STATUS[3]	Error_Code_1	Error ID • When Error_Decode = **80**: – **80**: Simultaneous positive edge at the input parameters START and END. – **81**: Length conflict at the CMD_PARAM and CMD_PARAM_LEN parameters. – **82-8F**: Other error messages (reserved) • When Error_Decode = **FE**: – **01**: "Service Request ID" invalid – **02**: Incorrect "Request_Reference" – **03**: "Modifier" invalid – **04**: "Data Structure Identifier RQ" invalid – **05**: "Data Structure Identifier RS" invalid – **06**: "PE energy-saving modes" are not supported – **07**: "Response" is too long (maximum transmissible length exceeded) – **08**: "Count" invalid – **50**: No suitable "energy mode" is available. – **51**: Time value specified is not supported. – **52**: "PE_Mode_ID" invalid – **53**: No switch to "PE energy-saving mode" because the device is in operation – **54**: Function not available at this time. Wrong device configured or incorrect setup. – **55** to **FF**: Reserved
STATUS[4]	Error_Code_2	Manufacturer-specific extension of the error ID

Note

Error messages of the instructions RDREC and WRREC

The instruction "PE_START_END" uses the instructions "WRREC (Page 3596)" and "RDREC (Page 3578)" for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

Please see the description of the corresponding STATUS (Page 3638) parameter for an explanation of the error codes of the "WRREC (Page 3596)" and "RDREC (Page 3578)" instructions.

PE_CMD: Start and exit energy-saving mode / Read out status information (S7-1200, S7-1500)

Description

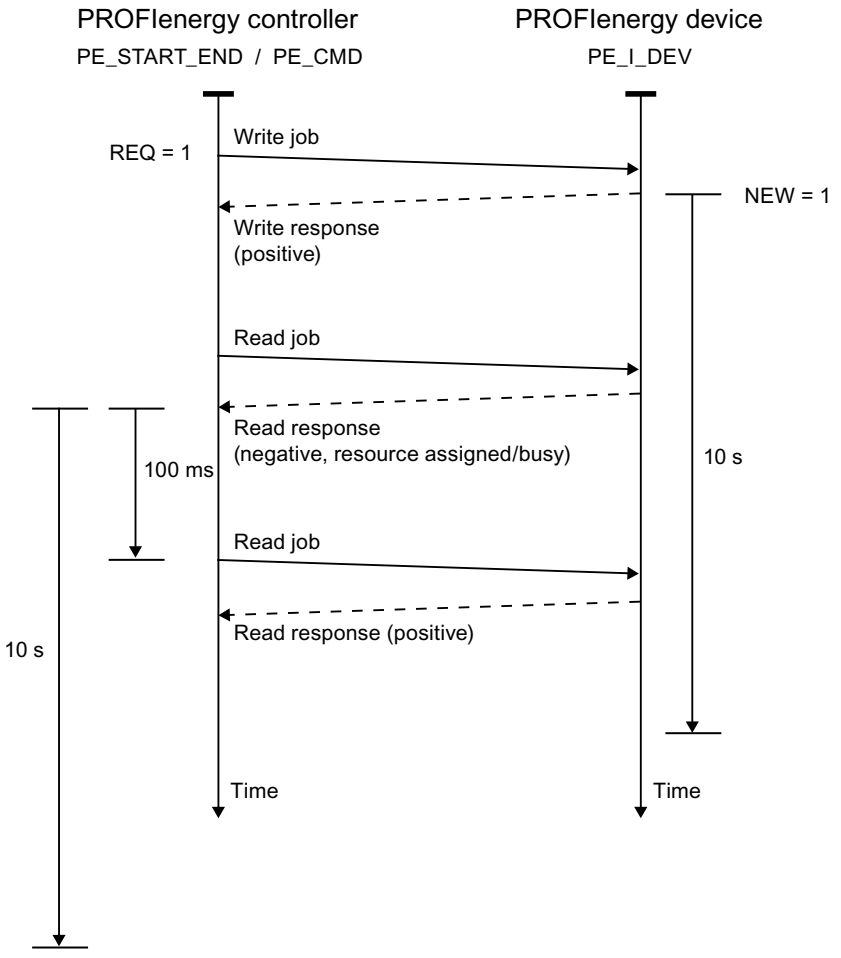
The instruction "PE_CMD" is used in the PE controller to start or terminate a pause in the energy-saving mode in the PE entity. Additional information and energy measurements are also read out from a PE entity using "PE_CMD".

The instruction is best used with PE controllers with assigned PE devices to which field devices are connected from which energy measurements are to be read out. If this is not the case, the instruction "PE_START_END (Page 3730)" can also be used to start and end the pauses.

Transfer of the PROFIenergy commands (PE commands)

The instruction "PE_CMD" transfers a PROFIenergy command to a PE entity.

The instruction can also be used if additional commands are to be added to the PROFIenergy profile in future. The commands which can be used with the current PROFIenergy profile are listed in the description of the CMD and CMD_MODIFIER parameters (see the "CMD and CMD_MODIFIER parameters" table).



- The individual PE commands which are transferred to the PE entity using the instruction are assigned defined "Service_Request_IDs". The Service_Request_IDs 01 to 05 and 16 are assigned at the CMD parameter.
- The two PE commands 04 (Query_Modes) and 16 (Query_Measurement) are defined in more detail with the CMD_MODIFIER parameter.
- Additional values are transferred at the CMD_PARA parameter for individual PE commands (see the description of the individual PE commands). The parameter CMD_PARA_LEN defines the length of the data at the parameter CMD_PARA.

The commands are transferred without plausibility test. The response data of the PE entity is saved to the RESPONSE_DATA data area that is addressed by VARIANT pointer (for information about the response frame contents, refer to the description of the respective PE command).

Write and read jobs of the "PE_CMD" instruction.

The instruction "PE_CMD" uses "WRREC (Page 3596)" internally to transmit a PROFIenergy command as a write job to the PE entity. "PE_CMD" then waits for the acknowledgment from the PE entity. The acknowledgment data record is read with the instruction "RDREC (Page 3578)" every 100 milliseconds. Until acknowledgment is received from the PE entity, the function repeats the read job for 10 seconds at intervals of 100 milliseconds. The response data of the PE entity is also read with the instruction "RDREC (Page 3578)".

Below is a flowchart of the write and read jobs:

Parameter

The following table shows the parameters of the "PE_CMD" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts transferring the PE command upon a positive edge.
ID	Input	HW_ SUBMODULE	I, Q, M, D, L or constant	Address of the PE entity Use the hardware ID of the head module for a PROFINET IO device. Refer to the system constants of the assigned IO controller for the hardware ID. The name of the head module is composed of the name of the IO device and the suffix [Head] (example: "IO_Device_1[Head]"). If the PE entity is an I-device, use the hardware identifier of a transfer area instead.

Parameter	Declaration	Data type	Memory area	Description
CMD	Input	BYTE	I, Q, M, D, L, P or constant	Service-Request-ID of the PROFIenergy command in accordance with the PROFIenergy profile (see "CMD and CMD_MODIFIER parameters"). Further service request IDs are possible following extensions of the PROFIenergy profile.
CMD_MODIFIER	Input	BYTE	I, Q, M, D, L, P or constant	PROFIenergy sub-command (only when CMD=3 or CMD=16, see "CMD and CMD_MODIFIER parameters") Further sub-commands are possible following extensions of the PROFIenergy profile.
CMD_PARA	Input	VARIANT	I, Q, M, D, L	Parameters for the PE commands: • Get mode: PE_mode_ID • Get measurement values: List of Measurement_Ids The complete Service Data Request is entered.
CMD_PARA_LEN	Input	INT	I, Q, M, D, L, P or constant	The actual length of the command parameters (<= length defined in CMD_PARA; is verified by the instruction).
RESPONSE_DATA	InOut	VARIANT	I, Q, M, D, L	PROFIenergy information May be complete response frame including block header, depending on the command. Note: If the buffer is too small, only the number of bytes which is specified in the VARIANT pointer will be entered.
VALID	Output	BOOL	I, Q, M, D, L	Command successfully sent.
BUSY	Output	BOOL	I, Q, M, D, L	Command still being processed.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred during processing.
STATUS	Output	DWORD	I, Q, M, D, L	Block status / error number (see "STATUS parameter"):

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters CMD and CMD_MODIFIER

CMD	CMD_ MODIFIER	PROFIenergy command	Description
01	0	Start_Pause (Page 3755)	Start energy-saving mode or switch to a different energy-saving mode.
02	0	End_Pause (Page 3755)	End energy-saving mode.

CMD	CMD_ MODIFIER	PROFIenergy command	Description
03	1	Query_Modes - List of energy-saving modes (Page 3756)	Output the energy-saving modes supported.
	2	Query_Modes - Get mode (Page 3757)	Output attributes of the energy-saving mode currently enabled.
04	0	PEM_Status (Page 3759)	Query status of energy-saving mode.
05	0	PE_Identify (Page 3761)	Read out the number and description of PE commands supported.
16	1	Query_Measurement - Get_Measurement_List (Page 3761)	List of measured values supported by the PE entity.
	2	Query_Measurement - Get_Measurement_Values (Page 3764)	Output the measured values of the PE entity.

Parameter STATUS

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error while reading the data record • B#16#**DF**: Error while writing the data record • B#16#**C0**: Error message from the internal communication instructions "RDREC (Page 3578)" and "WRREC (Page 3596)".
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific • **FE**: DP/PNIO profiles - PROFIenergy-specific error

Field element	Name	Meaning
STATUS[3]	Error_Code_1	Error ID • When Error_Decode = **80**: – **81**: Length conflict at the CMD_PARA and CMD_PARA_LEN parameters, or the maximum data record length (4095 bytes) was exceeded. – **82-8F**: Other error messages (reserved) • When Error_Decode = **FE**: – **01**: "Service Request ID" invalid – **02**: Incorrect "Request_Reference" – **03**: "Modifier" invalid – **04**: "Data Structure Identifier RQ" invalid – **05**: "Data Structure Identifier RS" invalid – **06**: "PE energy-saving modes" are not supported – **07**: "Response" is too long (maximum transmissible length exceeded) – **08**: "Count" invalid – **50**: A suitable energy-saving mode (energy mode) is not available. – **51**: Time value specified is not supported. – **52**: "PE_Mode_ID" invalid
STATUS[4]	Error_Code_2	Manufacturer-specific extension of the error ID

Note

Error messages of the instructions RDREC and WRREC

The instruction "PE_CMD" uses the instructions "WRREC (Page 3596)" and "RDREC (Page 3578)" for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

Please see the description of the corresponding STATUS (Page 3638) parameter for an explanation of the error codes of the "WRREC (Page 3596)" and "RDREC (Page 3578)" instructions.

PE_DS3_Write_ET200S: Set power module switching behavior (S7-1200, S7-1500)

Description

The instruction "PE_DS3_Write_ET200S" sends basic settings for power module switching behavior to the ET 200S. The switching behavior of up to 8 slots in the ET 200S (e.g. for power modules) is defined with the instruction "PE_DS3_Write_ET200S".

Note

This instruction is not part of the PROIenergy profile but instead supplements SIMATIC-specific functions.

Parameter

The following table shows the parameters of the "PE_DS3_Write_ET200S" instruction:

Parameter	Declaration	Data type	Memory area	Description
ENABLE	Input	BOOL	I, Q, M, D, L or constant	A positive edge triggers the transfer of the data record. Transfer the data record again following voltage OFF/ON.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the ET 200S Accept the address from the hardware configuration.
SLOT_NO_X	Input	INT	I, Q, M, D, L, P or constant	Slot number of switchable power module X.
FUNC_X	Input	INT	I, Q, M, D, L, P or constant	Function of the module in this slot. Use the parameter FUNC_X to define the switching behavior of the PM-E (power module of the ET 200S): • FALSE: – With "PAUSE_START": -No effect on PM-E -PM-E remains on – With "PAUSE_STOP": -Switches PM_E back on • TRUE: – With "PAUSE_START": -Switches PM_E off – With "PAUSE_STOP": -Switches PM-E back on
BUSY	Output	BOOL	I, Q, M, D, L	Transfer not yet complete.
DONE	Output	BOOL	I, Q, M, D, L	Transfer completed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Transfer completed with error.
STATUS	Output	DWORD	I, Q, M, D, L, P	Error number (see STATUS parameter of the instruction "PE_Start_End (Page 3730)")

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_WOL: Starting and stopping energy-saving mode via WakeOnLan (S7-1200, S7-1500)

Description PE_WOL (S7-1200, S7-1500)

Description

The "PE_WOL" instruction sends the PROFIenergy commands "Start_Pause" and "End_Pause" to multiple PROFIenergy-enabled devices in the PROFINET I/O systems.

Multiple PE devices can be coordinated via the instruction provided that the PE devices support the "Wake on LAN" function over a UDP connection.

The "PE_WOL" instruction can only be executed on a CPU with and integrated Ethernet interface. This CPU should be able to load blocks with a size of approx. 400 KB. If this CPU is connected via an Ethernet CP, it is not possible to use the block with PROFINET I/O systems.

The instruction "PE_WOL" is executed asynchronously.

The "PE_WOL" instruction only supports devices with a device number lower than 256. Devices with a higher device number are not taken into account.

