLO to "0" and end logic sequence.
MyLABEL: A BR	// Jump label "MyLABEL"
	// Query BR bit.

STL	Description
= "Tag_Output"	// Assign signal state of the RLO to the "Tag_Output" operand.

The query of the operand "TagEnable" provides the result of the preceding logic operation (RLO). The instruction "JNB: Jump if RLO = 0 and save RLO" saves the RLO in the BR bit. Additionally, the instruction evaluates the RLO and executes the following actions depending on the signal state:

- If the RLO is "0", the processing of the program is continued at the jump label "MyLABEL" with the query of the BR bit. The addition is not executed. The current RLO is assigned with the operand "Tag_Output".
- If the RLO is "1", the addition is executed. A query of the overflow bit (OV) shows whether an error occurred during the addition. The query result is saved in the BR. The instruction "CLR: Reset RLO to 0" resets the RLO to "0" and ends the logic sequence. The BR bit is then queried and assigned to the operand "Tag_Output". The signal state of the BR bit, and the operand "Tag_Output" shows whether the addition was executed without any error.

Example of a program block call with EN/ENO mechanism

The following example shows the call of the program block with EN/ENO circuit:

STL	Description
A "TagEnable"	// Query the signal state of the "TagEnable" operand for "1" and AND with the current RLO.
JNB MyLABEL	// Evaluation of the enable input EN
	// If RLO = "0", jump to jump label "MyLABEL" and save the current RLO in the BR bit. The following actions are not executed.
	// If the RLO = "1", execute the following actions.
CALL "Block name", "Block name_DB"	// The program block is called.
MyLABEL: A BR	// Jump label "MyLABEL"
	// Query BR bit and link with the RLO after AND.
= "Tag_Output"	// Assign signal state of the RLO to the "Tag_Output" operand.

Basics of the EN/ENO mechanism (Page 2177)

EN/ENO mechanism in SCL

Overview of the EN/ENO mechanism in SCL

To increase performance, the EN/ENO mechanism is disabled by default. However, it can be enabled at any time using the block attribute "Set ENO automatically". For additional information on the enabling and disabling of the EN/ENO mechanism, refer to: Enabling and disabling the ENO mechanism in SCL (Page 2191)

In addition to enabling the block attribute "Set ENO automatically", you can also influence the enable output EN using an IF instruction. Additional information is available here: Influencing enable output ENO using an IF instruction (Page 2193)

EN/ENO mechanism within an instruction.

The EN/ENO mechanism is optional for instructions.

Additional information is available here: Using enable output ENO with SCL instructions (Page 2192)

EN/ENO mechanism with program block calls

The call of an SCL program block is also executed unconditionally, regardless of whether the EN/ENO mechanism is enabled or not. However, you can link the call to an IF instruction and then make the call dependent on various conditions. One possible condition can, for example, be the block ENO of the SCL program block. However, the EN/ENO mechanism then has to be enabled for this.

If the block ENO returns the signal state "0" because of a runtime error in a previous instruction, the block call is not executed.

Additional information is available here: Influencing enable output ENO of an SCL program block (Page 2193)

Enabling and disabling the ENO mechanism in SCL

Description

The EN/ENO mechanism checks during runtime whether errors occur in the processing of certain instructions. If a runtime error occurs the block ENO is set to "0".

Enabling EN/ENO mechanism in the block properties

Proceed as follows to activate the EN/ENO mechanism in the block properties:

1. Open the "Program blocks" folder in the project navigator.
2. Right-click the SCL block whose properties you want to display.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.
4. Click the "Attributes" group in the area navigation.

5. Activate the property "Set ENO automatically".
6. Confirm your entries with "OK".

Result: The EN/ENO mechanism is activated only for the selected SCL program block.

Activate EN/ENO mechanism in the program properties

Proceed as follows to activate the EN/ENO mechanism in the program properties:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the working area.
2. In the area navigation, select the "PLC programming" group.
3. Select the group "SCL (Structured Control Language)".
4. Activate the property "Set ENO automatically".

Result: The EN/ENO mechanism is activated by default for all new SCL program blocks.

Using enable output ENO with SCL instructions

Description

With each SCL instruction, such as a mathematical function, you must query the enable output ENO in order to be able to work with it.

Procedure

To query the enable output ENO, proceed as follows:

1. Activate the EN/ENO mechanism.
2. After the SCL instruction, query the enable output ENO (for example, #MyOutputBool := ENO;)
   If the error case occurs, for example an overflow in the result, returns the enable output ENO returns the signal state "0". With this signal state you can continue to work and, for example, program the instruction "RETURN", a fault display or a substitute value.
3. Reset the signal state of the enable output ENO to "1" (for example, ENO :=1;) before processing the next instruction.
   The signal state for the next error case can hereby be reset to "0". If you do not do this, the signal state of the enable output ENO remains "0".

Note

Jump to an SCL block.

With a jump to an SCL block, the signal state of the enable output ENO is automatically set to "1".

Influencing enable output ENO of an SCL program block

Description

The last instruction ENO within an SCL program block always influences the block ENO.

In addition, you can jump out of the program block and at the same time assign the value "1" or "0" to the block ENO using the instruction "RETURN".

Procedure

To influence the signal state of the block ENO, follow these steps:

1. Activate the EN/ENO mechanism.
2. Then program:

```
IF ENO := 0 THEN
RETURN;
END_IF;
```

Result

In case of error (for example, an overflow in the result), the signal state "0" is initially returned at the enable output ENO, such as an addition instruction. The block ENO is hereby FALSE and a jump takes place from the program block to the next instruction after the previous program block call. This procedure can be programmed multiple times in an SCL program block (for example, with multiple mathematical functions, etc.).

However, it is not compulsory to program a jump out of the program block. Within the SCL program block you can also use the signal state "0" of the enable output ENO of a single instruction to determine that the subsequent instruction is not executed. For this purpose, the instruction ENO is linked with the following instruction in a subsequent IF instruction.

Note

Influencing of the block ENO

With an SCL program block the signal state of the last instruction ENO is forwarded at the end of the block to the block ENO

The instruction ENO thus directly influence the block ENO.

Influencing enable output ENO using an IF instruction

Description

If you influence the enable output EN using an IF instruction, you do not need to activate the block attribute "Set ENO automatically".

Procedure

To influence the ENO enable output using an IF instruction, proceed as follows:

1. Program an IF instruction.
2. Use the enable output ENO either within the IF instruction or with ELSE.

Result

Depending on a Boolean value or a value comparison, the enable output ENO within the IF instruction is set to signal state "1" (ENO := 1;) or with ELSE to the signal state "0" (ENO := 0;).

Example of the use of the EN/ENO mechanism in SCL

Example of an instruction with EN/ENO mechanism

To use the EN/ENO mechanism for instructions, you have to activate the block property "Set ENO automatically". The following example shows the use of the enable output ENO for the operation "a + b":

```
"MyOutputREAL":= #a + #b;
"MyOutputBOOL":= ENO;
```

If the operation "a/b" is executed error-free, the operand "MyOutputBool" has the signal state "1". In case of error, the enable output ENO has the signal state "0".

Example of a program block call with EN/ENO mechanism

The following example shows the call of the program block. For this purpose the EN/ENO mechanism must be activated and an instruction that influences the block ENO must be programmed beforehand:

```
IF ENO := 1 THEN
"Block name_DB"();
END_IF;
```

The program block is only called and executed if the enable output ENO has the signal state "1". The called program block also returns a block ENO if its EN/ENO mechanism is activated. This block Eno is then further used in the called program block.

Basics of the EN/ENO mechanism (Page 2177)

EN/ENO mechanism in GRAPH (S7-1500)

Overview of the EN/ENO mechanism in GRAPH (S7-1500)

EN/ENO mechanism within an instruction.

You have no access to the enable output ENO of the instructions, which means you cannot influence the status of the enable output ENO at the GRAPH function block. However, with conversions, mathematical functions or LAD/FBD instructions, for example, you can have the enable output ENO displayed in the program status.

EN/ENO mechanism with program block calls

You can use the enable input EN to call a program block depending on conditions. The program block is only executed if the signal state at the enable input EN is "1".

You can query the error status of the program block using the enable output ENO:

- The enable output ENO has the signal state "1", as soon as the called program block has been executed error-free.
- The enable output ENO has the signal state "0" if an error occurred during the execution of the called program block.
- The enable output ENO cannot be explicitly set or reset.
- The enable output ENO is not influenced by the ENO of the instructions.

Activating and deactivating EN/ENO mechanism in GRAPH (S7-1500)

Description

The status of the enable output ENO is displayed during testing with program status. This has the value TRUE if the action was successful and FALSE if the action failed.

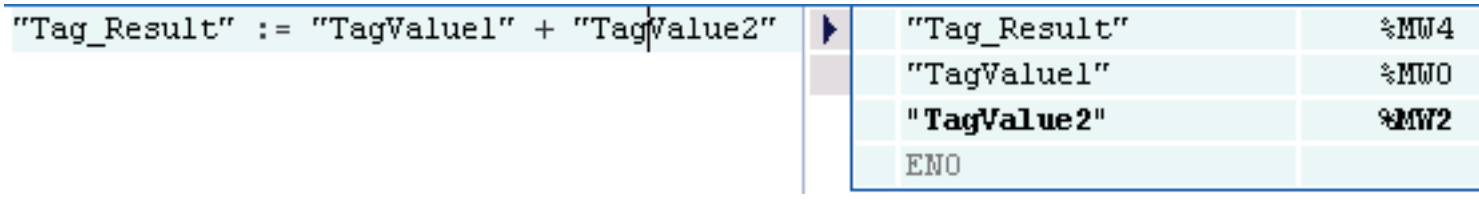
The display option of the status of the enable output ENO is available at the following positions in the GRAPH program block:

- Permanent pre-instructions
- Sequence view > Actions
- Permanent post-instructions

Enabling EN/ENO mechanism in the block properties

Proceed as follows to activate the EN/ENO mechanism in the block properties:

1. Open the "Program blocks" folder in the project navigator.
2. Right-click the GRAPH block whose properties you want to display.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.

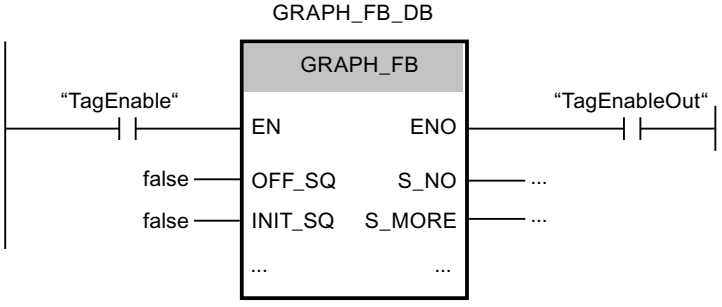


4. Click the "Attributes" group in the area navigation.
5. Activate the property "Set ENO automatically".
6. Confirm your entries with "OK".

Result: The EN/ENO mechanism is activated only for the selected GRAPH block.

Example of the EN/ENO mechanism in GRAPH (S7-1500)

Example of a program status with enable output ENO



The following example shows the program status of the enable output ENO in the sequence view under actions:

If an error occurs during the execution, the enable output ENO has the signal state FALSE.

Example of a program block call

The following example shows the call of the GRAPH program block in a LAD program block with EN/ENO connected:

The program block is executed only if the operand "TagEnable" has the signal state "1":

- If the operand "TagEnable" has the signal state "0", the called program block call is not executed. Both the enable input EN and the enable output ENO have the signal state "0".
- If the operand "TagEnable" has the signal state "1", the enable input "EN has the signal state "1" and the called program block is executed. The enable output ENO has a signal state that depends on what was programmed within the program block.

Basics of the EN/ENO mechanism (Page 2177)

EN/ENO mechanism in blocks with different network languages (S7-1200, S7-1500)

Description

You can also use the EN/ENO mechanism in blocks with different network languages. Each programming language displays the error status differently:

- SCL has an ENO tag that stores the error status and can be queried. Direct access to this tag is only possible with SCL.
- LAD/FBD/STL have no special tag for ENO. However, you can read the error status for STL from the BR bit, and query it via the RET coil for LAD/FBD.

The following rules apply to reading out the error status for the entire block:

- The last network in the block is a LAD/FBD network:
  If you do not use RET coils, the error status is TRUE by default.
- The last network in the block is an STL network:
  The BR bit determines the error status. The BR bit can be edited in STL networks using the BR tab.
- The last network in the block is an SCL network:
  The ENO tag determines the error status of the block.

Influencing of the block ENO

For LAD/FBD program blocks with multiple networks that could consist of different programming languages (such as LAD, FBD, STL or SCL), the last processed network determines the signal state of the block ENO.

If the last processed network of such a program block is a LAD or FBD network, the signal state of the block ENO is not necessarily influenced. With an instruction in which the EN/ENO mechanism is activated, it is only influenced if the enable output ENO has the signal state "0" and it is possible to return for the program block using the instruction "RET: Return". If this instruction was not programmed, the block ENO always has the signal state "1". The signal state "0", if any, of an instruction ENO has no influence on the block ENO, as the signal state "1" is always set at the start of a network.

This applies also to a LAD or FBD network that is before another network (LAD, FBD or SCL). The signal state of the block ENO is influenced only using the instruction "RET: Return". Otherwise, the signal state of the block ENO is reset to "1" at the transition to the network.

If the last network of a mixed program block is an SCL network, the block ENO is always influenced by this.

Basics of the EN/ENO mechanism (Page 2177)

11.1.5.4 Evaluating errors with output parameter RET_VAL

Basics on error analysis of library blocks (SFB and SFC)

Two additional error evaluation options are available in addition to the output parameter RET_VAL:

- With the EN/ENO mechanism (LAD, FBD, and SCL)
  For additional information on the EN/ENO mechanism, refer to: Basics of the EN/ENO mechanism (Page 2177)
- With the BR bit (binary result bit) of the status word (STL)
- With the output parameter RET_VAL (return value)

The enable output ENO only informs you that an error has occurred. If you want to know which error occurred exactly, the output parameter RET_VAL will provide more information. You can use it to determine whether or not the CPU was able to execute the instruction successfully. In the case of an error, you will also learn why the instruction could not be executed successfully.

The section below includes detailed information on the two error evaluation options RET_VAL and BR bit.

Recommendation for sequence of error analyses

Before evaluating the instruction-specific output parameters (for example, OUT), you should always follow the steps below:

1. First evaluate the enable output ENO or the BR bit of the status word in STL.
2. Then check the output parameter RET_VAL.

If the enable output ENO or the BR bit indicates that an error has occurred during the execution of the instruction or if output parameter RET_VAL contains a general error code, the instruction-specific output parameters return an invalid value.

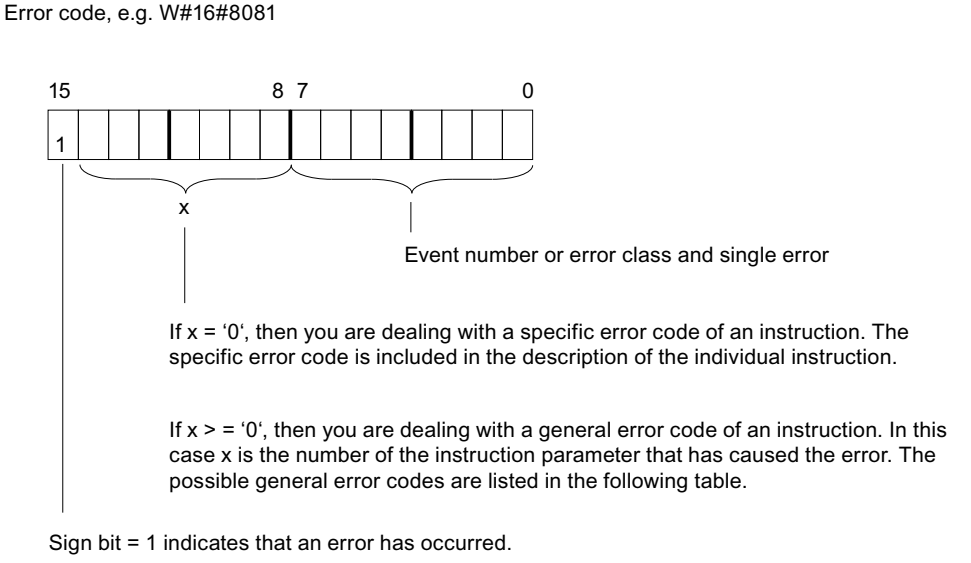
If a general error occurs with the output parameter RET_VAL, this is only indicated by the value "0" in the BR bit of the status word. The return value is of the data type integer (INT). The relationship of the return value to the value "0" indicates whether or not an error occurred during execution of the instruction.

General and specific error codes (RET_VAL)

The output parameter RET_VAL has two types of error codes:

- A general error code that all instructions can output and
- A specific error code that an instruction can output depending on its specific functions.

The data type of the output parameter RET_VAL is an integer (INT). The error codes of the instruction are grouped according to hexadecimal values. If you want to examine a return value and compare the value with the error codes listed in this documentation, then display the error code in hexadecimal format.



You can write your program so that it reacts to the errors that occur during execution of an instruction. This way you prevent further errors occurring as a result of the first error.

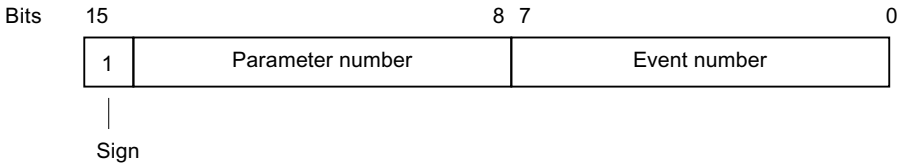
Note

Error during supply of the input parameters

When the instruction containing the RET_VAL parameter is executed and errors during supply of the input parameters occur, the RET_VAL parameter outputs an invalid error code and the output parameters of the instruction must not be evaluated.

The figure below shows the structure of a system function error codes in hexadecimal format:

It is easy for you to determine whether an error has occurred because the output parameter RET_VAL is of the type INT:



- If the value is < 0, there is an error.
- If the value is = 0, no error has occurred.
- If the value is > 0, no error has occurred but the instruction was not executed successfully. This is used in asynchronous instructions, for example, to indicate that processing of the instruction was started but is not yet complete. See the return values of T_SEND or WRIT_DBL.

General error codes

The general error code indicates errors that can occur in all instructions. A general error code consists of the following two numbers:

- A parameter number from 1 to 111, where 1 indicates the first parameter of the called instruction, 2 the second parameter, and so forth.
- An event number between 0 and 127. The event number indicates an error.

The figure below shows the structure of a general error code:

Note

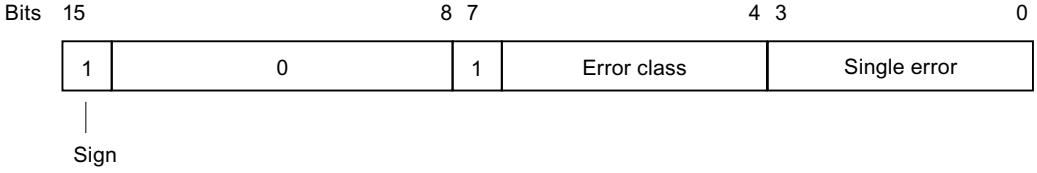
Reaction to a general error code

If a general error code was entered in the output parameter RET_VAL, the following situations are possible:

- The action associated with the instruction was started or has already been completed.
- A specific instruction error occurred when the action was performed. As a result of a general error that occurred later, the specific error could, however, no longer be indicated.

The following table explains the general error codes of a return value. The error code is shown in hexadecimal format. The letter x in each code number is simply a placeholder and represents the number of the system function parameter that caused the error:

Error code (W#16#...)	Description
8x01	Illegal syntax ID at an VARIANT parameter
8x22	Range length error when reading a parameter.
8x23	Range length error when writing a parameter. This error code indicates that the parameter x is located either entirely or partly outside the range of an address, or that the length of a bit range is not a multiple of 8 with an VARIANT parameter.
8x24	Range error when reading a parameter.
8x25	Range error when writing a parameter. This error code indicates that the parameter x is located in a range that is illegal for the system function. Refer to the descriptions of the individual functions for information about the illegal ranges.
8x26	The parameter contains a timer cell number that is too high. This error code indicates that the timer cell specified in parameter x does not exist.
8x27	The parameter contains a counter cell number that is too high (counter number error). This error code indicates that the counter cell specified in parameter x does not exist.
8x28	Alignment error when reading a parameter.
8x29	Alignment error when writing a parameter. This error code indicates that the reference to parameter x is an operand with bit address that is not equal to 0.
8x30	The parameter is located in a read-only global DB.
8x31	The parameter is located in a read-only instance DB. This error code indicates that parameter x is located in a read-only data block. If the data block was opened by the system function itself, the system function always returns the value W#16#8x30.
8x32	The parameter contains a DB number that is too high (DB number error).



Error code (W#16#...)	Description
8x34	The parameter contains an FC number that is too high (FC number error).
8x35	The parameter contains an FB number that is too high (FB number error). This error code indicates that parameter x contains a block number higher than the highest permitted number.
8x3A	The parameter contains the number of a DB that is not loaded.
8x3C	The parameter contains the number of an FC that is not loaded.
8x3E	The parameter contains the number of an FB that is not loaded.
8x42	An access error occurred while the system was attempting to read a parameter from the peripheral input area.
8x43	An access error occurred while the system was attempting to write a parameter to the peripheral output area.
8x44	Error in the nth (n > 1) read access after an error occurred.
8x45	Error in the nth (n > 1) write access after an error occurred. This error code indicates that access to the required parameter is denied.
8x7F	Internal error This error code indicates an internal error at parameter x.

Specific error codes

Some instructions have a return value that provides an error code specific for the instruction. A specific error code indicates errors that can occur only in specific instructions.

A specific error code consists of the following two numbers:

- An error class from 0 to 7.
- An error number from 0 to 15.

For further information on specific error codes, refer to the descriptions of the individual instructions in the information system.

Additional information in the Siemens Industry Online Support

You can find more information on the error codes in the Siemens Industry Online Support under the following FAQ ID: 770453 (https://support.industry.siemens.com/cs/ww/en/view/770453)

Difference between synchronous and asynchronous instructions (Page 2571)

11.1.5.5 Use of the instructions GET_ERROR and GET_ERR_ID

Introduction

Local error handling makes it possible to query the occurrence of errors within a program block and evaluate the associated error information. You can set local error handling for organization blocks (OBs), function blocks (FBs), and functions (FCs). If local error handling is enabled, the system reaction is ignored.

You can read out the error number from the error information of the instruction GET_ERR_ID. You can find out, for example, which parameter caused an access error from the error information of the instruction GET_ERROR. In order for the instructions to output the required error information, they must be programmed in the user program for each individual program block from which potential errors are to be evaluated. If you work with the instructions, no error OB is called and there is no entry in the diagnostics buffer. With this method of error handling, you actively intervene in the program sequence by programming a reaction to the errors that occurred. Because errors can occur at any location within the program block, we recommend that you integrate the instruction at the end of the program block.

The instructions GET_ERROR and GET_ERR_ID differ in the amount of error information that is output with each one.

As soon as you have integrated one of the two instructions in your program code, the "Handle errors within block" check box is selected in the inspector window under "Properties > Attributes". This setting cannot be edited in the Inspector window. Local error handling can be deactivated by deleting the inserted instructions for local error handling.

Note

Block property "Handle errors within block"

This setting is not applied by a calling block, nor is it transferred to called program blocks. The system settings still apply to higher-level and lower-level program blocks, provided dedicated local error handling has not been programmed for these blocks.

Error output priorities

In local error handling, information about the first error that occurred is displayed using the instructions GET_ERROR or GET_ERR_ID. If multiple errors occur at the same time while an instruction is being executed, these errors are displayed according to their priority. The following table shows the priority of different types of errors:

Priority	Error type
1	Error in the program code
2	Missing reference
3	Invalid range
4	DB does not exist
5	Operands are not compatible
6	Width of specified area is not sufficient
7	Timers or counters do not exist
8	No write access to a DB

Priority	Error type
9	I/O error
10	Instruction does not exist
11	Block does not exist
12	Invalid nesting depth

The highest priority is 1 and the lowest priority is 12.

Additional information

For additional information on the instructions, refer to the information system under PLC programming > Instructions > Instructions (S7-1200, S7-1500) > Basic instructions. The instructions are available in the programming languages LAD/FBD/STL/SCL and GRAPH.

11.1.5.6 Example of how to handle program execution errors

Introduction

The local error handling options can be programmed individually or in combination with one another. To ensure that every error scenario that may occur within your program is recognized, we recommend a combination of local error handling options, as shown in the example below.

For a more precise error analysis, in addition to the RET_VAL output parameter you can also use the "GET_ERROR" or "GET_ERR_ID" instruction. These options provide you with error codes whose detailed explanations are available in the descriptions of the respective instructions.

There are also error scenarios in which the RET_VAL output parameter does not output a valid error code. If an access error occurs while reading an input parameter, for example, the outputs of the instruction are no longer written, because the execution of the instruction is interrupted. In this case, we recommend that you integrate the two instructions "GET_ERROR" and "GET_ERR_ID" in your program because they provide reliable error information even when this type of error occurs.

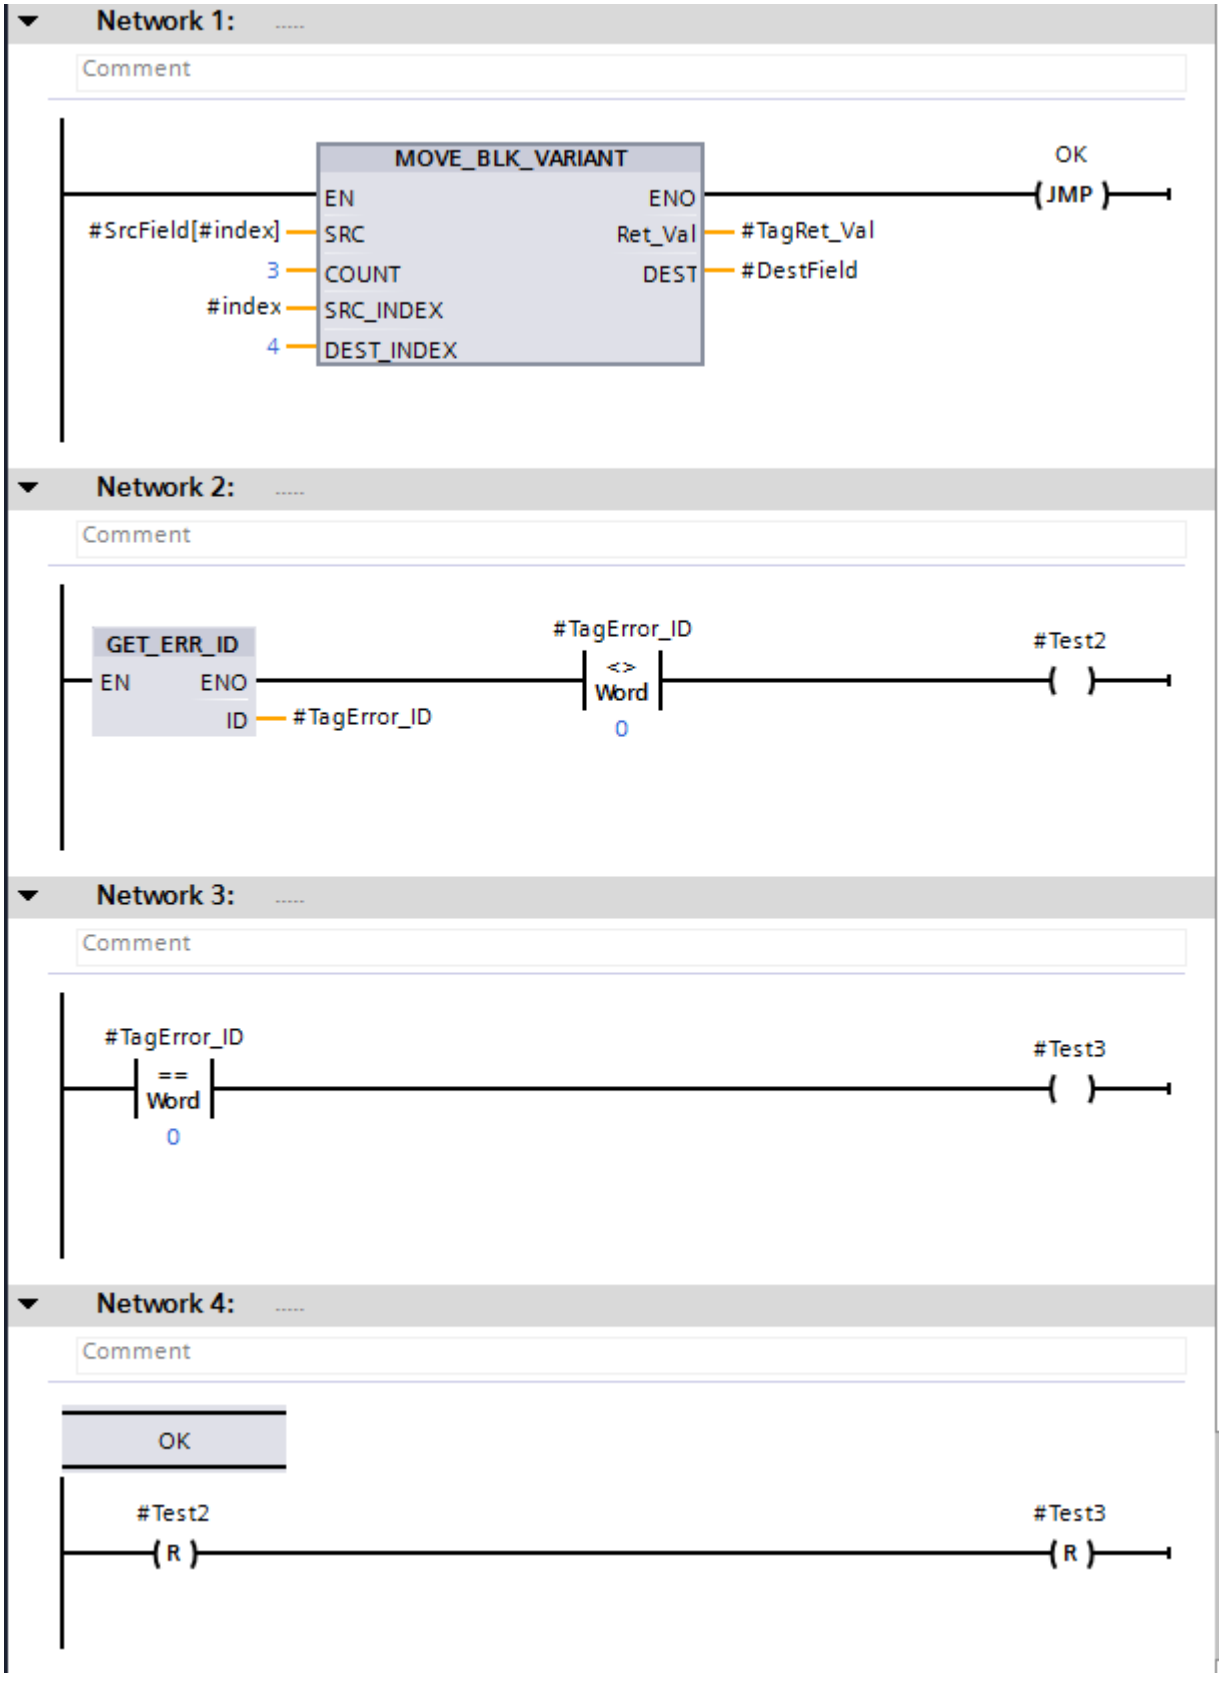
⚠ WARNING

Access error during reading of an input parameter

The RET_VAL parameter does not return a valid error code and no detailed error information is output in the diagnostics buffer.

A first indicator for an error can be either the BR bit of the status word or the ENO enable output. If these return signal state "0", there is an error in the execution of the instruction. Signal state "1" indicates that there is no error and no further error analysis is necessary, except when a memory access error is involved. In this case, signal state "1" can also indicate an error.

Procedure



The following example shows you how to recognize an access error during reading of an input parameter:

1. Declare the block interface of your program block as follows:

Interface

		Name	Data type	Default value
1		Input		
2		SrcField	Array [1..100] of Real	
3		index	DInt	0
4		<Add new>		
5		Output		
6		TagOutput	Real	0.0
7		Test2	Bool	false
8		TagRet_Val	Int	0
9		DestField	Array [0..20] of Real	
10		Test3	Bool	false
11		<Add new>		
12		InOut		
13		Static		
14		Temp		
15		TagError_ID	Word	

2. Write the following program code:

Network 1:
Comment
MOVE_BLK_VARIANT
EN
ENO
#SrcField[#index]
SRC
Ret_Val
#TagRet_Val
3
COUNT
DEST
#DestField
#index
SRC_INDEX
4
DEST_INDEX
OK
JMP
Network 2:
Comment
GET_ERR_ID
EN
ENO
ID
#TagError_ID
#TagError_ID
<>
Word
0
#Test2
Network 3:
Comment
#TagError_ID
==
Word
0
#Test3
Network 4:
Comment
OK
#Test2
R
#Test3
R

In network 1, the instruction "MOVE_BLK_VARIANT": Move block" is called. The "SrcField" source area is accessed using a variable index in the SRC parameter. If no errors occur during execution of the instruction, the ENO enable output returns signal state "1", and program execution jumps to network 4 and continues there.

If an access error occurs during execution of the instruction, for example, due to the variable index, the instruction "GET_ERR_ID: Get error ID locally" in network 2 returns an error ID. The comparison of the error ID for "UNEQUAL" with the value "0" in network 2 returns the result #Test2 = TRUE. The comparison of the error ID for "EQUAL" with the value "0" in network 3 returns the result #Test3 = TRUE.

The #TagRet_Val operand at the RET_VAL output parameter returns no valid error code in this case.

Exceptions

There are some instructions, however, for which you cannot program the error handling as described in the example above. These includes the following instructions:

- Instructions that generally have no EN/ENO mechanism
- Instructions in which the ENO was disabled
- S_COMP
- PEEK, PEEK_BOOL, POKE, POKE_BOOL and POKE_BLK

The BR bit or the ENO enable output is set to TRUE in these instructions even if it may result in an access error.

The following example shows how you can program reliable error handling in the STL programming language:

		Name	Data type
1		Input	
2		StringArray	Array[0..10] of String
3		index	DInt
4		Output	
5		TagResult	Bool
6		InOut	
7		Static	
8		Temp	
9		TagError_ID	Word
10		Constant	

```
STL                                 Explanation
SET                                 // The #Tag_ErrorID operand is initial-
L 0                                 ized with "0".
T #Tag_ErrorID

CALL S_COMP                         // The instruction is called.
```

STL	Explanation
src_type := String	// Data type of parameters IN1 and IN2
relation := EQ	// The comparison type of the instruction
IN1 := #StringArray.THIS[#index]	// Variable access to the ARRAY component.
IN2 := 'STRING'	// The two values are compared with each other.
OUT := #TagResult	// If both values are identical, the #TagResult operand receives the signal state "1".
A BR	// The BR bit is queried.
CALL GET_ERR_ID	// The instruction is called.
RET_VAL := #Tag_ErrorID	// The instruction outputs an error code in the case of an access error.

Even if the BR bit has signal state "1", the access error is detected. You can query the error code by evaluating the #Tag_ErrorID operand of instruction "GET_ERR_ID: Get error ID locally".

11.2 Programming recommendations (S7-1200, S7-1500)

11.2.1 The new S7-1200/1500 CPU functions and programming recommendations at a glance (S7-1200, S7-1500)

Higher performance

The S7-1200/1500 CPUs offer much higher performance than the S7-300/400 CPUs. When programming with STEP 7 V5.x, you were probably used to methods such as absolute addressing to achieve higher performance from the CPU and leaner program code. Due to the high performance provided by CPUs of the S7-1200/1500 series, this is now no longer necessary. If you wish to reuse the programming code created on an S7-300/400CPU on an S7-1200/1500 CPU, it will probably be necessary to modify the program code here and there in order to fully exploit the high performance.

In the paragraphs below, we would like to introduce some new programming options of the S7-1200/1500 CPUs.

You can find more tips on improving the performance here: Increasing performance in STEP 7 (TIA Portal) (https://support.industry.siemens.com/cs/ww/en/view/37571372)

Universal symbolism

The S7-1500 allows you to use the symbolism throughout the entire project. Using the auto-complete function, you are given context-dependent support for programming with symbols within the programming editors. The data elements, for example those in a data block, are assigned only a symbolic name in the declaration but no fixed address within the data block. This allows you to fully exploit the high performance of the S7-1500 when accessing these data elements. The absolute addresses of operands need not be known and access errors are avoided.

Your program code will be clearer due to the symbolism and you have to comment less. All points of use are automatically updated when a correction is made to the symbolism.

Note

You can find additional information on the use of universal symbols at:

How can I address symbolically?

Symbolic addressing (Page 2213)

Optimized block access

With optimized block access, the declared data elements are arranged automatically in the available memory area of the block in a way that makes optimal use of its capacity. The data is structured and saved in way that is optimal for the CPU used. The storage is left to the system. The data elements are assigned only a symbolic name in the declaration by which the tag within the block can be addressed. This allows you to increase the performance of the CPU. Access errors, from the HMI, for example, are not possible.

Comparison of block accesses
Standard < > Optimized

SIEMENS

	Standard block access (S7-1200/1500 compatible with S7-300/400)	Optimized block access (S7-1200/1500 only)
Data management	You can address tags using both symbolic (memory-optimized) and absolute (user-defined) addresses.	The system manages and optimizes the data storage. This results in optimal use of the memory capacity.
Performance	The access to a CPU of the S7-1200/1500 series does not always occur as fast as possible because the data storage can be inefficient due to absolute addressing.	The access always occurs as fast as possible because the data storage is optimized by the system and no fixed addresses are assigned.
Susceptibility to errors	Absolute addressing (e.g., from HMI or when indirect addressing is used) can lead to inconsistencies after a change to the fixed address.	Access errors, e.g., from HMI or when indirect addressing is used, are not possible because the access is symbolic.
Retentivity	Valid for all tags of a data block	Valid for individual tags

Recommendation:
To achieve the best-possible performance, the combining of different block access types within your program is not recommended.

Note

You can find additional information on blocks with optimized access here:

AUTOHOTSPOT

New data types

The new data types LWORD, LINT, ULINT, LTIME, LTOD, LDT and ARRAY (32-bit limit) offer much higher calculation accuracy when using mathematical functions. In the area of implicit and explicit data type conversion, you have more options in comparison to the CPUs of the S7-300/400 series.

Note

You can find additional information on the new data types here:

AUTOHOTSPOT

PLC data types

PLC data types (UDT) are data structures that you define and that can be used multiple times within the program. The structure of a PLC data type is made up of several components, each of which can contain different data types. You define the type of components in the declaration of the PLC data type.

You can use the PLC data type as a base data type for defining tags and as a template for creating global data blocks. If you later make changes to the PLC data type, the changes are automatically updated at all points of use.

You can also symbolically access individual elements of an ARRAY within a PLC data type.

Note

You can find additional information on the PLC data types here:

What does a PLC data type look like and how can I declare it in my program?

- PLC data types (UDT) (Page 2277)

You can find programming recommendations for the PLC data type here:

- Using PLC data types (UDT) (Page 2229)
- Using the DB_ANY data type (Page 2218)

Uniform instructions in all programming languages

You are provided with a uniform set of instructions in all programming languages (LAD, FBD, STL, SCL, and GRAPH).

Slice access

Slice access gives you the option of specifically addressing areas within declared tags. You can implement symbolic access to a single bit up to the level of the tag. The single bit is then addressed absolutely.

Note

You can find additional information on slice access here:

How can I address with slice access?

- AUTOHOTSPOT
- AUTOHOTSPOT

Indirect addressing

Indirect addressing offers you the option of addressing operands whose address is not calculated until runtime. All programming languages provide general methods for indirect addressing, for example, via POINTER. In the STL and SCL programming languages, you can also use PEEK and POKE instructions.

Note

You can find additional information on indirect addressing here:

AUTOHOTSPOT

"Sample Library for Instructions"

You can use the "Sample Library for Instructions" to assist in programming. You will find practical and easy-to-understand programming examples for SIMATIC S7-1500 and S7-1200 in the LAD language here. You can simply insert the examples into your program and reuse them there.

Note

You can find additional information on the program examples here:

Sample Library for Instructions (Page 2568)

Additional programming recommendations

You can find additional information about programming recommendations and a programming guide in the Siemens Industry online support under:

- FAQs: Programming recommendations (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=0&lang=en&referer=%2fWW%2f&func=cslib.csinfo&siteid=csius&Datakey=47071380&extranet=standard&groupid=40000002&viewreg=WW&nodeid0=29156492&objaction=csopen)
- Background and system descriptions in the Programming Guideline and Programming Styleguide (https://support.industry.siemens.com/cs/document/81318674/programming-guideline-and-programming-styleguide-for-s7-1200-and-s7-1500?dti=0&lc=en-WW)

11.2.2 Symbolic addressing (S7-1200, S7-1500)

Advantages of symbolic addressing

The use of universally applied and meaningful symbols in the overall project makes the program code easier to read and understand.

This gives you the following advantages:

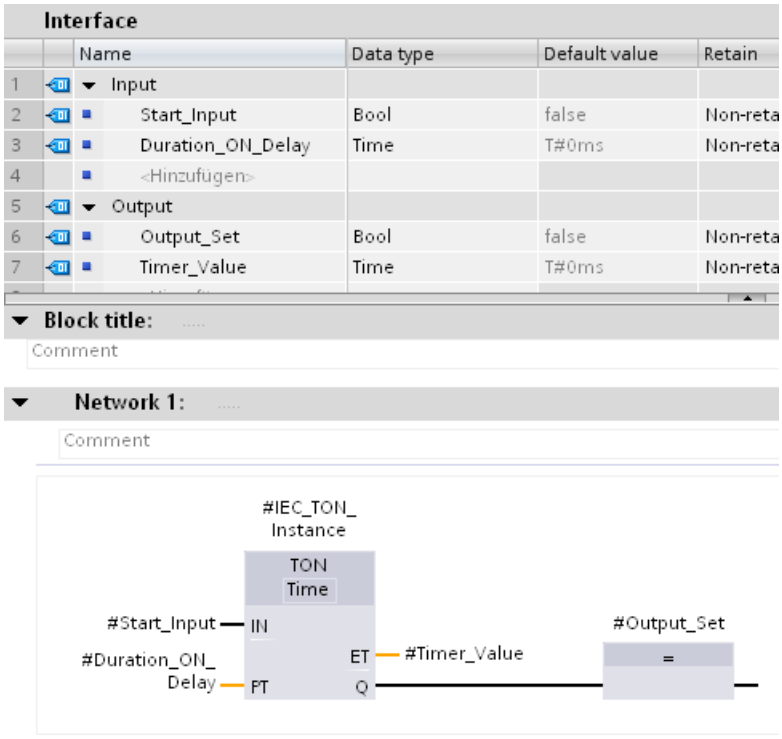
- You do not have to write detailed comments.
- Data access is faster.
- No errors occur when accessing data.
- You no longer have to work with absolute addresses.
- The assignment of the symbol to the memory address is monitored by STEP 7, which means all points of use are automatically updated when the name or the address of a tag changes.

Programming in STEP 7 V5.x

STEP 7 V5.x already gave you the option to write a program that is easier to read by using descriptive names for operands and blocks. You did this by assigning the symbolic operands to memory addresses and blocks in the symbol table. In order for a change in the symbolism to also have an affect on the program code in the program editor, you had to use the "Operand priority" property to specify whether the symbol or the absolute value had priority.

The use of symbolic addressing allowed you to create a program with greater clarity. However, in some cases, such as when programming with user-defined data types (UDT), this could impair performance.

You could increase the performance by ignoring the symbolism in the UDT and using absolute addressing. This made it necessary, however, to know the data storage. Changes to the UDT were not automatically updated. Using absolute addressing, you could also access parts of a tag and edit these. The disadvantage of exclusively absolute addressing, however, was that the program code became cluttered after a certain level and you had to insert additional comments for better orientation.



Procedure in STEP 7 TIA Portal

The S7-1500 CPU offers much higher performance than the S7-300/400 CPUs. To make full use of this high performance, we recommend that you enable optimized block access for all blocks and use symbolic addressing in the program code.

The program editor helps you work with symbols through context-sensitive input help, for example, auto-completion. Using it, you can easily access existing tags or instructions during programming.

Programming example

The following example shows you how to symbolically access individual elements:

You can use the tag names that you have defined in the block interface directly at the parameters of the TON instruction without knowing the absolute address of the tags.

See also

Using autocompletion (Page 4706)

11.2.3 Indirect addressing of ARRAY components (S7-1200, S7-1500)

Implementing ARRAY access in TIA Portal with a variable index

It is advisable to use an ARRAY when you want to process assembled data of the same data type. For addressing ARRAY elements, you can specify either constants or tags of the integer data type as index. Integers with lengths of up to 32 bits are allowed here.

With indirect addressing using a tag, the index is only calculated during program runtime. You can, for example, use a different index for each cycle in program loops. You can also access an ARRAY within a PLC data type (UDT).

This gives you the following advantages:

- No addressing is necessary with address registers or with self-assembled pointers, for example, an ANY pointer.
- More flexibility within your program.
- The variable index is available in all STEP 7 programming languages.
- It uses the existing names of data blocks and ARRAY tags (symbolic addressing). This improves readability of the program code.
- The start address of the ARRAY does not have to be known.
- The program code is easier to create and the compiler generates optimized program code.

Procedure in STEP 7 V5.x

In STEP 7 V5.x, you had to use an address register with the help of a self-configured POINTER for indirect addressing of ARRAY elements. The following aspects had to be taken into consideration for this:

- The name of the ARRAY was not used. This reduced the readability of the program code and make additional comments necessary.
- The start address of the ARRAY had to be known to perform the addressing.

The SCL programming language already supported indirect addressing with variable index.

Programming example in STEP 7 V5.x

The "Data_classic" data block is required for the following STL example. To address an element of the "Quantities" ARRAY, the following commands must be used:

STL	Explanation
OPN "Data_classic"	// The "Data_classic" data block is called.
L #index	// The value of the local tag #index is loaded into accumulator 1.
SLD 3	// Move bits 0 to 31 of accumulator 1 by 3 positions to the left.
	// Fill the now empty bit places with zeros.
LAR1	// Load address register 1 with contents of accumulator 1.

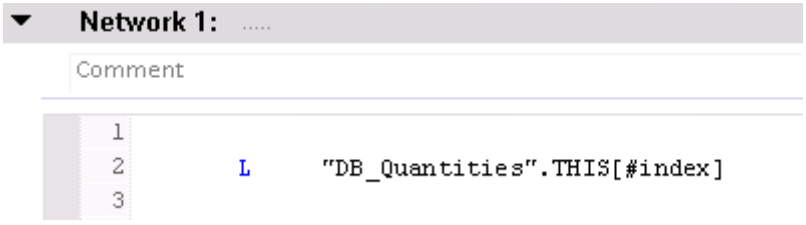
STL	Explanation
`L DBW [AR1, P#10.0]`	`// Load the ARRAY element addressed with #index into accumulator 1.` `// P#10.0 = Start address of the array`

Programming example in STEP 7 TIA Portal

In the example below, you see the indirect addressing of an ARRAY element in STL in the TIA Portal.

Create a global data block for this purpose:

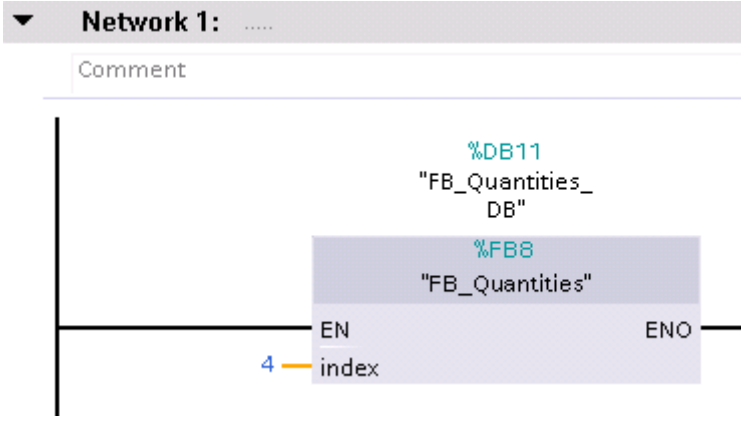
1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_Quantities".
4. Select the type of the data block "ARRAY DB".
5. Select the "DINT" data type as ARRAY data type.
6. Specify "10" as high ARRAY limit.
7. Click "OK".



DB_Quantities

	Name	Data type
1	DB_Quantities	Array[0..10] of DInt
2	DB_Quantities[0]	DInt
3	DB_Quantities[1]	DInt
4	DB_Quantities[2]	DInt
5	DB_Quantities[3]	DInt
6	DB_Quantities[4]	DInt
7	DB_Quantities[5]	DInt
8	DB_Quantities[6]	DInt
9	DB_Quantities[7]	DInt
10	DB_Quantities[8]	DInt
11	DB_Quantities[9]	DInt
12	DB_Quantities[10]	DInt

1. Create a function block and name it "FB_Quantities".
2. Declare the block interface as follows:



FB_Quantities		
	Name	Data type
1	Input	
2	Output	
3	InOut	
4	Static	
5	Temp	
6	Index	Int
7	Constant	

3. Write the following program code:

You need just one more program line for addressing an ARRAY element in the TIA Portal. The value of the ARRAY element #index is loaded directly from the data block into accumulator 1.

4. Call the "FB_Quantities" function block in OB1 and assign it an index between 0 - 10:

Note the following to get the best performance:

- Declare tags that are used as an ARRAY index as an integer of less than or equal to 32 bits.
- Store intermediate results and ARRAY indexes in the temporary local data area.

Basic information on ARRAY (Page 2286)

ARRAY (Page 2286)

11.2.4 Using the DB_ANY data type (S7-1200, S7-1500)

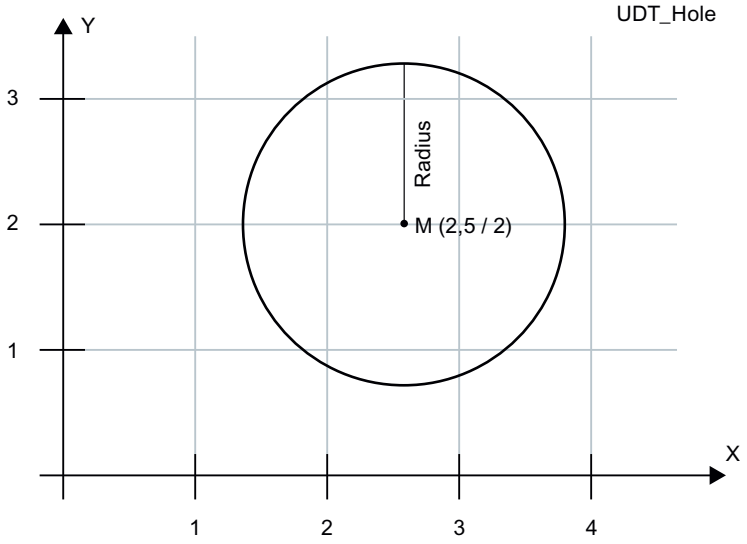
Using the DB_ANY data type (S7-1200/1500)

The DB_ANY data type is used to identify any data block. For CPUs of the S7-1200/1500 series, you have the option of accessing a data block that is not yet available during programming. For this purpose, create a block parameter of the DB_ANY data type in the block interface of the accessing block. The data block name or a tag of data type DB_ANY which was previously assigned to the data block name is transferred to this parameter during runtime. You can symbolically process the content of a data block by means of the following instructions:

- VARIANT_TO_DB_ANY: Convert VARIANT to DB_ANY
- DB_ANY_TO_VARIANT: Convert DB_ANY to VARIANT

For more information about the instructions, refer to "Basic instructions > STL/SCL > Conversion operations > VARIANT".

The advantage of this procedure: You can create the program code before you know which data block will be processed.



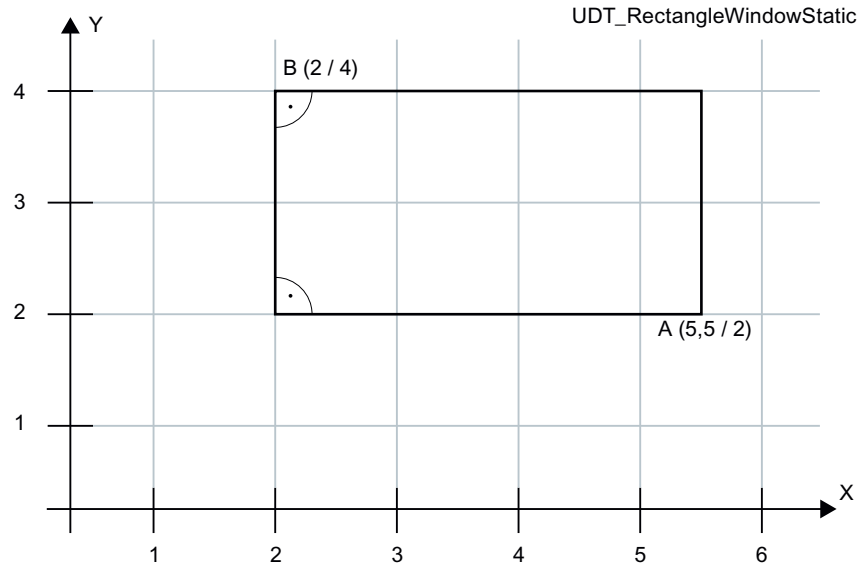
Programming example

The following example shows you how to use the DB_ANY data type:

A punching machine can punch out a variety of geometric shapes. The punching jobs are transferred to the machine and there are specific job data for each individual job. The job data differ in their job type as well as in their values.

Procedure - Creating the PLC data types

In the first job, a round hole is to be punched out of a piece of sheet metal. For the punching machine to be able to execute this job, it needs the center point coordinates and the radius of the hole. You can transfer these job data to the punching machine collectively in a PLC data type (UDT).



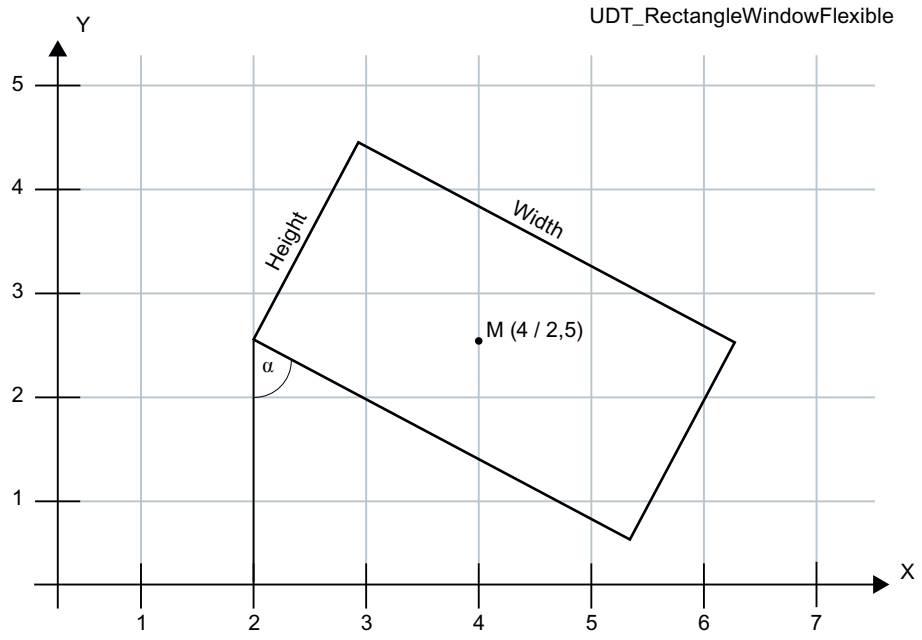
Create the PLC data type "UDT_Hole" to transfer the job data:

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare the following lines within the PLC data type:
   X-coordinate > REAL
   Y-coordinate > REAL
   Radius > REAL

UDT_Hole

	Name	Data type
1	X-coordinate	Real
2	Y-coordinate	Real
3	Radius	Real

A rectangle is to be punched out of a piece of sheet metal in the second job. For this job, you need two coordinates which define the upper left-hand point and the bottom right-hand point of the rectangle. You can transfer these job data to the punching machine collectively in the PLC data type "UDT_RectangleWindowStatic".



Create the PLC data type "UDT_RectangleWindowStatic":

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare the following lines within the PLC data type:
   X1-coordinate > REAL
   Y1-coordinate > REAL
   X2-coordinate > REAL
   Y2-coordinate > REAL

UDT_RectangleWindowStatic			
		Name	Data type
1		X1-coordinate	Real
2		Y1-coordinate	Real
3		X2-coordinate	Real
4		Y2-coordinate	Real

The job data of the "UDT_RectangleWindowStatic" can only be used to punch out rectangles whose edges are aligned parallel to the x and y axis.

If you want to punch out a rectangle with different alignment, i.e., not parallel to the x and y axis, you need an additional PLC data type. In it, you can specify the height and width, for example, as well as the alignment of the rectangle to the x axis by means of an angle.

Create the PLC data type "UDT_RectangleWindowFlexible":

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare the following lines within the PLC data type:
   X-coordinate > REAL
   Y-coordinate > REAL
   Height > REAL
   Width > REAL
   Angle > REAL

UDT_RectangleWindowFlexible

	Name	Data type
1	X-coordinate	Real
2	Y-coordinate	Real
3	Height	Real
4	Width	Real
5	Angle	Real

The x and y coordinates specify the center of the rectangle.

Procedure - Creating the data blocks

In the next section, you will learn how to transfer simple geometric shapes whose job data you have defined in the PLC data types to the punching machine. The punch jobs are broken down into individual punches in the program code; these punches are then executed consecutively by the punching machine. The punching machine has a cross table on which a sheet metal has been firmly clamped. You can move a cross table along the x and/or y axis just as in a coordinate system. The cross table is moved by two motors. The tool has different dies to punch out shapes from the sheet metal, such as circles and rectangles of different sizes. The tool can also be rotated by up to 90 degrees to cut out rectangles at different alignments.

You now use the PLC data types to create a data block. The data block then includes the specific values, for example, for a hole.

Create the data block "DB_OrderHole":

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_OrderHole".
4. Select the data block "UDT_Hole" as the type.
5. Click "OK".

Enter the appropriate start values:

DB_OrderHole

	Name	Data type	Start value
1	Static		
2	Hole	"UDT_Hole"	
3	X-coordinate	Real	10.0
4	Y-coordinate	Real	900.0
5	Diameter	Real	4.0

To manufacture a specific sheet metal part such as the side panel of a control cabinet, for example, the necessary geometric shapes are loaded to the punching machine. For this purpose, you need to create another data block which includes a list of data blocks.

Create the data block "DB_OrderList":

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_OrderList".
4. Select "Global DB" as the type of the data block.
5. Click "OK".

Create the following job list in the data block:

DB_OrderList

		Name	Data type
1		Static	
2		Order	Array[0..100] of DB_ANY
3		Order[0]	DB_ANY
4		Order[1]	DB_ANY
5		Order[2]	DB_ANY
6		Order[3]	DB_ANY
7		Order[4]	DB_ANY
8		Order[5]	DB_ANY
9		Order[6]	DB_ANY
10		Order[7]	DB_ANY
11		Order[8]	DB_ANY

Procedure - Creating the program code

The punching machine should now start processing the jobs. If it is already processing the jobs, it should get the next job from the job list and prepare it.

1. Create an SCL function block.
2. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
3. Click the "Function block (FB)" button.
4. Specify the name "FB_PickNextOrder".

5. Declare the block interface as follows:

FB_PickNextOrder		
	Name	Data type
1	Input	
2	Output	
3	InOut	
4	Static	
5	OrderReady	Bool
6	OrderNo	DInt
7	Order	DB_ANY
8	Temp	
9	Error	Int

6. Write the following program code:

```
1
2 IF #OrderReady THEN
3     #Order := "DB_OrderList".Order[#OrderNo];
4     #OrderNo := #OrderNo + 1;
5     #OrderReady := false;
6 END_IF;
```

The next job on the list is prepared by breaking down the current punch job into individual punches. The punching machine must be able to recognize which punch job it is processing.

1. Create an SCL function.
2. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
3. Click the "Function (FC)" button.
4. Specify the name "FC_PrepareOrder".

5. Declare the block interface as follows:

FC_PrepareOrder

	Name	Data type
1	Input	
2	Order	DB_ANY
3	Output	
4	Error	Int
5	InOut	
6	Temp	
7	WindowFlexible	"UDT_RectangleWindowFlexible"
8	WindowStatic	"UDT_RectangleWindowStatic"
9	Hole	"UDT_Hole"
10	a	Variant
11	Constant	
12	Return	
13	FC_PrepareOrder	Void

6. Write the following program code. The calls of the three functions are not yet given a red underline because they still have to be created.

```
1
2   #a := DB_ANY_TO_VARIANT(in := #Order, err => #Error);
3
4   CASE TypeOf(#a) OF
5       UDT_Hole:
6           VariantGet(SRC := #a,
7                      DST => #Hole);
8           "FC_PrepareHole"(#Hole);
9           ;
10
11      UDT_RectangleWindowStatic:
12          VariantGet(SRC := #a,
13                     DST => #WindowStatic);
14          "FC_PrepareWindowStatic"(#WindowStatic);
15          ;
16
17      UDT_RectangleWindowFlexible:
18          VariantGet(SRC := #a,
19                     DST => #WindowFlexible);
20          "FC_PrepareRectangleWindow"(#WindowFlexible);
21          ;
22      ELSE
23          ;
24  END_CASE;
```

The "VariantGet" instruction copies the information from the #a tag to the #Hole tag.

In the following section, you create the functions "FC_PrepareHole" and "FC_PrepareWindowStatic".

A separate function is created for each job type. The punch jobs are broken down into individual punches here and collected in an ARRAY.

1. Create a PLC data type.
2. Double-click the "Add new data type" command under "PLC data types".
   A new PLC data type with the name "UserDataType_x" is created.
3. Rename the PLC data type to "UDT_Punch".
4. Declare the following lines within the PLC data type:
   Tool > DINT
   x > REAL
   y > REAL
   w > BOOL

UDT_Punch

	Name	Data type
1	Tool	DInt
2	x	Real
3	y	Real
4	w	Bool

5. Create the global data block "DB_PunchList":

DB_PunchList

	Name	Data type
1	Static	
2	Punch	Array[0..100] of "UDT_Punch"
3	Punch[0]	"UDT_Punch"
4	Punch[1]	"UDT_Punch"
5	Punch[2]	"UDT_Punch"
6	Punch[3]	"UDT_Punch"
7	Punch[4]	"UDT_Punch"
8	Punch[5]	"UDT_Punch"
9	Punch[6]	"UDT_Punch"
10	Punch[7]	"UDT_Punch"
11	Punch[8]	"UDT_Punch"

To prepare the punch job for a hole, create an SCL function and name it "FC_PrepareHole".

1. Declare the block interface as follows:

FC_PrepareHole

		Name	Data type
1		Input	
2		a	"UDT_Hole"
3		Output	
4		InOut	
5		Temp	
6		Constant	
7		Return	
8		FC_PrepareHole	Void

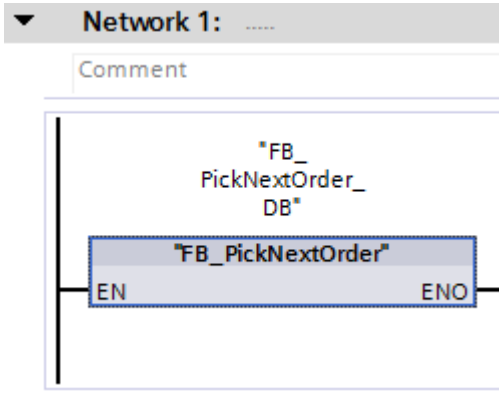
2. Write the following program code:

```
1
2  IF #a.Radius = 4.0 THEN
3      "DB_PunchList".Punch[0].Tool := 1;
4
5  ELSIF #a.Radius = 6.0 THEN
6      "DB_PunchList".Punch[0].Tool := 2;
7
8  ELSE
9      ;
10     "DB_PunchList".Punch[0].x := #a."X-coordinate";
11     "DB_PunchList".Punch[0].y := #a."Y-coordinate";
12
13 END_IF;
```

To prepare the punch job for a window, you need a function which combines four punch sequences into the punch job. Create an SCL function and name it "FC_PrepareWindowStatic".