Definition: Wake on LAN

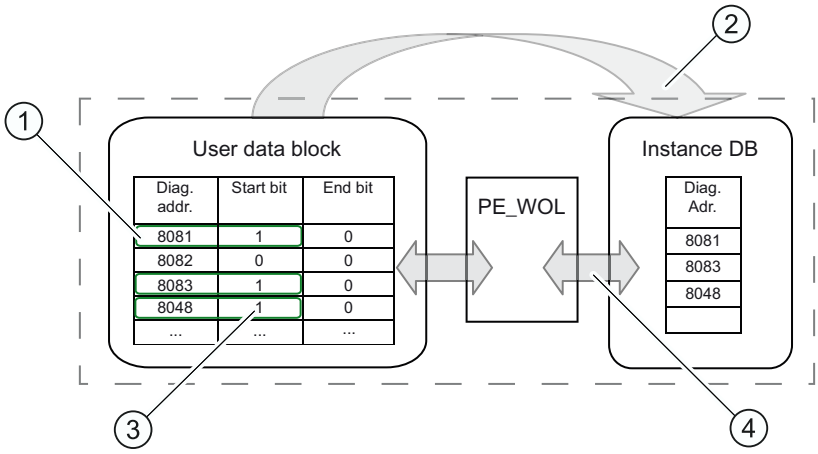
Using Wake on LAN, deactivated devices can be reactivated through the receipt of a special Ethernet packet.

For this procedure to work, the data processing equipment must have a network controller that is capable of receiving such a packet.

This packet (Magic Packet™) has a special format. It contains the MAC address of the network adapter 15 times.

Selection of devices

The devices are selected using the user data block at the parameter PENERGY (Type: "PE_PLUS"). The user DB represents the database for processing multiple devices.



Prior to initialization of "PE_WOL", you must store at least the following information in the user DB:

- ID of the PROFINET I/O system
- Data of the connection which is used for "Wake On LAN".

- Port number which is used for "Wake On LAN".
- For each device
  - Pause time (PauseTime)
  - Switching of the device to the PE_SLEEP_MODE (EnableSleep)

You initialize the "PE_WOL" instruction with the COM_RST parameter. The jobs stored in the user DB are processed one after the other after initialization.

The graphic below illustrates how the PE command "Start_Pause" is transmitted to several devices:

(1) Step 1: The bit "CmdStartPause" of the devices to be shut down is set to "1" by the user.

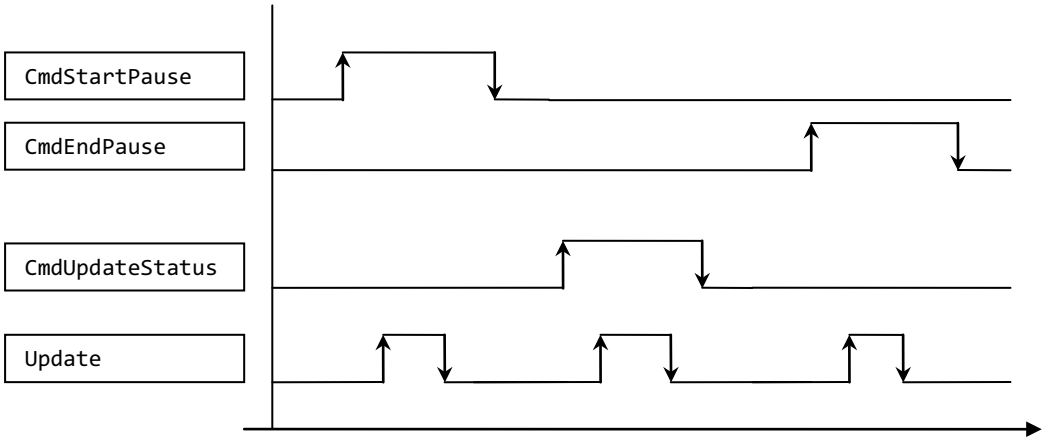
(2) Step 2: The diagnostic addresses of the devices to be shut down (CmdStartPause = "1") are linked to the queue.

(3) Step 3: The bit "CmdStartPause" is reset automatically once the jobs have been linked.

(4) Step 4: The instruction "PE_WOL" processes the jobs as soon as they are linked.

A PROFIenergy command "CmdStartPause" or "CmdEndPause" can be sent for all recognized devices in the PROFINET IO system via the START and END parameters.

The status of the job processing as well as possible errors during processing are output by the STATUS parameter.



Operation of the instruction using the user DB

The instruction "PE_WOL" can only be operated via the user DB. A basic procedure applies in this case:

1. Selection of the command to be executed for a device:
   - START_PAUSE ("CmdStartPause" in user DB)
   - ENDE_PAUSE ("CmdEndPause" in user DB)
   - UPDATE_STATUS ("CmdUpdateStatus" in user DB)
2. Setting the bit for updating ("Update" in the header of the user DB)
   At least one CPU cycle should pass with an "Update" = False between two updates; otherwise, edge detection cannot be guaranteed.

Prioritizing the PE commands

The graphic below shows the chronological sequence of three possible commands.

These are processed one after the other, regardless of whether the previous command call was successful or completed with an error.

Only one command is executed if you set two commands, such as "CmdEndPause" and "CmdUpdateStatus" simultaneously. There is a prioritization within the block:

- The command "CmdStartPause" has the highest priority and is therefore always executed if selected.
- The command "CmdEndPause" has the second highest priority.
- The command "CmdUpdateStatus" has the lowest priority.

If all three commands are set at the same time, the commands that are not executed remain preselected. In this case, the next rising edge executes the next command.

Parameters

The following table shows the parameters of the "PE_WOL" instruction:

Parameter	Declaration	Data type	Memory area	Description
COM_RST (Page 3744)	Input	BOOL	I, Q, M, D, L	Resets the block and performs a re-initialization. As long as True is set here, the initialization is started but not yet fully completed. Only the falling edge continues the initialization and switches to the normal operating mode after initialization.
START (Page 3745)	Input	BOOL	I, Q, M, D, L	A rising edge performs a "CmdStartPause" PROFIenergy command for all detected devices that support this function.
END (Page 3746)	Input	BOOL	I, Q, M, D, L	A rising edge performs a "CmdEndPause" PROFIenergy command for all detected devices that support this function.

Parameter	Declaration	Data type	Memory area	Description
PENERGY (Page 3746)	InOut	PE_PLUS	D	Pointer to the user DB that contains the database for processing multiple devices.
STATUS (Page 3751)	Output	DWORD	I, Q, M, D, L	Status/error number for the current status of the instruction (see "STATUS parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

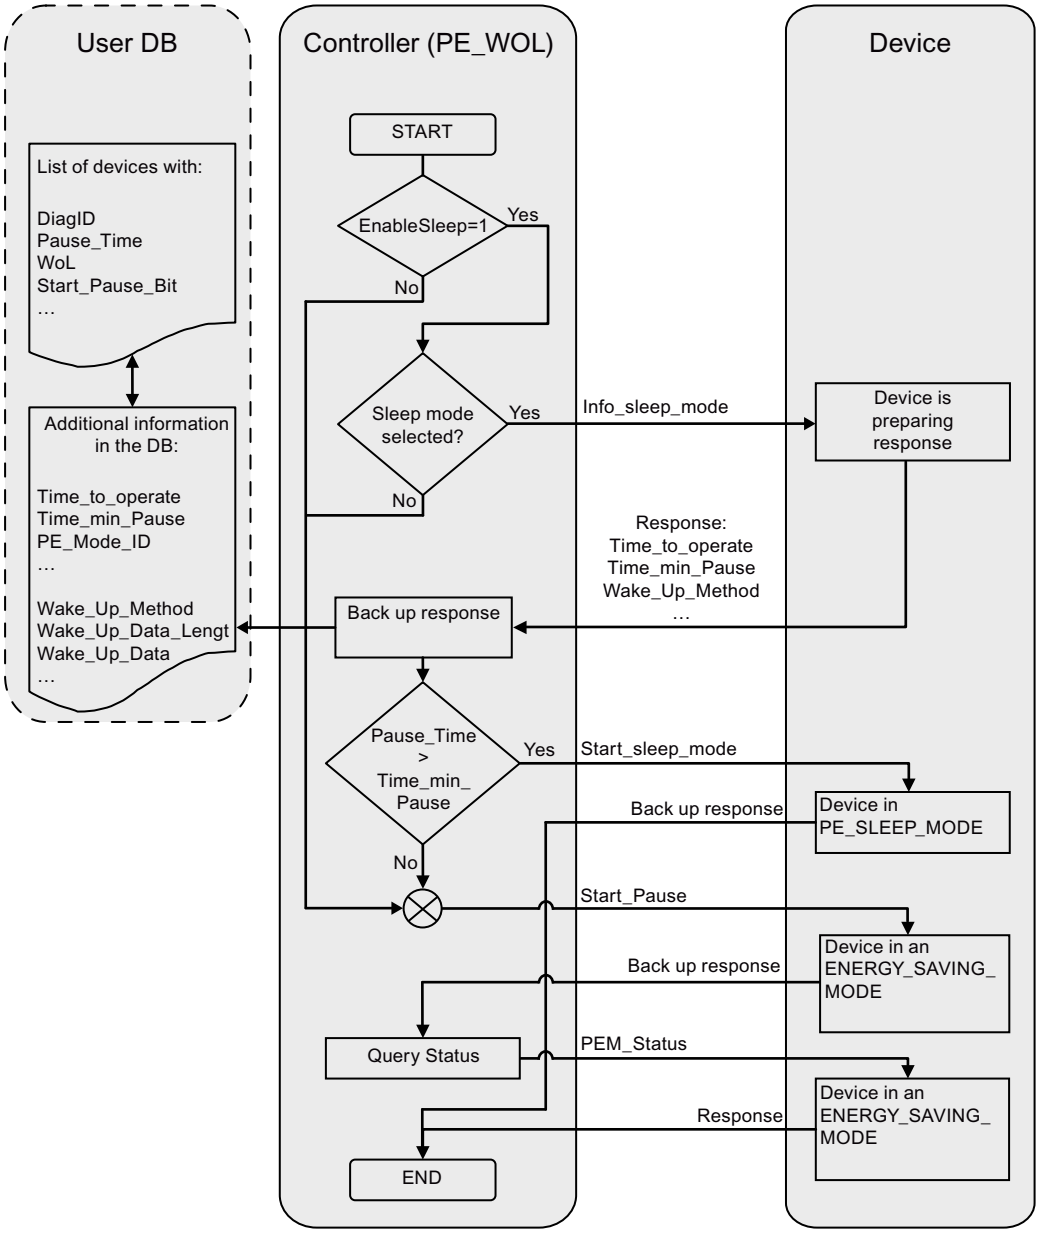
Difference between synchronous and asynchronous instructions (Page 2571)

Parameter COM_RST (S7-1200, S7-1500)

Sequence of the initialization routine

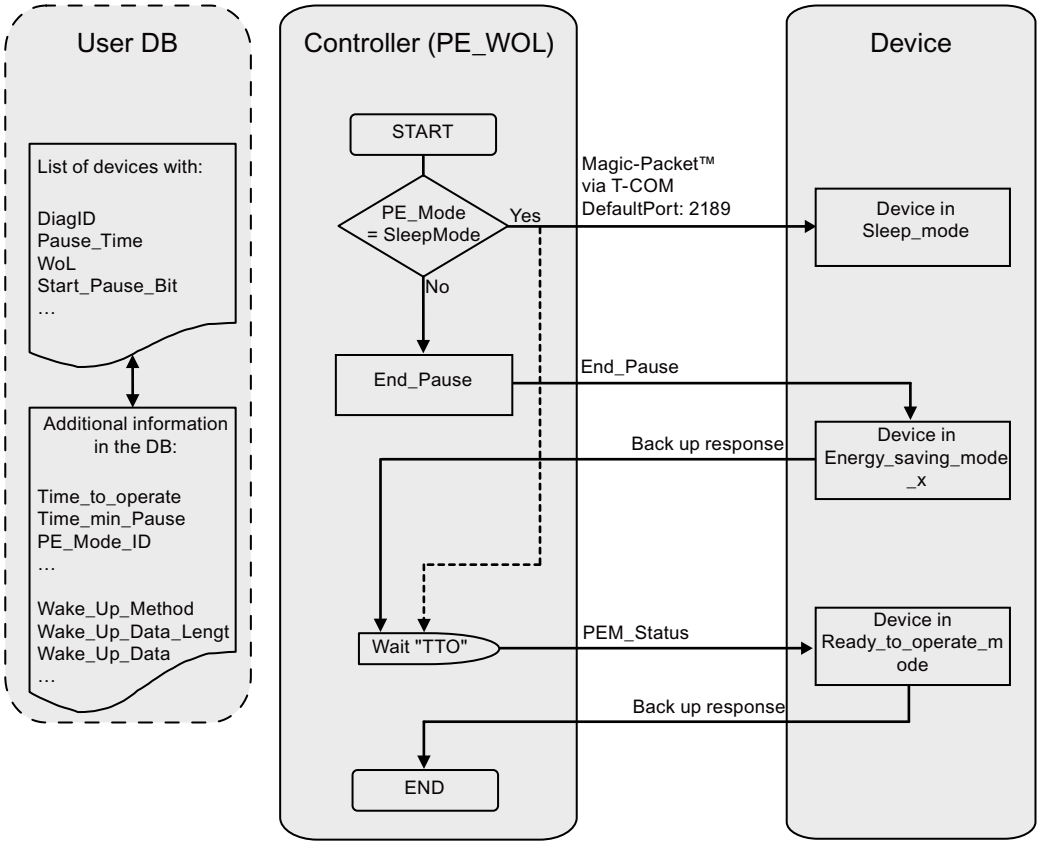
You start the initialization of the "PE_WOL" instruction with the COM_RST parameter.