1. Declare the block interface as follows:

FC_PrepareWindowStatic		
	Name	Data type
1	Input	
2	a	"UDT_RectangleWindowStatic"
3	Output	
4	InOut	
5	Temp	
6	delta	Real
7	x	Real
8	x2	Real
9	y	Real
10	i	DInt
11	Constant	
12	Return	
13	FC_PrepareWindowStatic	Void



2. Write the following program code:

```
1
2  #delta := 6.0;  // Defined by tool 7
3  #i := 0;
4  #x := #a."X1-coordinate" + #delta;
5  WHILE #x < #a."X2-coordinate" - #delta  DO
6      "DB_PunchList".Punch[#i].Tool := 7;
7      "DB_PunchList".Punch[#i].x := #x;
8      "DB_PunchList".Punch[#i].y := #y + #delta;
9      "DB_PunchList".Punch[#i].w := 0; // Don't rotate
10     #x := #x + 2 * #delta;
11 END_WHILE;
12
13 #y := #a."Y1-coordinate" + #delta;
14 WHILE #y < #a."Y2-coordinate" - #delta DO
15     "DB_PunchList".Punch[#i].Tool := 7;
16     "DB_PunchList".Punch[#i].x := #x2 + #delta;
17     "DB_PunchList".Punch[#i].y := #y;
18     "DB_PunchList".Punch[#i].w := 0; // Don't rotate
19     #y := #y + 2 * #delta;
20 END_WHILE;
```

Call the SCL function block "FC_PrepareOrder" in the SCL function block "FB_PickNextOrder":

```
1
2  IF #OrderReady THEN
3      #Order := "DB_OrderList".Order[#OrderNo];
4      #OrderNo := #OrderNo + 1;
5      #OrderReady := false;
6      "FC_PrepareOrder"(Order:=#Order,
7                        Error=>#Error);
8
9  END_IF;
```

Then, call the "FB_PickNextOrder" in OB1:

Result

This example shows you how to use the instruction "DB_ANY_TO_VARIANT: Convert DB_ANY to VARIANT" to determine the PLC data type of a data block and how to select and execute a suitable function based on this.

11.2.5 Using PLC data types (UDT) (S7-1200, S7-1500)

Using a PLC data type

PLC data types (UDT) are data structures that you define yourself and that can be used multiple times in the program. The structure can be composed of multiple elements of different data types. You define the data types of the individual elements during the declaration of a PLC data type.

PLC data types are frequently used if an assembled data record with various data types is required and these are to be processed from different points in the program. For example, these could be:

- Data records for material tracking
- Parameter sets for a motor setting
- Recipes

The use of PLC data types provides you with the following benefits:

- The elements of a PLC data type can also be addressed indirectly, which means the address is variable and is not calculated until during runtime.
- Tags based on a PLC data type inherit all properties of the PLC data type. When there is a change to the PLC data type, all tags based on this PLC data type are therefore adapted automatically.
- Using universal symbolism makes the program easier to read, because the names of the individual elements of a PLC data type are displayed in the program.
- Optimum utilization of the high performance of an S7-1500 CPU.
- The PLC data type can be passed as a complete structure for a block call.
- A simplified call interface due to a lower number of parameters to be supplied.

Procedure in STEP 7 V5.x

STEP 7 V5.x already gave you the option to create a data record as a structured tag using the STRUCT data type or a PLC data type (UDT). However, the performance was adversely affected by the use of symbolic addressing.

The declaration in the data blocks was mostly implemented as an anonymous structure. The blocks themselves were then programmed to pass the values of the structure as actual parameters and the calculated values were copied back into the structure. This enabled you to also pass the data block number and use absolute addressing in the block. The number of parameters that you had to supply was often very large. The actual data was stored in the data blocks and the calculated values were passed to other blocks. However, no symbolism was available when passing the data block tags.

Programming example in STEP 7 TIA Portal

You can assign both a formula parameter and an actual parameter to a PLC data type. This means that you no longer have to declare individual parameters. If a block has an input parameter that is based on a PLC data type, you must transfer a tag of the same PLC data type as actual parameter.

The following example shows the call and the parameter assignment of a function block (FB) with two formal parameters:

1. To create a PLC data type, double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Rename the PLC data type to "UDT_Material".
3. Declare the following lines within the PLC data type:
   ArticleNumber > Data type: DINT
   ArticleName > Data type: STRING
   Amount > Data type: REAL
   Unit > Data type: STRING

UDT_Material

	Name	Data type
1	ArticleNumber	DInt
2	ArticleName	String
3	Amount	Real
4	Unit	String

Use the PLC data type within a global data block. You can specify the PLC data type either directly as data type of the data block or within the data block as data type of a tag.

Create a global data block for this purpose:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Specify the name "DB_MaterialBuffer".
4. Select the type of the data block "ARRAY DB".
5. Select the PLC data type "UDT_Material" as ARRAY data type.

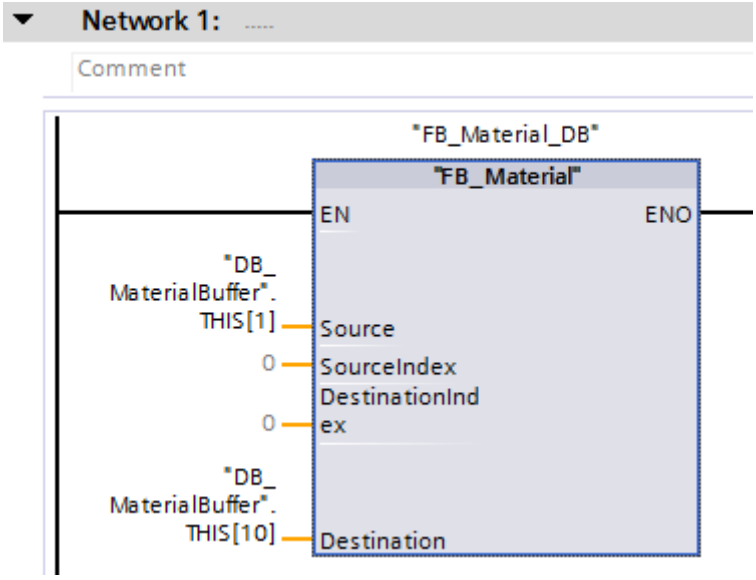
6. Specify "1000" as high ARRAY limit.
7. Click "OK".

DB_MaterialBuffer

	Name	Data type
1	DB_MaterialBuffer	Array[0..1000] of "UDT_Material"
2	DB_MaterialBuffer[0]	"UDT_Material"
3	ArticleNumber	DInt
4	ArticleName	String
5	Amount	Real
6	Unit	String
7	DB_MaterialBuffer[1]	"UDT_Material"
8	DB_MaterialBuffer[2]	"UDT_Material"
9	DB_MaterialBuffer[3]	"UDT_Material"
10	DB_MaterialBuffer[4]	"UDT_Material"
11	DB_MaterialBuffer[5]	"UDT_Material"

At the function block call, interconnect the formal parameters with tags from the global data block "DB_MaterialBuffer".

1. Create an SCL function block and name it "FB_Material".
2. Declare the block interface as follows:



FB_Material

	Name	Data type
1	Input	
2	Source	Variant
3	SourceIndex	DInt
4	DestinationIndex	DInt
5	Output	
6	InOut	
7	Destination	Variant
8	Static	
9	Temp	
10	Result	Int
11	Constant	

3. Write the following program code:

```
1
2 #Result := MOVE_BLK_VARIANT(SRC:=#Source,
3                              COUNT:=3,
4                              SRC_INDEX:=#SourceIndex,
5                              DEST_INDEX:=#DestinationIndex,
6                              DEST=>#Destination);
```

4. Call the "FB_Material" function block in OB1 and interconnect the formal parameters with tags of the global data block "DB_MaterialBuffer":

The material data are moved within the global data block "DB_MaterialBuffer".

PLC data types (UDT) (Page 2277)

11.2.6 Using MOVE instructions in STL (S7-1500)

Possible applications

You can now program with MOVE instructions in STL on an S7-1500 CPU.

This gives you the following advantages:

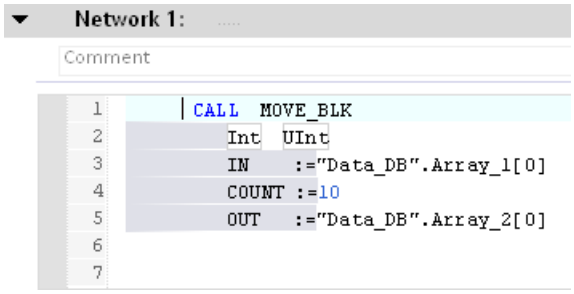
- The program structure is easier to create.
- The performance of the CPU increases.

Programming in STEP 7 V5.x

In STEP 7 V5.x, you used the "BLKMOV: Move block" and "UBLKMOV: Move block uninterruptible" system functions to implement the MOVE functionality.

Procedure in STEP 7 TIA Portal

The following new MOVE instructions are available in STEP 7 TIA Portal:



- MOVE: Move value
- MOVE_BLK: Move block
- MOVE_BLK_VARIANT: Move block
- UMOVE_BLK: Move block uninterruptible

Programming example

The following example shows you how the "MOVE_BLK instruction works: Move block". An ARRAY block is copied into another ARRAY block:

Data_DB

	Name	Data type
1	Static	
2	Array_1	Array [0..10] of Int
3	Array_1[0]	Int
4	Array_1[1]	Int
5	Array_1[2]	Int
6	Array_1[3]	Int
7	Array_1[4]	Int
8	Array_1[5]	Int
9	Array_1[6]	Int
10	Array_1[7]	Int
11	Array_1[8]	Int
12	Array_1[9]	Int
13	Array_1[10]	Int
14	Array_2	Array [0..10] of Int
15	Array_2[0]	Int
16	Array_2[1]	Int
17	Array_2[2]	Int
18	Array_2[3]	Int
19	Array_2[4]	Int
20	Array_2[5]	Int
21	Array_2[6]	Int
22	Array_2[7]	Int
23	Array_2[8]	Int
24	Array_2[9]	Int
25	Array_2[10]	Int

Using the MOVE_BLK instruction, ten elements from "Array_1" of the "Data_DB" data block are copied into "Array_2" of the same data block.

11.2.7 Using IEC timers and counters (S7-1200, S7-1500)

Advantages of IEC timers and counters

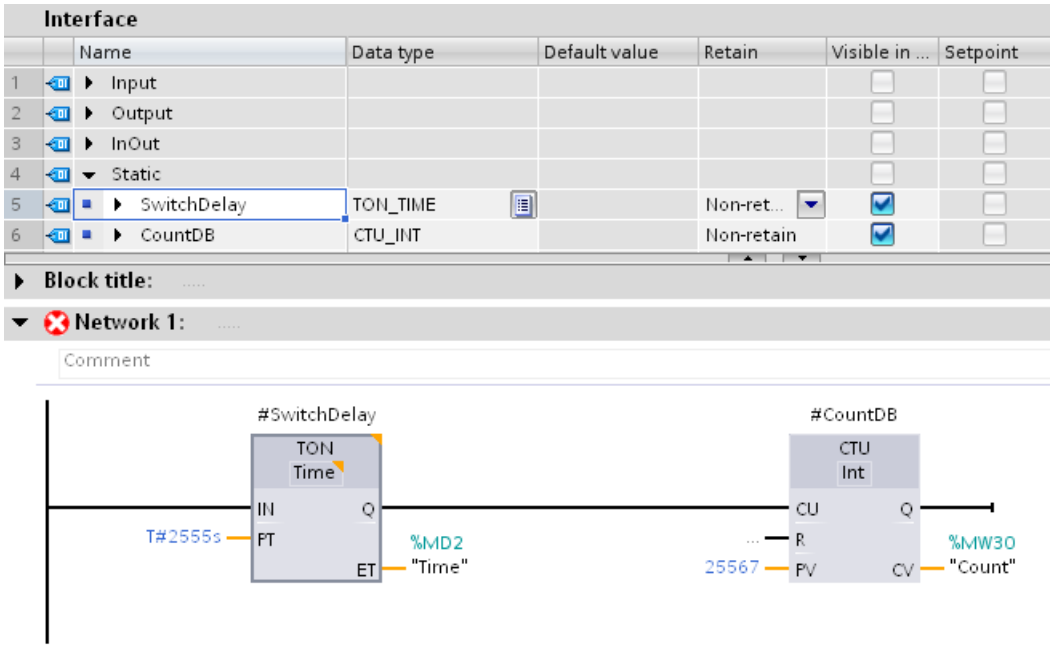
The universal use of IEC timers and counters makes your program code more efficient.

This gives you the following advantages:

- The blocks can be called multiple times with newly generated instance data blocks.
- The IEC counters have a large counting range.
- Compared to S5 timers, IEC timers have better performance and greater time accuracy.

Programming in STEP 7 V5.x

The S5 timers and counters in STEP 7 V5.x were addressed absolutely via a number. Due to this dependency on numbers, program blocks were not reusable with S5 timers and counters.



The value range of a timer was limited to 9990 seconds and that of a counter limited to a maximum of 999.

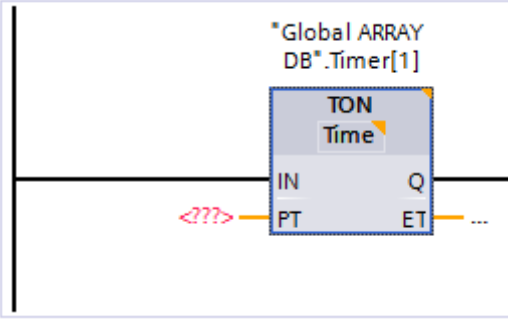
Procedure in STEP 7 TIA Portal

You declare IEC timers and counters in the program block where they are called or needed. The IEC timer is a structure of data type IEC_TIMER, IEC_LTIMER, or TON_TIME and TON_LTIME, for example, which you can also declare as a local tag in a block. The IEC counter is a structure of data type IEC_SCOUNTER, IEC_USCOUNTER, etc.

Programming examples in the TIA Portal

The following example shows you how to declare an IEC timer and IEC counter as a local tag:

The data of the TON IEC timer and the CTU IEC counter is stored as a local tag (multi-instance) in the block interface.



You also have the option to create IEC timers and IEC counters within structures as multiple instances and to use them in your program code.

1. To do this, for example, create a global data block with an ARRAY of TON. The data type TON does not appear in the drop-down list, but can be entered manually:

Global ARRAY DB

	Name	Data type
1	Static	
2	Timer	Array[0..10] of TON
3	Timer[0]	TON
4	Timer[1]	TON
5	Timer[2]	TON
6	Timer[3]	TON
7	Timer[4]	TON
8	Timer[5]	TON
9	Timer[6]	TON
10	Timer[7]	TON
11	Timer[8]	TON
12	Timer[9]	TON
13	Timer[10]	TON

2. Create a function block and drag the instruction "TON: Generate on-delay" to a network. Call the instance of IEC timer TON as follows:

Call of a timer as multi-instance

If you want to use the IN parameter to start a timer as multi-instance, you must not initialize it beforehand in your program code. In this case, the timer called at the IN parameter no longer recognizes a positive signal edge and the timer is not started:

1. Create the timer "Time_1" as a multi-instance of the data type "TP_TIME" in the "Static" section of the block interface.

2. Write the following program code:

STL	Explanation
`A "Tag_Output"`	`// When the "Tag_Output" output receives the signal state 1,`

STL	Explanation
`= #Time_1.IN`	`// the IN parameter of the multi-instance timer #Timer_1 is initialized with a positive signal edge.`

`CALL #Time_1`
`time_type := Time`
`IN := "Tag_Output"`
`PT := T#30s`
`Q := "Tag_4"`
`ET := "Tag_ElapsedTime"`
	`// When the multi-instance timer is now called and the IN parameter queried again, the timer is not started because there is no new positive signal edge.`
	
	`// Enter TIME as data type of the instruction.`

This is why you must program the initialization of the multi-instance timer within the call.

STL	Explanation

`CALL #Time_1`
`time_type := Time`
`IN := "Tag_Output"`
`PT := T#30s`
`Q := "Tag_4"`
`ET := "Tag_ElapsedTime"`
	`// The timer is called and started.`
	
	`// Enter TIME as data type of the instruction.`

11.3 Data types

11.3.1 Overview of the valid data types

Validity of data type groups

The data type groups define the properties of the data, for example, the representation of the contents and the valid memory areas.

In the user program, you have the option of using pre-defined data types, which you add to the data types you have defined yourself. The following type categories are available for this:

- Elementary data types (binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR)
- Complex data types (DT, LDT, DTL, STRING, WSTRING, ARRAY, STRUCT)
- User-defined data types (PLC data type (UDT))
- Pointer
- Parameter types
- System data types
- Hardware data types

The following tables show the availability of data types in the various S7-CPUs:

Table 11-1 Binary numbers

Binary numbers	S7-300/400	S7-1200	S7-1500
BOOL (Page 2243)	X	X	X
Bit strings			
BYTE (Page 2244)	X	X	X
WORD (Page 2245)	X	X	X
DWORD (Page 2245)	X	X	X
LWORD (Page 2246)	-	-	X

Table 11-2 Integers

Integers	S7-300/400	S7-1200	S7-1500

Note

Depending on the CPU version, the actually valid data types can deviate slightly from the table.

11.3.2 Binary numbers

11.3.2.1 BOOL (bit)

Description

An operand of data type BOOL represents a bit value and contains one of the following values:

- TRUE
- FALSE

The following table shows the properties of data type BOOL:

Length (bits)	Format	Value range	Examples of value input
1	Boolean	FALSE or TRUE BOOL#0 or BOOL#1 BOOL#FALSE or BOOL#TRUE	TRUE BOOL#1 BOOL#TRUE
	Unsigned integers (decimal system)	0 or 1	1
	Binary numbers	2#0 or 2#1	2#0
	Octal numbers	8#0 or 8#1	8#1
	Hexadecimal numbers	16#0 or 16#1	16#1

Note

Applies to CPUs of the S7-1500 series

For a block with the block property "Optimized block access", the bit has a length of 1 byte.

11.3.2.2 Bit strings

BYTE

Description

An operand of data type BYTE is a bit string of 8 bits.

The following table shows the properties of data type BYTE:

Length (bits)	Format	Value range	Examples of value input	
			Constants	Absolute and symbolic addresses
8	Integers[1] (decimal system)	Signed integers: -128 to +127 Unsigned integers: 0 to 255	• 15 • BYTE#15 • BYTE#10#15 • B#15	• IB2 • MB10 • DB1.DBB4 • Tag_Name
	Binary numbers	2#0 to 2#1111_1111	• 2#0000_1111 • BYTE#2#0000_1111 • B#2#0000_1111	
	Octal numbers	8#0 to 8#377	• 8#17 • BYTE#8#17 • B#8#17	
	Hexadecimal numbers	16#0 to 16#FF	• 16#0F • BYTE#16#0F • B#16#0F	
[1] The value range depends on the relevant interpretation or conversion.				

Note

The BYTE data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the SINT and USINT data types.

WORD

Description

An operand of data type WORD is a bit string of 16 bits.

The following table shows the properties of data type WORD:

Length (bits)	Format	Value range	Examples of value input	
			Constants	Absolute and symbolic addresses
16	Integers (decimal system)	Signed integers: -32_768 to +32_767 Unsigned integers: 0 to 65_535	• 61_680 • WORD#61_680 • WORD#10#61_680 • W#61_680	• MW10 • DB1.DBW2 • Tag_Name
	Binary numbers	2#0 to 2#1111_1111_1111_1111	• 2#1111_0000_1111_0000 • WORD#2#1111_0000_1111_0000 • W#2#1111_0000_1111_0000	
	Octal numbers	8#0 to 8#177_777	• 8#170_360 • WORD#8#170_360 • W#8#170_360	
	Hexadecimal numbers	16#0 to 16#FFFF	• 16#F0F0 • WORD#16#F0F0 • W#16#F0F0	
	BCD	C#0 to C#999	C#55	
	Decimal sequence	B#(0, 0) to B#(255, 255)	B#(127, 200)	

Note

The WORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the INT and UINT data types.

DWORD

Description

An operand of data type DWORD is a bit string of 32 bits.

The following table shows the properties of data type DWORD:

Length (bits)	Format	Value range	Examples of value input	
			Constants	Absolute and symbolic addresses
32	Integers (decimal system)	Signed integers: -2_147_483_648 to +2_147_483_648 Unsigned integers: 0 to 4_294_967_295	• +15_793_935 • DWORD#+15_793_935 • DWORD#10# +15_793_935 • DW#+15_793_935	• MD10 • DB1.DBD8 • Tag_Name
	Binary numbers	2#0 to 2#1111_1111_1111_1111_1111_1111_1111_1111	• 2#0000_0000_1111_0000_1111_1111_0000_1111 • DWORD#2#0000_0000_1111_0000_1111_1111_0000_1111 • DW#2#0000_0000_1111_0000_1111_1111_0000_1111	
	Octal numbers	8#0 to 8#37_777_777_777	• 8#74_177_417 • DWORD#8#74_177_417 • DW#8#74_177_417	
	Hexadecimal numbers	16#0000_0000 to 16#FFFF_FFFF	• 16#00F0_FF0F • DWORD#16#00F0_FF0F • DW#16#00F0_FF0F	
	Decimal sequence	B#(0, 0, 0, 0) to B#(255, 255, 255, 255)	B#(127, 200, 127, 200)	

Note

The DWORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the DINT and UDINT data types.

LWORD (S7-1500)

Description

An operand of data type LWORD is a bit string of 64 bits.

The following table shows the properties of data type LWORD:

Length (bits)	Format	Value range	Examples of value input
64	Integers (decimal system)	Signed integers: -9_223_372_036_854_775_808 to +9_223_372_036_854_775_807 Unsigned integers: 0 to 18_446_744_073_709_551_615	• +26_123_590_360_715 • LWORD#+26_123_590_360_715 • LWORD#10#+26_123_590_360_715 • LW#+26_123_590_360_715
	Binary numbers	2#0 to 2#1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111	• 2#0000_0000_0000_0000_0000_1011_1110_0001_0010_1111_0101_0010_1101_1110_1000_1011 • LWORD#2#0000_0000_0000_0000_0000_1011_1110_0001_0010_1111_0101_0010_1101_1110_1000_1011 • LW#2#0000_0000_0000_0000_0000_1011_1110_0001_0010_1111_0101_0010_1101_1110_1000_1011
	Octal numbers	8#0 to 8#1_777_777_777_777_777_777_777	• 8#13_724_557_213 • LWORD#8#13_724_557_213 • LW#8#13_724_557_213
	Hexadecimal numbers	16#0000_0000 to 16#FFFF_FFFF_FFFF_FFFF	• 16#0000_0000_5F52_DE8B • LWORD#16#0000_0000_5F52_DE8B • LW#16#0000_0000_5F52_DE8B
	Decimal sequence	B#(0, 0, 0, 0, 0, 0, 0, 0) to B#(255, 255, 255, 255, 255, 255, 255, 255)	B#(127, 200, 127, 200, 127, 200, 127, 200)

Note

The LWORD data type cannot be compared for more than or less than. It can only be supplied with the same decimal data that can be processed by the LINT and ULINT data types.

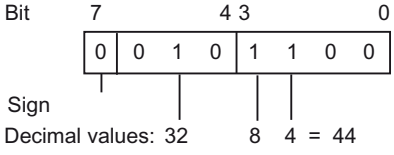
11.3.3 Integers

11.3.3.1 SINT (8-bit integers) (S7-1200, S7-1500)

Description

An operand of data type SINT (Short INT) has a length of 8 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 6 represent the number value. The signal state of bit 7 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.



An operand of data type SINT occupies one BYTE in the memory.

The following table shows the properties of data type SINT:

Length (bits)	Format	Value range	Examples of value input
8	Signed integers (decimal system)	-128 to +127	• +44 • SINT#+44 • SINT#10#+44 The value range extends to a maximum of SINT#255 when using the type SINT#. This value is interpreted as an integer with -1.
	Binary numbers (only positive)	2#0 to 2#0111_1111	• 2#0010_1100 • SINT#2#0010_1100 • SINT#2#10
	Octal numbers (only positive)	8#0 to 8#177	• 8#54 • SINT#8#54
	Hexadecimal numbers (only positive)	16#0 to 16#7F	• 16#2C • SINT#16#2C The value range extends to a maximum of SINT#16#FF when using the type SINT#. This value is interpreted as an integer with -1.

Example

The following figure shows the integer +44 as a binary number:

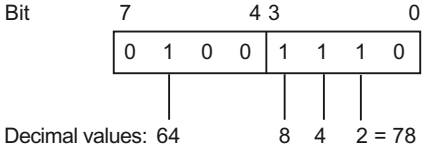
Data type conversion for S7-1200 (Page 2465)

11.3.3.2 USINT (8-bit integers) (S7-1200, S7-1500)

Description

An operand of data type USINT (Unsigned Short INT) has a length of 8 bits and contains unsigned numerical values:



An operand of data type USINT occupies one BYTE in the memory.

The following table shows the properties of data type USINT:

Length (bits)	Format	Value range	Examples of value input
8	Unsigned integers (decimal system)	0 to 255	• 78 • USINT#78 • USINT#10#78
	Binary numbers	2#0 to 2#1111_1111	• 2#0100_1110 • USINT#2#0100_1110 • USINT#2#10
	Octal numbers	8#0 to 8#377	• 8#116 • USINT#8#116
	Hexadecimal numbers	16#0 to 16#FF	• 16#4E • USINT#16#4E

Example

The following figure shows the integer 78 as a binary number:

See also

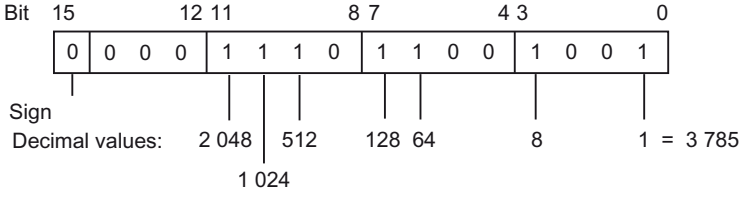
Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.3.3 INT (16-bit integers)

Description

An operand of data type INT has a length of 16 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 14 represent the number value. The signal state of bit 15 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.



An operand of data type INT occupies two BYTE in the memory.

The following table shows the properties of data type INT:

Length (bits)	Format	Value range	Examples of value input
16	Signed integers (decimal system)	-32_768 to +32_767	• +3_785 • INT#+3_785 • INT#10#+3_785
	Binary numbers (only positive)	2#0 to 2#0111_1111_1111_1111	• 2#0000_1110_1100_1001 • INT#2#0000_1110_1100_1001 • INT#2#10
	Octal numbers	8#0 to 8#7_7777	• 8#7311 • INT#8#7311
	Hexadecimal numbers (only positive)	16#0 to 16#7FFF	• 16#0EC9 • INT#16#0EC9

Example

The following figure shows the integer +3785 as a binary number:

See also

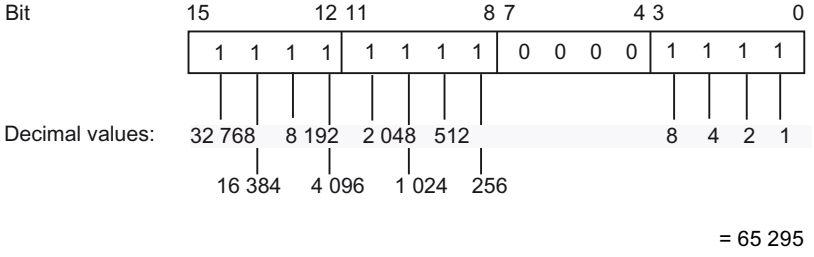
Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.3.4 UINT (16-bit integers) (S7-1200, S7-1500)

Description

An operand of data type UINT (Unsigned INT) has a length of 16 bits and contains unsigned numerical values.



An operand of data type UINT occupies two BYTE in the memory.

The following table shows the properties of data type UINT:

Length (bits)	Format	Value range	Examples of value input
16	Unsigned integers (decimal system)	0 to 65_535	• 65_295 • UINT#65_295 • UINT#10#65_295
	Binary numbers	2#0 to 2#1111_1111_1111_1111	• 2#1111_1111_0000_1111 • UINT#2#1111_1111_0000_1111 • UINT#2#10
	Octal numbers	8#0 to 8#17_7777	• 8#17_7417 • UINT#8#17_7417
	Hexadecimal numbers	16#0 to 16#FFFF	• 16#FF0F • UINT#16#FF0F

Example

The following figure shows the integer 65295 as a binary number:

See also

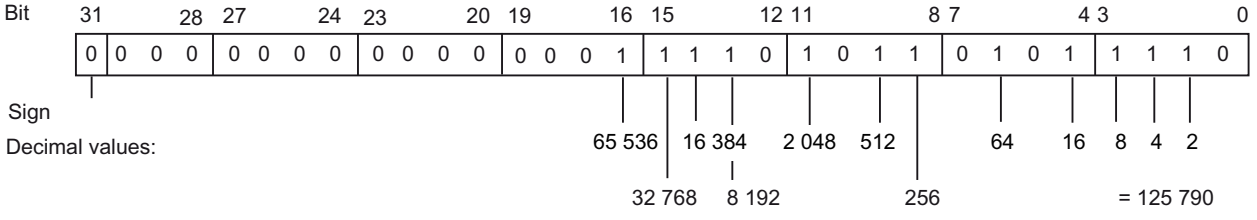
Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.3.5 DINT (32-bit integers)

Description

An operand of data type DINT (Double INT) has a length of 32 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 30 represent the number value. The signal state of bit 31 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.



An operand of data type DINT occupies four BYTE in the memory.

The following table shows the properties of data type DINT:

Length (bits)	Format	Value range	Examples of value input
32	Signed integers (decimal system)	-2_147_483_648 to +2_147_483_647	• +125_790 • DINT#+125_790 • DINT#10#+125_790 • L#275
	Binary numbers (only positive)	2#0 to 2#0111_1111_1111_1111_1111_1111_1111_1111	• 2#0000_0000_0000_0001_1110_1011_0101_1110 • DINT#2#0000_0000_0000_0001_1110_1011_0101_1110 • DINT#2#10
	Octal numbers (only positive)	8#0 to 8#177_7777_7777	• 8#36_5536 • DINT#8#36_5536
	Hexadecimal numbers	16#0 to 16#7FFF_FFFF	• 16#0001_EB5E • DINT#16#0001_EB5E

Example

The following figure shows the integer +125790 as a binary number:

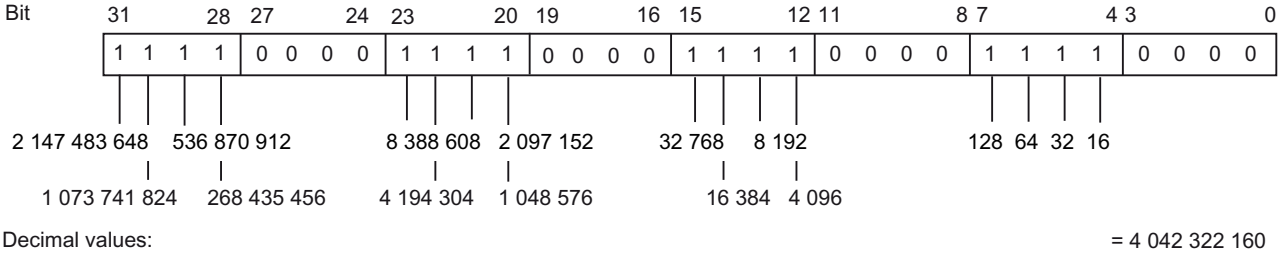
Data type conversion for S7-1200 (Page 2465)

11.3.3.6 UDINT (32-bit integers) (S7-1200, S7-1500)

Description

An operand of data type UDINT (Unsigned Double INT) has a length of 32 bits and contains unsigned numerical values.



An operand of data type UDINT occupies four BYTE in the memory.