The following flow diagram shows the initialization routine.

Parameter START (S7-1200, S7-1500)

Sequence of the CmdStartPause command



The flow diagram shows the internally used functions and interaction with a device when executing the CmdStartPause command.

Parameter END (S7-1200, S7-1500)

Sequence of the CmdEndPause command

The flow diagram shows the internally used functions and interaction with a device when executing the CmdEndPause command.

PENERGY parameter (S7-1200, S7-1500)

Data block at the PENERGY parameter

The user DB for the "PE_WOL" PROFIenergy instruction represents a data base for processing multiple devices.

The data block is usually divided into two parts. These are:

- Header 110 bytes
- Device section for a maximum of 256 devices each with 100 bytes (Device). These include:
  - Device-specific data (Device)
  - PROFIenergy-specific data (PE)
  - Data for the job processing (Task)
  - User data (UserData)

The data block operates with optimized access.

Connection parameter "Connection"

The "PE_WOL" instruction reserves a connection resource in the area of "Open User Communication". This is used as a UDP connection. The following parameters must be defined in the data block for this:

- Connection ID ("Connection.id" parameter)
  The connection ID is an integer within the range of 1 to 4095. It is used to identify the communication resources allocated by the firmware, for example the send and receive buffers.
  The connection ID must be unique throughout the CPU.
- Port number that is used for the "Wake on LAN" function ("Header.PortNo" parameter)
  Number of the UDP port via which a "Wake On LAN" packet is sent. These port numbers are part of the communication resources, which are identified and provided by the firmware through the connection ID. The default setting for port 2189 used here is currently not assigned by IANA. The port number is transferred to the connection configuration and applied to parameter "Connection.local_tsap_id[1]". The port number and the length of the remote port are defined using parameters "Connection.rem_tsap_id[1]" and "Connection.rem_tsap_id_LEN" and must be assigned manually.

Structure of the data block

The data block has the following structure:

Name	Data type	Offset	Comment
Header	PE_HEADER	-	Header information
Update (1)	BOOL	-	Signal for indicating a change in the data area. • True= indicates a change by the user. • False = indicates the application of changes.
Initialized	BOOL	-	Signal indicating the completed initialization. • True=Initialization finished. • False= indicates that the block is not initialized.
LinkUp	BOOL	-	Indicates successful configuration of the Ethernet interface. • True=interface ready for use. • False=interface not yet configured.
LinkDown	BOOL	-	Indicates an unconfigured interface. • True=interface is not yet configured. • False=interface is currently being configured or is now configured.
PROFINET_ID (1)	INT	-	ID of the PROFINET I/O system
Reserved	ARRAY [1..37] OF BYTE	-	Reserved
LastDeviceID	INT	-	Contains the highest Device-ID in this PROFINET I/O system.
PortNo (1)	WORD	-	Port number that is used for the "Wake on LAN" function (default= 2189).
Connection	TCON_Param	-	Contains the connection configuration of the "Wake on LAN" connection.

Name	Data type	Offset	Comment
BLOCK_LENGTH	UInt	-	Length of the structure (always B#16#40).
ID (1)	CONN_OUC	-	Connection ID
CONNECTION_TYPE (1)	USINT	-	Connection type (UDP = B#16#13)
ACTIVE_EST (1)	BOOL	-	Active connection establishment (always passive for UDP)
LOCAL_DEVICE_ID (1)	USINT	-	Contains the interface ID (CPU dependent)
LOCAL_TSAP_ID_LEN (1)	USINT	-	Contains the length in bytes of the own/local UDP port
REM_SUBNET_ID_LEN (1)	USINT	-	Unused (always B#16#00)
REM_STADDR_LEN (1)	USINT	-	Contains the length of the remote IP address or B#16#00.
REM_TSAP_ID_LEN (1)	USINT	-	Contains the length in bytes of the remote UDP port. The length specification must be entered manually.
NEXT_STADDR_LEN (1)	USINT	-	Contains the length of the default router address (not relevant).
LOCAL_TSAP_ID (1)	ARRAY[1..16] OF BYTE	-	Contains your own local port number. The value is applied from parameter PortNo during initialization.
REM_SUBNET_ID (1)	ARRAY[1..6] OF USINT	-	Unused (always B#16#00)
REM_STADDR (1)	ARRAY[1..6] OF USINT	-	Contains the remote IP address.
REM_TSAP_ID (1)	ARRAY[1..16] OF BYTE	-	Contains the remote UDP port number. The port number must be entered manually.
NEXT_STADDR (1)	ARRAY[1..6] OF BYTE	-	Irrelevant
SPARE (1)	WORD	-	
Device	ARRAY[1..256] OF PE_DEVICE	-	Array of devices
Device	PE_DEV	-	Contains data for each device
DeviceID	HW_DEVICE	-	Hardware identifier of the device. Assigned by the hardware configuration.
PE_EntityID	HW_IO	-	Hardware identifier of the PROFIenergy entity. Assigned by the hardware configuration.
MACAdr	ARRAY[1..6] OF BYTE	-	Contains the MAC address of the device.
IPAdr	ARRAY[1..4] OF BYTE	-	Contains the IP address of the device.
OrderID_MxLen	Byte	-	Contains the maximum length of the OrderID.
OrderId_ActLen	Byte		Contains the actual length of the OrderID.
OrderID_Data	ARRAY[1..20] OF CHAR		Contains the OrderID of the device.
PE	PE_PE	-	PROFIenergy-specific data.

Name	Data type	Offset	Comment
ModeID	BYTE	-	PE_MODE_ID according to PROFIenergy specification.
Result	BYTE	-	PE ErrorCode according to PROFIenergy specification.
PauseTime (1)	TIME	-	Contains the idle time in ms.
TimeToPause	TIME	-	Contains the time it takes for the device to go into Pause mode.
TimeToOperate	TIME	-	Contains the time it takes for the device to go into operating mode.
MinSleepTime	TIME	-	Contains the minimum time of the device in PE_SLEEP_MODE.
SleepToOperate	TIME	-	Contains the time it takes for the device to go from PE_SLEEP_MODE into operating mode.
StatusOperate	BOOL	-	Indicates the operating mode of the device.
StatusPause	BOOL	-	Indicates the Pause mode of the device.
StatusSleep	BOOL	-	Indicates the PE_SLEEP_MODE of the device.
StatusTransitOK	BOOL	-	Indicates the transition from one energy state to another.
StatusInTransit	BOOL	-	Indicates a current state transition.
StatusTransitNOK	BOOL	-	Indicates that the state change was not successful.
StatusError	BOOL	-	Indicates an error with the device.
StatusRetryEx	BOOL	-	Indicates an unsuccessful execution of a command. No more attempts will be made to execute this command.
CmdStartPause (1)	BOOL	-	Places a START_PAUSE command for this device in the queue.
CmdEndPause (1)	BOOL	-	Places a END_PAUSE command for this device in the queue.
CmdUpdateStatus (1)	BOOL	-	Places a PEM_STATUS command for this device in the queue.
EnableSleep (1)	BOOL	-	Allows PE_SLEEP_MODE for this device. • True= device should go to PE_SLEEP_MODE if idle time is sufficient • False=device may not go into PE_SLEEP_MODE.
Services	WORD	-	Shows all supported PROFIenergy services.
UserData (2)	ARRAY[1..24] OF BYTE	-	User-defined data
Task	PE_TASK	-	Job processing

Name	Data type	Offset	Comment
Cmd	BYTE	-	Internal bits for job processing
CmdJ	BYTE	-	Internal bits for job processing
TimeStart	BOOL	-	Starts a delay time.
TimeStarted	BOOL	-	The delay time has just started.
TimeDone	BOOL	-	Shows the expiration of the delay time.
Done	BOOL	-	Indicates that this job has been completed.
DelayedCmd	BOOL	-	Indicates that a delayed command is still pending.
IsV1_0	BOOL	-	Indicates that this device is a Spec. V1.0 device.
IsWakeOnLAN	BOOL	-	Indicates that this device is woken up by "Wake On LAN".
RetryCount	BYTE	-	Repetition counter for PE_COMMANDS
Duration	TIME	-	Contains the value for the delay in ms.
StartTime	TIME	-	Contains the start time for the delay time.
MachineState	INT	-	Contains the internal status of the job.

(1) To be filled in by the user.

(2) Available for use by the user.

Parameter STATUS (S7-1200, S7-1500)

Parameter STATUS

The output value at the STATUS parameter is divided into three areas:

- Bits 31 to 24: MESSAGE
- Bits 23 to 16: LOCATION
- Bits 15 to 0: INFORMATION

You can learn the meaning of each error code for the three areas in the following tables:

Table 11-40 Possible values for MESSAGE

Error code (W#16#...)	Description
00	No error.
50	Instruction initialized.
51	Determining configuration of the PROFINET I/O system.
52	The instruction could not determine any configured devices in the PROFINET I/O system.
53	Determining the logical addresses of configured devices.
54	Reading interface information out of the devices.
55	Determining I&M data (data record 0 only) of the configured devices.
56	Configuring PROFINET interface for sending the "Wake on LAN" MagicPaket™ via UDP.
57	Determining PROFIenergy capabilities of the connected devices.
62	Invalid PROFINET I/O system ID detected. The causative number is displayed in the INFORMATION field.

Error code (W#16#...)	Description
70	The instruction is initiated and processing jobs. The value in the INFORMATION field contains the number of currently active jobs.
80	The instruction has lost the initialization during processing of jobs. This generally occurs when either the instance DB or the user DB has been reloaded.
FF	Unknown error has occurred.

Table 11-41 Possible values for LOCATION

Error code (W#16#...)	Description
00	The instruction is either not initialized or it is idle.
70	The instruction is waiting for jobs.
71	The instruction has appended a job to the job list.
72	The instruction is preparing to send a job.
73	The instruction is sending a job to a device.
74	The instruction is waiting for a response from the device.
75	The instruction is evaluating the response of the device.
76	The instruction is removing the job from the job list.
FF	Unknown error has occurred.

Table 11-42 Possible values for INFORMATION

Error code (W#16#...)	Description
0000	No additional information available and no jobs active.
0001 -00FF	1 – 255 jobs are currently being processed.
7000	Re-initialization with COM_RST started but not yet completed.
8001	Error at 1st parameter
8002	Error at 2nd parameter
8003	Error at 3rd parameter
8004	Error at 4th parameters
8005	Error at 5th parameter This error is reported if there is no interconnection or an invalid interconnection to the user DB. Possible causes: • The user DB is too small. • The user DB is write-protected. • There is no user DB in the RAM. • The user DB is invalid for the employed CPU.

Error code (W#16#...)	Description
8085 to 80CE	Error when configuring the connection. The error messages of the internally used TCON instruction are output. The description of the error messages can be found in the table for the STATUS (Page 4478) parameter.
8100	An attempt has been made to place more than the maximum of 256 possible jobs. This is a temporary error, which is resolved by completing a few jobs. The placed jobs are not accepted and must be placed again.
8200	An attempt was made to send an invalid or an unsupported PROFIenergy command (PE_COMMAND).
8400	Connection ID outside the permitted range. Initialization aborted. Check the ID of the connection configuration for "Wake on LAN". See data block at parameter PENERGY > Header > Connection > ID.
84xx	A communication error has occurred. The number of the device that generated the error is output to "xx".
85xx	An error has been returned from device xx. The number of the device that generated the error is output to "xx".
8600	The requested wake-up method is currently not supported.
FFFF	Unknown error has occurred.

Structure of the message frames (S7-1200, S7-1500)

Structure of the response frame in accordance with the PROFIenergy profile

The table below shows the basic structure of the response frame in accordance with the PROFIenergy profile. The response frame consists of a general section (Header) and a specific section (Service Data Response). The contents of the specific section of the response frame can be found in the description of the relevant PROFIenergy command.

Block definition	Attributes	Value	Data type	Description
BlockHeader	BlockType	801_{hex}	WORD	
	BlockLength		WORD	Number of bytes without consideration of the fields BlockType and BlockLength.
	BlockVersionHigh	1_{hex}	BYTE	
	BlockVersionLow	0_{hex}	BYTE	

Block definition	Attributes	Value	Data type	Description
Response Header	Service_Request_ID	1_{hex} to FF $_{hex}$	BYTE	ID of the PI command executed. The ID of the PE command processed by the PE entity is returned in the response frame: • 01: Start_Pause • 02: End_Pause • 03: Query_Modes • 04: PEM_Status • 05: PE_Identify • 06 to 09: Reserved • 16: Query_Measurement • 11 to CF: Reserved • D0 to FF: Manufacturer-specific
	Request_Reference	1_{hex} to FF $_{hex}$	BYTE	Unique number to identify the query/response pair (returned by the server in the response).
Service Header Response	Status	1_{hex} to FF $_{hex}$	BYTE	Information whether or not the PI command was executed: • 00: Reserved • 01: Completed • 02: Completed with error • 03: Data incomplete • 04 to CF: Reserved • D0 to FF: Depends on the Service_Request_ID
	Data_Structure_ Identifier_RS	1_{hex} to FF $_{hex}$	BYTE	• 00: Reserved • 01 to FF: Data structure depends on the Service_Request_ID • 0xFF - Error
Service Data Response				Depends on the Service-Request-ID: • For the service request IDs, see the CMD and CMD_MODIFIER parameters of the instruction "PE_CMD (Page 3735)". • The specific contents of the response frame can be found in the description of the PE command (see for example the "Start_Pause (Page 3755)" command).

PI Command "Start_Pause" (S7-1200, S7-1500)

Description

Use the PE command "Start_Pause" to start the energy-saving mode. The command Start_Pause can be used to:

- Switch the PE from "ready" state (PE_ready_to_operate) to an energy-saving mode (PE_energy_saving_mode).
- The PE entity can automatically switch between the energy-saving modes. Energy consumption can increase or decrease when you switch energy-saving mode.

Calling the PI command "Start_Pause"

The command "Start_Pause" is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	1	Call of PE command "Start_Pause".
CMD_MODIFIER	0	There are no additional specifications of the command call for command "Start_Pause".
CMD_PARA_LEN	4	Length of the CMD_PARA parameter of 4 bytes.
CMD_PARA	VARIANT	VARIANT pointer to the value for "Pause_Time" (TIME).

Response frame (Service Data Response)

The following response frame data of the PE entity is written to the data block that is referenced at parameter RESPONSE_DATA (see instruction "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
PE_Mode_ID	1 to 255	BYTE	Identification number of the energy-saving mode
Reserved	0	BYTE	-

PI Command "End_Pause" (S7-1200, S7-1500)

Description

The PE command "End_Pause" is used to end the energy-saving mode of the PE entity.

Calling the PE command "End_Pause"

The command "End_Pause" is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	2	Call of PE command "End_Pause".
CMD_MODIFIER	0	There are no additional specifications of the command call for command "End_Pause".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
Time_to_operate	-	DWORD	Expected time it takes to switch to the "PE_ready_to_operate" mode.

PI command "Query_modes" - "List_Energy_Saving_Modes" (S7-1200, S7-1500)

Description

Use PE command "Query_modes" and sub-command (modifier) "List_Energy_Saving_Modes" to output all energy-saving modes (PE_Mode_ID) supported by the PE entity.

The query result is written in the form of a response frame to the data block referenced by theRESPONSE_DATA parameter.

Calling the PE command "Query_modes" - "List_Energy_Saving_Modes"

The command "List_Energy_Saving_Modes" is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	3	Call of PE command "Query_modes".
CMD_MODIFIER	1	Specification of the command call: Select the sub-command "List_Energy_Saving_Modes" to output the number and types of energy-saving modes supported.
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
Number_of_PE_Mode_IDs	1	BYTE	The number of energy-saving modes.
PE_Mode_IDs	-	Array [...] of BYTE	Array with the IDs of the supported energy-saving modes. The meaning of the individual IDs depends on the PE entity.

PI command "Query_modes" - "Get_Mode" (S7-1200, S7-1500)

Description

You use the PE command "Query_modes" and the sub-command (modifier) "Get_Mode" to output the attributes of the energy-saving mode which is currently enabled.

Calling the PE command "Query_modes" - "Get_Mode"

The call of the command with the instruction "PE_CMD" occurs with the following parameters:

Parameter	Value	Description
CMD	3	Call of the PE command "Query_modes"
CMD_MODIFIER	2	Specification of the command call: Select the sub-command "Get_Mode" to output the status of the mode which is currently enabled
CMD_PARA_LEN	1	Length of the CMD_PARA parameter of 1 byte
CMD_PARA	VARIANT	VARIANT pointer to the value for PE_MODE_ID

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
PE_Mode_ID	• 0 "PE_power_off" mode • 1...254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	ID of the energy-saving mode currently enabled
PE_Mode_Attributes	Bit 0: • = 0: Only static energy consumer and time values are available. • = 1: Dynamic energy consumer and time values are available. Bit 1 to 7: • Reserved	BYTE	
Time_min_Pause [1]	Time difference without date	DWORD	Minimum pause time for the PI mode. The minimum pause time is the sum of the values of the following attributes: • Time_to_Pause • Time_to_operate • Time_min_length_of_stay See the description "PAUSE_TIME parameter" of the instruction "PE_START_END: Start and exit energy-saving mode (Page 3730)".
Time_to_Pause [1]	Time difference without date	DWORD	Switch off time: Duration from call of energy-saving mode to start of energy-saving mode (transition duration of PE_ready_to_operate to PE_energy_saving_mode). The switch-off time depends on the PE entity.
Time_to_operate [1]	Time difference without date	DWORD	Switch-on time: Duration of the transition from energy-saving mode (PE_energy_saving_mode) to ready to operate mode (PE_ready_to_operate). The PE entity calculates the duration dynamically in the output operation.
Time_min_length_of_stay [1]		DWORD	Minimum duration of the energy-saving mode in the PE entity
Time_max_length_of_stay [1]		DWORD	Maximum duration of the energy-saving mode in the PE entity
Mode_Power_Consumption [2]		REAL	Power consumption of the PE entity in active energy-saving mode Unit: kW

Attribute	Value	Data type	Description
Energy_ Consumption_ to_pause [2]		REAL	Energy consumption of the PE entity during transition from ready-to-operate mode (PE_ready_to_operate) to energy-saving mode (PE_energy_saving_mode) Unit: kWh
Energy_ Consumption_ to_operate [2]		REAL	Energy consumption of the PE entity during transition from energy-saving mode (PE_energy_saving_mode) to ready-to-operate mode (PE_ready_to_operate) Unit: kWh
[1] If the duration is infinite, 0xFFFFFFFF is output. If the duration is zero, "0" is output. [2] If the data for energy and power consumption by the PE entity is not defined, "0.0" is output as value.			

PI command "PEM_Status" (S7-1200, S7-1500)

Description

The PE command "PEM_Status" is used to query the status of a PE entity energy-saving mode that is currently enabled.

Calling the PE command "PEM_Status"

The command "PEM_Status" is called with the instruction "PE_CMD" with the following parameters:

Parameter	Value	Description
CMD	4	Call of PE command "PEM_Status".
CMD_MODIFIER	0	There are no other specifications of the command call for command "PEM_Status".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
PE_Mode_ID_ Source	• 0 "PE_power_off" mode • 1 to 254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	Mode of the PE entity before a PE command is sent.
PE_Mode_ID_ Destination	• 0 "PE_power_off" mode • 1 to 254 Energy-saving mode of the PE entity (manufacturer-specific) • 255 "PE_ready_to_operate" mode	BYTE	Mode of the PE entity after a PE command is executed.
Time_to_operate	Time difference without date	DWORD	Switch-on time: Duration of the transition from energy-saving mode (PE_energy_saving_mode) to ready to operate mode (PE_ready_to_operate). The PE entity calculates the duration dynamically during output.
Remaining_time_to_ destination	Time difference without date	DWORD	Remaining time to switch to another mode.
Mode_Power_ Consumption		REAL	Power consumption of the PE entity in active energy-saving mode. Unit: kW
Energy_ Consumption_ to_Destination		REAL	Energy consumption for the current PI transition Unit: kWh
Energy_ Consumption_ to_operate		REAL	Energy consumption of the PE entity during transition from energy-saving mode (PE_energy-saving mode) to ready-to-operate mode (PE_ready_to_operate) Unit: kWh

PI command "PE_Identify" (S7-1200, S7-1500)

Description

The PE command "PE_Identify" is used to read out the number and description of PE commands supported by the PE entity. The number of specific commands supported depends on the PE entity. As PE_Identify is itself a PE command, at least three supported PE commands are output for a positive response: Start_Pause, End_Pause and PE_Identify.

Call of the PE command "PE_Identify"

The command "PE_Identify" is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	5	Call of the command "PE_Identify".
CMD_MODIFIER	0	There are no other specifications of the command call for command "PE_Identify".
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	Irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
Count [1]	6	BYTE	Number of supported PROFIenergy commands
Start_Pause	1	BYTE	First PE command supported (Service_Request_ID)
End_Pause	2	BYTE	...
Query_Modes	3	BYTE	...
PEM_Status	4	BYTE	...
PE_Identify	5	BYTE	...
Query_Measurement	16	BYTE	Last PE command supported (Service_Request_ID)

[1] The number of commands supported is manufacturer-specific and depends on the PE entity used. When all 6 PE commands are supported, the values given are an example of a response frame.

PI Command "Query_Measurement" - "Get_Measurement_list" (S7-1200, S7-1500)

Description

Use the PE command "Query_Measurement" and sub-command (modifier) "Get_measurement_list" to query the specific measured values supported by the PE entity. The supported measured values are output as a list in the data block referenced by the RESPONSE_DATA parameter.

Calling the PE command "Query_Measurement" - "Get_Measurement_list"

The command is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	16	Call of the command "Query_Measurement".
CMD_MODIFIER	1	Specification of the command call: Select the sub-command "Get_Measurement_List" to output a list of supported measured values.
CMD_PARA_LEN	0	Length of the CMD_PARA parameter of 0 bytes.
CMD_PARA	irrelevant	-

Response frame (Service Data Response)

The following data of the PE entity response frame is written to the data block referenced at the RESPONSE_DATA parameter (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
Count	-	BYTE	Number of measurement IDs
reserved	-	BYTE	
...			
Measurement_ID	-	WORD	First supported Measurement_ID The Measurement_ID is manufacturer-specific. For more information, refer to the manual of the respective PE entity.
Accuracy_Domain	-	BYTE	See "accuracy domain" table.
Accuracy_Class	-	BYTE	See "accuracy classes" table.
Range	-	REAL	Specifies the scale end value of the measured value (only for accuracy domain 1). The attribute range uses the same unit as defined using attribute Measurement_ID (only one unit is used for each Measurement_ID).
...			
Measurement_ID	-	WORD	Last supported Measurement_ID
Accuracy_Domain	-	BYTE	See "accuracy domain" table.
Accuracy_Class	-	BYTE	See "accuracy classes" table.
Range	-	REAL	Specifies the scale end value of the measurement value (only for accuracy domain 1). The attribute range uses the same unit as defined using attribute Measurement_ID (only one unit is used for each Measurement_ID).

Accuracy domains

Accuracy domain	Description
0	Reserved
1	The accuracy deviation is output in percentages of the scale end value. The percentage of the possible deviation is divided into accuracy classes (see table: Accuracy classes of the accuracy domains 1 and 2).

Accuracy domain	Description
2	The accuracy deviation is output in percentages of the current measurement value. The percentage of the possible deviation is divided into accuracy classes (see table: Accuracy classes of the accuracy domains 1 and 2).
3	The measuring accuracy adheres to the standard IEC 61557-12. The function performance classes for performance measurement and monitoring devices (PMD) without external sensors, and the system performance classes for PMD with external sensors, are coded as set out in the "Accuracy classes of accuracy domain 3" table.
4	The entry of the accuracy adheres to the standard EN 50470-3, chapter 8 (see also table: Accuracy classes of accuracy domain 4).

Accuracy classes

Table 11-43 Accuracy classes of the accuracy domains 1 and 2

Accuracy class	0	1	2	3	4	5	6	7	8
Meaning	Reserved	0.01%	0.02%	0.05%	0.1%	0.2%	0.5%	1%	1.5%

Accuracy class	9	10	11	12	13	14	15	>15
Meaning	2%	2.5%	3%	5%	10%	20%	>20%	Not defined

Table 11-44 Accuracy classes of accuracy domain 3

Accuracy class	0	1	2	3	4	5	6	7	8
Meaning	Reserved	0,02	0,05	0,1	0,2	0,5	1	1,5	2

Accuracy class	9	10	11	12	13	14	>13
Meaning	2,5	3	5	10	20	20%	Not defined

Table 11-45 Accuracy classes of accuracy domain 4

Accuracy class	0	1	2	3	4	5	6	>7
Meaning	Reserved	0,5	1,0	1,5	2,0	2,5	3,0	Not defined

PI Command "Query_Measurement" - "Get_Measurement_values" (S7-1200, S7-1500)

Description

Use the PE command "Query_Measurement" and sub-command (modifier) "Get_measurement_values" to output a list of measured values supported by the PE entity. The measured values are output as a list in the data block referenced by the RESPONSE_DATA parameter.

Calling the PE command "Query_Measurement" - "Get_Measurement_values"

The command is called with the instruction "PE_CMD (Page 3735)" with the following parameters:

Parameter	Value	Description
CMD	16	Call of the command "Query_Measurement".
CMD_MODIFIER	2	Specification of the command call: Select the command "Get_Measurement_Values" to output a list of supported measurement values.
CMD_PARA_LEN	0	Depends on the number of measurement values. The length of the parameters results from the attribute count and the sum of the lengths of the attributes for the transferred measurement values.
CMD_PARA	VARIANT	VARIANT pointer to data structure with list of measured values to be queried (see "CMD_PARA parameter").