The following table shows the properties of data type UDINT:

Length (bits)	Format	Value range	Examples of value input
32	Unsigned integers (decimal system)	0 to 4_294_967_295	• 4_042_322_160 • UDINT#4_042_322_160 • UDINT#10#4_042_322_160
	Binary numbers	2#0 to 2#1111_1111_1111_1111_1111_1111_1111_1111	• 2#1111_0000_1111_0000_1111_0000_1111_0000 • UDINT#2#1111_0000_1111_0000_1111_0000_1111_0000 • UDINT#2#10
	Octal numbers	8#0 to 8#377_7777_7777	• 8#360_7417_0360 • UDINT#8#360_7417_0360
	Hexadecimal numbers	16#0 to 16#FFFF_FFFF	• 16#F0F0_F0F0 • UDINT#16#F0F0_F0F0

Example

The following figure shows the integer 4042322160 as a binary number:

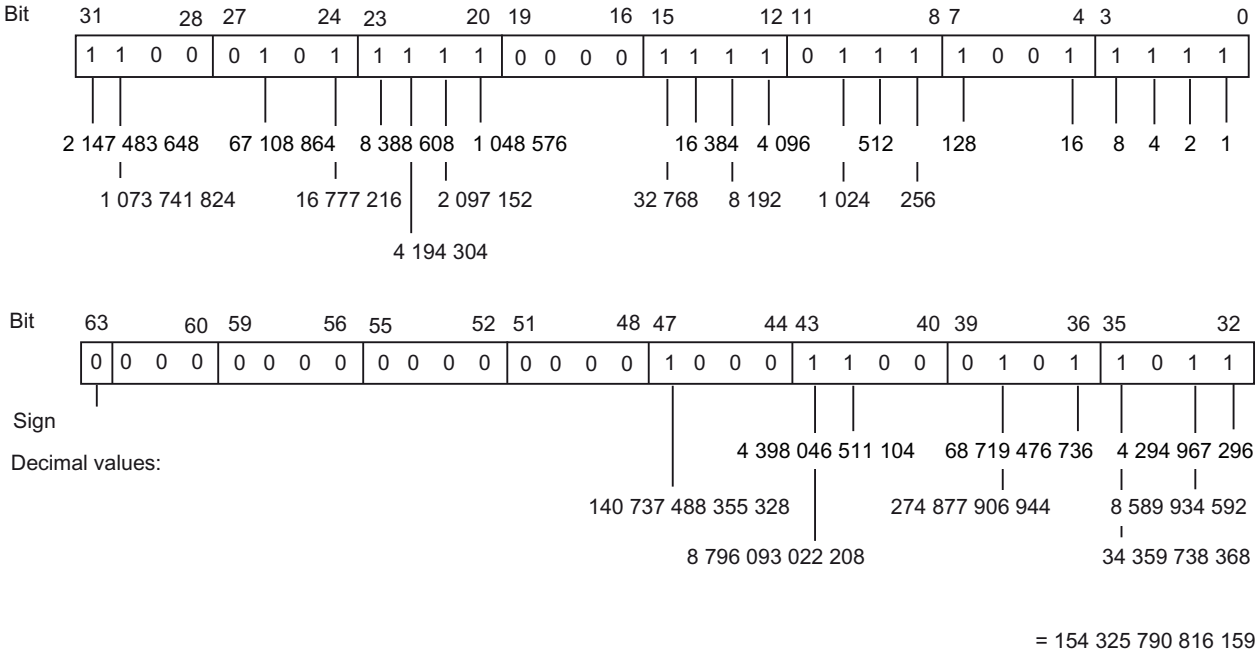
11.3.3.7 LINT (64-bit integers) (S7-1500)

Description

An operand of data type LINT (Long INT) has a length of 64 bits and consists of two components: a sign and a numerical value in the two's complement. The signal states of bits 0 to 62 represent the number value. The signal state of bit 63 represents the sign. The sign may assume "0" for the positive, or "1" for the negative signal state.



An operand of data type LINT occupies eight BYTE in the memory.

The following table shows the properties of data type LINT:

Length (bits)	Format	Value range	Examples of value input
64	Signed integers (decimal system)	-9_223_372_036_854_775_808 to +9_223_372_036_854_775_807	• +154_325_790_816_159 • LINT#+154_325_790_816_159 • LINT#10#+154_325_790_816_159
	Binary numbers (only positive)	2#0 to 2#0111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111	• 2#0000_0000_0000_0000_1000_1100_0101_1011_1100_0101_1111_0000_1111_0111_1001_1111 • LINT#2#0000_0000_0000_0000_1000_1100_0101_1011_1100_0101_1111_0000_1111_0111_1001_1111 • LINT#2#10
	Octal numbers	8#0 to 8#7_7777_7777_7777_7777_7777	• 8#4305_5705_7417_3637 • LINT#8#4305_5705_7417_3637
	Hexadecimal numbers (only positive)	16#0 to 16#7FFF_FFFF_FFFF_FFFF	• 16#0000_8C5B_C5F0_F79F • LINT#16#0000_8C5B_C5F0_F79F

Example

The following figure shows the integer +154325790816159 as a binary number:

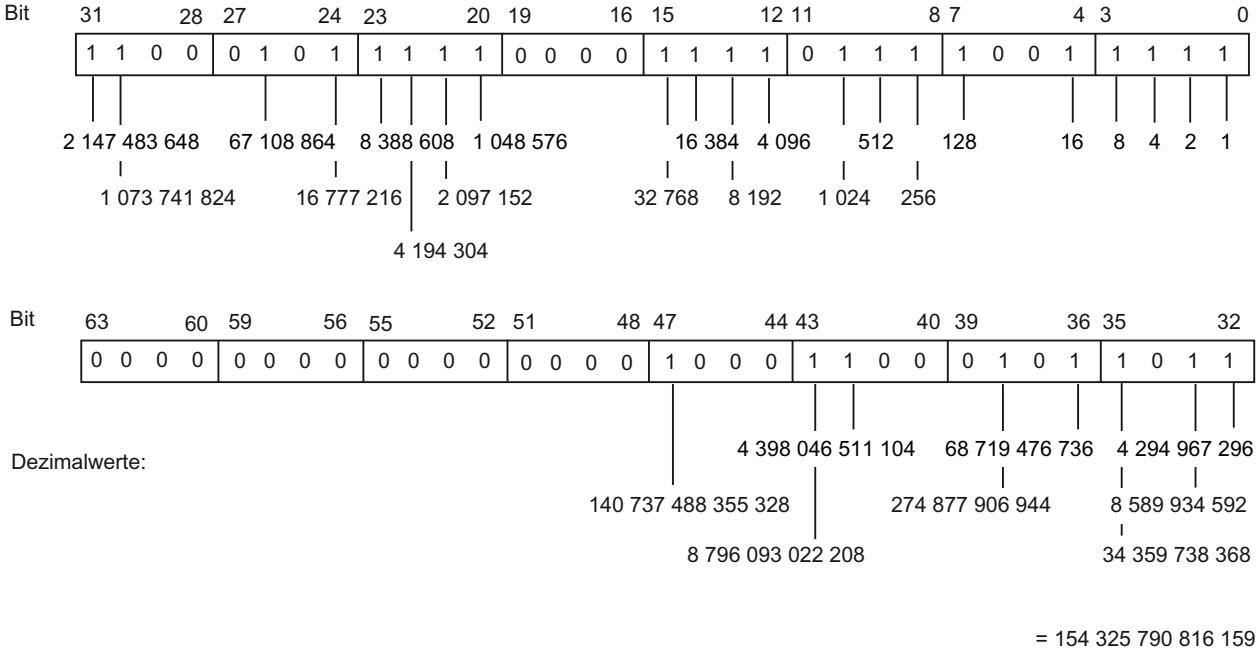
11.3.3.8 ULINT (64-bit integers) (S7-1500)

Description

An operand of data type ULINT (Unsigned Long INT) has a length of 64 bits and contains unsigned numerical values.



An operand of data type ULINT occupies eight BYTE in the memory.

The following table shows the properties of data type ULINT:

Length (bits)	Format	Value range	Examples of value input
64	Unsigned integers (decimal system)	0 to 18_446_744_073_709_551_615	• 154_325_790_816_159 • ULINT#154_325_790_816_159 • ULINT#10#154_325_790_816_159
	Binary numbers	2#0 to 2#1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111_1111	• 2#0000_0000_0000_0000_1000_1100_0101_1011_1100_0101_1111_0000_1111_0111_1001_1111 • ULINT#2#0000_0000_0000_0000_1000_1100_0101_1011_1100_0101_1111_0000_1111_0111_1001_1111 • ULINT#2#10
	Octal numbers	8#0 to 8#17_7777_7777_7777_7777_7777	• 8#4305_5705_7417_3637 • ULINT#8#4305_5705_7417_3637
	Hexadecimal numbers	16#0 to 16#FFFF_FFFF_FFFF_FFFF	• 16#0000_8C5B_C5F0_F79F • ULINT#16#0000_8C5B_C5F0_F79F

Example

The following figure shows the integer 154325790816159 as a binary number:

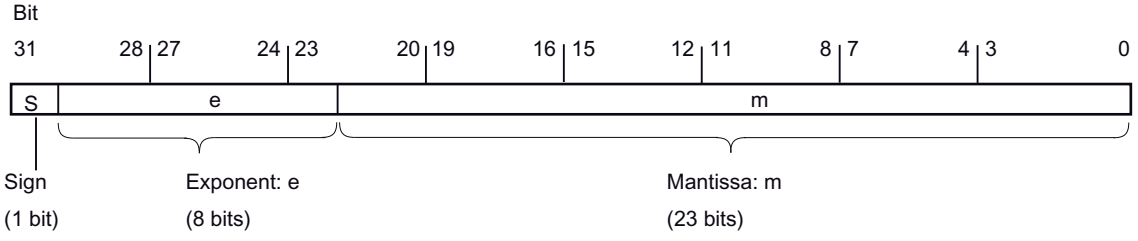
11.3.4 Floating-point numbers

11.3.4.1 REAL



Description

Operands of the data type REAL have a length of 32 bits and are used to represent floating-point numbers. An operand of the REAL data type consists of the following three components:

- Sign: The sign is determined by the signal state of bit 31. The bit 31 assume the value "0" (positive) or "1" (negative).
- 8-bit exponents to basis 2: The exponent is increased by a constant (base, +127), so that it has a value range of 0 to 255.
- 23-bit mantissa: Only the fraction part of the mantissa is shown. The integer part of the mantissa is always 1 with normalized floating-point numbers and is not stored.

The REAL data type is processed with a precision of 6 digits.

The following figure shows the structure of the REAL data type:

Note

With floating-point numbers, only the precision defined by the IEEE754 standard is stored. Additionally specified decimals are rounded off according to IEEE754.

The number of decimal places may decrease for frequently nested arithmetic calculations.

If more decimal places are specified than can be stored by the data type, the number is rounded to the value corresponding to the precision allowed by this value range.

The following table shows the properties of data type REAL:

Length (bits)	Format	Value range	Examples of value input
32	Floating-point numbers according to IEEE754	-3.402823e+38 to -1.175495e-38 ±0.0 +1.175495e-38 to +3.402823e+38	1.0e-5; REAL#1.0e-5
	Floating-point numbers		1.0; REAL#1.0

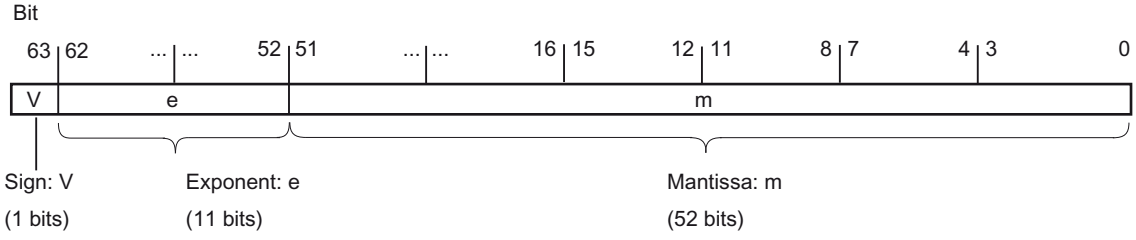
Calculating with floating-point numbers (REAL and LREAL) in SCL (Page 5005)

Data type conversion for S7-1200 (Page 2465)

11.3.4.2 LREAL (S7-1200, S7-1500)



Description

Operands of the data type LREAL have a length of 64 bits and are used to represent floating-point numbers. An operand of the LREAL data type consists of the following three components:

- Sign: The sign is determined by the signal state of bit 63. The bit 63 assumes the value "0" (positive) or "1" (negative).
- 11-bit exponents to base 2: The exponent is increased by a constant (base, +1023), so that it has a value range of 0 to 2047.
- 52-bit mantissa: Only the fraction part of the mantissa is shown. The integer part of the mantissa is always 1 with normalized floating-point numbers and is not stored.

The LREAL data type is processed with a precision of 15 digits.

The following figure shows the structure of the LREAL data type:

The following table shows the properties of data type LREAL:

Length (bits)	Format	Value range	Examples of value input
64	Floating-point numbers according to IEEE754	-1.7976931348623158e+308 to -2.2250738585072014e-308 ±0.0	1.0e-5; LREAL#1.0e-5
	Floating-point numbers	+2.2250738585072014e-308 to +1.7976931348623158e+308	1.0; LREAL#1.0

Note

With floating-point numbers, only the precision defined by the IEEE754 standard is stored. Additionally specified decimals are rounded off according to IEEE754.

The number of decimal places may decrease for frequently nested arithmetic calculations.

If more decimal places are specified than can be stored by the data type, the number is rounded to the corresponding value of the precision allowed by this value range .

Data type conversion for S7-1200 (Page 2465)

11.3.4.3 Invalid floating-point numbers

Description

We distinguish between four number ranges for data types REAL and LREAL:

- normalized numbers stored with full accuracy
- denormalized numbers not stored with full accuracy
- Infinite numbers: +Inf/-Inf (infinity)
- Invalid numbers: NaN (Not a Number)

Note

Floating-point numbers are stored as specified by the IEEE754 standard. Results of conversion or arithmetic functions with a denormalized, infinite or NaN (Not a Number) floating point depend on the CPU.

If you are not working with normalized floating-point numbers in mathematical functions, the result will show significant differences depending on the series of the CPU which you are using.

A CPU cannot calculate with denormalized floating-point numbers, with the exception of older CPU versions of the S7-300 and S7-400 series. The bit pattern of a denormalized number is interpreted as a zero. If the result of calculation falls into this range, it is continued with zero; the status bits OV and OS are set (number range undershoot).

Even though the values of invalid floating-point numbers can only be displayed with limited accuracy for mathematical functions, numbers with an exponent of -39 (e.g. 2.4408e-039) can be monitored in the TIA Portal and therefore do not necessarily represent a faulty result. This means that floating-point values may be located outside the range of valid numerical values.

Note

The following applies to CPUs of the series S7-1200 V1, V2 and V3:

The comparison operation "Equal" uses the bit pattern of the invalid floating-point number. If two "NaN numbers" with the same bit pattern are compared, the output of the "Equal" comparison operation returns the result TRUE.

Note

The following applies to CPUs of the S7-1200 V4 and S7-1500 series:

If two invalid numbers (NaN) are compared with each other, the result is always FALSE, regardless of the bit pattern of the invalid number or the relation (>, >, ...).

Note

Comparison of denormalized floating-point numbers

For the comparison operation "Equal" with two denormalized floating-point numbers, the output for CPUs of the S7-300/400 series is set to the signal state "0" and for CPUs of the S7-1200/1500 series to the signal state "1".

If the input variables of a mathematical function represent an invalid floating-point number, an invalid floating-point number will also be output as result.

You have the following options to evaluate possible errors caused by invalid floating-point numbers:

- In LAD/FBD and SCL, you can query the enable output ENO for FALSE
- In STL, you can evaluate the status bit OV

Data type conversion for S7-1200 (Page 2465)

11.3.5 Timers

11.3.5.1 S5TIME (duration) (S7-300, S7-400)

Format

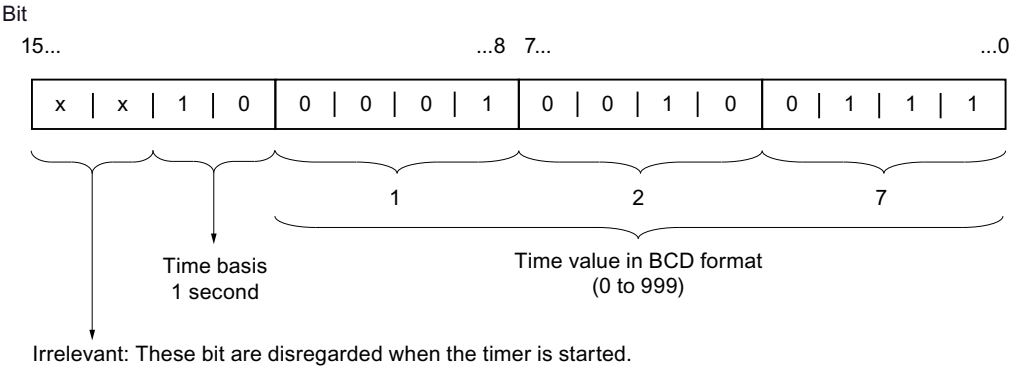
Data type S5TIME stores the duration in BCD format. The duration is the product from a time in the range 0 to 999 and a time basis. The time basis indicates the interval at which a timer decrements the time value by one unit until it reaches "0". The resolution of the times can be controlled via the time basis.

The following table shows the range of values for data type S5TIME:

Length (bits)	Format	Range of values	Examples of value input
16	S7 time in increments of 10 ms (default value)	S5T#0MS to S5T#2H_46M_30S_0MS	S5T#10s, S5TIME#10s
	Hexadecimal numbers	16#0 to 16#3999	16#2

The following table shows the time base coding for S5TIME:

Time basis	Binary code for time basis
10 ms	00
100 ms	01
1 s	10
10 s	11



Always observe range limits and the resolution of time values when using data type S5TIME with timers. The table below specifies the range associated with each resolution:

Resolution	Range
0.01 s	10 ms to 9 s 990 ms
0.1 s	100 ms to 1 min 39 s 900 ms
1 s	1 s to 16 min 39 s
10 s	10 s to 2 h 46 min 30 s

Values that exceed 2h46m30s are not accepted.

Example

The following figure shows the content of the time operand for a time value of 127 and a time base of 1 s:

See also

Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.5.2 TIME (IEC time)

Description

The contents of an operand of the data type TIME is interpreted as milliseconds. The representation contains information for days (d), hours (h), minutes (m), seconds (s) and milliseconds (ms).

The following table shows the properties of data type TIME:

Length (bits)	Format	Value range	Examples of value input
32	Signed duration	T#-24d_20h_31m_23s_648ms to T# +24d_20h_31m_23s_647ms	T#10d_20h_30m_20s_630ms, TIME#10d_20h_30m_20s_630ms
	Hexadecimal numbers	16#0000_0000 to 16#FFFF_FFFF	16#0001_EB5E

It is not necessary to specify all time units. T#5h10s is a valid entry, for example. If only one unit is specified, the absolute value of days, hours, and minutes must not exceed the high or low limits. When more than one time unit is specified, the value must not exceed 24 days, 23 hours, 59 minutes, 59 seconds or 999 milliseconds.

See also

Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.5.3 LTIME (IEC time) (S7-1500)

Description

The contents of an operand of data type LTIME is interpreted as nanoseconds. The representation contains information for days (d), hours (h), minutes (m), seconds (s) and milliseconds (ms), microseconds (us) and nanoseconds (ns).

The following table shows the properties of data type LTIME:

Length (bits)	Format	Value range	Examples of value input
64	Signed duration	LT#-106751d_23h_47m_16s_854ms_775us_808ns to LT#+106751d_23h_47m_16s_854ms_775us_807ns	LT#11350d_20h_25m_14s_830ms_652us_315ns, LTIME#11350d_20h_25m_14s_830ms_652us_315ns
	Hexadecimal numbers	16#0 to 16#7FFF_FFFF_FFFF_FFFF	16#2

It is not necessary to specify all time units. LT#5h10s is therefore a valid entry, for example. If only one unit is specified, the absolute value of days, hours, and minutes must not exceed the high or low limits. When more than one time unit is specified, the value must not exceed 106751 days, 23 hours, 59 minutes, 59 seconds, 999 milliseconds, 999 microseconds or 999 nanoseconds.

11.3.6 Date and time

11.3.6.1 DATE

Format

The DATE data type saves the date as an unsigned integer. The representation contains the year, the month, and the day.

The contents of an operand of DATE data type correspond in hexadecimal format to the number of days since 01-01-1990 (16#0000).

The following table shows the properties of data type DATE:

Length (bytes)	Format	Value range	Examples of value input
2	IEC date (Year-Month-Day)	D#1990-01-01 to D#2169-06-06	D#2009-12-31, DATE#2009-12-31
	Hexadecimal numbers	16#0000 to 16#FFFF	16#00F2

See also

Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.6.2 TIME_OF_DAY (TOD)

Format

Data type TOD (TIME_OF_DAY) occupies a double word and stores the number of milliseconds since the beginning of the day (0:00 h) as unsigned integer.

The following table shows the properties of data type TOD:

Length (bytes)	Format	Value range	Examples of value input
4	Time-of-day (hours:minutes:seconds.milliseconds)	TOD#00:00:00.000 to TOD#23:59:59.999	TOD#10:20:30.400, TIME_OF_DAY#10:20:30.400

You always need to specify the hours, minutes and seconds. The specification of milliseconds is optional.

See also

Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.6.3 LTOD (LTIME_OF_DAY) (S7-1500)

Format

Data type LTOD (LTIME_OF_DAY) occupies two double words and stores the number of nanoseconds since the beginning of the day (0:00 h) as unsigned integer.

The following table shows the properties of data type LTOD:

Length (bytes)	Format	Value range	Examples of value input
8	Time-of-day (hours:minutes:seconds.nanoseconds)	LTOD#00:00:00.000000000 to LTOD#23:59:59.999999999	LTOD#10:20:30.400_365_215, LTIME_OF_DAY#10:20:30.400_365_215

You always need to specify the hours, minutes and seconds. The specification of nanoseconds is optional.

11.3.6.4 DATE_AND_TIME (date and time of day)

Format

The DT (DATE_AND_TIME) data type saves the information on date and time of day in BCD format.

The following table shows the properties of data type DT:

Length (bytes)	Format	Value range	Example of value input
8	Date and time (year-month-day-hour:minute:second:millisecond [3])	Min.: DT#1990-01-01-00:00:00.000 Max.: DT#2089-12-31-23:59:59.999	DT#2008-10-25-08:12:34.567, DATE_AND_TIME#2008-10-25-08:12:34.567

The following table shows the structure of the DT data type:

Byte	Contents	Value range
0	Year	0 to 99 (Years 1990 to 2089) BCD#90 = 1990 ... BCD#0 = 2000 ... BCD#89 = 2089
1	Month	BCD#1 to BCD#12
2	Day	BCD#1 to BCD# 31
3	Hour	BCD#0 to BCD#23
4	Minute	BCD#0 to BCD#59
5	Second	BCD#0 to BCD#59
6	The two most significant digits of MSEC	BCD#0 to BCD#999
7 (4MSB) [1]	The least significant digit of MSEC	BCD#0 to BCD#9
7 (4LSB) [2]	Weekday	BCD#1 to BCD#7 BCD#1 = Sunday ... BCD#7 = Saturday
[1] MSB: Most significant bit [2] LSB: Least significant bit [3] Fixed point number

Data type conversion for S7-1200 (Page 2465)

11.3.6.5 LDT (DATE_AND_LTIME) (S7-1500)

Format

Data type LDT (DATE_AND_LTIME) stores the date and time-of-day information in nanoseconds since 01/01/1970 0:0.

The following table shows the properties of data type LDT:

Length (bytes)	Format	Value range	Example of value input
8	Date and time (Year-Month-Day-Hour:Minute:Second.Nanoseconds)	Min.: LDT#1970-01-01-00:00:00.000000000 Max.: LDT#2262-04-11-23:47:16.854775807	LDT#2008-10-25-08:12:34.567
	Hexadecimal numbers	16#0 to 16#7FFF_FFFF_FFFF_FFFF	16#7FFF

11.3.6.6 DTL (S7-1200, S7-1500)

Description

An operand of data type DTL has a length of 12 bytes and stores date and time information in a predefined structure.

The following table shows the properties of data type DTL:

Length (bytes)	Format	Value range	Example of value input
12	Date and time (Year-Month-Day-Hour:Minute:Second.Nanoseconds)	Min.: DTL#1970-01-01-00:00:00.0 Max.: DTL#2262-04-11-23:47:16.854775807	DTL#2008-12-16-20:30:20.250

The structure of data type DTL consists of several components each of which can contain a different data type and range of values. The data type of a specified value must match the data type of the corresponding components.

Note

Invalid monitor value of DTL tags in hexadecimal format

If the monitor value of the DTL tags is represented in hexadecimal format, this can be because one of the values (YEAR, MONTH, DAY, etc.) is invalid. For example, this is the case if a value > 24 was specified at the HOUR tag.

The following table shows the structure components of data type DTL and their properties:

Byte	Component	Data type	Value range
0	Year	UINT	1970 to 2262
1			
2	Month	USINT	1 to 12
3	Day	USINT	1 to 31
4	Weekday	USINT	1(Sunday) to 7(Saturday) The weekday is not considered in the value entry.
5	Hour	USINT	0 to 23
6	Minute	USINT	0 to 59
7	Second	USINT	0 to 59
8	Nanosecond	UDINT	0 to 999999999
9			
10			
11

Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)

11.3.7 Character strings

11.3.7.1 Character

CHAR

Description

A tag of the CHAR (Character) data type has a length of 8 bits and occupies one BYTE of memory.

The CHAR data type stores a single character in ASCII coding. You can find information on the encoding of special characters under "See also > STRING".

The following table shows the value range of the CHAR data type:

Length (bits)	Format	Value range	Example of value inputs
8	ASCII characters	ASCII character set	'A', CHAR#'A'

See also

Overview of the valid data types (Page 2239)

STRING (Page 2270)

WCHAR (S7-1200, S7-1500)

Description

A tag of the data type WCHAR (Wide Characters) has a length of 16 bits and occupies two BYTE of memory.

The WCHAR data type saves a single character of an expanded character set in UFT-16 coding. However, only a subset of the entire Unicode range is covered. Characters that cannot be displayed are made displayable using an escape character.

The following table shows the value range of the WCHAR data type:

Length (bits)	Format	Value range	Example of value input
16	Unicode	$0000 - $D7FF	WCHAR#'a'

See also

Overview of the valid data types (Page 2239)

11.3.7.2 Character strings

STRING

Description

An operand of the STRING data type saves several characters in a character string that can consist of up to 254 characters. In a character string, all characters of the codepage created on the system are permitted. The characters are specified in single quotation marks.

A character string can also contain special characters. The escape character $ is used to identify control characters, dollar signs and single quotation marks.

Note

Different code pages

Please note that the special characters are coded using the code page currently set in Windows. This means that a string that contains special characters can be displayed differently on a different operating system with a different code page.

The dependency of the codepage on the created system makes an international use of the user program more difficult. Only the characters from the 7-bit ASCII coding are internationally valid.

The following table shows the properties of a STRING tag:

Length (bytes)	Format	Value range	Example of value input
n + 2 [1]	ASCII character string incl. special characters	0 to 254 characters	• 'Name' • STRING#'NAME' • STRING#'Na... (The actual length of the string is longer than the space available on the screen.) • STRING#'' (The string is empty.)
[1] An operand of the STRING data type occupies two bytes more than the specified maximum length in the memory.			

The table below shows examples for the notation of special characters:

Character	Hex	Meaning	Example
$L or $l	0A	Line feed	'$LText', '$0AText'
$N	0A and 0D	Line break The line break occupies 2 characters in the character string and is converted to RL in the display in the editor.	'$NText', '$0A$0DText'
$P or $p	0C	Page feed	'$PText', '$0CText'
$R or $r	0D	Carriage return (CR)	'$RText','$0DText'

Character	Hex	Meaning	Example
$T or $t	09	Tab	'$TText', '$09Text'
$$	24	Dollar sign	'100$$', '100$24'
$'	27	Single quotation mark	'$'Text$'','$27Text$27'

If the escape character $ is followed by a letter from the table, the character indicated in the table is entered in the string. If the escape character $ is followed by a letter that is not in the table, this letter is entered in the string. If the escape character $ is followed by two hexadecimal digits or only one digit, this code is entered in the string.

Use in the watch table

The following applies to a CPU of the S7-300/400 series: If a tag of the STRING data type is being monitored, only the first 30 characters will be displayed. If the actual length is greater than 30 characters, an ellipsis (…) is displayed instead of the final apostrophe ('). STRING values with more than 30 characters cannot be used for modifying.

Maximum length of a character string

The maximum length of the character string can be specified during the declaration of an operand using square brackets after the keyword STRING (for example, STRING[4]). You can also use local or global constants to declare the maximum length (for example, STRING[#loc_const] or STRING["glob_const"]). If the specification of the maximum length is omitted, the standard length of 254 characters is set for the respective operand.

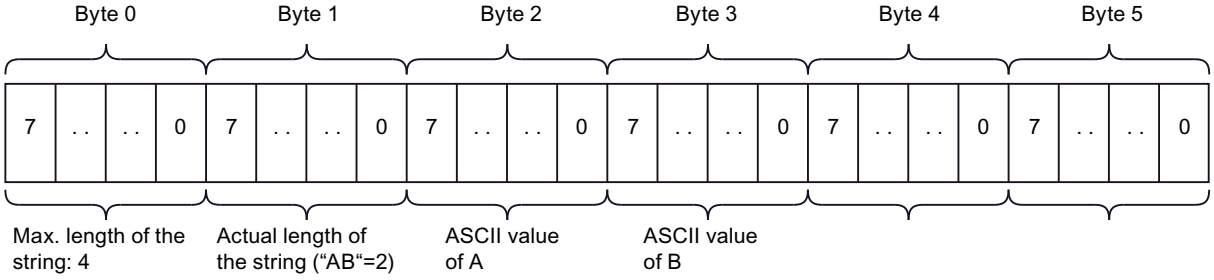
You can find additional information about using local or global constants to declare the maximum length here:

- Declaring the block interface: Declare variables of the STRING and WSTRING data types (Page 4778)
- Programming data blocks: Declaring tags of the STRING data type (Page 4806)
- AUTOHOTSPOT

If the actual length of a specified character string is shorter than the declared maximum length, the characters are written to the character string left-justified and the remaining character spaces remain undefined. Only occupied character spaces that define the actual length of the string are considered for the value processing and all displays.

Note

For S7-300/400 CPUs, please note: If a temporary tag of the STRING data type was defined, you must describe the BYTE "Max. length of string" with the defined length before you use the tags in the user program.



Transferring a STRING for parameter supply

You can transfer the STRING data type as a parameter. You can find additional information on parameter supply with STRING here:

- Transferring a tag of the STRING or WSTRING data type (Page 2277)
- For S7-1200/1500: Valid data types in the block interface (Page 4768)
- For S7-300/400: Valid data types in the block interface (Page 4767)

Example

The example below shows the byte sequence if the STRING[4] data type is specified with output value 'QB':

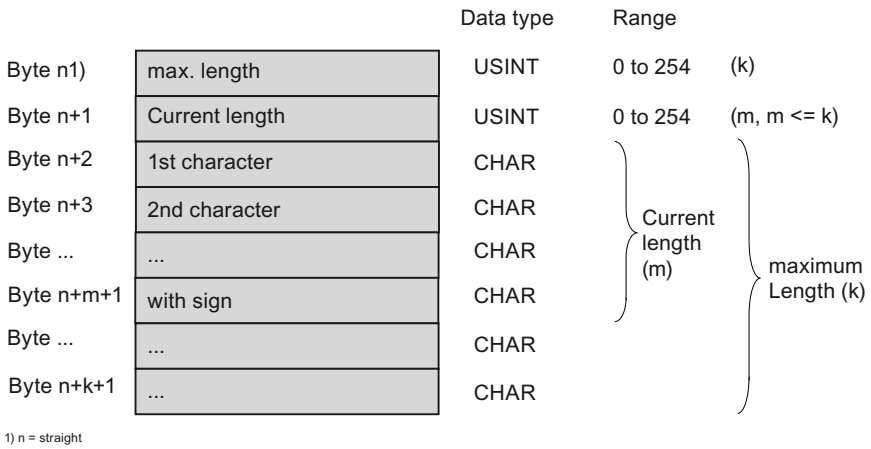
Overview of the valid data types (Page 2239)

Data type conversion for S7-1200 (Page 2465)



Structure of a STRING tag

Introduction

A tag with STRING data type (character string) is maximum 256 characters long with 254 bytes user data. It starts in a non-optimized block at a word limit (at a byte with even address). In an optimized block it can start at any byte limit.

When tags are created their maximum length is specified. In the case of the preassignment or editing of the character string, the current length (the actually used length of the character string = number of valid characters) is entered. The maximum length is located in the first byte of the character string. The current length is in the second byte. This is followed by the characters, coded according to the codepage set in Windows.

Structure of a STRING tag

WSTRING (S7-1200, S7-1500)

Description

An operand of data type WSTRING (Wide Character String) stores several Unicode characters of data type WCHAR in one character string. If you do not specify a length, the character string has a preset length of 254 characters. In a character string, all characters that are supported by the operating system are permitted. This means you can also use Chinese characters in a character string. Windows supports only some (but sufficient number) of the characters defined in Unicode.

When declaring an operand of data type WSTRING you can define its length using square brackets (for example WSTRING[10]). If you do not specify a length, the length of the WSTRING is set to 254 characters by default. You can declare a length of up to 16382 characters (WSTRING[16382]).

The specification of the characters occurs in single quotes and always with the qualifier WSTRING#.

The following table shows the properties of a WSTRING tag:

Length (WORD)	Format	Value range	Example of value input
n + 2 [1]	Unicode character string; n specifies the length of the character string.	Preset value: 0 to 254 characters Max. possible value: 0 to 16382	• WSTRING#'Hello World' • WSTRING#'Hello Wo... (The actual length of the string is longer than the space available on the screen.) • WSTRING#'' (The string is empty.)
[1] An operand of the WSTRING data type occupies two WORDs more in the memory than the specified maximum length.			