Parameter CMD_PARA

The structure specified with the VARIANT pointer at the CMD_PARA parameter must have the following setup:

Attribute	Value	Data type	Description
Count	-	BYTE	Number of measured values (Measurement-IDs)
reserved	0	BYTE	Not used
Measurement_ID	-	WORD	First measured value queried
...			
Measurement_ID	-	WORD	Last measured value queried

Response frame (Service Data Response)

The following response frame data of the PE entity is written to the data block that is referenced at parameter RESPONSE_DATA (see "PE_CMD (Page 3735)"):

Attribute	Value	Data type	Description
Count [1]	-	BYTE	Number of measured values (Measurement-IDs)
reserved	0	BYTE	Not used
Length_of_Structure	2 to 65535	WORD	Length of the structure in bytes

Attribute	Value	Data type	Description
Measurement_Data_Structure_ID	1 = simple value	BYTE	Defines the following structure.
Measurement_ID	0 to 65535	WORD	ID of the supported measurement value.
Status_of_ Measurement_Value	1 to 3	BYTE	Status of the measurement value: • 1: Valid • 2: Not supported • 3: Invalid
Transmission_Data_Type	-	REAL	
End_of_demand	-	TOD	Optional time stamping with data type TimeOfDay.
...			
Length_of_Structure	-	WORD	Length of the structure in bytes
Measurement_Data_Structure_ID	-	BYTE	Defines the following structure.
Measurement_ID	-	WORD	ID of the supported measurement value.
Status_of_Measurement_Value	-	BYTE	Status of the measurement value: • 1: Valid • 2: Not supported • 3: Invalid
Transmission_Data_Type	-	REAL	
End_of_demand	-	TOD	Optional time stamping with data type TimeOfDay.

[1] If the data length of the measurement values queried exceeds the size of the PDU (Protocol Data Unit) of the protocol layer, the data will not be completely transferred and only the supported measurement values will be output.

iDevice / iSlave (S7-1200, S7-1500)

PE_I_DEV: Control PROFIenergy commands in the I-Device (S7-1200, S7-1500)

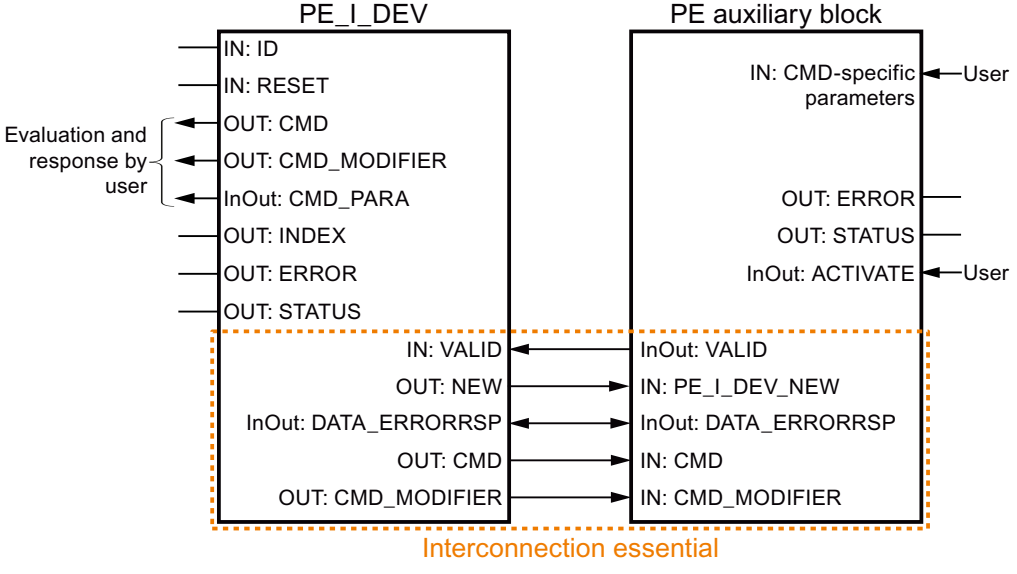
Description

The instruction "PE_I_DEV" is used to process the PROFIenergy profile in the intelligent IO device (iDevice).

- The instruction "PE_I_DEV" is called cyclically by the user program of the iDevice and receives all PROFIenergy commands.
- The PROFIenergy response is generated by configuring an auxiliary block. The response in the pause is fully programmable. The response data must be provided within 10 seconds; otherwise, "State conflict 0x80B5" will occur at the STATUS parameter of the instruction in the IO controller.

Note: The functions are executed by the firmware in a standard PROFIenergy-compatible IO device such as the ET 200S.

No specific knowledge of the PROFIenergy standard is required to use the instruction.



PROFIenergy auxiliary blocks (PE auxiliary blocks)

The PE auxiliary blocks are used to generate the response frame. Enter the response data (in plain text) at the input parameters of the relevant block.

- For each PROFIenergy command, there is a corresponding auxiliary block for a positive response:
  - PE command "Start_Pause": PE_Start_RSP (Page 3770)
  - PE command "End_Pause": PE_End_RSP (Page 3771)
  - PE command "Query_modes" - "List_Energy_Saving_Modes": PE_List_Modes_RSP (Page 3773)
  - PE command "Query_modes" - "Get_Mode": PE_Get_Mode_RSP (Page 3774)
  - PE command "PEM_Status": PE_PEM_Status_RSP (Page 3776)
  - PE command "PE_Identify": PE_Identify_RSP (Page 3777)
  - PE command "Query_Measurement" - "Get_Measurement_list": PE_Measurement_List_RSP (Page 3779)
  - PE command "Query_Measurement" - "Get_Measurement_values": PE_Measurement_Value_RSP (Page 3780)
- Irrespective of the PROFIenergy command, there is an additional shared auxiliary block for a negative response (see PE_Error_RSP (Page 3769)).

Interconnection of the auxiliary blocks

The instruction "PE_I_DEV" and the auxiliary blocks are coordinated. Some of the parameters are simply interconnected. The diagram below shows which of the parameters need to be interconnected.

Parameters

The following table shows the parameters of the instruction "PE_I_DEV":

Parameter	Declaration	Data type	Memory area	Description
RESET	Input	BOOL	I, Q, M, D, L or constant	Resets the instruction.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the transfer area, which is supplied in the IO controller with the data for PROFIenergy. The hardware identifier can be found in the system constants.
VALID	Input	BOOL	I, Q, M, D, L or constant	The response data for the PROFIenergy controller is ready and can be sent.
CMD_PARA	Output	VARIANT	I, Q, M, D, L	Parameters for: • Get mode: PE_mode_ID • Get measurement values: List of Measurement_IDs (list of IDs of the tags to be read; either one tag or multiple tags may be read at any given time). Maximum length: 234 bytes Note: With S7-1200 the pointer must not reference 64-bit data types (in other words not the data types LWORD, LINT und ULINT).
DATA_ERRORRSP	InOut	VARIANT	I, Q, M, D, L	Pointer to the data area containing the acknowledgment data for the PROFIenergy controller. This must correspond to the pointer which is also used with the auxiliary blocks. Note: With S7-1200 the pointer must not reference 64-bit data types (in other words not the data types LWORD, LINT und ULINT).
INDEX	Output	INT	I, Q, M, D, L	Data record number of the PROFIenergy record (set at 0x80A0)
CMD	Output	INT	I, Q, M, D, L	Service-Request-ID of the PROFIenergy command in accordance with the PROFIenergy profile (see "CMD and CMD_MODIFIER parameters"). Further PE commands (Service-Request-IDs) are possible following extensions of the PROFIenergy profile.
CMD_ MODIFIER	Output	INT	I, Q, M, D, L	PROFIenergy sub-command: • Only when CMD=3 or CMD=16; see "CMD and CMD_MODIFIER parameters". • For all other commands: "0". Further sub-commands are possible following extensions of the PROFIenergy profile.
NEW	Output	BOOL	I, Q, M, D, L	New data available from the PROFIenergy controller.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Command completed with error.
STATUS	Output	DWORD	I, Q, M, D, L	Error information (see "STATUS parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

CMD and CMD_MODIFIER parameters

CMD	CMD_ MODIFIER	PROFIenergy command	Description
01	0	Start_Pause	Start energy-saving mode or switch to a different energy-saving mode.
02	0	End_Pause	End energy-saving mode.
03	1	Query_Modes - List energy saving Modes	Output the energy-saving modes supported.
	2	Query_Modes - Get Mode	Output attributes of the energy-saving mode currently enabled.
04	0	PEM_Status	Query status of energy-saving mode.
05	0	PE_Identify	Read out the number and description of PE commands supported.
16	1	Query_Measurement - Get_Measurement_List	List of measured values supported by the PE entity.
	2	Query_Measurement - Get_Measurement_Values	Output of the measured values of the PE entity.

STATUS parameter

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error while reading the data record • B#16#**DF**: Error while writing the data record • B#16#**C0**: Error message from the "PE_I_DEV" instruction or the internally used "PRVREC (Page 3706)" and "RCVREC (Page 3704)" communication instructions.
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific
STATUS[3]	Error_Code_1	Error ID (when Error_Decode = **80**): • **B1**: Write length error (error in write length or insufficient length information on the data type VARIANT).
STATUS[4]	Error_Code_2	For PROFINET errors: Output of IO controller error message If no PROFINET error has occurred, the value in STATUS[4] = "0".

Note

Error messages of the "PRVREC" and "RCVREC" instructions

The "PE_I_DEV" instruction uses the "PRVREC (Page 3706)" and "RCVREC (Page 3704)" instructions for communication. Error messages for these instructions are output in the field elements STATUS[1] to STATUS[4].

For the meaning of the error codes of the "PRVREC" and "RCVREC" instructions, see the description of the corresponding STATUS (Page 3638) parameter.

Description of PROFIenergy (Page 3728)

Auxiliary blocks of the instruction PE_I_DEV (S7-1200, S7-1500)

PE_Error_RSP: Generate negative answer to command (S7-1200, S7-1500)

Description

The auxiliary block "PE_Error_RSP" (Response with failure) generates a negative response if the command requested is not supported (either in general or temporarily). Response generation does not depend on the command requested.

Parameter

The following table shows the parameters of the "PE_Error_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
ERROR_CODE	Input	BYTE	I, Q, M, D, L or constant	Error number
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.

Parameter	Declaration	Data type	Memory area	Description
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_Start_RSP: Generate answer to command at start of pause (S7-1200, S7-1500)

Description

The auxiliary block "PE_Start_RSP" (Start Pause) generates the response to the PE command Start_Pause (Page 3755). The instruction returns the energy-saving mode to which the device has switched (PE_MODE_ID parameter).

If the response differs depending on the length of the pause, you can return this fact in the feedback on the energy-saving mode (PE_Mode_ID = 1 for a brief pause, PE_Mode_ID = 2 for a longer pause, etc.).

Parameter

The following table shows the parameters of the "PE_Start_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.

Parameter	Declaration	Data type	Memory area	Description
PE_MODE_ID	Input	BYTE	I, Q, M, D, L or constant	PE mode that the process assumes
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_End_RSP: Generate answer to command at end of pause (S7-1200, S7-1500)

Description

The auxiliary block "PE_End_RSP" generates the response to the PE command End_Pause (Page 3755). To switch from the current mode to "Ready_To_Operate" mode, the time required is returned as response.

Parameter

The following table shows the parameters of the "PE_End_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
Time_to_Operate	Input	DWORD	I, Q, M, D, L or constant	Time required to switch from the current mode to "Ready_To_Operate".
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_List_Modes_RSP: Generate queried energy savings modes as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_List_Modes_RSP" generates the response to the PE command List_Energy_Saving_Modes (Page 3756). The response generated includes the number and the IDs of energy-saving modes supported.

Parameter

The following table shows the parameters of the "PE_List_Modes_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Number_of_PE_Mode_IDs	Input	BYTE	I, Q, M, D, L or constant	Number of energy-saving modes supported. Permitted values: 1 to 254
PE_MODE_ID	Input	VARIANT	I, Q, M, D, L	Points to the area in which the IDs of the energy-saving modes supported (PE_Mode_ID) are stored. Valid range: 1 to 254.
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.

Parameter	Declaration	Data type	Memory area	Description
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_Get_Mode_RSP: Generate queried energy data as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_Get_Mode_RSP" generates the response to the command Get_Mode (Page 3757). The response frame contains the time, performance, or energy data of an energy-saving mode.

Parameters

The following table shows the parameters of the "PE_Get_Mode_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
PE_Mode_ID	Input	BYTE	I, Q, M, D, L or constant	ID of the energy-saving mode currently enabled.
PE_Mode_Attributes	Input	BYTE	I, Q, M, D, L or constant	Additional information regarding energy saving mode

Parameter	Declaration	Data type	Memory area	Description
Time_min_Pause	Input	DWORD	I, Q, M, D, L or constant	Minimum pause duration for this PE energy-saving mode. This is the sum of the following three parameters: • Time_to_Pause • Time_to_operate • Time_min_length_of_stay
Time_to_Pause	Input	DWORD	I, Q, M, D, L or constant	Time between the edge at the START parameter (see "PE_I_DEV (Page 3765)") and the requested PE energy-saving mode being reached.
Time_to_Operate	Input	DWORD	I, Q, M, D, L or constant	Maximum switch-on time to "PE_ready_to_operate". The "Time_to_operate" parameter can be used directly for the relevant calculations. The value may be a static maximum, or be calculated dynamically by the PE entity.
Time_min_Lenght_of_stay	Input	DWORD	I, Q, M, D, L or constant	Minimum dwell time of the PE entity in this PE mode.
Time_max_Lenght_of_stay	Input	DWORD	I, Q, M, D, L or constant	Maximum dwell time of the PE entity in this PE mode.
Mode_Power_Consumption	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the current PE mode in [kW].
Energy_Consum_to_Pause	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from "PE_ready_to_operate" to the current PE mode in [kWh].
Energy_Consum_to_operate	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from the current PE mode to "PE_ready_to_operate" in [kWh].
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_PEM_Status_RSP: Generate PEM status as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_PEM_Status_RSP" generates the response to the command PEM_Status (Page 3759).

Parameter

The following table shows the parameters of the "PE_PEM_Status_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
PE_MODE_ID_ Source	Input	BYTE	I, Q, M, D, L or constant	Source and Destination for PEM_STATUS. Values: • 0x00: PE_POWER_OFF • 0x01 – 0xFE: manufacturer-specific • 0xFF: PE_READY_TO_OPERATE
PE_MODE_ID_ Destination	Input	BYTE	I, Q, M, D, L or constant	
Time_to_Operate[1]	Input	DWORD	I, Q, M, D, L or constant	Maximum switch-on time to "PE_ready_to_operate". Time_to_operate" can be used directly for the relevant calculations. The value may be a static maximum, or be calculated dynamically by the PE entity.
Remaining_time_ to_destination[1]	Input	DWORD	I, Q, M, D, L or constant	Optional: Time remaining until the requested PE mode. Dynamic value or static maximum value
Mode_Power_ Consumption[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the current PE mode in [kW].

Parameter	Declaration	Data type	Memory area	Description
Energy_ Consumption_ to_Destination[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption in the time until the requested PE mode in [kW].
Energy_ Consumption_ to_operate[2]	Input	DWORD	I, Q, M, D, L or constant	Energy consumption from the current PE mode to "PE_ready_to_operate" in [kWh].
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

[1] If the time period is unlimited, the maximum value "0xFFFFFFFF" can be specified. If the time period is "Zero", "0x00" can be used.

[2] If no energy consumption value has been defined, "0.0" can be specified.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_Identify_RSP: Generate supported PROFIenergy commands as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_Identify_RSP" generates the response to the command PE_Identify (Page 3761). In the response to the command, specify which PROFIenergy commands are supported. Please note that PE_IDENTIFY is itself a PE command and has to be included in the response.

Parameter

The following table shows the parameters of the "PE_Identify_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
Start_Pause	Input	BOOL	I, Q, M, D, L or constant	One parameter for each of the relevant PROFIenergy commands: • 0: PE command is not supported • 1: PE command is supported
End_Pause	Input	BOOL	I, Q, M, D, L or constant	
Query_Modes	Input	BOOL	I, Q, M, D, L or constant	
PEM_Status	Input	BOOL	I, Q, M, D, L or constant	
PE_Identify	Input	BOOL	I, Q, M, D, L or constant	
Query_ Measurement	Input	BOOL	I, Q, M, D, L or constant	
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_Measurement_List_RSP: Generate list of supported measured values as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_Measurement_List_RSP" generates the response to the command Get_measurement_list (Page 3761). In the response, specify which measured values (Measurement-IDs) are supported.

Parameter

The following table shows the parameters of the "PE_Measurement_List_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Count	Input	BYTE	I, Q, M, D, L or constant	Number of measured values supported (measurement IDs)
Measurement_List	Input	VARIANT	D	Pointer to the array with the Measurement_IDs supported. For information on the structure of the array in accordance with the PROFIenergy profile, see: PI Command "Query_Measurement" - "Get_Measurement_list" (Page 3761)

Parameter	Declaration	Data type	Memory area	Description
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

PE_Measurement_Value_RSP: Generate queried measured values as answer (S7-1200, S7-1500)

Description

The auxiliary block "PE_Measurement_Value_RSP" generates the response to the command Get_measurement_values (Page 3764). In the response, return the values of the requested measurements.

Parameter

The following table shows the parameters of the "PE_Measurement_Value_RSP" auxiliary block:

Parameter	Declaration	Data type	Memory area	Description
PE_I_DEV_NEW	Input	BOOL	I, Q, M, D, L or constant	The parameter must be interconnected with the NEW output parameter of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block is processed if the parameter value is set to "1".
CMD	Input	INT	I, Q, M, D, L or constant	Service-Request-ID of the PROFIenergy command The parameter must be interconnected with the CMD output parameter of the "PE_I_DEV (Page 3765)" instruction.
CMD_MODIFIER	Input	INT	I, Q, M, D, L or constant	PROFIenergy sub-command (evaluated only if CMD=3, or CMD=16). The parameter must be interconnected with the CMD_MODIFIER output parameter of the "PE_I_DEV" instruction.
Count	Input	BYTE	I, Q, M, D, L or constant	Number of measured values (Measurement_Values).
Measurement_Values	Input	VARIANT	D	Pointer to the array with the measured values (Measurement_IDs). For information on the structure of the array in accordance with the PROFIenergy profile, see PI Command "Query_Measurement" - "Get_Measurement_values" (Page 3764)
ACTIVATE	InOut	BOOL	I, Q, M, D, L	The instruction copies the input parameters to the DATA_ERROR_RSP data area at a rising edge at input ACTIVATE. The parameter is then reset by the instruction. The parameter must be set within 10 seconds after a rising edge is detected at parameter NEW of the "PE_I_DEV (Page 3765)" instruction.
VALID	InOut	BOOL	I, Q, M, D, L	The parameter must be interconnected with the VALID input of the "PE_I_DEV (Page 3765)" instruction. The auxiliary block sets the parameter once the response data for the PROFIenergy controller is available and ready for transmission.
DATA_ERRORRSP	InOut	VARIANT	D	Pointer on the data area in which the response data is stored. The parameter is identical to the pointer for DATA_ERRORRSP of the "PE_I_DEV (Page 3765)" instruction. The addressed data area contains the complete PROFIenergy frame. Minimum length: 244 bytes

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	• "0": No error • "1": Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	• "0": No error • "0x80B1": Error in VARIANT setting, e.g. incorrect range

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

11.4.4.6 Module parameter assignment (S7-1500)

Writing and reading data records (S7-1500)

Principle

Some modules have a write-only system data area to which your program can transfer data records. This area contains data records with numbers from 0 to a maximum of 240. Not every module contains all of the data records (see following table).

Modules can also have a system data area. From your program, you have read-access only to the system data area. This area contains data records with numbers from 0 to a maximum of 240. Not every module contains all of the data records (see following table).

Note

There are modules that have both system data areas. These are physically separate areas and the only thing they have in common is their logical structure.

Write-only system data area

The following table shows the structure of the write-only system data area. This table also shows how the permitted size of the individual data records and which instructions can be used to write them.

Data record number	Contents	Size	Can be written with instruction
0	Parameter	-	WR_DPARM (Page 3793)
1	Parameter	-	WR_DPARM (Page 3793)
2 to 127	User data	Each ≤ 240 bytes	WR_DPARM (Page 3793) WR_REC (Page 3699)
128 to 240	Parameter	Each ≤ 240 bytes	WR_DPARM (Page 3793) WR_REC (Page 3699)

Read-only system data area

The following table shows the structure of the read-only system data area. This table also shows the permitted size of the individual data records and which instructions can be used to read them.

Data record number	Contents	Size	Can be read with instruction
0	Module-specific diagnostics data (set as standard for the entire system)	4 bytes	RD_REC (Page 3694)
1	Channel-specific diagnostics data (incl. data record 0)	4 to 220 Bytes	RD_REC (Page 3694)
2 to 127	User data	Each ≤ 240 bytes	RD_REC (Page 3694)
128 to 240	Diagnostics data	Each ≤ 240 bytes	RD_REC (Page 3694)

System resources

If you start several asynchronous data record transfers one after the other with only short intervals between them, the allocation of system resources by the operating system ensures that all the jobs are executed and that they do not interfere with each other.

If the limits of the system resources are reached, this is indicated in RET_VAL. You remedy this temporary error situation by repeating the job.

The maximum number of "simultaneously" active jobs of a single instruction type depends on the CPU.

RD_DPAR: Read module data record (S7-1500)

Description

You use the instruction to read the data record with the number INDEX of the addressed component from the configured system data. This may be a module in a central rack or a distributed component (PROFIBUS DP or PROFINET IO).

The value TRUE for the output parameter VALID indicates that the data record was successfully transferred to the target range RECORD. In this case, the LEN output parameter contains the length of the read data in bytes.

If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR . In this case, the output parameter STATUS contains the error information.

Note

Information about the data records

For information on the data record numbers and the data record structure, refer to the product manual for the relevant module.

Functional description

The "RD_DPAR" instruction works asynchronously, that is, its execution extends over multiple calls. You start the data record transfer by calling "RD_DPAR" with REQ = 1.

The output parameter BUSY and bytes 2 and 3 of the output parameter STATUS show the status of the job. Bytes 2 and 3 of STATUS match the output parameter RET_VAL of the instructions that operate asynchronously.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

The transfer of the data record is complete when the output parameter BUSY has the value FALSE.

Parameter

The following table shows the parameters of the "RD_DPAR" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module (e.g. input module). The number is assigned automatically and is stored in the properties of the module under "HW identifier" (e.g. "Input 0 - 15 > HW identifier").
INDEX	Input	INT	I, Q, M, D, L or constant	Data record number
RECORD	InOut	VARIANT	I, Q, M, D, L	Target range for the read data record
VALID	Output	BOOL	I, Q, M, D, L	New data record was received and is valid
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The job is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the reading process.
STATUS	Output	DWORD	I, Q, M, D, L	• Call ID (bytes 2 and 3) or error code • Byte 1: B#16#00, if no error. Otherwise function ID from DPV1-PDU: In the case of error for data record reading B#16#DE, in the case of error for data record writing B#16#DF. If no DPV1 protocol element is used: B#16#C0. • Byte 4: Manufacturer-specific error ID extension
LEN	Output	INT	I, Q, M, D, L	Length of the read data record information

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

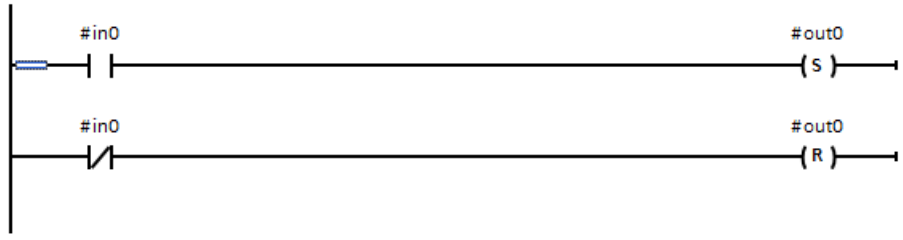
Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value "0".	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.	-
8093	Address specified at parameter LADDR is invalid.	-
80B0	Instruction for module type not possible, or module does not recognize the data record.	-
80B1	The length of the data record to be sent is incorrect.	-
80C1	The data of the previous write job on the module for the same data record has not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are occupied at this time.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated.	Distributed I/O
80C6	Data record transfer cancelled due to priority class abort (restart or background).	Distributed I/O
80D0	There is no entry for the module.	-
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

Example

In the following example, you read the complete parameter data record of a digital input module.

Create nine tags in a global data block for storing the data and the structure “record“. (You can find the organization of the structure below.)

SLI_gDB_RD_DPAR			
	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	laddr	HW_IO	257
4	dataRecNbr	Int	128
5	checkedValid	Bool	false
6	busy	Bool	false
7	error	Bool	false
8	status	DWord	16#0
9	lengthRec	Int	0
10	record	Struct	
11	Mode_C0_Bool	Array[0..7] of Bool	



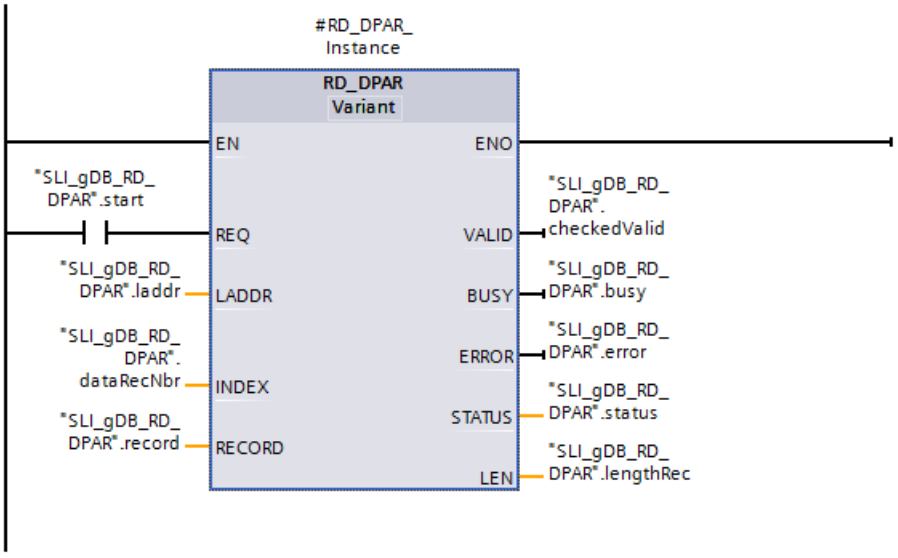
Interconnect parameters: "SLI_itemiseByte_RD_DPAR" FC

To transfer the values of a bit sequence (0..7) create the FC "SLI_itemiseByte_RD_DPAR".