A character string can also contain special characters. The escape character $ is used to identify control characters, dollar signs and single quotation marks.

The table below shows examples for the notation of special characters:

Character	Hex	Meaning	Example
$L or $l	000A	Line feed	'$LText', '$000AText'
$N	000A and 000D	Line break The line break occupies 2 characters in the character string and is converted to RL in the display in the editor.	'$NText', '$000A $000DText'
$P or $p	000C	Page feed	'$PText', '$000CText'
$R or $r	000D	Carriage return (CR)	'$RText','$000DText'
$T or $t	0009	Tab	'$TText', '$0009Text'
$$	0024	Dollar sign	'100$$', '100$0024'
$'	0027	Single quotation mark	'$'Text$'','$0027Text $0027'

If the escape character $ is followed by a letter from the table, the character indicated in the table is entered in the string. If the escape character $ is followed by a letter that is not in the table, this letter is entered in the string. If the escape character $ is followed by four hexadecimal digits, this code is entered in the string.

Note

Conversion of WSTRING tags

Implicit conversion of the WSTRING data type is not possible. Explicit conversion of the WSTRING data type to STRING is generally possible. However, as standard, it is only possible to convert characters in the code range from 0 - 127 in all Windows code pages. For all characters outside this range, the code page character and the lower byte of the Unicode character must be in exactly the same position for the conversion to work without errors.

Use in the watch table

If a tag of the WSTRING data type is being monitored, only the first 254 characters are displayed. If the actual length is greater than 254 characters, an ellipsis (…) is displayed instead of the closing apostrophe ('). WSTRING values with more than 254 characters cannot be used for modifying.

Maximum length of a character string

The maximum length of the character string can be specified during the declaration of an operand using square brackets after the keyword WSTRING (for example, WSTRING[4]). You can also use local or global constants to declare the maximum length (for example, WSTRING[#loc_const] or WSTRING["glob_const"]). If the specification of the maximum length is omitted, the standard length of 254 characters is set for the respective operand.

You can find additional information about using local or global constants to declare the maximum length here:

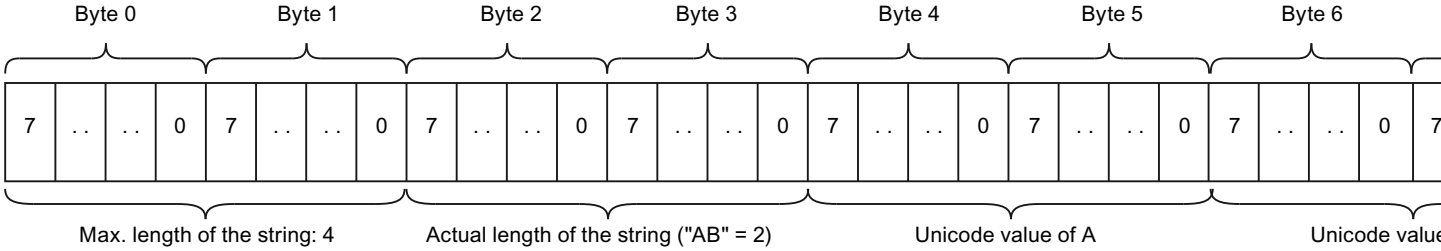
- Declaring the block interface: Declare variables of the STRING and WSTRING data types (Page 4778)
- Programming data blocks: Declaring tags of the STRING data type (Page 4806)
- AUTOHOTSPOT

If the actual length of a specified character string is shorter than the declared maximum length, the characters are written to the character string left-justified and the remaining character spaces remain undefined. Only occupied character spaces are considered in the value processing.

Transferring a WSTRING for parameter supply

Operands of the data type WSTRING can be transferred as parameters up to the maximum length for blocks with "optimized" access.

For function blocks (FB) with "standard" access, operands of the data type WSTRING can be declared as parameters in all sections of the block interface except in the section "InOut". For a function (FC) with "standard" access, only operands of the WSTRING data type can be transferred as parameters.



The function value of an FC in the "Return" section and expressions in the SCL programming language are another exception to this rule. In these cases, the WSTRING tag must not be longer than 1022 characters.

The declared lengths of formal and actual parameters may be different. You can find additional information on parameter supply with WSTRING here:

- Transferring a tag of the STRING or WSTRING data type (Page 2277)
- Valid data types in the block interface (Page 4768)

Example

The example below shows the byte sequence if the WSTRING[4] data type is specified with output value 'QB':

See also

Overview of the valid data types (Page 2239)

Addressing individual characters of a STRING or WSTRING (S7-1200, S7-1500)

Addressing individual characters of a STRING or WSTRING

Use the syntax `StringName[i]` to access an individual character of a STRING or WSTRING tag. The counting index "i" begins with "1". Thus, you access the first character of the string with StringName[1].

You cannot access individual characters of a STRING or WSTRING constant.

Examples

The following examples show the addressing of (W)STRINGs:

Addressing	Explanation
"myDB".mySTRING[3]	Addresses the third character of the STRING in the data block.
#myWSTRING[3]	Addresses the third character of the WSTRING.

Troubleshooting W(STRING) access

Access errors result during runtime when you access a character that is located outside the STRING length. On read access to the character string, you receive the character '$00' or '$0000'; write access to the character string is not executed. If the instruction has the enable output ENO, ENO is set to the signal state FALSE. The CPU does not change to STOP.

The only exception is when the character is written directly after the actual length of the character string.

The following example shows the string 'Hello' with the actual length of 5. The 27th character of the STRING lies outside the actual length and can therefore not be written. The STRING remains unchanged; the result of the assignment is 'hello'.

SCL

```
MyDB.mystring := 'hello';
MyDB.mystring[27] := CHAR_TO_BYTE('!');
```

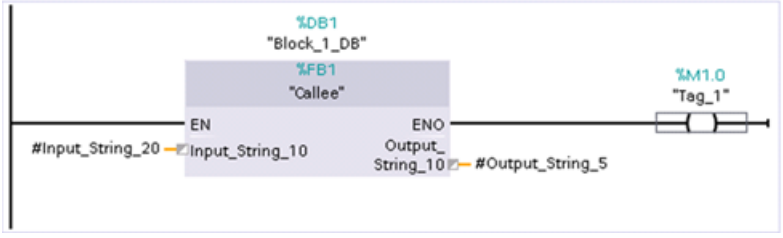
The following example shows the specified exception: The character is written directly after the STRING in the 6th character. The result of the assignment is 'hello!'.

SCL

```
MyDB.mystring := 'hello';
MyDB.mystring[6] := CHAR_TO_BYTE('!');
```

Where possible, use instructions from the "Extended instructions > String + Char" pane to handle STRINGs.

```
CONCAT(IN1 := 'hello', IN2 := '!');
```



Transferring a tag of the STRING or WSTRING data type

Description

You can transfer tags of the STRING or WSTRING data type as parameters. The following table shows the rules that apply to the (W)STRING transfer in the various CPU families:

CPU family	Data type	Rules for transfer at the block call
S7-300/400	STRING	The declared lengths of formal and actual parameters must be identical.
S7-1200/1500	STRING WSTRING	The declared lengths of formal and actual parameters may be different. If the declared length of the target parameter during runtime is insufficient to accept the (W)STRING, the (W)STRING is truncated and the enable output ENO is set to FALSE. In the programming editor, a gray rectangle at the parameter indicates that (W)STRING might be truncated during runtime. Exception: When calling STL blocks, the declared lengths of formal and actual parameters must always be identical.

The following figure shows a block call in which the lengths of the declared formal and actual parameters differ. Due to the different declared lengths, both "Input_String_20" and "Output_String_10" could be truncated during runtime.

11.3.8 PLC data types (UDT)

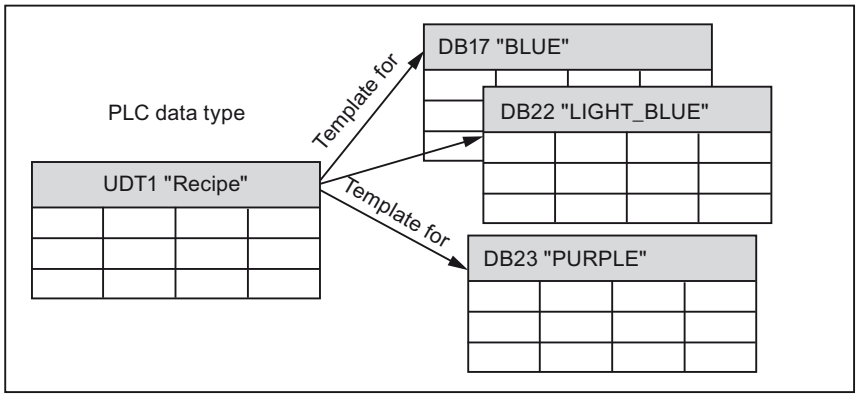
11.3.8.1 Basics of PLC data types (UDT)

Description

A PLC data type (UDT) is a complex, user-defined data type that is used for the declaration of a tag. It represents a data structure made up of several components of different data types. The components can also be derived from another PLC data type, from an ARRAY or directly using the STRUCT keyword as a structure. The nesting depth is hereby limited to 8 levels.

You can change a PLC data type (UDT) centrally and use it repeatedly in the program code. All locations of use are updated automatically.

Advantages of the PLC data types:



- Simple data exchange via block interfaces among several blocks
- Group data according to the process control
- Transferring a parameter as a data unit

Using a PLC data type

You can declare PLC data types as a type when creating data blocks. Based on this type, you can create a number of data blocks, all of which have the same data structure. These data blocks can be adapted by entering different actual values for the corresponding task.

For instance, create a PLC data type for a recipe for blending paints. You can then assign this data type to several data blocks, each of which contains different quantity information.

The following figure shows this application:

PLC data types can be used for the following applications:

- PLC data types can be used as data types for tags in the tag declaration of logic blocks or in data blocks.
- PLC data types can be used as templates for the creation of global data blocks with identical data structures.
- PLC data types can be used in S7-1200 and S7-1500 as a template for the creation of structured PLC tags.

Nesting depth and potential number of PLC data types

A maximum of 64K objects of FCs, FBs, DBs and PLC data types are defined (the total number is restricted accordingly for CPUs, however).

A maximum of 16K components can be defined per hierarchy level for each structure description (for example, a DB or a PLC data type (UDT)). These components can also be an ARRAY or a STRUCT data type. When a structured component is hereby derived from an explicitly declared PLC data type, there is no restriction. In other words, 16K components of PLC data type (UDT)/SDT are supported for each hierarchy level. However, a maximum of 252 of the 16K components can have "anonymous structures".

PLC data types can be nested to a depth of 8 hierarchy levels. This nesting depth is independent of the CPU used.

Generating external sources from blocks

When generating external sources from blocks, the changes made directly in the block interface to the default values of PLC data types are not exported to the sources. This means that these values are not available when the sources are imported once again. The default values are applied instead. To prevent this loss of data for the modified default values, the changes must be made directly in the PLC data type and not in the block interface. In this case, the changes are also exported when external sources are generated.

Disadvantages of anonymous structures

The components of the structured tag can be identically addressed. This is regardless of whether the declaration has been made using a PLC data type or an anonymous structure.

The following disadvantages apply when using anonymous structures:

- Reusability of the same structure by copying. This makes it difficult to change the structure
- Anonymous structures are not compatible with PLC data types (UDT) of the same structure
- Performance, since the matching types for structural components are checked during runtime
- The high limit is more easily reached when using anonymous structures, since all components must be evaluated individually.

Example

The following example shows the data type definition of the "MyUDT" PLC data type:

myUDT

	Name	Datentyp
1	FirstEntry	Struct
2	Value1	Int
3	Value2	Real
4	Value3	"myOtherUDT"
5	Station1	Int
6	Station2	UInt
7	Station3	DInt

CMP ==: Equal (Page 2662)

Transferring a tag of the PLC data type (UDT) (Page 2281)

11.3.8.2 Transferring a tag of the PLC data type (UDT)

Description

You can also transfer tags that are declared as PLC data type (UDT) as actual parameters. If the formal parameter is declared as a PLC data type (UDT) in the tag declaration, you must transfer a tag that has the same PLC data type (UDT) as an actual parameter.

An element of a tag declared using the PLC data type (UDT) can also be transferred as an actual parameter for the block call, provided the data type of the element of the tag matches the data type of the formal parameter.

Structures and user-defined PLC data types can be assigned to one another if they have identical structures. This means that the data types and the order of all structure components must be identical. In nested structures, the data types and the order of the lower-level structures and their components must also match.

Two different PLC data types can also be assigned to one another if the data types and the order of all structure components including the lower-level structures are identical. The names of the PLC data types do not have to match.

User-defined PLC data types and structures cannot be assigned to system data types.

11.3.8.3 Addressing PLC data types (UDT)

Addressing data elements of an PLC data type

The following syntax is used to access elements of a PLC data type:

```
<PLCDataTypeName>.<ElementName>
```

Examples

The following examples show the addressing of structured data type tags:

Addressing	Description
Values.Temperature	Addressing of the "Temperature" element in the "Values" tag, which is based on a PLC data type.

11.3.9 STRUCT data structure (anonymous structures)

11.3.9.1 Basic information on STRUCT

Description

The STRUCT data type represents a data structure that consists of a fixed number of components of different data types. Components of STRUCT or ARRAY data type can also be nested in a structure. Structures can be used to group data according to the process control system and to transfer parameters as one data unit.

Structure declarations that are used directly at the tag are called anonymous structures. An anonymous structure can have the following form:

Global_DB

	Name	Data type
1	Static	
2	Porsche	Struct
3	Motor	Struct
4	Valves	Array[0..5] of Bool
5	Speed_Min	Byte
6	Speed_Max	Byte
7	Temperature	Word
8	Axes	Array[0..4] of Bool
9	Oil	Byte
10	Carriage	Struct
11	Tuning	Struct
12	BMW	Struct
13	Audi	Struct

All of the subsequent explanations refer to this structure image.

Nesting depth and potential number of structures

A nested structure contains at least on additional structure as component. In each case 65535 FCs, FBs, DBs and PLC data types can be defined. For each CPU there is a special high limit relating to the block types and the total of all blocks.

A maximum of 16K components can be defined per hierarchy level for each structure description (for example, a DB or a PLC data type (UDT)). These components can also be an ARRAY or a STRUCT data type. When a structured component is hereby derived from an explicitly declared PLC data type, there is no restriction. For each hierarchy level, 16K components of PLC data type (UDT)/SDT are supported. However, a maximum of 252 "anonymous structures" may exist within a block.

Structures (STRUCT) can be nested to a depth of 8 hierarchy levels. This nesting depth is independent of the CPU used.

Transferring a STRUCT for parameter supply

You can transfer the STRUCT data type as a parameter. You can find additional information on parameter supply with STRUCT here:

Transferring tags of the STRUCT data type (Page 2285)

Disadvantages of anonymous structures

The components of the structured tag can be identically addressed. This is regardless of whether the declaration has been made using a PLC data type or an anonymous structure.

The following disadvantages apply when using anonymous structures:

- Increased maintenance costs: If an anonymous structure was copied multiple times, then it must also have been changed multiple times during a change.
- Anonymous structures are not compatible with PLC data types (UDT) of the same structure
- Performance, since the matching types of all structural components are checked
- Increased memory requirement: Each anonymous structure is a separate object, whose description is loaded to the AS.

Example

If you declare the tag of the data type STRUCT in a PLC data type (UDT), more usage options are available to you (see figure on left). However, you can also declare the tag directly with the data type STRUCT (see figure on right).

Declaration of the structured tag "Motor" with or without PLC data type (UDT):

Structured tag with PLC data type (UDT)

Global_DB

	Name	Data type
1	Static	
2	Porsche	"Vehicle"
3	Motor	Struct
4	Valves	Array[0..5] of Bool
5	Speed_Min	Byte
6	Speed_Max	Byte
7	Temperature	Word
8	Axes	Array[0..4] of Bool
9	Oil	Byte
10	Carriage	Struct
11	Tuning	Struct
12	BMW	"Vehicle"
13	Audi	"Vehicle"

Structured tag without PLC data type (UDT)

Global_DB

	Name	Data type
1	Static	
2	Porsche	Struct
3	Motor	Struct
4	Valves	Array[0..5] of Bool
5	Speed_Min	Byte
6	Speed_Max	Byte
7	Temperature	Word
8	Axes	Array[0..4] of Bool
9	Oil	Byte
10	Carriage	Struct
11	Tuning	Struct
12	BMW	Struct
13	Audi	Struct

See also

Overview of the valid data types (Page 2239)

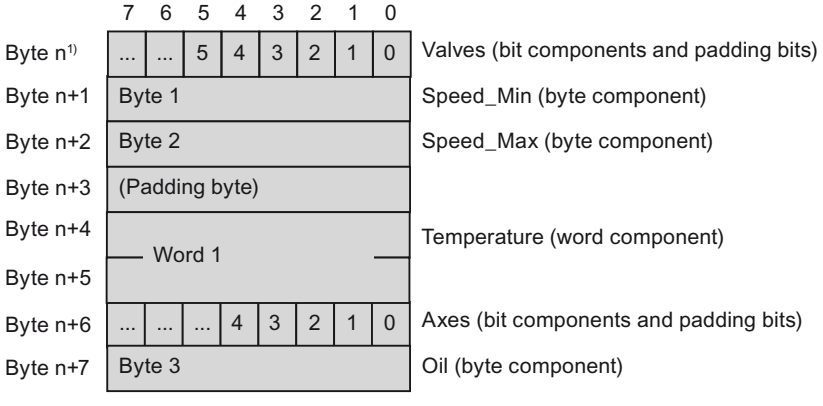
11.3.9.2 Structure of a STRUCT tag

Introduction

A STRUCT tag always starts in a non-optimized block at a word limit, i.e. at a byte with even address. The individual components are then located in the order of their declaration in the memory. STRUCT tags occupy the memory up to the next word limit.

Components with BOOL data type start in the least significant bit. Components with BYTE and CHAR data type start in the next byte. Components with different data type start at a word limit. In optimized blocks the structures are stored so that all components are aligned according to their size. The order in the memory does not correspond to the display in the editor.

A nested structure is a structure that is a component of another structure. A nesting depth of maximum 8 structures is possible. All components can be separately addressed. The individual names of components are separated by a dot.



Structure of a STRUCT tag with elementary and complex data types in the non-optimized memory area:

- Declaration of the "Motor" STRUCT tag

Global_DB

	Name	Data type
1	Static	
2	Porsche	Struct
3	Motor	Struct
4	Valves	Array[0..5] of Bool
5	Speed_Min	Byte
6	Speed_Max	Byte
7	Temperature	Word
8	Axes	Array[0..4] of Bool
9	Oil	Byte
10	Carriage	Struct
11	Tuning	Struct
12	BMW	Struct
13	Audi	Struct

- Required memory of the "Motor" STRUCT tag

1) n = even

11.3.9.3 Addressing STRUCT components

Addressing components in structures

You access individual components of a structure using the following syntax:

```
"DBname".name1.name2.name3
```

Example

The following example shows the addressing of structured data type tags:

Addressing	Explanation
"Global_DB".Motor.Valves[2]	Addressing of the 3rd valve of the "Valves" element in the "Motor" structure of the "Global_DB" global data block.

11.3.9.4 Transferring tags of the STRUCT data type

Description

You can also transfer individual components of a STRUCT tag as actual parameters if the components correspond to the data type of the formal parameter.

You can also transfer complete structures as parameters. If a block has an input parameter of the STRUCT data type, you must transfer a STRUCT with identical structure as the actual parameter. This means that the names and data types of all structure components have to be identical.

Structures and user-defined PLC data types can be assigned to one another if they have identical structures. This means that the data types and the order of all structure components must be identical. In nested structures, the data types and the order of the lower-level structures and their components must also match.

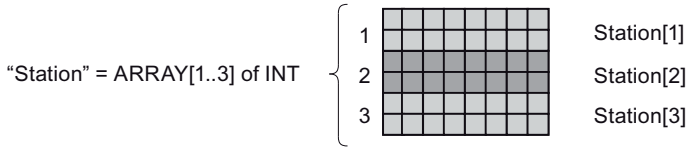
Two different PLC data types can also be assigned to one another if the data types and the order of all structure components including the lower-level structures are identical. The names of the PLC data types do not have to match.

User-defined PLC data types and structures cannot be assigned to system data types.

Note

We recommend that you program structures as PLC data types (UDT). PLC data types (UDT) make programming easier, since they can be used repeatedly and changed centrally.

11.3.10 ARRAY



11.3.10.1 Basic information on ARRAY

Description

A tag of the ARRAY data type represents a data structure that consists of a fixed number of components of the same data type. All data types except ARRAY are permitted for the components.

When you create an ARRAY tag the index limits are defined in square brackets and the data type is defined after the keyword "of". The ARRAY limits can be either defined fixed using integers or global and local constants or as formal parameters of a block, or defined variably using ARRAY[*]. The low limit must be smaller than or equal to the high limit. An ARRAY may contain up to six dimensions, the limits of which can be specified separated by a comma.

The structure of a one-dimensional tag of the ARRAY data type has, for example, the following form:

The maximum ARRAY limits depend on the following factors:

- Data type of the ARRAY component
- Memory reserve (only in blocks with optimized access)
  You can find additional information under: AUTOHOTSPOT.
- Maximum size of the data block
- Maximum memory capacity of the CPU (you can find more information in the manual for the device)

The following table shows the properties of the ARRAY data type:

Block property	Format	ARRAY limits	Data type
Standard	ARRAY[low limit..high limit] of <DataType>	[-32 768..32 767] of <DataType>	All data types except ARRAY
Optimized		[-2 147 483 648..2 147 483 647] of <DataType>	Multi-instances

Various options are available for defining the ARRAY limits depending on the ARRAY that you declared.

ARRAY limits	Global data block / tag table	Block interface
Using integers as fixed ARRAY limits	x	x
Using global constants as fixed ARRAY limits	x	x

ARRAY limits	Global data block / tag table	Block interface
Using local constants as fixed ARRAY limits	-	x
Using variable ARRAY limits ARRAY[*]	-	x
ARRAY of multi-instances	-	x

For more information on the section of the block interface in which you can define an ARRAY or an ARRAY[*], refer to: Valid data types in the block interface (Page 4768)

Note

Applies to CPUs of the S7-1500 series

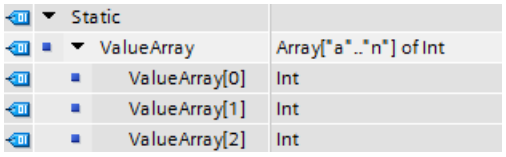
For a block with the "Optimized block access" block property, an element of the BOOL data type requires 1 byte of memory. This is also true when you use an ARRAY of <data type>. An ARRAY[0..1] of BOOL, for example, thus requires 2 bytes in an optimized program block.

Using integers as fixed ARRAY limits

You can use integers as fixed ARRAY limits:

- Example of a one-dimensional ARRAY

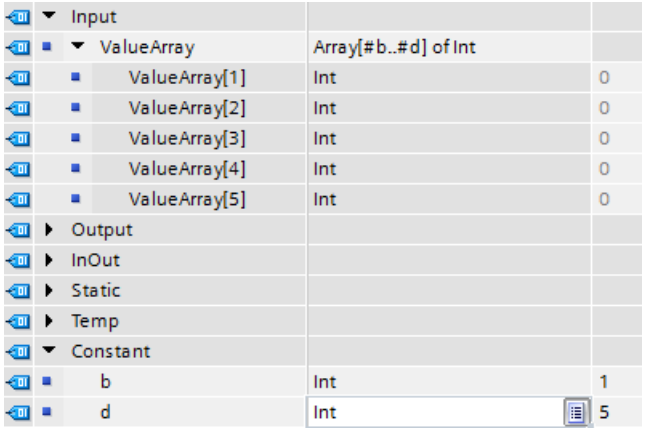
Static	
ValueArray	Array[0..2] of Int
ValueArray[0]	Int
ValueArray[1]	Int
ValueArray[2]	Int



- Example of a three-dimensional ARRAY:

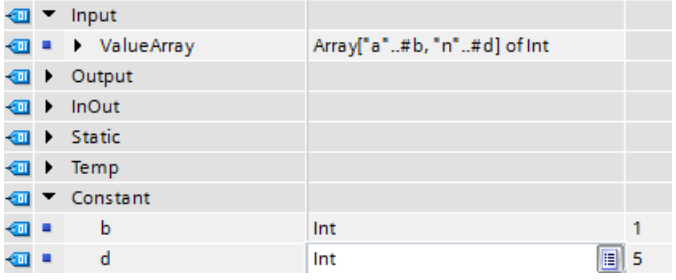
Static	
ValueArray	Array[0..2, 0..2] of Int
ValueArray[0,0]	Int
ValueArray[0,1]	Int
ValueArray[0,2]	Int
ValueArray[1,0]	Int
ValueArray[1,1]	Int
ValueArray[1,2]	Int
ValueArray[2,0]	Int
ValueArray[2,1]	Int
ValueArray[2,2]	Int

Using constants as fixed ARRAY limits



You can use local or global constants as fixed ARRAY limits:

- Fixed ARRAY limits for a one-dimensional ARRAY, consisting of two global user constants

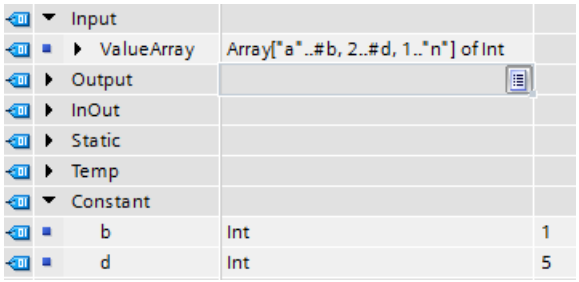


Static		
ValueArray	Array["a".."n"] of Int	
ValueArray[0]	Int	
ValueArray[1]	Int	
ValueArray[2]	Int	

- Fixed ARRAY limits for a one-dimensional ARRAY, consisting of two global user constants

Input		
ValueArray	Array[#b..#d] of Int	
ValueArray[1]	Int	0
ValueArray[2]	Int	0
ValueArray[3]	Int	0
ValueArray[4]	Int	0
ValueArray[5]	Int	0
Output		
InOut		
Static		
Temp		
Constant		
b	Int	1
d	Int	5

- Fixed ARRAY limits for a two-dimensional ARRAY, consisting of global and local user constants



Input		
ValueArray	Array["a"..#b, "n"..#d] of Int	
Output		
InOut		
Static		
Temp		
Constant		
b	Int	1
d	Int	5

For more information on creating and using constants as ARRAY limits, refer to:

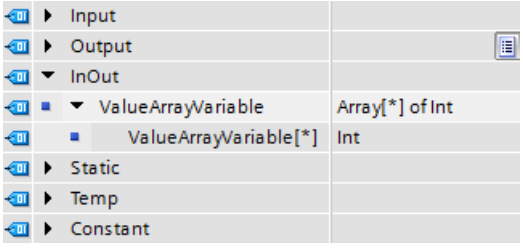
- Declaring local tags and constants in the block interface (Page 4772)
- AUTOHOTSPOT

Using integers and global and local constants as fixed ARRAY limits

You can also combine all three above-named options with each other and also used integers and global and local constants mixed within an ARRAY as ARRAY limits.

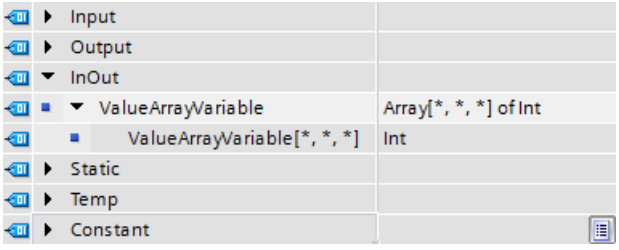
Using variable ARRAY limits ARRAY[*] (only in blocks with optimized access)

You can use an ARRAY[*] to program blocks that can process an ARRAY with flexible length. To do this, you declare variable ARRAY limits for the parameters of a function or function block. ARRAY[*] is available in all programming languages.



Using the "LOWER_BOUND" and "UPPER_BOUND" instructions, you can read the low and high limits of an ARRAY with variable limits during runtime.

Note

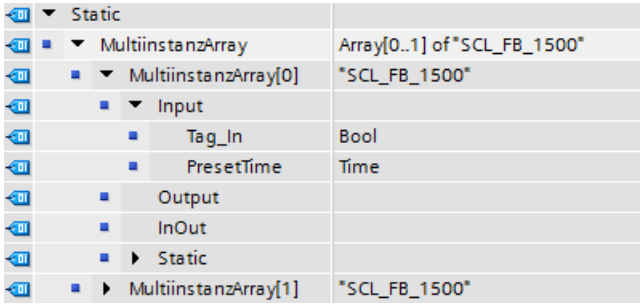


Availability of ARRAY[*]

ARRAY[*] is available in optimized blocks for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. In functions (FC) you can use ARRAY[*] in all declaration subsections. In function blocks (FB) you can declare ARRAY[*] only as an in-out parameter in the "InOut" section.

- Variable ARRAY limits for a one-dimensional ARRAY:

- Variable ARRAY limits for a one-dimensional ARRAY:



You can find additional information on the use of ARRAY[*] here:

- Transferring tags of the ARRAY / ARRAY[*] data type (Page 2294)
- Declaring tags of the ARRAY data type (Page 4775) in the block interface

Using multiple instances (only in blocks with optimized access)

You can also create multi-instances as ARRAY, in order to be able, for example, to use a variable index to address the individual multi-instances during the processing of program loops:

For more information on creating and using multi-instances, refer to:

- AUTOHOTSPOT
- Declaring multi-instances (Page 4780)

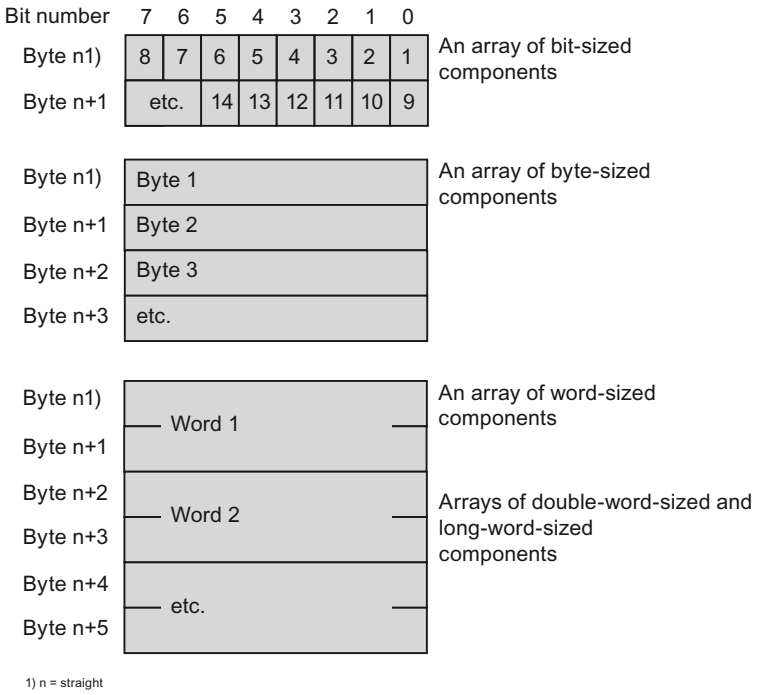
Overview of the valid data types (Page 2239)

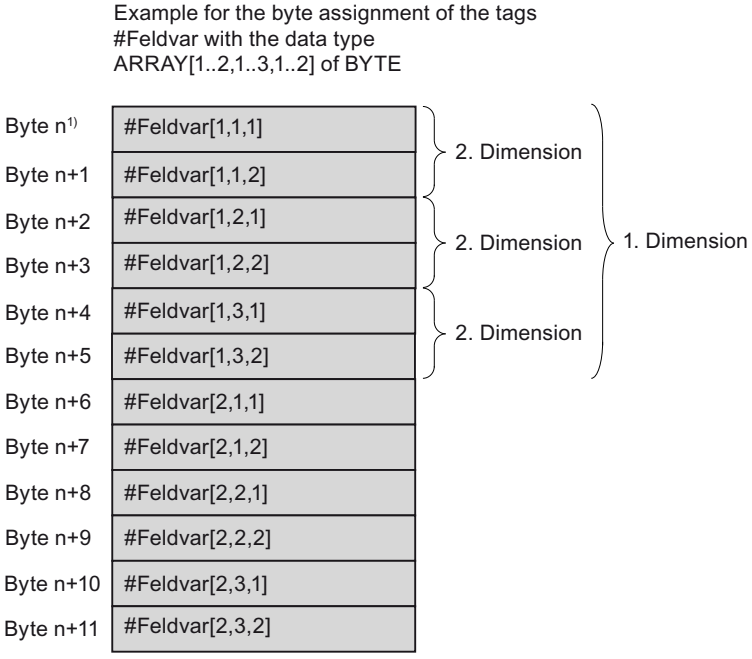
Indirect addressing of ARRAY components (Page 2215)



11.3.10.2 Structure of an ARRAY tag

Introduction

In non-optimized blocks an ARRAY tag never starts at a word limit, i.e. at a byte with even address. ARRAY tags occupy the memory up to the next word limit.



In optimized block the ARRAY requires as much space as the widest element of the structure. This means, for example, that an ARRAY of BYTE is located at a Byte limit and an ARRAY of LREAL is located at an 8-byte limit.

Structure of an ARRAY tag in the one-dimensional array:

Components with BOOL data type start in the least significant bit. Components with BYTE and CHAR data type start in the right byte. The individual components are listed in order.

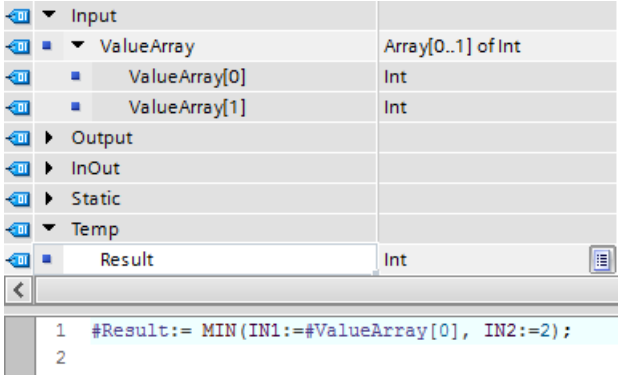
Structure of an ARRAY tag in the multidimensional array:

In multidimensional arrays, the components are stored line-by-line (dimension-by-dimension), starting with the first dimension. In bit and byte components a new dimension always starts at

the next byte. In components of other data types a new dimension always starts in the next word (in the next even byte) in non-optimized blocks.

In optimized blocks each dimension requires as much space as the first dimension.

11.3.10.3 Addressing ARRAY components



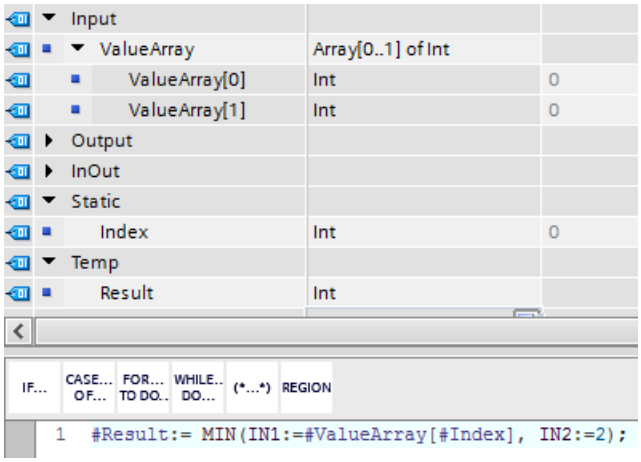
Introduction

ARRAY components are addressed using fixed of variable index. The components of an ARRAY tag can be treated like tags of the same data type.

The index of the component is specified in square brackets. The index includes an integer value (fixed index) or a tag (variable index) for each ARRAY dimension.

Addressing of ARRAY components using fixed index

The addressing of an ARRAY component using fixed index has the following form:



Addressing ARRAY components using variable index

An ARRAY component can also be addressed with a tag the value of which is only calculated during runtime. The tag can be an absolute or symbolic addressed global or local tag of integer data type. This addressing is also possible with multidimensional ARRAYs and with the addressing of sub-arrays. (<ArrayName>[i,j,k...])

A change of the tags in the called block has no effect on an ARRAY component that is created as actual parameter at an in/out parameter and addressed using a variable index. The value is written back to the same ARRAY component, transferred during the call, from which it was read.

The addressing of an ARRAY component using an index tag has the following form:

For more information on the indirect addressing of ARRAY components, refer to:

- AUTOHOTSPOT
- Programming recommendations:Indirect addressing of ARRAY components (Page 2215)

Error handling for ARRAY access

Access errors result when you access an element during runtime which is located outside the declared ARRAY limits. The various CPU families react differently to violations of the ARRAY limits:

- S7-300/400
  - The CPU changes to "STOP" mode.
  - You can program the program execution error OB (OB 85) to prevent this.
  - In SCL, you also have the option of enabling the attribute "Check ARRAY limits" in the block properties. This causes the enable output ENO to be set to FALSE in the case of ARRAY access errors.
- S7-1200
  - The CPU generates a diagnostic buffer entry and remains in "RUN" mode.
- S7-1500
  - The CPU changes to "STOP" mode.
  - You can program the programming error OB (OB 121) to prevent this.
  - You also have the option of programming the local error handling with the instructions "GET_ERROR: Get error locally" or "GET_ERROR_ID: Get error ID locally".

Note

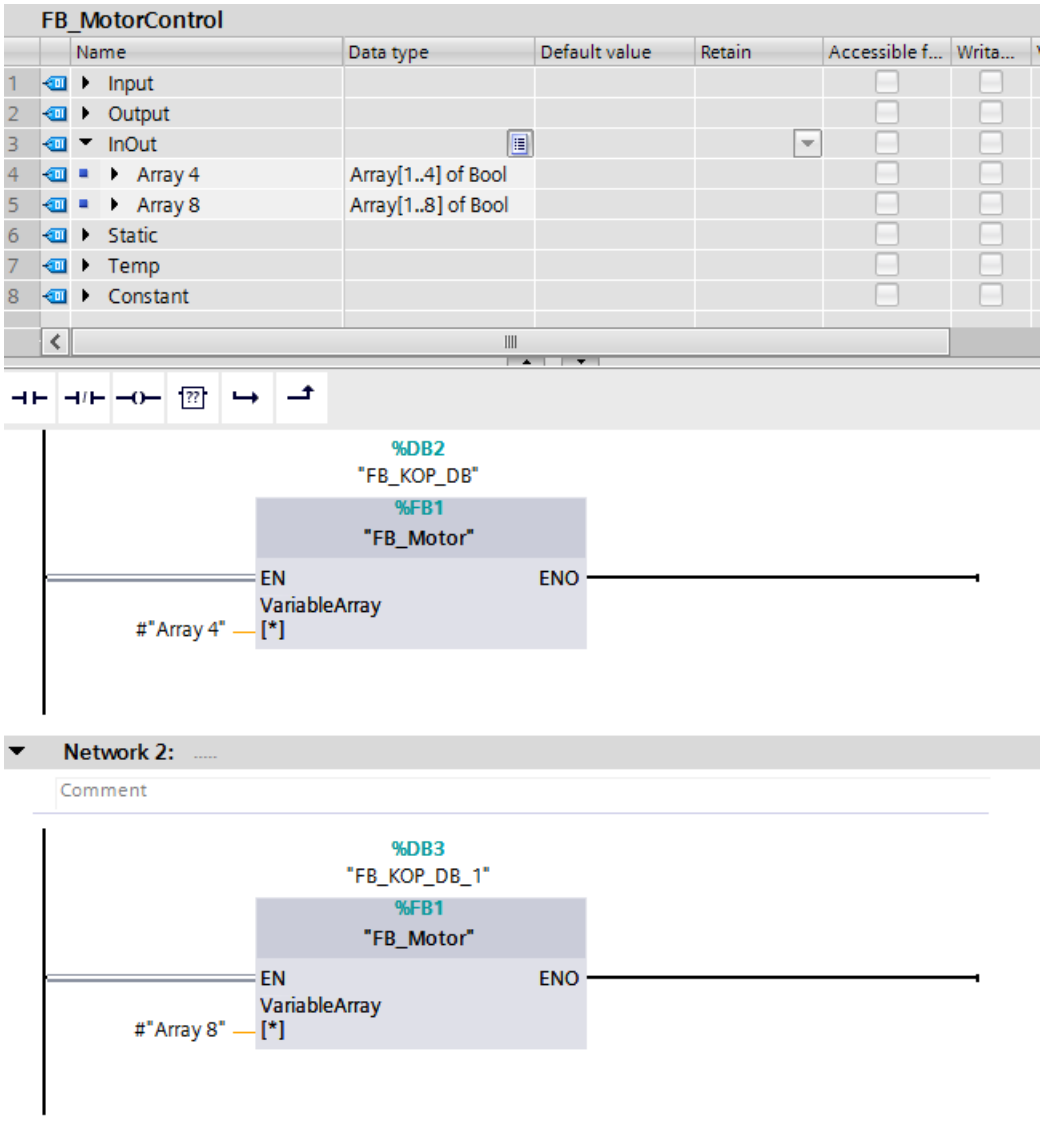
Monitoring ARRAY access errors with ENO

The enable output ENO is not set to the signal state FALSE if the ARRAY limits are violated during execution of an instruction. The only exception is SCL blocks on CPUs of the S7-300/400 series for which the block property "Check ARRAY limits" is set.

11.3.10.4 Transferring tags of the ARRAY / ARRAY[*] data type

Transferring tags of the ARRAY data type

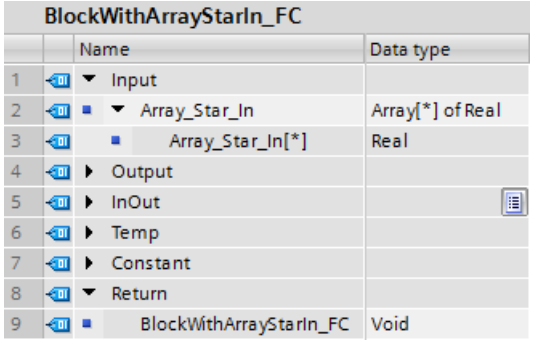
You can also transfer individual elements of an ARRAY as actual parameter if the element corresponds to the data type of the formal parameter.



You can transfer tags of the ARRAY data type as parameters. If a block has an input parameter of ARRAY data type, you must pass an ARRAY with identical structure as the actual parameter. This means that the data type, the number of dimensions and the number of field components must be identical.

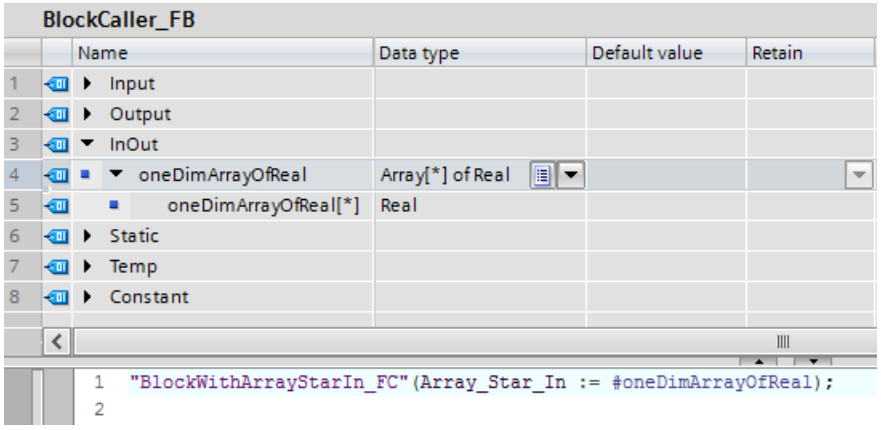
ARRAYs can be assigned to one another if they have an identical structure. This means that the data type, the number of dimensions and the number of array components must be identical. The names of the ARRAYs do not have to match.

Transferring tags of the ARRAY data type[*]



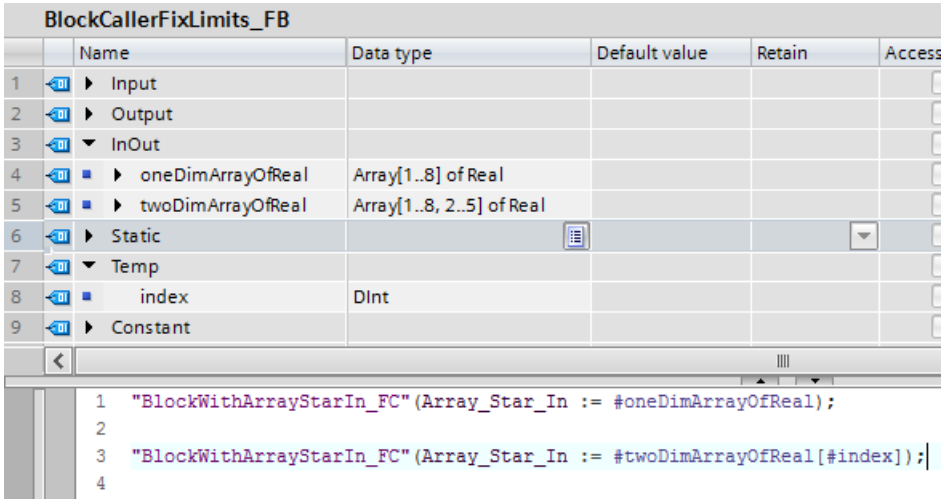
You can use ARRAY[*] to declare ARRAYs with variable limits at the parameters of a function or function block. When you create the block you can define the limits of the ARRAY that will be transferred later during runtime after the call during runtime.

The following figure shows two calls of a block with an input parameter of the ARRAY[*] data type. ARRAYs of different length are transferred with each call.



Applicable rules when transferring ARRAYs with flexible limits

Create the function "BlockWithArrayStarIn_FC" for the example so that it can be called later:



The assignment of ARRAY[*] to ARRAY[*] is permitted if the number of dimensions and the data type match. However, you cannot transfer individual ARRAY components in this process:

1. Declare the function block "BlockCaller_FB" and call the function "BlockWithArrayStarIn_FC":

The assignment of an ARRAY with known limits to an ARRAY[*] is permitted if the number of dimensions and the data type match. Here, you can also assign individual ARRAY components.

1. Declare the function block "BlockCallerFixLimits_FB" and call the function "BlockWithArrayStarIn_FC" twice:

The assignment of ARRAY[*] to VARIANT is permitted. Here, you can also assign individual ARRAY components.

1. Create the function "BlockWithVariantIn_FC" so that it can be called:

BlockWithVariantIn_FC

	Name	Data type
1	Input	
2	Variant_In	Variant
3	Output	
4	InOut	
5	Temp	
6	Constant	
7	Return	
8	BlockWithVariantIn_FC	Void

2. Declare the function "BlockWithArrayStarInVariant_FC" and call the function "BlockWithVariantIn_FC":

BlockWithArrayStarInVariant_FC

	Name	Data type	Default value	Supervision
1	Input			
2	array_star_in	Array[*] of Real		
3	Output			
4	InOut			
5	Temp			
6	index	DInt		
7	Constant			
8	Return			
9	BlockWithArrayStarInVariant_FC	Void		

IF... CASE... OF... FOR... TO DO.. WHILE... DO... (*...*) REGION R_TRIG

```
1  "BlockWithVariantIn_FC"(Variant_In := #array_star_in);
2
3  "BlockWithVariantIn_FC"(Variant_In := #array_star_in[#index]);
4
```

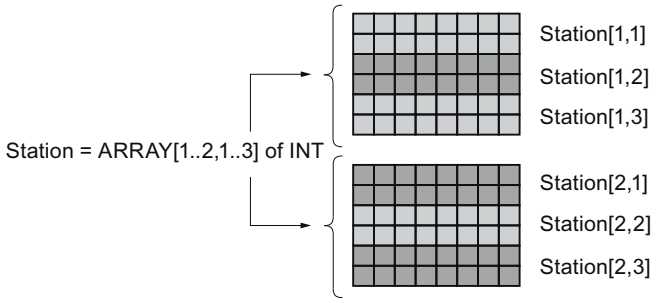
The assignment of ARRAY[*] to ARRAYs with fixed limits is not permitted.

Note

Block parameters of the ARRAY[*] type must be supplied with an actual parameter.

11.3.10.5 Examples of how to use ARRAYs

Example of a multi-dimensional ARRAY



Description

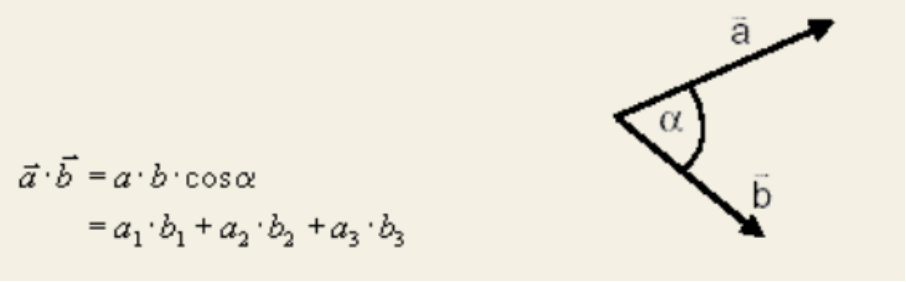
Tags of the ARRAY data type can contain up to 6 dimensions. The same rules apply as for one-dimensional ARRAYs. The dimension areas are written in the declaration in square brackets, each separated by a comma. In multidimensional arrays, the components are stored starting with the first dimension.

The following table shows the declaration of a two-dimensional tag of the ARRAY data type:

Name	Data type	Value	Comment
Betr_Temp	ARRAY[1..2, 1..3] of INT	1,1,4(0)	Two-dimensional tag of the ARRAY data type with 6 components The first two components are assigned the value "1". The remaining four components are assigned the value "0".

The following figure shows the structure of the declared tag of the ARRAY data type:

Access to the components



The values of the individual components are accessed via an index. You can use a constant or a tag for the index. The index of the first component is, for example, [1,1] and the index of the fourth array component is [2,1]. For example, you need to declare "Station[2,1]" in the program to enable access to the value of the fourth component.

Example for calculating the scalar product of two vectors with ARRAY[*]

Description

The scalar product is a mathematical link that assigns a number to two vectors (scalar).

The scalar product of two vectors results in a scalar variable and is defined by:

$$\vec{a} \cdot \vec{b} = a \cdot b \cdot \cos\alpha$$
$$= a_1 \cdot b_1 + a_2 \cdot b_2 + a_3 \cdot b_3$$

Here ∝ is the angle between the two vectors -$\vec{a}$ and $\vec{b}$.

An example for calculating the scalar product is:

$$\vec{a} = \begin{pmatrix} 1 \\ 3 \\ 5 \end{pmatrix}, \vec{b} = \begin{pmatrix} 2 \\ 0 \\ 4 \end{pmatrix}, \vec{a} * \vec{b} = (1*2+3*0+5*4) = 22$$

In this case, the result is the number 22.

In the following programming example, you see how you can calculate the scalar product of two vectors with flexible ARRAY bounds using ARRAY[*]. Here, the function "ScalarProduct_FC" serves as a template for calculating the individual scalar products.

You need the following objects for the programming example:

- Two data blocks and a PLC data type (UDT) for managing the vector data.
- Function that contains the program code for calculating the scalar product.
- The two instructions "LOWER_BOUND" and "UPPER_BOUND" to read out the ARRAY bounds.
- Organization block for calculating the scalar products

Procedure

In this example vectors, that is to say ARRAYs with 1 dimension, are used. Other calculations, such as matrix multiplications, can of course work with multi-dimensional ARRAYs.

To calculate the scalar products, follow these steps:

1. Create the PLC data type (UDT) "VectorArrays_UDT":

VectorArrays_UDT

	Name	Data type
1	VectorD5Coordinates	Array[1..5] of Real
2	VectorD5Coordinates[1]	Real
3	VectorD5Coordinates[2]	Real
4	VectorD5Coordinates[3]	Real
5	VectorD5Coordinates[4]	Real
6	VectorD5Coordinates[5]	Real
7	VectorE13Coordinates	Array[1..13] of Real
8	VectorE13Coordinates[1]	Real
9	VectorE13Coordinates[2]	Real
10	VectorE13Coordinates[3]	Real
11	VectorE13Coordinates[4]	Real
12	VectorE13Coordinates[5]	Real
13	VectorE13Coordinates[6]	Real
14	VectorE13Coordinates[7]	Real
15	VectorE13Coordinates[8]	Real
16	VectorE13Coordinates[9]	Real
17	VectorE13Coordinates[10]	Real
18	VectorE13Coordinates[11]	Real
19	VectorE13Coordinates[12]	Real
20	VectorE13Coordinates[13]	Real

   The two ARRAYs "VectorD5Coordinates" and "VectorE13Coordinates" provide a data basis with which you can then calculate scalar products.

2. Create the "VectorArrays1_DB" data block on the basis of the "VectorArrays_UDT" PLC data type:

VectorArrays1_DB

	Name	Data type
1	Static	
2	VectorD5Coordinates	Array[1..5] of Real
3	VectorE13Coordinates	Array[1..13] of Real

3. Create the second "VectorArrays2_DB" data block. Besides the vectors from the "VectorArrays_UDT" PLC data type, it also contains two other vectors:

VectorArrays2_DB

	Name	Data type
1	Static	
2	VectorA10Coordinates	Array[1..10] of Real
3	VectorB13Coordinates	Array[1..13] of Real
4	VectorsC	"VectorArrays_UDT"
5	VectorD5Coordinates	Array[1..5] of Real
6	VectorE13Coordinates	Array[1..13] of Real

   You have now created the data basis for calculating the scalar products.

4. Create the "ScalarProduct_FC" function as a template for creating the calculation procedure for calculating the scalar product:
   The block interface:

ScalarProduct_FC

	Name	Data type	Comment
1	Input		
2	Vector1	Array[*] of Real	Interface for data input for Vector 1
3	Vector1[*]	Real	Interface for data input for Vector 1
4	Vector2	Array[*] of Real	Interface for data input for Vector 1
5	Vector2[*]	Real	Interface for data input for Vector 1
6	Output		
7	InOut		
8	Temp		
9	Sum	Real	
10	i	Int	
11	LowerBound1	DInt	
12	LowerBound2	DInt	
13	Upperbound1	DInt	
14	UpperBound2	DInt	
15	Constant		
16	Return		
17	ScalarProduct_FC	Real	

   Program code:

```
1  #LowerBound1 := LOWER_BOUND(ARR := #Vector1, DIM := 1);
2  #LowerBound2 := LOWER_BOUND(ARR := #Vector2, DIM := 1);
3  #Upperbound1 := UPPER_BOUND(ARR := #Vector1, DIM := 1);
4  #Upperbound1 := UPPER_BOUND(ARR := #Vector1, DIM := 1);
5
6  IF #LowerBound1 <> #LowerBound2 OR #Upperbound1 <> #UpperBound2 THEN
7      #ScalarProduct_FC := -1;
8      RETURN;
9  END_IF;
10 #Sum := 0;
11 FOR #i := #LowerBound1 TO #Upperbound1 DO
12     #Sum += #Vector1[#i] * #Vector2[#i];
13 END_FOR;
14
15 #ScalarProduct_FC := #Sum;
16
```

   The upper and lower ARRAY bounds of vector 1 and vector 2 are queried in rows 1–4. It is then known how many coordinates the two ARRAYs of the vectors have. As the scalar product cannot be established until the number of coordinates of the two vectors that you wish to multiply is equal, rows 6 to 9 are required
   If the two lower or upper bounds of the ARRAYs are not the same, the "ScalarProduct_FC" function produces the function value "-1" and the program block is exited (RETURN).
   If the two lower or upper bounds of the ARRAY are the same, the #Sum tag in initialized (row 10) with the value "0" and the calculation of the scalar product is executed (rows 11 - 13).

5. Create the "Main_OB" organization block with the event class "Program cycle". The "ScalarProduct_FC" function created in step 4 now serves as a template for calculating scalar products in "Main_OB":
   The block interface:

Main_OB

		Name	Data type
1		Input	
2		Initial_Call	Bool
3		Remanence	Bool
4		Temp	
5		Result1	Real
6		Result2	Real
7		Result3	Real
8		Result4	Real
9		Result5	Real
10		Result6	Real
11		Result7	Real
12		Constant	

Program code:

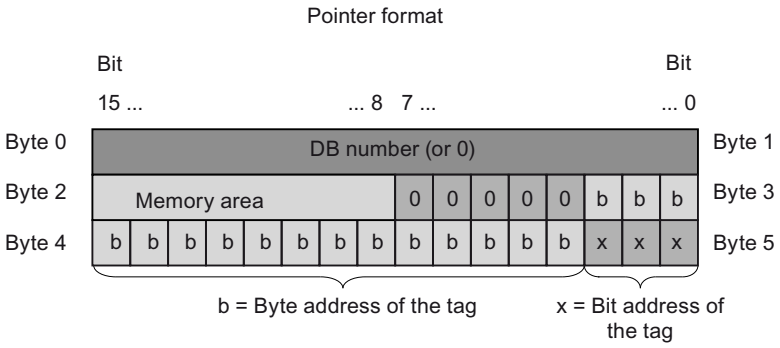
```
#Result1 := "ScalarProduct_FC"(Vector1 := "VectorArrays2_DB".VectorA10Coordinates,
                               Vector2 := "VectorArrays1_DB".VectorE13Coordinates);
#Result2 := "ScalarProduct_FC"(Vector1 := "VectorArrays2_DB".VectorsC.VectorD5Coordinates,
                               Vector2 := "VectorArrays1_DB".VectorD5Coordinates);
#Result3 := "ScalarProduct_FC"(Vector1 := "VectorArrays2_DB".VectorB13Coordinates,
                               Vector2 := "VectorArrays1_DB".VectorE13Coordinates);
#Result4 := "ScalarProduct_FC"(Vector1 := "VectorArrays2_DB".VectorA10Coordinates,
                               Vector2 := "VectorArrays2_DB".VectorA10Coordinates);
#Result5 := "ScalarProduct_FC"(Vector1 := "VectorArrays2_DB".VectorA10Coordinates,
                               Vector2 := "VectorArrays1_DB".VectorE13Coordinates);

```

Result

The results of the individual scalar product calculations are written in the tags #Result1 -5.

11.3.11 Pointer



11.3.11.1 POINTER (S7-300, S7-400, S7-1500)

Description

A parameter of the type POINTER is a pointer that can point to a specific tag. It occupies 6 bytes (48 bits) in memory and may contain the following tag information:

- DB number, or 0 if the data is not stored in a DB
- Memory area in the CPU
- Tag address

The following figure shows the structure of parameter type POINTER:

Types of pointer

Depending on the information, you can use parameter type POINTER to declare the following four types of pointer:

- Area-internal pointer:
  An area-internal pointer contains information on the address of a tag.
- Cross-area pointer:
  A cross-area pointer contains information on the memory area and the address of a tag.
- DB pointer:
  You can use a DB pointer to point to a data block tag. A DB pointer also contains a data block number in addition to the memory area and the address of a tag.
- Zero pointer:
  Use the zero pointer to indicate a missing value. A missing value may indicate that no value exists, or that the value is not yet known. A zero value represents the absence of a value, but is also a value.

The following table shows the formats for the declaration of various pointer types:

P#ByteRepresentation	Format	Example of value input	Description
Symbolic	P#Byte.Bit	"MyTag"	Area-internal pointer
	P#OperandAreaByte.Bit	"MyTag"	Cross-area pointer
	P#Data_block.Data_operand	"MyDB"."MyTag"	DB pointer
	P#Zero value	-	Zero pointer
Absolute	P#Byte.Bit	P#20.0	Area-internal pointer
	P#OperandAreaByte.Bit	P#M20.0	Cross-area pointer
	P#Data_block.Data_operand	P#DB10.DBX20.0	DB pointer
	P#Zero value	P#0.0, ZERO	Zero pointer

The prefix P#

Enter the actual value without prefix P# in the block call to supply a formal parameter of the POINTER data type. The entry is then automatically converted to the POINTER format.

If you use the prefix P#, you can only point to memory areas with "Standard" access mode. You can find additional information and a direct comparison of the two access options here:

- AUTOHOTSPOT
- The new S7-1200/1500 CPU functions and programming recommendations at a glance (Page 2209)

The following should be noted when using the prefix P# in the STL programming language:

Block type	"Optimized" access mode	"Standard" access mode
Function (FC)	A tag cannot be used in the program code with the prefix P#.	The following tags can be used in the program code with the prefix P#. • Structured tags that are declared in the InOut section of the block interface. Tags with elementary data types cannot be used with the prefix P#.
Function block (FB)	A tag cannot be used in the program code with the prefix P#.	The following tags can be used in the program code with the prefix P#. • Tags that have been declared in the sections Static, Input and Output of the block interface. • Tags with the PLC data type (UDT) that are declared in the InOut section of the block interface.

You can find additional information about structured and elementary data types here: AUTOHOTSPOT

Memory areas

The following table shows the hexadecimal codes of the memory areas for parameter type POINTER:

Hexadecimal code	Memory area	Description
B#16#80[1)]	P	Peripherals on a CPU S7-300/400
16#1	P	Peripheral inputs on a CPU S7-1500
16#2	P	Peripheral outputs on a CPU S7-1500
B#16#81	I	Memory area of inputs
B#16#82	Q	Memory area of outputs
B#16#83	M	Memory area of bit memory
B#16#84	DBX	Data block
B#16#85	DIX	Instance data block
B#16#86	L	Local data
B#16#87	V	Previous local data
[1)] These data types can only be used for the POINTER pointer on a CPU S7-300/400.

Overview of the valid data types (Page 2239)

11.3.11.2 ANY (S7-300, S7-400, S7-1500)

Description

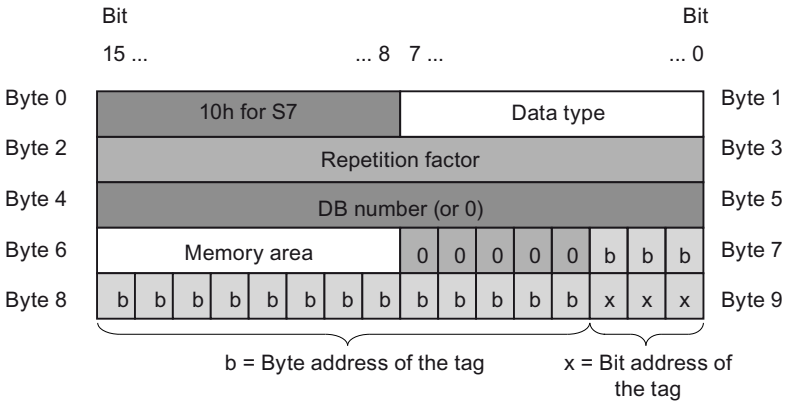
An ANY type parameter points to the start of a data area and specifies its length. An ANY pointer occupies 10 bytes of memory and may contain the following information:

- Data type:
  Data type of the elements of the data area
- Repetition factor:
  Number of elements of the data area
- DB number:
  Data block that contains the declaration of data area elements.
- Memory area:
  Memory area of the CPU that stores the data area elements.
- Start address of the data in the format "byte.bit":
  Data area start identified by the ANY pointer.
- Zero pointer:
  Use the zero pointer to indicate a missing value. A missing value may indicate that no value exists, or that the value is not yet known. A zero value represents the absence of a value, but is also a value.

Note

Access options

For a CPU of the S7-1500 series, the ANY pointer can also only point to memory areas with "Standard" access mode. You can find additional information and a direct comparison of the two access options here:



- AUTOHOTSPOT
- The new S7-1200/1500 CPU functions and programming recommendations at a glance (Page 2209)

In the programming languages SCL and STL, memory of any kind can be transferred upon a block call if an ANY pointer has been programmed at a block parameter.

The ANY pointer cannot, however, store any information on the structure of the memory. For example, the ANY pointer does not save the information that it points to a tag of the PLC data type. The ANY pointer sees this as an ARRAY of BYTE.

Parameters of the ANY data type can be passed to system function blocks (SFBs) or system functions (SFCs).

The following figure shows the structure of the ANY pointer:

An ANY pointer cannot identify structures. It can only be assigned to local tags.

The following table shows the formats for the declaration of an ANY pointer:

Representation	Format	Example of value input	Description
Symbolic	P#DataBlock.MemoryArea DataAddress Type Number	"MyDB".StructTag.InitialComponents	Area with 10 words in global DB11 starting with DBB20.0
	P#MemoryArea DataAddress Type Number	"MyMarkerTag"	Area with 4 bytes starting with MB 20.0
		"MyTag"	Input I1.0
	P#Zero value	-	Zero value
Absolute	P#DataBlock.MemoryArea DataAddress Type Number	P#DB11.DBX20.0 INT 10	Area with 10 words in global DB11 starting with DBB20.0
	P#MemoryArea DataAddress Type Number	P#M20.0 BYTE 10	Area with 10 bytes starting with MB 20.0
		P#I1.0 BOOL 8	Range with 8 bits from input I1.0 (the range length specified must be divisible by 8.)
	P#Zero value	P#P0.0 VOID 0, NULL [1]	Zero value
[1] In the programming languages LAD and FBD, only NULL is a value entry for the zero value.			