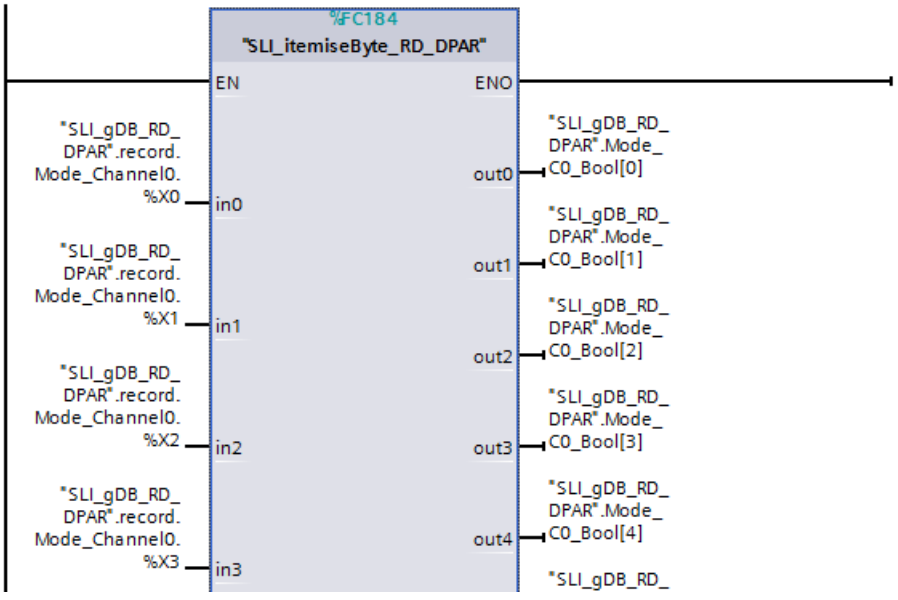
Create the following local tags in it.

	Name	Data type
1	Input	
2	in0	Bool
3	in1	Bool
4	in2	Bool
5	in3	Bool
6	in4	Bool
7	in5	Bool
8	in6	Bool
9	in7	Bool
10	Output	
11	out0	Bool
12	out1	Bool
13	out2	Bool
14	out3	Bool
15	out4	Bool
16	out5	Bool
17	out6	Bool
18	out7	Bool

Network 1: According to the example of network 1, create interconnections for all bits (0..7).



Interconnect parameters: "SLI_FB_RD_DPAR" FB



Create the following local tags in the "SLI_FB_RD_DPAR" FB.

Network 1: Interconnect the parameters of the "RD_DPAR" instruction as follows.

Network 2: To convert the tag, interconnect the “Mode_Channel0“ tag as follows All inputs and outputs (0..7) of the "SLI_itemiseByte_RD_DPAR" FC are interconnected in this case.

Hardware identifier

You create an input module and read the hardware ID in the properties of the input module. You store the hardware identifier via the input parameter LADDR ("laddr").

Result (FB "SLI_FB_RD_DPAR")

When the input parameter REQ ("start") returns the signal state "TRUE", the "RD_DPAR" instruction is started. Via the input parameter LADDR ("laddr") the instruction "RD_DPAR" calls the module. Using the input parameter INDEX ("dataRecNbr") the data record with the number "128" of the module is called. During several calls the "RD_DPAR" instruction reads out the data record and saves the data record using the parameter RECORD ("record").

The length of the read data record is stored using the output parameter LEN ("lengthRec"). According to the value of the input parameter MLEN ("maxLen"), has the value “0“ the data record information that is to be read is unlimited.

During processing the output parameter BUSY ("busy") is set to "TRUE" and VALID ("checkedValid") to "FALSE". A successful reading result ("checkedValid" to "TRUE") is not output until processing is complete. The block status is displayed at the output parameter STATUS ("status"). Processing takes place without errors.

SLI_gDB_RD_DPAR

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	laddr	HW_IO	257	16#0101
4	dataRecNbr	Int	128	128
5	checkedValid	Bool	false	TRUE
6	busy	Bool	false	FALSE
7	error	Bool	false	FALSE
8	status	DWord	16#0	16#0000_0000
9	lengthRec	Int	0	34
10	record	Struct		
11	Mode_C0_Bool	Array[0..7] of Bool		

The data record 128 contains the parameter information of all channels of the module. The value "2" of the tag "ByteOfDataRec" relates to the length of the data per channel. It also provides information on the status and the operating mode.

Excerpt of the read data record up to channel 1:

record	Struct		
Version	USInt	0	16
ByteOfDataRec	USInt	0	2
Diag_Channel0	Byte	16#0	16#00
Mode_Channel0	Byte	16#0	16#06
Diag_Channel1	Byte	16#0	16#00
Mode_Channel1	Byte	16#0	16#06

For a more detailed explanation of the data of the data record 128 convert the BYTE values to a bit string. Here an example of the operating mode of the channel 0: Since bits 1 and 2 are set to "TRUE" the channel 0 has an input delay of 3.2 ms. You can find the explanation of the structure of the parameter data record or the channel in the device manual of the module.

11	Mode_C0_Bool	Array[0..7] o...		
12	Mode_C0_Bool[0]	Bool	false	FALSE
13	Mode_C0_Bool[1]	Bool	false	TRUE
14	Mode_C0_Bool[2]	Bool	false	TRUE
15	Mode_C0_Bool[3]	Bool	false	FALSE
16	Mode_C0_Bool[4]	Bool	false	FALSE
17	Mode_C0_Bool[5]	Bool	false	FALSE
18	Mode_C0_Bool[6]	Bool	false	FALSE
19	Mode_C0_Bool[7]	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

RD_DPARM: Read data record from configured system data (Page 3791)

Overview of the types of data records (Page 3571)

RD_DPARA: Read module data record asynchronously (S7-1500)

Description

You use the instruction to read the data record with the number RECNUM of a selected module from the configured system data. The read data record is entered in the target range defined by the parameter RECORD .

Note

Information about the data records

For information on the data record numbers and the data record structure, refer to the product manual for the relevant module.

Functional description

The "RD_DPARA" instruction works asynchronously, that is, its execution extends over multiple calls. You start the reading process by calling the instruction with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "RD_DPARA" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module (e.g. input module). The number is assigned automatically and is stored in the properties of the module under "HW identifier" (e.g. "Input 0 - 15 > HW identifier").
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. If no error occurred during the transmission, the following cases are distinguished: • RET_VAL contains the length of the actually read data record in bytes if the target range is larger than the read data record. • RET_VAL contains "0" if the length of the read data record is equal to the length of the target range.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The job is not yet complete.
RECORD	Output	VARIANT	I, Q, M, D, L	Target range for the data record read.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.	-
8093	Address specified at parameter LADDR is invalid.	-
80B0	Instruction for module type not possible, or module does not recognize the data record.	-

Error code* (W#16#...)	Explanation	Restriction
80B1	The length of the data record to be sent is incorrect. With RD_DPARM (Page 3791): The target range spanned by RECORD is too short.	-
80C3	The required resources (memory, etc.) are occupied at this time.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

RD_DPARM: Read data record from configured system data (S7-1500)

Use

Note
Restriction on use

The "RD_DPARM" instruction is only intended for the migration from S7-300/400 CPUs to S7-1500 CPUs. In all other cases, use the "RD_DPARA" instruction.

Description

You use instruction to read the data record with the number RECNUM of the addressed module from the configured system data. The read data record is entered into the target range spanned by the RECORD parameter.

Note
Information about the data records

For information on the data record numbers and the data record structure, refer to the product manual for the relevant module.

Functional description

The "RD_DPARM" instruction works asynchronously, that is, its execution extends over multiple calls.

The job status is indicated by the output parameter RET_VAL.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "RD_DPARM" instruction:

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Address area identifier: • B#16#54 = Peripheral input (PI) • B#16#55 = Peripheral output (PQ) If the module is a mixed module, the area identifier of the lower address must be specified. If the addresses are identical, specify B#16#54.
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module (e.g. input module). The number is assigned automatically and is stored in the properties of the module under "HW identifier" (e.g. "Input 0 - 15 > HW identifier").
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	Length of the data record read in bytes if the read data record fits in the target range and no error occurred in the transfer. If an error occurs while the instruction is being executed, the return value contains an error code.
RECORD	Output	VARIANT	I, Q, M, D, L	Target range for the data record read.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7001	First call: Data transfer started	Distributed I/O
7002	Intermediate call: Data transfer already active	Distributed I/O
8090	Specified logical base address invalid.	-
8092	A type other than BYTE is specified in the VARIANT reference at the RECORD parameter.	-
8093	This instruction is not valid for the module selected with LADDR.	-
80B0	Instruction for module type not possible, or module does not recognize the data record	-
80B1	The target range spanned by RECORD is too short.	-
80C1	The data of the previous write job on the module for the same data record has not yet been processed by the module.	-

Error code* (W#16#...)	Explanation	Restriction
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are occupied at this time.	-
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated	Distributed I/O
80C6	Data record transfer stopped due to priority class abort (restart or background)	Distributed I/O
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

WR_DPARM: Transfer data record (S7-1500)

Description

You use the instruction "WR_DPARM" to transfer the data record with the number RECNUM from the configuration data to the addressed module. The data record can be static or dynamic.

Note

Information about the data records

For information on the data record numbers and the data record structure, refer to the product manual for the relevant module.

Parameters

The following table shows the parameters of the "WR_DPARM" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Write request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module (e.g. input module). The number is assigned automatically and is stored in the properties of the module under "HW identifier" (e.g. "Input 0 - 15 > HW identifier").
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8093	Address specified at parameter LADDR is invalid.	-
80A1	Negative acknowledgment during sending of data record to module (module defective or unplugged during sending).	-
80A2	DP protocol error at layer 2, possible hardware/interface error in DP slave.	Distributed I/O
80A3	DP protocol error at user interface/user.	Distributed I/O
80A4	Communication on PBUS+ disrupted	-
80B0	Instruction for module type not possible, or module does not recognize the data record.	-
80B1	The length of the data record to be sent is incorrect.	-
80B2	The configured slot is not occupied.	-
80B3	Actual module type does not correspond to specified module type.	-
80C1	The data of the previous write job on the module for the same data record has not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are occupied at this time.	
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available or deactivated.	Distributed I/O
80C6	Data record transfer cancelled due to priority class abort (restart or background).	Distributed I/O
80D0	There is no entry for the module.	-

Error code* (W#16#...)	Explanation	Restriction
80D1	The data record number is not configured for the module (data record numbers > 241 are rejected).	-
80D2	The module cannot be assigned parameters according to its type identifier.	-
80D5	The data record is static.	-
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

11.4.4.7 Interrupts (S7-1200, S7-1500)

ATTACH: Attach an OB to an interrupt event (S7-1200, S7-1500)

Description

You use the instruction "ATTACH" to assign an organization block (OB) to a hardware interrupt event.

- You enter the symbolic or numeric name of the organization block in the OB_NR parameter. This will then be assigned to the event specified in the EVENT parameter.
- You select the hardware interrupt event at the EVENT parameter. Hardware interrupt events already generated are listed in the PLC tags under "System constants".

If the event in the EVENT parameter occurs following error-free execution of the "ATTACH" instruction, the organization block in the OB_NR parameter will be called and its program executed.

With the ADD parameter, you specify whether previous assignments of the organization block to other events should be canceled or retained. If the ADD parameter has the value "0", the existing assignments will be replaced by the current assignment.

Hardware interrupt events

Hardware interrupts can be used if events are not pending long enough. They react to these during runtime. Each hardware interrupt can be assigned to hardware interrupt OBs. These OBs contain the reaction to a particular event.

Hardware interrupts can be created for different events. Examples for this are:

- The detection of rising or falling edges for digital inputs.
- Violation of defined low and high limits for analog inputs.
- External reset, overflow/underflow, direction reversal etc. for high-speed counters.

Functional principle

Each hardware interrupt can be assigned to a hardware interrupt OB, which is placed in the queue for processing when the hardware interrupt event occurs. The assignment of OB and event can occur during configuration or at runtime:

- To assign an event to an OB during configuration, select a hardware interrupt OB for an event in the hardware configuration under "Hardware interrupts".
- Use the ATTACH instruction to make the assignment during runtime. The assignment of event and hardware interrupt OB is made via the EVENT and OB_NR parameters.