Coding of data types

The following table lists the coding of data types for the ANY pointer:

Hexadecimal code	Data type	Description
B#16#00	NIL	Null pointer
B#16#01[1]	BOOL	Bits
B#16#02	BYTE	bytes, 8 bits
B#16#03	CHAR	8-bit characters
B#16#04	WORD	16-bit words
B#16#05	INT	16-bit integers
B#16#06	DWORD	32-bit words

Hexadecimal code	Data type	Description
B#16#07	DINT	32-bit integers
B#16#08	REAL	32-bit floating-point numbers
B#16#0B	TIME	Time duration
B#16#0C	S5TIME	Time duration
B#16#09	DATE	Date
B#16#0A	TOD	Date and time
B#16#0E	DT	Date and time
B#16#13	STRING	Character string
B#16#17[1)]	BLOCK_FB	Function block
B#16#18[1)]	BLOCK_FC	Function
B#16#19[1)]	BLOCK_DB	Data block
B#16#1A[1)]	BLOCK_SDB	System data block
B#16#1C[1)]	COUNTER	Counter
B#16#1D[1)]	TIMER	Timer
[1)] These data types can only be used for the ANY pointer on a CPU S7-300/400.		

Coding of the memory area

The following table lists the coding of the memory areas for the ANY pointer:

Hexadecimal code	Area	Description
B#16#80[1)]	P	I/O
B#16#81	I	Memory area of inputs
B#16#82	Q	Memory area of outputs
B#16#83	M	Memory area of bit memory
B#16#84	DBX	Data block
B#16#85[1)]	DIX	Instance data block
B#16#86	L	Local data
B#16#87	V	Previous local data
[1)] These memory areas can only be used for the ANY pointer on an S7-300/400 CPU.

11.3.11.3 VARIANT (S7-1200, S7-1500)

Basic information on VARIANT (S7-1200, S7-1500)

Description

A parameter of VARIANT data type is a pointer or a reference It can point to tags of various data types. The VARIANT pointer cannot point to an instance and therefore cannot point to a multiple instance or ARRAY of multiple instances. The VARIANT pointer can be an object of an elementary data type, such as INT or REAL. It can also be a STRING, DTL, ARRAY of STRUCT, UDT, or ARRAY of UDT. The VARIANT pointer can recognize structures and point to individual structure components. An operand of data type VARIANT occupies no space in the instance data block or work memory. However, it will occupy memory space on the CPU.

A tag of the VARIANT type is not an object but rather a reference to another object. Individual elements of the VARIANT type can only be declared on formal parameters within the block interface of a function in the VAR_IN, VAR_IN_OUT and VAR_TEMP sections. For this reason, it cannot be declared in a data block or in the static section of the block interface of a function block, for example, because its size is unknown. The size of the referenced objects can change.

Using the VARIANT data type, you can in particular create generic, standardized function blocks (FB) or functions (FC) for various data types. Various instructions in all programming languages are available to you for this purpose. During the creation of the program, you can specify which data types the block should be able to process. The VARIANT data type supports you here by allowing the interconnection of any tags. You can then react accordingly to their data types in the block. When a block is called, you can connect the parameters of the block to tags of any data type. When a block is called, the type information of the tag is transferred in addition to a pointer to the tag. The code of the block can then be executed according to its type in line with the tag transferred during runtime.

If, for example, a block parameter of a function has the VARIANT data type, then a tag of the integer data type can be transferred at one point in the program, and a tag of the PLC data type can be transferred at another point in the program. With the help of the VARIANT instructions, the function is then in a position to react to the situation without errors.

Note

You can only point to a complete data block if it was originally derived from a user-defined data type (UDT).

Note

Address I/O

Direct reading or writing of a signal from an I/O input or output is only possible on a CPU of an S7-1500 module. (<Operand>: P)

The following table shows the properties of the VARIANT pointer:

Length (bytes)	Repre-sentation	Format	Example of value input
0	Symbolic	Operand	"TagResult"
		NameDataBlock.NameOper-and.Component	"Data_TIA_Portal".StructVariable.First-Component
	Absolute	Operand	%MW10
		DataBlockNumber.Operand Type Length (valid only for blocks with standard access)	P#DB10.DBX10.0 INT 12 [1]
		P#Zero value [1]	P#0.0 VOID 0, ZERO [1]
[1] If you use the prefix P#, you can only point to memory areas with "standard" access mode.			

Coding of data types

If you use absolute addressing with P#, the following data types are permitted:

Hexadecimal code	Data type	Description
B#16#00	NIL	Null pointer
B#16#01	BOOL	Bits
B#16#02	BYTE	bytes, 8 bits
B#16#03	CHAR	8-bit characters
B#16#04	WORD	16-bit words
B#16#05	INT	16-bit integers
B#16#06	DWORD	32-bit words
B#16#07	DINT	32-bit integers
B#16#08	REAL	32-bit floating-point numbers
B#16#0B	TIME	Time duration
B#16#0C	S5TIME	Time duration
B#16#09	DATE	Date
B#16#0A	TOD	Date and time
B#16#0E	DT	Date and time
B#16#13	STRING	Character string
B#16#17	BLOCK_FB	Function block
B#16#18	BLOCK_FC	Function
B#16#19	BLOCK_DB	Data block
B#16#1A	BLOCK_SDB	System data block
B#16#1C	COUNTER	Counter
B#16#1D	TIMER	Timer

Example

The following example shows how VARIANT works using the "MOVE: Move value" instruction of STL:

STL	Explanation
`CALL MOVE`	`// The instruction is called.`
`value_type := VARIANT`	`// Data type of the parameters IN and OUT`
`IN := "Data_TIA_Portal".StructVaria-ble.FirstComponent`	`// The contents of the "FirstComponent" operand are moved from the "Data_TIA_Portal" DB.`
`OUT := "MotorDB".StructResult.TagResult`	`// And transferred to the "TagResult" operand from the "MotorDB" DB.`

VARIANT instructions (Page 2311)

Data type conversion for S7-1200 (Page 2465)

Applications for pointers in the comparison (S7-1200, S7-1500)

Application cases for pointers with an S7-1200/1500 CPU as compared to S7-300/400

The following table provides you with an overview of the various applications for pointers on a CPU of the S7-300/400 series (ANY pointer) and their solution with a CPU of the S7-1200/1500 series.

In most applications, the use of a pointer is no longer required on a CPU of the S7-1200/1500 series. Instead, much simpler language resources are available.

It is only advisable to use the VARIANT data type for indirect addressing, when the data types are only determined during the program runtime.

What is the purpose of the ANY pointer?	Recommendations in the TIA Portal (S7-1200/ S7-1500)
Moving data of any source and destination data type in the program using the instruction "BLKMOV: Move block".	Definition of tags within a PLC data type. You can use the instructions "Serialize" and "Deserialize" to move the tags.
Initializing an ARRAY structure	Using the instruction "FILL_BLK: Fill block", you initialize or fill an ARRAY structure.
Moving ARRAY elements	Using the instruction "MOVE_BLK: Move block". you move the content of multiple elements of an ARRAY structure to another ARRAY structure.

What is the purpose of the ANY pointer?	Recommendations in the TIA Portal (S7-1200/ S7-1500)
Memory and performance optimization using structured data	Use the InOut section in the block interface to optimize memory and performance. You can find additional information in the "Programming Guideline for S7-1200/1500" under the following link Programming Guideline for S7-1200/1500 (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=4&lang=en&referer=%2fWW%2f&func=cslib.csinfo&siteid=csius&groupid=4000002&extranet=standard&viewreg=WW&nodeid4=20229695&objaction=csopen)
Access to individual bits/bytes of a WORD	Use the "slice access" You can find additional information here: Example of a slice access (http://support.automation.siemens.com/WW/llisapi.dll?aktprim=0&lang=en&referer=%2fWW%2f&func=cslib.csinfo&siteid=csius&groupid=4000002&extranet=standard&viewreg=WW&nodeid0=29156492&objaction=csopen)
Determination of the length of structures or data blocks	Use an ARRAY and read its length using the instruction "CountofElements: Get number of ARRAY elements". The instruction only works in conjunction with the data type VARIANT.
Indirect addressing	You can use the VARIANT pointer for the indirect addressing of data types that will only be known during runtime. You can use the data type DB_ANY for indirect access to a data block.

VARIANT instructions (S7-1200, S7-1500)

VARIANT instructions

The following instructions for working with VARIANT are available to you in the TIA Portal:

Basic instructions		
Category	**Instruction**	**Description**
Comparator operations	EQ_Type	Compare data type for EQUAL with the data type of a tag
	NE_Type	Compare data type for UNEQUAL with the data type of a tag
	EQ_ElemType	Compare data type of an ARRAY element for EQUAL with the data type of a tag
	NE_ElemType	Compare data type of an ARRAY element for UNEQUAL with the data type of a tag
	IS_NULL	Query for EQUALS ZERO pointer
	NOT_NULL	Query for UNEQUALS ZERO pointer
	IS_ARRAY	Check for ARRAY
	TypeOf	Check data type of a VARIANT tag
	TypeOfElements	Check element data type of a VARIANT tag

Basic instructions		
Category	**Instruction**	**Description**
Move operations	MOVE_BLK_VARIANT	Move block
	VariantGet	Read out VARIANT tag value
	VariantPut	Write VARIANT tag value
	CountOfElements	Get number of ARRAY elements
Conversion operations	VAR-IANT_TO_DB_ANY	Convert VARIANT to DB_ANY
	DB_ANY_TO_VARIANT	Convert DB_ANY to VARIANT

Note

Differences between MOVE, MOVE_BLK and MOVE_BLK_VARIANT

- You can use the "MOVE" instruction to copy complete structures.
- You can use the "MOVE_BLK" instruction to move parts of ARRAYs with known data type.
- The MOVE_BLK_VARIANT instruction is only required if you want to move parts of ARRAYs with a data type that is only known during program runtime.

You can find additional information on the individual instructions in the information system under "Basic instructions > Respective programming language".

You can also find additional instructions which also work with the VARIANT data type under the "Extended instructions".

Application options for VARIANT instructions (S7-1200, S7-1500)

Introduction

In the following chapter, you will learn which application options you have with VARIANT instructions.

Evaluating data types of tags to which a VARIANT points

In the table below, you see which instructions are available to you to evaluate data types of tags to which a VARIANT points:

Function	Instruction	Description
To determine the data type	TypeOf(): Check data type of a VARIANT tag (This instruction is available only in SCL and only in conjunction with an IF instruction.)	You use this instruction to compare the data type to which a VARIANT tag points with the data type of any other tag. You can also make the comparison with a PLC data type.
	TypeOfElements(): Check element data type of a VARIANT tag (This instruction is available only in SCL and only in conjunction with an IF instruction.)	You use this instruction to compare the data type to which a VARIANT tag points with the data type of any other tag. You can also make the comparison with a PLC data type. If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.
	EQ_Type: Compare data type for EQUAL with the data type of a tag NE_Type: Compare data type for UNEQUAL with the data type of a tag	You use this instruction to compare the data type to which a VARIANT tag points with the data type of any other tag. You can also make the comparison with a PLC data type.
	EQ_ElemType: Compare element data type for EQUAL with the data type of a tag NE_ElemType: Compare element data type for UNEQUAL with the data type of a tag	You use this instruction to compare the data type to which a VARIANT tag points with the data type of any other tag. You can also make the comparison with a PLC data type. If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.
To evaluate ARRAY elements	IS_ARRAY: Check for ARRAY	You use this instruction to check whether the data type to which a VARIANT tag points is an ARRAY.
	CountOfElements: Get number of ARRAY elements	You use this instruction to read out how many ARRAY elements the tag has to which the VARIANT tag points.

You can find additional information on the individual instructions in the information system under "Basic instructions > Respective programming language".

Reading data to which a VARIANT points

To be able to use the data you must move this data to a tag as an intermediate step, as it cannot be processed directly.

Instruction	Description	Example		Result
		VARIANT points to	Destination data type	
VariantGet: Read out VARIANT tag value	You use this instruction to move the value of a single tag to another tag. The data types of both tags must match.	UDT_1	UDT_1	The instruction is executed
		REAL	REAL	
		DINT	DWORD	The instruction is not executed.

Assigning data to a VARIANT tag

You cannot use the instruction to initialize VARIANT tags. The VARIANT tags must therefore already be initialized when the data is returned to the tag. Do not use uninitialized temporary VARIANT tags.

Instruction	Description	Example		Result
		Source data type	VARIANT points to:	
VariantPut: Write VARIANT tag value	You use this instruction to move the value of a single tag to another tag. The data types of both tags must match.	UDT_1	UDT_1	The instruction is executed
		REAL	REAL	
		DINT	DWORD	The instruction will not be executed, as the data types are different.

Processing dynamic ARRAY structures

To evaluate ARRAY elements	TypeOfElements(): Check data type of an ARRAY element of a VARIANT tag (This instruction is available only in SCL and only in conjunction with an IF instruction.)	You use this instruction to compare the data type to which a VARIANT tag points with the data type of any other tag. You can also make the comparison with a PLC data type. If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.
	IS_ARRAY: Check for ARRAY	You use this instruction to check whether the data type to which a VARIANT tag points is an ARRAY.
	CountOfElements: Get number of ARRAY elements	You use this instruction to read out how many ARRAY elements the tag has to which the VARIANT tag points.
	MOVE_BLK_VARIANT: Move block	This instruction is used to move dynamic and type-safe (integrated type test) ARRAYs. You can freely select the limit values for the source and destination ARRAYs. The data types of ARRAY elements must match.

Note

Differences between MOVE, MOVE_BLK and MOVE_BLK_VARIANT

- You can use the "MOVE" instruction to copy complete structures.
- You can use the "MOVE_BLK" instruction to move parts of ARRAYs with known data type.
- The MOVE_BLK_VARIANT instruction is only required if you want to move parts of ARRAYs with a data type that is only known during program runtime.

Additional information on the use of the MOVE_BLK_VARIANT instruction can be found in the "Moving data" programming example.

Example of moving data (Page 2316)

Initializing VARIANT (S7-1200, S7-1500)

Description

Initialize the VARIANT data type by assigning a specific tag to the VARIANT block parameter at the block call. This forms a reference to the address of the passed tag. To do this, create a block parameter of the VARIANT data type in the block interface. In the following example, these are the two block parameters SourceArray and DestinationArray in the section InOut.

FC_PartialArrayCopy

		Name	Data type
1		Input	
2		Count	UDInt
3		SourceIndex	DInt
4		DestinationIndex	DInt
5		Output	
6		InOut	
7		SourceArray	Variant
8		DestinationArray	Variant
9		Temp	
10		Error	Int
11		Constant	
12		<Add new>	
13		Return	
14		FC_PartialArrayCopy	Int

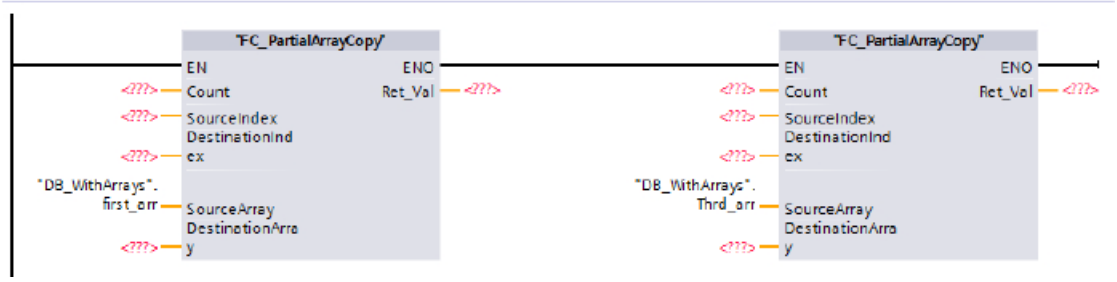
The example shows a section from the programming example "Example of moving data". You can find the detailed program code under "See also".

Note

Direct passing of a tag to a VARIANT tag is not possible, such as myVARIANT := #Variable

See also

Example of moving data (Page 2316)



Transferring and reading out various data types with VARIANT (S7-1200, S7-1500)

The example shows a section from the programming example "Example of moving data". You can find the detailed program code under "See also".

Passing various data types

In the following example, you see how the VARIANT block parameter can be initialized with different tags when a generic, standardized function is called multiple times:

The "FC_PartialArrayCopy" function is called twice. The VARIANT parameter SourceArray is interconnected with an ARRAY of "my_struct" with the left call. The VARIANT parameter SourceArray is interconnected with an ARRAY of REAL with the right call.

Reading out and checking data types

Various comparison instructions are available to you to read out the data type of a tag or an element and compare it with data types of other tags or elements.

In the figure below, you see the usage of multiple comparison instructions to check whether the elements of the ARRAYs have the same data type:

```
IF IS_ARRAY(#SourceArray) AND IS_ARRAY(#DestinationArray)
    AND TypeOfElements(#SourceArray) = TypeOfElements(#DestinationArray) THEN
    #Error := MOVE_BLK_VARIANT(COUNT := #Count, SRC := #SourceArray, SRC_INDEX := #SourceIndex,
                               DEST => #DestinationArray, DEST_INDEX := #DestinationIndex);
END_IF;
```

The MOVE_BLK_VARIANT instruction is only executed if the data types of the ARRAY elements are the same.

See also

Example of moving data (Page 2316)

Examples of using the VARIANT data type (S7-1200, S7-1500)

Example of moving data (S7-1200, S7-1500)

Programming example

In this programming example, data values, which are collected for example during a production shift, are moved for further processing. The data is collected in an ARRAY. Using the "MOVE_BLK_VARIANT instruction: Move block", you can move either the entire ARRAY or only individual ARRAY elements dynamically and type-safe. You can freely select the ARRAY limits for the respective source and destination ARRAYs and these do not have to match. However, the data type of the data values that are to be moved must match. This instruction is available in all programming languages.

By using the VARIANT data type, you can use the created program code to move data for other production shifts as well, by specifying a different source and destination area at the block call.

Procedure

1. Create a function using the SCL programming language and give it the name "FC_PartialArrayCopy".
2. Declare the block interface as follows:

FC_PartialArrayCopy

	Name	Data type
1	Input	
2	Count	UDInt
3	SourceIndex	DInt
4	DestinationIndex	DInt
5	Output	
6	InOut	
7	SourceArray	Variant
8	DestinationArray	Variant
9	Temp	
10	Error	Int
11	Constant	
12	<Add new>	
13	Return	
14	FC_PartialArrayCopy	Int

3. Create the SCL program code as follows:
   You can find the program code below as template.

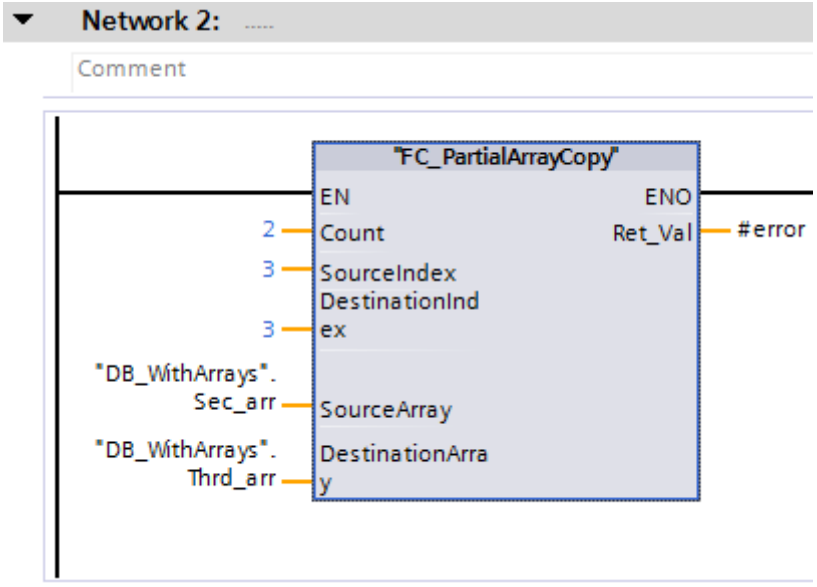
```
IF IS_ARRAY(#SourceArray) AND IS_ARRAY(#DestinationArray)
    AND TypeOfElements(#SourceArray) = TypeOfElements(#DestinationArray) THEN
    #Error := MOVE_BLK_VARIANT(COUNT := #Count, SRC := #SourceArray, SRC_INDEX := #SourceIndex,
                               DEST => #DestinationArray, DEST_INDEX := #DestinationIndex);
END_IF;
#FC_PartialArrayCopy := #Error;
```

4. Create the PLC data type "UDT_MyStruct":

UDT_MyStruct

	Name	Data type	Default value
1	a	Bool	1
2	b	Bool	false
3	c	Bool	1
4	d	Bool	false
5	e	Bool	1
6	arr_int	Array[1..100] of Int	
7	f	Int	0
8	g	Real	0.0
9	h	LReal	0.0

5. Create the global data block "DB_WithArrays":



DB_WithArrays

	Name	Data type
1	Static	
2	first_arr	Array[0..100] of "UDT_MyStruct"
3	Sec_arr	Array[1..200] of "UDT_MyStruct"
4	Thrd_arr	Array[1..200] of Real
5	For_arr	Array[1..500] of Real

6. Call the "FC_PartialArrayCopy" function in an organization block, for example OB1, and initialize the parameters with the DB_WithArrays data block. Enter the named constants:

7. Instead of using the first two ARRAYs, which have the data type UDT_MyStruct, you can also use the third and fourth ARRAY, which have the data type REAL:

Result

As soon as the "FC_PartialArrayCopy" block is called in the program cycle, two data values, starting with the fourth element, are copied from the first ARRAY of the "DB_WithArrays" global data block to the second ARRAY of the data block. The copied data values are inserted in the second ARRAY, starting from the fourth element.

SCL program code for copying:

SCL

```
IF IS_ARRAY(#SourceArray) AND TypeOfElements(#SourceArray) =
TypeOfElements(#DestinationArray) THEN
#Error := MOVE_BLK_VARIANT(COUNT := #Count, SRC := #SourceArray, SRC_INDEX := #SourceIndex,
                           DEST => #DestinationArray, DEST_INDEX := #DestinationIndex);
END_IF;
#FC_PartialArrayCopy := #Error;
```

Basic information on VARIANT (Page 2308)

Example of programming a queue (FIFO) (S7-1200, S7-1500)

Programming example

In the following example, you program a ring buffer which consists of an ARRAY and is written and read according to the FIFO principle. The program code has a read-VARIANT pointer and a write-VARIANT pointer. Using the VARIANT instructions, you can program the program code robustly and ensure reliable copying or deleting.

Using the VARIANT data type, program sections can be influenced during runtime. The VARIANT pointer is a type-safe pointer, i.e. a type test is performed during runtime. For blocks that have been created with the block property "optimized", sub-functions that were previously programmed with an ANY pointer can now be resolved with a VARIANT pointer. The VARIANT data type is used to transfer structures to system function blocks.

Procedure

1. Create an SCL function block and name it "FIFOQueue".
2. Declare the block interface as follows:

Declaration	Parameters	Data type	Comment
Input	request	BOOL	The instruction is executed when a positive signal edge is detected at the "request" parameter.
	mode	BOOL	0 = The first entry in the ring buffer is returned. 1 = An entry is written at the last position in the ring buffer.
	initialValue	VARIANT	Value with which the ARRAY of the ring buffer is initialized.
Output	error	INT	Error information
InOut	item	VARIANT	The entry that is either returned from the ring buffer or written to the ring buffer.
	buffer	VARIANT	An ARRAY that is used as a ring buffer.
Static	edgeupm	BOOL	Edge memory bit in which the RLO of the previous query is saved.
	firstItemIndex	INT	Index of the oldest entry in the ring buffer
	nextEmptyItemIndex	INT	Index of the next free entry in the ring buffer
Temp	edgeup	BOOL	Result of edge evaluation
	internalError	INT	Error information
	newFirstItemIndex	INT	Variable index
	newNextEmptyItemIndex	INT	Variable index
	bufferSize	UDINT	Number of ARRAY elements in the ring buffer

3. Create the following program code in the "FIFOQueue" function block:

```
(* This program code section is only executed once after a positive signal
edge. If there is no change in the signal state of the result of logic
operation, the program processing of the "FIFOQueue" FB is terminated. *)
#edgeup := #request & NOT #edgeupm;
#edgeupm := #request;
IF NOT (#edgeup) THEN
   RETURN;
END_IF;
```

```
// ------Validation of whether all parameter inputs are valid.----
(* This program code section checks whether the ring buffer is an ARRAY. If
so, the number of the ARRAY elements is read out. If it is not an ARRAY,
the program execution is terminated at this point and the error code "-10"
is output. *)
IF NOT (IS_ARRAY(#buffer)) THEN
   #error := -10;
   RETURN;
ELSE
   #bufferSize := CountofElements(#buffer);
END_IF;

(* This program code section checks whether the data type of the ARRAY
elements matches the data type of the entry (tag #item). If the data types
do not match, the program execution is terminated at this point and the
error code "-11" is output. *)
IF NOT (TypeOf(#item) = TypeOfElements(#buffer)) THEN
   #error := -11;
   RETURN;
END_IF;

(* This program code section checks whether the initial value of the ring
buffer matches the entry (tag #item). If the data types do not match, the
program execution is terminated at this point and the error code "-12" is
output. *)
IF NOT (TypeOf(#item) = TypeOf(#initialValue)) THEN
   #error := -12;
   RETURN;
END_IF;

(* This program code section checks whether the variable indices are within
the ARRAY limits. If this is not the case, the program execution is
terminated at this point and either error code "-20" or "-21" is output
depending on the index. *)
IF (#nextEmptyItemIndex >= #bufferSize) THEN
   #error := -20;
   RETURN;
END_IF;
IF (#firstItemIndex >= #bufferSize) THEN
   #error := -21;
   RETURN;
END_IF;
```

```
//-----------Program code execution, depending on the Mode
parameter-------------
// The execution of the instructions depends on the signal state of the Mode
parameter.
IF #mode = 0 THEN

// If the Mode parameter has the signal state "0", the first entry from the
passed ring buffer is returned.
(* This program code section checks whether the ring buffer is empty. If
this is the case, program execution is terminated at this point and the
error code "-40" is output. *)
   IF (#firstItemIndex = -1) THEN
      #error := -40;
      RETURN;
   END_IF;

// This program code section returns the first entry of the ring buffer.
   #internalError := MOVE_BLK_VARIANT(SRC := #buffer,
                                      COUNT := 1,
                                      SRC_INDEX := #firstItemIndex,
                                      DEST_INDEX := 0,
                                      DEST => #item);

   IF (#internalError = 0) THEN
(* This program code section checks whether the ring buffer contains ARRAY
elements. If it does, the first entry is passed on and the index is
incremented by 1. *)
      #internalError := MOVE_BLK_VARIANT(SRC := #initialValue,
                                         COUNT := 1,
                                         SRC_INDEX := 0,
                                         DEST_INDEX := #firstItemIndex,
                                         DEST => #buffer);

// This program code section calculates the new index of the first entry.
      #newFirstItemIndex := #firstItemIndex +1;
      #newFirstItemIndex := #newFirstItemIndex MOD
UDINT_TO_INT(#bufferSize);

// This program section checks whether the ring buffer is empty.
      IF (#nextEmptyItemIndex = #newFirstItemIndex) THEN
// If the ring buffer is empty, the index is set to 0.
         #firstItemIndex := -1;
         #nextEmptyItemIndex := 0;
      ELSE
// The index of the first entry is changed.
         #firstItemIndex := #newFirstItemIndex;
```

```
      END_IF;
   END_IF;
ELSE

// If the Mode parameter has the signal state "1", the entry is written to
the passed ring buffer.
(* This program code section checks whether the ring buffer is full. If this
is the case, program execution is terminated at this point and the error
code "-50" is output. *)
   IF (#nextEmptyItemIndex = #firstItemIndex) THEN
      #error := -50;
      RETURN;
   END_IF;

// This program code section writes the entry to the ring buffer.
   #internalError := MOVE_BLK_VARIANT(SRC := #item,
                                      COUNT := 1,
                                      SRC_INDEX := 0,
                                      DEST_INDEX := #nextEmptyItemIndex,
                                      DEST => #buffer);

   IF (#internalError = 0) THEN
// This program code section increments the index by 1 and calculates the
new empty entry index.
      #newNextEmptyItemIndex := #nextEmptyItemIndex +1;
      #newNextEmptyItemIndex := #newNextEmptyItemIndex MOD #bufferSize;
      #nextEmptyItemIndex := #newNextEmptyItemIndex;

(* This program code section checks which index the "#firstItemIndex" tag
has. If the number = -1, the ring buffer is initialized and the entry is
written to the ring buffer. This is why the tag value "0" must be assigned.
*)
      IF (#firstItemIndex = -1) THEN
         #firstItemIndex := 0;
      END_IF;
   END_IF;
END_IF;

//-------------------------Local error handling-----------------------------
(* This program code section checks whether a local error has occurred. If
this is the case, program execution is terminated at this point and the
error code "-100" is output. *)
IF (#internalError > 0) THEN
   #error := -100;
   RETURN;
```

```
END_IF;

// If no error occurred during program execution, the error code "0" is
output.
#error := 0;
```

Result

Call the SCL function block at the position in your program at which the FIFO queue is to run.

11.3.12 Parameter types

11.3.12.1 Parameter types

Description

The parameter types are data types for formal parameters that are transferred to called blocks. A parameter type can also be a PLC data type.

The following table shows the available parameter data types and their purpose:

Parameter type	Length (bits)	Description
TIMER	16	Is used to specify a timer that is used in the called code block. If you supply a formal parameter of the TIMER parameter type, the associated actual parameter must be a timer. Example: T1
COUNTER	16	Is used to specify a counter that is used in the called code block. If you supply a formal parameter of the COUNTER parameter type, the associated actual parameter must be a counter. Example: C10
BLOCK_FC	16	Is used to specify a block that is used as input in the called code block. The declaration of the parameter determines the block type (for example FB, FC, DB) that is to be used. If you supply a formal parameter of the BLOCK parameter type, specify a block address as the actual parameter. Example: DB3
BLOCK_FB	16	
BLOCK_DB	16	
BLOCK_SDB	16	
BLOCK_SFB	16	
BLOCK_SFC	16	
BLOCK_OB	16	

Parameter type	Length (bits)	Description
VOID	-	The VOID parameter type does not save any values. This parameter type is used if the return values of an output are not required. The VOID parameter type can be specified at the STATUS output, for example, if no error information is required.
PARAMETER	-	The PARAMETER data type enables the symbol of a local tag of the program block containing instructions "GetSymbolName: Read out name of a tag at input parameter" and "GetSymbolPath: Query composite global name of the input parameter assignment" to be used with the corresponding input of these instructions.

11.3.13 System data types

11.3.13.1 System data types

Description

The system data types (SDT) are made available by the system and have a predefined structure. The structure of a system data type consists of a fixed number of components that can have various data types. It is not possible to change the structure of a system data type.

System data types can only be assigned to one another if they are of the same type and their name matches. This also applies to PLC data types generated by the system, such as IEC_Timer, etc.

The system data types can only be used for specific instructions. The following table shows the available system data types and their purpose:

System data type	Length (bytes)	Description
IEC_TIMER	16	Structure of a timer in which the PT, ET, IN and Q parameters are declared. The time values are of TIME data type. This data type is used for the "TP", "TOF", "TON", "TONR", "RT" and "PT" instructions, for example.
IEC_LTIMER	32	Structure of a timer in which the PT, ET, IN and Q parameters are declared. The time values are of LTIME data type. This data type is used for the "TP", "TOF", "TON", "TONR", "RT" and "PT" instructions, for example.
IEC_SCOUNTER	3	Structure of a counter whose count values are of SINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.

System data type	Length (bytes)	Description
IEC_USCOUNTER	3	Structure of a counter whose count values are of USINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_COUNTER	6	Structure of a counter whose count values are of INT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_UCOUNTER	6	Structure of a counter whose count values are of UINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_DCOUNTER	12	Structure of a counter whose count values are of DINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_UDCOUNTER	12	Structure of a counter whose count values are of UDINT data type. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_LCOUNTER	24	Structure of a counter with count values of data type UDINT. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
IEC_ULCOUNTER	24	Structure of a counter with count values of data type UINT. This data type is used for the "CTU", "CTD" and "CTUD" instructions, for example.
ERROR_STRUCT	28	Structure of an error information to a programming or I/O access error. This data type is used, for example, for the "GET_ERROR" instruction.
CREF	8	Components of the ERROR_STRUCT data type, in which information about the address of a block is saved.
NREF	8	Components of the ERROR_STRUCT data type, in which information about the address of an operand is saved.
VREF	12	Is used for storage of a VARIANT pointer. This data type is, for example, used for instructions from S7-1200 Motion Control.
SSL_HEADER	4	Specifies the data structure in which information about the data records are saved during the reading of the system status lists. This data type is used, for example, for the "RDSYSST" instruction.
CONDITIONS	52	User-defined data structure defining the conditions for start and end of a data reception. This data type is used, for example, for the "RCV_CFG" instruction.

System data type	Length (bytes)	Description
TADDR_Param	8	Specifies the structure of a data block which stores descriptions of connections for Open User Communication via UDP. This data type is used for the "TUSEND" and "TURSV" instructions, for example.
TCON_Param	64	Specifies the structure of a data block which stores descriptions of connections for Open User Communication via Industrial Ethernet (PROFINET). This data type is used for the "TSEND" and "TRSV" instructions, for example.
HSC_Period	12	Specifies the structure of the data block for the time period measurement with the extended high-speed counter. This data type is used, for example, for the "CTRL_HSC_EXT" instruction.

11.3.14 Hardware data types

11.3.14.1 Hardware data types

Description

The hardware data types are made available by the CPU. The number of available hardware data types depends on the CPU.

Constants of a specific hardware data type are stored based on the modules set in the hardware configuration. When an instruction for controlling or activating a configured module is inserted in the user program, the available constants can be used for the parameters.

The following table shows the available hardware data types and their purpose:

Data type	Basic data type	Description
REMOTE	ANY	Serves to specify the address of a remote CPU. This data type is used, for example, for the "PUT" and "GET" instructions.
HW_ANY	UINT	Identification of any hardware component, e.g. a module.
HW_DEVICE	HW_ANY	Identification of a DP slave/PROFINET IO device
HW_DPMASTER	HW_INTERFACE	Identification of a DP master
HW_DPSLAVE	HW_DEVICE	Identification of a DP slave
HW_IO	HW_ANY	Identification number of the CPU or the interface The number is automatically allocated and is stored in the properties of the CPU or of the interface in the hardware configuration.

Data type	Basic data type	Description
HW_IOSYSTEM	HW_ANY	Identification of a PN/IO system or DP master system
HW_SUBMODULE	HW_IO	Identification of a central hardware component
HW_MODULE	HW_IO	Identification of a module
HW_INTERFACE	HW_SUBMODULE	Identification of an interface component
HW_IEPORT	HW_SUBMODULE	Identification of a port (PN/IO)
HW_HSC	HW_SUBMODULE	Identification of a high-speed counter This data type is used, for example, for the "CTRL_HSC" and "CTRL_HSC_EXT" instructions.
HW_PWM	HW_SUBMODULE	Identification of a pulse width modulation This data type is used, for example, for the "CTRL_PWM" instruction.
HW_PTO	HW_SUBMODULE	Identification of a pulse encoder This data type is used for Motion Control.
EVENT_ANY	AOM_IDENT	Used to identify any event
EVENT_ATT	EVENT_ANY	Is used to specify an event that can be assigned dynamically to an OB This data type is used, for example, for the "ATTACH" and "DETACH" instructions.
EVENT_HWINT	EVENT_ATT	Is used to specify a hardware interrupt event
OB_ANY	INT	Serves to specify any organization block.
OB_DELAY	OB_ANY	Used to specify an organization block that is called when a time-delay interrupt occurs. This data type is used, for example, for the "SRT_DINT" and "CAN_DINT" instructions.
OB_TOD	OB_ANY	Specifies the number of a time-of-day interrupt OB. This data type is used, for example, for the "SET_TINT", "CAN_TINT", "ACT_TINT" and "QRY_TINT" instructions.
OB_CYCLIC	OB_ANY	Is used to specify an organization block that is called when a watchdog interrupt occurs.
OB_ATT	OB_ANY	Is used to specify an organization block that can be assigned dynamically to an event. This data type is used, for example, for the "ATTACH" and "DETACH" instructions.
OB_PCYCLE	OB_ANY	Is used to specify an organization block that can be assigned to an event of the "Cyclic program" event class.
OB_HWINT	OB_ATT	Is used to specify an organization block that is called when a hardware interrupt occurs.
OB_DIAG	OB_ANY	Is used to specify an organization block that is called when a diagnostic interrupt occurs.
OB_TIMEERROR	OB_ANY	Is used to specify an organization block that is called when a time error occurs.
OB_STARTUP	OB_ANY	Is used to specify an organization block that is called when a startup event occurs.

Data type	Basic data type	Description
PORT	HW_SUBMODULE	Serves to specify a communication port. This data type is used for point-to-point communication.
RTM	UINT	Serves to specify the number of an operating hours counter. This data type is used, for example, for the "RTM" instruction.
PIP	UINT	Is used to create and connect a "Synchronous Cycle" OB. This data type is used for the SFCs 26, 27, 126 and 127.
CONN_ANY	WORD	Serves to specify any connection.
CONN_PRG	CONN_ANY	Serves to specify a connection for open communication over UDP.
CONN_OUC	CONN_ANY	Used to specify a connection for open communication over Industrial Ethernet (PROFINET).
CONN_R_ID	DWORD	Data type for the R_ID parameter on the S7 communication blocks.
DB_ANY	UINT	Identification (name or number) of a DB The data type "DB_ANY" has the length 0 in the section "Temp".
DB_WWW	DB_ANY	Number of a DB generated via the Web application (for example, "WWW" instruction) The data type "DB_WWW" has the length 0 in the section "Temp".
DB_DYN	DB_ANY	Number of a DB generated by the user program

11.3.15 Data type conversion for S7-1500: (S7-1500)

11.3.15.1 Overview of data type conversion (S7-1500)

Introduction

If you combine several operands in an instruction, you must make sure that the data types are compatible. This also applies when you assign or supply block parameters. If the operands are not of the same data type, a conversion has to be carried out.

There are two options for conversion:

- Implicit conversion
  Implicit conversion is supported by the programming languages LAD, FBD, SCL and GRAPH. Implicit conversion is not possible in the STL programming language.
- Explicit conversion
  You use an explicit conversion instruction before the actual instruction is executed.

Note

Converting bit strings to SCL

All bit strings (BYTE, WORD, DWORD and LWORD) are handled like the corresponding unsigned integers (USINT, UINT, UDINT and ULINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

Implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to strict or less strict criteria:

- With IEC check (default setting)
  If IEC check is set, the following rules are applied:
  - Implicit conversion of BOOL into other data types is not possible.
  - Only the data types REAL, BYTE, WORD, DWORD, DINT, INT, SINT, UDINT, UINT, USINT, TIME, LDT, DTL, DT, TOD, WCHAR and CHAR can be converted implicitly.
  - The bit length of the source data type may not exceed the bit length of the target data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.
- Without IEC check
  If IEC check is not set, the following rules are applied:
  - Implicit conversion of BOOL into other data types is not possible.
  - Only the data types REAL, LREAL, BYTE, WORD, DWORD, LWORD, SINT, INT, DINT, LINT, USINT, UINT, UDINT, ULINT, TIME, LTIME, S5TIME, LDT, DTL, TOD, LTOD, DATE, STRING, WSTRING, WCHAR and CHAR can be converted implicitly.
  - The bit length of the source data type may not exceed the bit length of the target data type. A DWORD data type operand, for example, cannot be specified at a parameter at which the WORD data type is expected.
  - The bit length of an operand entered at in-out parameters (InOut) must be the same as the programmed bit length for the parameter in question.

  Note

  Implicit conversion without IEC check

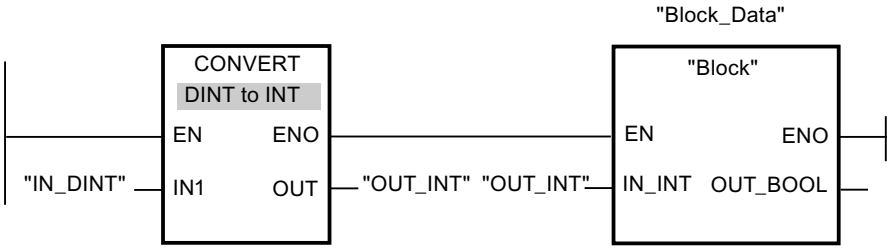
  The programming editor uses a gray rectangle to mark operands that are implicitly converted. The dark gray rectangle signals that an implicit conversion is possible without any accuracy loss, for example, if you convert the data type INT to DINT. A light gray rectangle signals that implicit conversion is possible, but errors could occur during runtime. If, for example, you are converting the data type LINT to DINT and an overflow occurs, the enable output ENO is set to "0".

For more information about the setting of the IEC check and the implicit conversion, refer to "See also".

Explicit conversion

If the operands are not compatible and implicit conversion is therefore not possible, you can perform an explicit conversion. You can do this by using the conversion instructions in the "Instructions" Task Card or you can insert the conversion into the program manually. You can find the format for explicit conversion functions under "See also".

Any overflow will be displayed on the ENO enable output. An overflow occurs, for example, if the value of the source data type is greater than the value of the target data type.



Note

Shifting of bit patterns

If the explicit conversion involves shifting a bit pattern, the enable output ENO is not set.

You can find additional information on explicit conversion under "See also".

The following figure shows an example in which explicit data type conversion must be carried out:

The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. The value of the "IN_DINT" tag has therefore to the converted first from DINT to INT. Conversion is performed if the value of the "IN_DINT" tag is within the admissible value range for the INT data type. Otherwise an overflow is reported. However, a conversion takes place even in the event of an overflow, but the values are truncated and the ENO enable output is set to "0".

Explicit conversions (Page 2382)

11.3.15.2 Implicit conversions (S7-1500)

Setting and disabling the IEC check (S7-1500)

The data types of the operands used are checked for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Binary numbers (S7-1500)

Implicit conversion of BOOL (S7-1500)

Implicit conversion options

The BOOL data type cannot be implicitly converted.

Implicit conversion of WORD (S7-1500)

Implicit conversion options

The following table shows the options for the implicit conversion of WORD data type:

Source	Destination	With IEC check	Without IEC check	Explanation
WORD	BOOL	-	-	No implicit conversion
	BYTE	-	X	The low byte is transferred to the destination data type; the high byte is ignored.
	DWORD	X	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LWORD	X	X	
	SINT	-	X	The low byte is transferred to the destination data type; the high byte is ignored.
	USINT	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	INT	-	X	
	UINT	-	X	
	DINT	-	X	
	UDINT	-	X	
	LINT	-	X	
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	LTIME	-	-	
	S5TIME	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LDT	-	-	No implicit conversion
	DTL	-	-	
	DT	-	-	
	DATE	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	TOD	-	-	No implicit conversion
	LTOD	-	-	
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.

Implicit conversion of DWORD (S7-1500)

Implicit conversion options

The following table shows the options for the implicit conversion of DWORD data type:

Source	Destination	With IEC check	Without IEC check	Explanation
DWORD	BOOL	-	-	No implicit conversion
	BYTE	-	X	The right byte is transferred to the destination data type; the left byte is ignored.
	WORD	-	X	
	LWORD	X	X	
	SINT	-	X	
	USINT	-	X	
	INT	-	X	
	UINT	-	X	
	DINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type.
	UDINT	-	X	
	LINT	-	X	
	ULINT	-	X	
	REAL	-	X	The value is converted to the destination data type format. (The value "-1", for example, is converted to the value "-1.0".)
	LREAL	-	-	No implicit conversion
	TIME	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LTIME	-	-	No implicit conversion
	S5TIME	-	-	
	LDT	-	-	
	DTL	-	-	
	DT	-	-	
	DATE	-	-	
	TOD	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LTOD	-	-	No implicit conversion
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

	DWORD	-	X	
	LWORD	-	X	
	SINT	-	X	The bit pattern of the source value is converted and transferred to the destination data type. (for example, value conversion from DINT #-1 -> SINT #-1 or DINT #-1 -> USINT #255)
	USINT	-	X	
	INT	-	X	
	UINT	-	X	
	UDINT	-	X	
	LINT	X	X	
	ULINT	-	X	
	REAL	-	X	The bit pattern of the source value is converted and transferred to the destination data type. (for example, value conversion from DINT #-1 -> REAL #-1.0, but there is a loss in accuracy for numbers with an absolute value greater than 8 388 608)
	LREAL	X	X	The value is converted to the destination data type format. (The value "-1", for example, is converted to the value "-1.0".)
	TIME	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LTIME	-	-	No implicit conversion
	S5TIME	-	-	
	LDT	-	-	
	DTL	-	-	
	DT	-	-	
	DATE	-	-	
	TOD	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	LTOD	-	-	No implicit conversion
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

Implicit conversion of TIME (S7-1500)

Implicit conversion options

The following table shows the options for the implicit conversion of TIME data type:

Source	Destination	With IEC check	Without IEC check	Explanation
TIME	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.
	LWORD	-	-	No implicit conversion
	SINT	-	-	
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of conversion shows the duration in milliseconds.
	UDINT	-	X	
	LINT	-	-	No implicit conversion
	ULINT	-	-	
	REAL	-	-	
	LREAL	-	-	
	S5TIME	-	-	
	LTIME	X	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds. (1 ms = 1 000 000 ns)
	LDT	-	-	No implicit conversion
	DTL	-	-	
	DT	-	-	
	DATE	-	-	
	TOD	-	X	If the source value is between 0 s and 84599.999 s, the bit pattern of the source value is transferred unchanged to the destination data type. (Display in nanoseconds) The target value remains unchanged otherwise. The result of the conversion shows the time that has passed since midnight.
	LTOD	-	-	No implicit conversion
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	-	
	WCHAR	-	-	
x: Conversion possible -: Conversion not possible

Implicit conversion options

The following table shows the options for the implicit conversion of LTIME data type:

Source	Destination	With IEC check	Without IEC check	Explanation
LTIME	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	-	
	LWORD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds.
	SINT	-	-	No implicit conversion
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	-	
	UDINT	-	-	
	LINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds.
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	S5TIME	-	-	
	TIME	-	X	If the source value is outside the value range of the destination data type, the target value remains unchanged. (0.123456789 s becomes 0.123 s)
	LDT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds since 1/1/1970.
	DTL	-	-	No implicit conversion
	DT	-	-	
	DATE	-	-	
	TOD	-	-	
	LTOD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion shows the duration in nanoseconds since 1/1/1970.
	STRING	-	-	No implicit conversion
	WSTRING	-	-	
	CHAR	-	-	
	WCHAR	-	-	
x: Conversion possible -: Conversion not possible

Implicit conversion options

The following table shows the options for the implicit conversion of LTOD data type:

Source	Destination	With IEC check	Without IEC check	Explanation
LTOD	BOOL	-	-	No implicit conversion
	BYTE	-	-	
	WORD	-	-	
	DWORD	-	-	
	LWORD	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion corresponds to the number of nanoseconds since the start of day (0:00 hrs).
	SINT	-	-	No implicit conversion
	USINT	-	-	
	INT	-	-	
	UINT	-	-	
	DINT	-	-	
	UDINT	-	-	
	LINT	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion corresponds to the number of nanoseconds since the start of day (0:00 hrs).
	ULINT	-	X	
	REAL	-	-	No implicit conversion
	LREAL	-	-	
	TIME	-	-	
	LTIME	-	X	The bit pattern of the source value is transferred unchanged to the destination data type. The result of the conversion corresponds to the number of nanoseconds since the start of day (0:00 hrs).
	S5TIME	-	-	No implicit conversion
	LDT	-	-	
	DT	-	-	
	DTL	-	-	
	DATE	-	-	
	TOD	-	X	The source value is transferred unchanged with the same value rounded off to the destination data type. (12:34:56.123456789 becomes 12:34:56.123)
	STRING	-	-	No implicit conversion
	WSTRING	-	-	
	CHAR	-	-	
	WCHAR	-	-

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the SINT data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
SINT	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO "1". • If bit is not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	SINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_BYTE
	WORD[1)]	X		SINT_TO_WORD
	DWORD[1)]	X		SINT_TO_DWORD
	LWORD[1)]	X		SINT_TO_LWORD
	USINT	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_USINT
	INT	X		SINT_TO_INT
	UINT	X		SINT_TO_UINT
	DINT	X		SINT_TO_DINT
	UDINT	X		SINT_TO_UDINT
	LINT	X		SINT_TO_LINT
	ULINT	X		SINT_TO_ULINT
	REAL	X	The value is converted to the destination data type format. (The value "-1" is changed to the value "-1.0", for example, with the instruction "Convert value" (CONVERT).	SINT_TO_REAL, NORM_X
	LREAL	X		SINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the destination data type and interpreted as milliseconds.	SINT_TO_TIME
	LTIME	X	The value is transferred to the destination data type and interpreted as nanoseconds.	SINT_TO_LTIME
	S5TIME	-	No explicit conversion	-
	LDT	X	The result is returned in nanoseconds since 1970-1-1-0:0:0.0.	SINT_TO_LDT
	DT	-	No explicit conversion	-
	DTL	-		-
	TOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value	SINT_TO_TOD

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
			"-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0)	
	LTOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in nanoseconds since 0:0)	SINT_TO_LTOD
	DATE	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in days since 1990-1-1)	SINT_TO_DATE
	STRING	X	The value is converted into a character string.	SINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X	• LAD/FBD: The first characters of the string are padded with spaces. The number of spaces depends on the length of the numerical value. Positive numeric values are output without a sign. • STL/SCL: No spaces are inserted. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	SINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	SINT_TO_CHAR
	WCHAR[1)]	X		SINT_TO_WCHAR

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	LINT_TO_BYTE
	WORD[1)]	X		LINT_TO_WORD
	DWORD[1)]	X		LINT_TO_DWORD
	LWORD[1)]	X		LINT_TO_LWORD
	SINT	X		LINT_TO_SINT
	USINT	X		LINT_TO_USINT
	INT	X		LINT_TO_INT
	UINT	X		LINT_TO_UINT
	DINT	X		LINT_TO_DINT
	UDINT	X		LINT_TO_UDINT
	ULINT	X		LINT_TO_ULINT
	REAL	X	The value is converted to the destination data type format. (The value "-1" is changed to the value "-1.0", for example, with the instruction "Convert value" (CONVERT).	LINT_TO_REAL, NORM_X
	LREAL	X		LINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the destination data type and interpreted as milliseconds.	LINT_TO_TIME, T_CONV
	LTIME	X	The value is transferred to the destination data type and interpreted as nanoseconds.	LINT_TO_LTIME, T_CONV
	S5TIME	-	No explicit conversion	-
	LDT	X	The result is returned in nanoseconds since 1970-1-1-0:0:0.0.	LINT_TO_LDT
	DT	-	No explicit conversion	-
	DTL	-		-
	TOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative	LINT_TO_TOD

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
			value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0)	
	LTOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in nanoseconds since 0:0)	LINT_TO_LTOD
	DATE	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0". (interpretation in days since 1990-1-1)	LINT_TO_DATE
	STRING	X	The value is converted into a character string. • LAD/FBD: The first characters of the string are padded with spaces. The number of spaces depends on the length of the numerical value. Positive numeric values are output without a sign. • STL/SCL: No spaces are inserted. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	LINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		LINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the destination data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted into an unsigned destination data type, the enable output ENO is set to "0".	LINT_TO_CHAR
	WCHAR[1)]	X		LINT_TO_WCHAR

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the ULINT data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
ULINT	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO "1". • If bits are not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	ULINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	ULINT_TO_BYTE
	WORD[1)]	X		ULINT_TO_WORD
	DWORD[1)]	X		ULINT_TO_DWORD
	LWORD[1)]	X		ULINT_TO_LWORD
	SINT	X		ULINT_TO_SINT
	USINT	X		ULINT_TO_USINT
	INT	X		ULINT_TO_INT
	UINT	X		ULINT_TO_UINT
	DINT	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type. If the sign bit is overwritten during the conversion, the enable output ENO is set to "0".	ULINT_TO_DINT
	UDINT	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	ULINT_TO_UDINT
	LINT	X		ULINT_TO_LINT
	REAL	X	The value is converted to the destination data type format. (The value "1" is changed to the value "1.0", for example, with the instruction "Convert value" (CONVERT).	ULINT_TO_REAL, NORM_X
	LREAL	X		ULINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the destination data type and interpreted as milliseconds.	ULINT_TO_TIME
	LTIME	X	The value is transferred to the destination data type and interpreted as nanoseconds.	ULINT_TO_LTIME
	S5TIME	-	No explicit conversion	-
	LDT	X	The result is returned in nanoseconds since 1970-1-1-0:0:0.0.	ULINT_TO_LDT
	DT	-	No explicit conversion	-

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
	DTL	-		-
	TOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (interpretation in milliseconds since 0:0)	ULINT_TO_TOD, T_CONV
	LTOD	X	The bit pattern of the source value is converted and transferred to the destination data type. (interpretation in nanoseconds since 0:0)	ULINT_TO_LTOD, T_CONV
	DATE	X	The bit pattern of the source value is converted and transferred to the destination data type. (interpretation in days since 1990-1-1)	ULINT_TO_DATE
	STRING	X	The value is converted into a character string. If the permitted length of the character string is violated, the enable output ENO is set to "0".	ULINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		ULINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the destination data type.	ULINT_TO_CHAR
	WCHAR[1)]	X		ULINT_TO_WCHAR

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width (the non-existing sign is replaced with zeros), and then the bits are copied. The source type determines the interpretation.

Explicit conversion of REAL (S7-1500)

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the REAL data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
REAL	BOOL	-	No explicit conversion	-
	BYTE	-		-
	WORD	-		-
	DWORD	X	The bit pattern of the source value is transferred unchanged right-justified to the destination data type.	REAL_TO_DWORD
	LWORD	-	No explicit conversion	-
	SINT	X	The value is converted into the destination data type. The result of conversion depends on the instruction employed. The enable output ENO is set to "0" if the admissible range of values of the destination data type is exceeded during conversion or the value to be converted has an invalid floating-point number.	REAL_TO_SINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	USINT	X		REAL_TO_USINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	INT	X		REAL_TO_INT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	UINT	X		REAL_TO_UINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	DINT	X		REAL_TO_DINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	UDINT	X		REAL_TO_UDINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	LINT	X		REAL_TO_LINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	ULINT	X		REAL_TO_ULINT, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	LREAL	X	The value is converted into the destination data type. The result of the conversion depends on the instruction used, e.g. TRUNC(2.5) = 2.0; CEIL(2.5) = 3.0	REAL_TO_LREAL, ROUND, CEIL, FLOOR, TRUNC, NORM_X, SCALE_X
	TIME	-	No explicit conversion	-
	LTIME	-		-

Explicit conversion of DATE (S7-1500)

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the DATE data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
DATE	BOOL	-	No explicit conversion	-
	BYTE[1]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	DATE_TO_BYTE
	WORD[1]	X		DATE_TO_WORD
	DWORD[1]	X		DATE_TO_DWORD
	LWORD[1]	X		DATE_TO_LWORD
	SINT	X	The number of days since 1/1/1990 is returned as result.	DATE_TO_SINT
	USINT	X		DATE_TO_USINT
	INT	X		DATE_TO_INT
	UINT	X		DATE_TO_UINT
	DINT	X		DATE_TO_DINT
	UDINT	X		DATE_TO_UDINT
	LINT	X		DATE_TO_LINT
	ULINT	X		DATE_TO_ULINT
	REAL	-	No explicit conversion	-
	LREAL	-		-
	S5TIME	-		-
	TIME	-		-
	LTIME	-		-
	DT	X	The conversion sets the date in the destination type.	DATE_TO_DT
	LDT	X		DATE_TO_LDT
	DTL [2]	X		DATE_TO_DTL
	TOD	-	No explicit conversion	-
	LTOD	-		-
	STRING	-		-
	WSTRING	-		-
	CHAR	-		-
	WCHAR	-		-

x: Conversion possible

- : Conversion not possible

[1] Bit strings (BYTE, WORD, DWORD, LWORD) and the data types CHAR and WCHAR are initially extended to the necessary width, and then the bits are copied. The source type determines the interpretation.

[2] The data type DTL is initialized as follows: 1970-1-1-0:0:0. Conversion from DATE_TO_DTL only sets the corresponding part of the DTL. The rest of the DTL remains as it was initialized. This results in the following differences for the instructions "T_COMBINE" and "T_CONV":

- T_COMBINE(D#2015-24-12, LTOD#12:13:14) returns DTL#2015-24-12-12:13:14
- myDTL := T_CONV(D#2015-24-12); myDTL := T_CONV(LTOD#12:13:14) results in myDTL = DTL#1970-1-1-12:13:14

Explicit conversion of STRING (S7-1500)

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the STRING data type:

Source	Destination	Conversion	Explanation	Mnemonics of the instruction
STRING	BOOL	-	No explicit conversion	-
	BYTE	-		-
	WORD	-		-
	DWORD	-		-
	LWORD	-		-
	SINT	X	Conversion begins with the first character in the character string (STRING) and stops at the end of the string or at the first inadmissible character. The following characters are admissible for conversion: • Digit • Sign • Dot The first character in the character string may be a sign (+, -) or a digit. Leading spaces are ignored. The dot is used as separation for the conversion of floating-point numbers. The exponential notation "e" or "E" is not permitted. The comma as thousand separator to the left of the decimal point is permitted but is ignored. If the layout of the character string is invalid for the conversion or an overflow occurs, then the enable output ENO will be set to "0".	STRING_TO_SINT, S_CONV, STRG_VAL
	USINT	X		STRING_TO_USINT, S_CONV, STRG_VAL

11.3.16 Data type conversion for S7-1200 (S7-1200)

11.3.16.1 Overview of data type conversion (S7-1200)

Introduction

If you link several operands in an instruction, you must make sure that the data types are compatible. This applies also for assignments or for supplying block parameters. If the operands are not the same data type, a conversion has to be carried out.

There are two options for the conversion:

- Implicit conversion
  The conversion take place automatically when the instruction is executed.
- Explicit conversion
  You use an explicit conversion instruction before the actual instruction is executed.

Note

The data type conversion options described always refer to the latest version of the CPU (V. 4) Conversions marked as possible may not be available in CPU versions 1 - 3.

Note

Converting bit strings in SCL

All bit strings (BYTE, WORD, and DWORD) are handled like the corresponding unsigned integers (USINT, UINT, and UDINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

An implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to criteria that are more or less strict:

- With IEC check (default)
  If IEC check is set, the following rules are applied:
  - Implicit conversion of BOOL to other data types is not possible.
  - Only the REAL, BYTE, WORD, DINT, INT, SINT, UDINT, UINT, USINT, TIME, DT, STRING, CHAR and WCHAR data types can be converted implicitly.
  - The bit length of the source data type must not exceed the bit length of the target data type. An operand of data type WORD, for example, cannot be declared at a parameter at which data type BYTE is expected.
- Without IEC check
  If IEC check is not set, the following rules are applied:
  - Implicit conversion of BOOL to other data types is not possible.
  - Only the REAL, LREAL, BYTE, WORD, DWORD, SINT, INT, DINT, USINT, UINT, UDINT, TIME, DTL, TOD, DATE, STRING, CHAR and WCHAR data types can be converted implicitly.
  - The bit length of the source data type must not exceed the bit length of the target data type. An operand of data type DWORD, for example, cannot be declared at a parameter at which data type WORD is expected.
  - The bit length of an operand entered in-out parameters InOut) must be the same as the programmed bit length for the parameter in question.

Note

Implicit conversion without IEC check

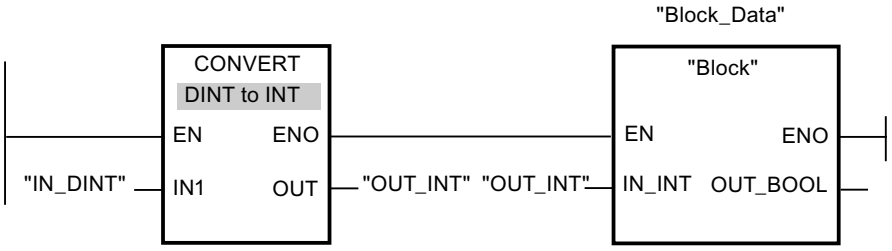
The programming editor uses a gray rectangle to mark operands that are implicitly converted. The dark gray rectangle signals that an implicit conversion is possible without any accuracy loss, for example, if you convert the data type SINT to INT. A light gray rectangle signals that implicit conversion is possible, but errors could occur during runtime. If, for example, you are converting the data type DINT to INT and an overflow occurs, the enable output ENO is set to "0".

For more information about the setting of the IEC check and the implicit conversion, refer to "See also".

Explicit conversion

If the operands are not compatible and an implicit conversion is therefore not possible, you can use an explicit conversion instruction. You can find the conversion instructions in the "Instructions" task card.

A possible overflow is displayed at the ENO enable output. An overflow is created, for example, if the value of the source data type is greater than the value of the target data type.



Note

Shifting of bit patterns

If the explicit conversion involves shifting a bit pattern, the enable output ENO is not set.

For more information about explicit conversion, refer to "See also".

The following figure shows an example in which an explicit data type conversion must be carried out:

The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. Therefore, the value of the "IN_DINT" tag must first be converted from DINT to INT. If the value of the "IN_DINT" tag is within the permitted value range of the INT data type, the conversion takes place. Otherwise, an overflow is signaled. A conversion still takes place even in case of an overflow, but the values are cut off and the enable output ENO is set to "0".

Setting and canceling the IEC check (Page 2467)

Implicit conversions (Page 2467)

Explicit conversions (Page 2487)

11.3.16.2 Implicit conversions (S7-1200)

Setting and canceling the IEC check (S7-1200)

The data types of the operands used are check for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the Inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Binary numbers (S7-1200)

Implicit conversion of BOOL (S7-1200)

Options for implicit conversion

The implicit conversion of the BOOL data type is not possible.

Explicit conversion of SINT (Page 2497)

Implicit conversion of USINT (S7-1200)

Options for implicit conversion

The following table shows the options for implicit conversion of the USINT data type:

Source	Target	With IEC check	Without IEC check	Explanation
USINT	BOOL	-	-	No implicit conversion
	BYTE	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. The remaining bits are filled with "0".
	WORD	-	X	
	DWORD	-	X	
	SINT	-	X	The bit pattern of the source value is converted and transferred to the target data type. (for example, value conversion from USINT #10 -> DINT #10 or USINT #128 -> SINT #-128)
	INT	X	X	
	UINT	X	X	
	DINT	X	X	
	UDINT	X	X	
	REAL	X	X	The value is converted to the format of the target data type. (The value "1", for example, is converted to the value "1.0".)
	LREAL	X	X	
	TIME	-	-	No implicit conversion
	DTL	-	-	
	TOD	-	-	
	DATE	-	-	
	STRING	-	-	
	WSTRING	-	-	
	CHAR	-	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.
	WCHAR	-	X	
x: Conversion possible -: Conversion not possible

	WCHAR	X		WORD_TO_WCHAR
WORD_BCD16	INT	X	The value to be converted has data type WORD and is accepted as a BCD-coded value between -999 and +999. The result is available after conversion as an integer (in binary notation) of the type INT. A real conversion takes place. If the bit pattern includes an invalid tetrad, a synchronous error is not triggered but only the status bit OV is set instead.	WORD_BCD16_TO_INT
BCD16	INT	X		BCD16_TO_INT

x: Conversion possible

- : Conversion not possible

[1] Bit strings (BYTE, WORD, DWORD) are interpreted as an unsigned integer with the same bit length.. Data type BYTE is interpreted as USINT, WORD as UINT and DWORD as UDINT.

Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the SINT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
SINT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	SINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	SINT_TO_BYTE
	WORD[1)]	X		SINT_TO_WORD
	DWORD[1)]	X		SINT_TO_DWORD
	USINT	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type.	SINT_TO_USINT
	INT	X		SINT_TO_INT
	UINT	X		SINT_TO_UINT
	DINT	X		SINT_TO_DINT
	UDINT	X		SINT_TO_UDINT
	REAL	X	The value is converted into the format of the target data type (the value "-1" will be converted into the value "-1.0" with the "Convert value" (CONVERT) instruction.	SINT_TO_REAL, NORM_X
	LREAL	X		SINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the target data type and interpreted as milliseconds.	SINT_TO_TIME
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in milliseconds since 0:0)	SINT_TO_TOD
	DATE	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type. (interpretation in days since 1990-1-1)	SINT_TO_DATE
	STRING	X	The value is converted to a character string. • LAD/FBD: The first characters of the string are padded with spaces. The number of	SINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		SINT_TO_WSTRING

Source	Target	Conversion	Explanation	Mnemonics of the instruction
			spaces depends on the length of the numerical value. Positive numeric values are output without a sign. • STL/SCL: No spaces are inserted. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF). Enable output ENO is set to "0" if a negative value is converted to an unsigned target data type.	SINT_TO_CHAR
	WCHAR[1)]	X		SINT_TO_WCHAR
x: Conversion possible - : Conversion not possible [1)] Bit strings (BYTE, WORD, DWORD) and data type CHAR are first extended to the necessary width including sign, and then the bits are copied. The source type determines the interpretation.