Parameters

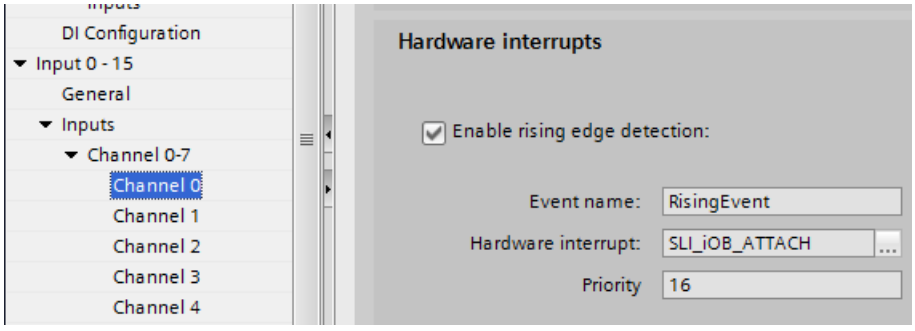
The following table shows the parameters of the "ATTACH" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_ATT	I, Q, M, D, L or constant	Organization block (numbers up to 32767 are supported.)
EVENT	Input	EVENT_ATT	I, Q, M, D, L or constant	Hardware interrupt event to be assigned to the OB. The hardware interrupt event must first be enabled in the hardware device configuration for inputs or high-speed counters.
ADD	Input	BOOL	I, Q, M, D, L or constant	Effects on previous assignments: • ADD=0 (default): This event replaces all previous event assignments for this OB. • ADD=1: This event is added to the previous event assignments for this OB.
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

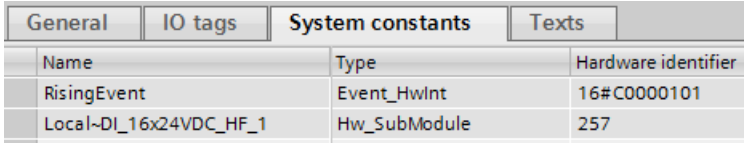
Parameter RET_VAL

Error code* (W#16#....)	Description
0	No error
8090	OB does not exist
8091	OB is incorrect type



Error code* (W#16#....)	Description
8093	Event does not exist
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

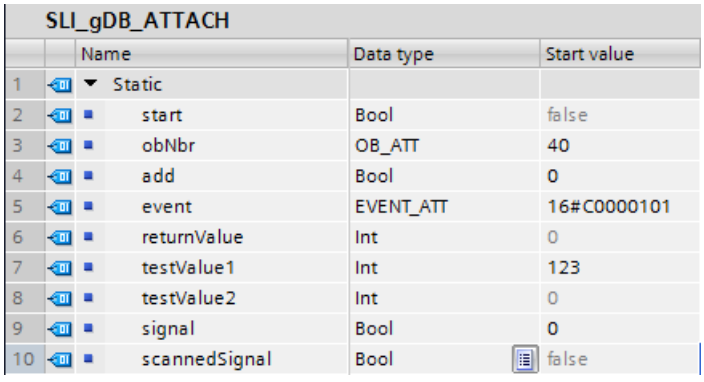
Example



In the following example, you assign a hardware interrupt OB (OB40) to a created hardware interrupt event.

Requirements:

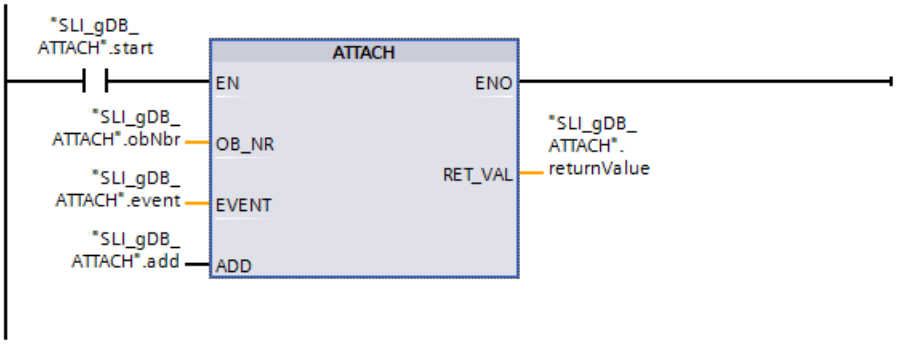
You create an input module (DI) and configure a hardware interrupt event for a positive edge under "Properties > Inputs 0-15 > ... > Channel 0".



The following hardware ID of the configured hardware interrupt event is stored at the input parameter EVENT ("event").

Data storage

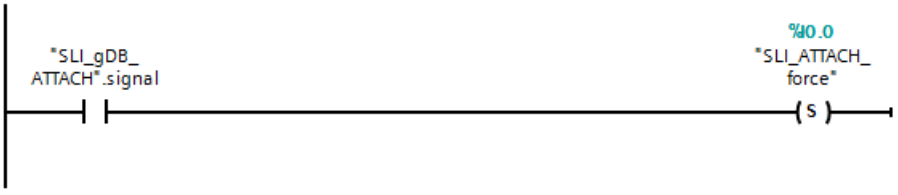
Create nine tags in a global data block for storing the data. You store the number of the OB to be assigned (OB40) with the input parameter OB_NR ("obNbr") of the instruction "ATTACH".



To call the hardware interrupt event, you create a tag table with a PLC tag (address "I0.0").

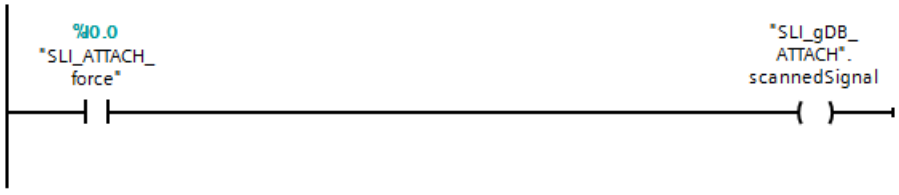
SLI_Var_ATTACH

		Name	Data type	Address
1		SLI_ATTACH_force	Bool	%I0.0



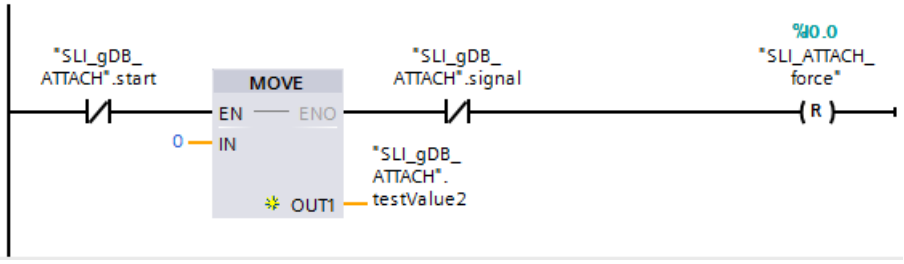
Interconnection

Interconnect the parameters of the instruction as follows.

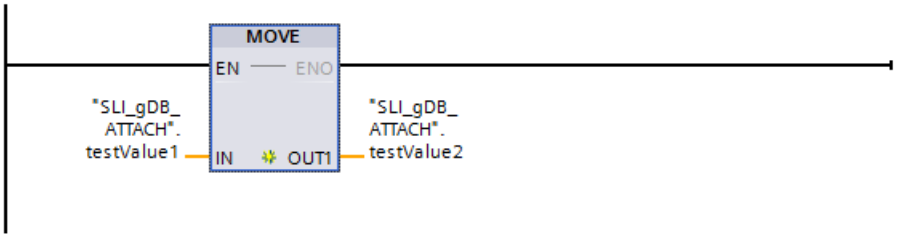


Interconnect the PLC tag as follows to call the hardware interrupt event.

Network 2:



Network 3:



To reset, interconnect "testValue2" and "SLI_ATTACH_force" as follows.

Network 4:

Create the following interconnection in OB40:

Processing

When the normally open contact ("start") supplies the signal state "TRUE", the "ATTACH" instruction is executed and the event is assigned to the OB. With the value "FALSE" of the input parameter ADD ("add"), the event replaces all previous event assignments for OB40. The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

When the normally open contact ("signal") in network 2 supplies the signal state "TRUE", the PLC tag "SLI_ATTACH_force" is set to the signal state "TRUE" and OB40 is executed. While OB40 is being called, the value of "testValue1" is transferred to "testValue2".

When the normally open contacts ("start" and "signal") supply the signal state "FALSE", the values of "testValue2" and "SLI_ATTACH_force" are reset in network 4.

SLI_gDB_ATTACH

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	obNbr	OB_ATT	40	40
4	add	Bool	0	FALSE
5	event	EVENT_ATT	16#C0000101	16#C000_0101
6	returnValue	Int	0	0
7	testValue1	Int	123	123
8	testValue2	Int	0	123
9	signal	Bool	0	TRUE
10	scannedSignal	Bool	false	TRUE

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

DETACH: Detach an OB from an interrupt event (S7-1200, S7-1500)

Description

You use this instruction to cancel the existing assignment of an organization block to one or more hardware interrupt events during runtime.

You enter the symbolic or numeric name of the organization block in the OB_NR parameter. This assignment to the event specified in the EVENT parameter will be canceled.

- If you have selected an individual hardware interrupt event at the EVENT parameter, the assignment of the OB to this hardware interrupt event is cancelled. All other currently existing assignments remain active. You can select an individual hardware interrupt event using the drop-down list of the operand placeholder.
- If you have not selected a hardware interrupt event, all the events currently assigned to this OB_NR organization block are separated.

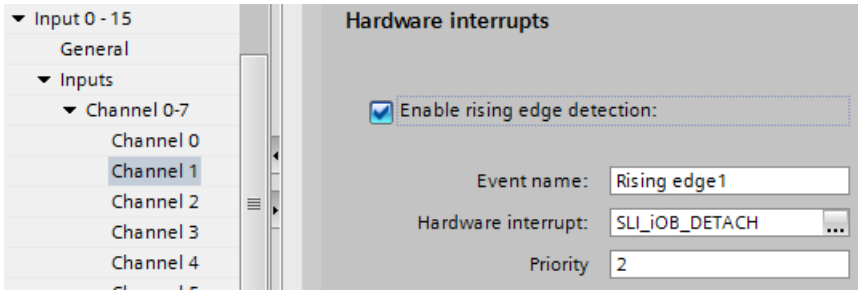
Parameters

The following table shows the parameters of the "DETACH" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_ATT	I, Q, M, D, L or constant	Organization block (numbers up to 32767 are supported.)
EVENT	Input	EVENT_ATT	I, Q, M, D, L or constant	Hardware interrupt event
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL



Error code* (W#16#....)	Description
0	No error
1	No assignment exists (warning)
8090	OB does not exist
8091	OB has incorrect type
8093	Event does not exist
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, you assign a hardware interrupt event to a hardware interrupt OB (OB41), and dissolve the assignment.

Requirements:

A hardware interrupt OB (OB41 with the name "SLI_iOB_DETACH") has already been created. You create an input module (DI) and configure a hardware interrupt event for a positive edge under "Properties > Inputs 0-15 > ... > Channel 1".

The following hardware ID of the configured hardware interrupt event ("Rising edge 1") is stored at the input parameter EVENT ("event").

DI 16x24VDC HF_1 [DI 16x24VDC HF]

General | IO tags | System constants | Texts

Name	Type	Hardware identi.
Rising edge0	Event_HwInt	16#C0000101
Rising edge1	Event_HwInt	16#C0010101
Local~DI_16x24VDC_HF_1	Hw_SubModule	257

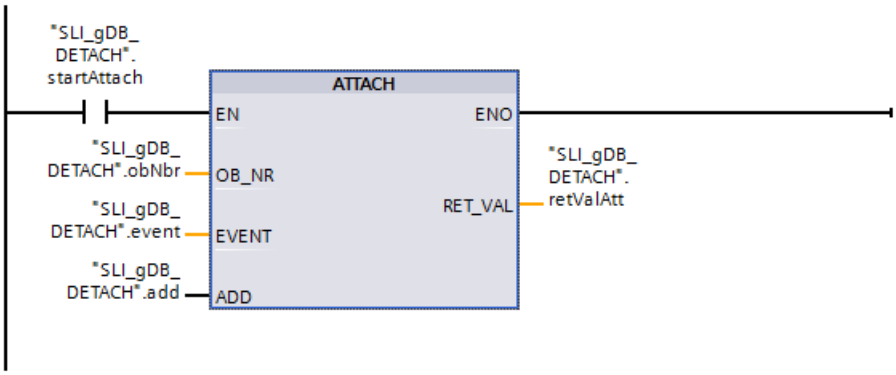
Data storage:

Create ten tags in a global data block for storing the data. You store the number of the OB to be assigned (OB41) with the input parameter OB_NR ("obNbr") of the instructions "ATTACH" and "DETACH".

SLI_gDB_DETACH

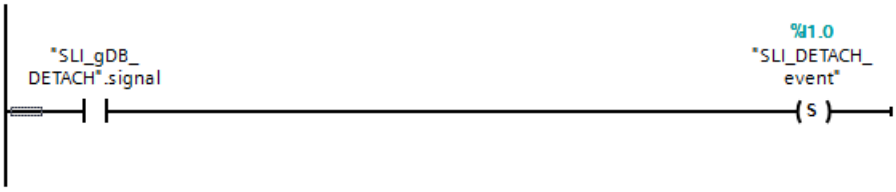
	Name	Data type	Start value
1	Static		
2	startAttach	Bool	false
3	add	Bool	0
4	retValAtt	Int	0
5	obNbr	OB_ATT	41
6	event	EVENT_ATT	16#C0010101
7	retValDet	Int	0
8	testValue1	Int	125
9	testValue2	Int	0
10	signal	Bool	0
11	scannedSignal	Bool	false

To call the hardware interrupt event, you create a tag table with a PLC tag (address "I1.0").



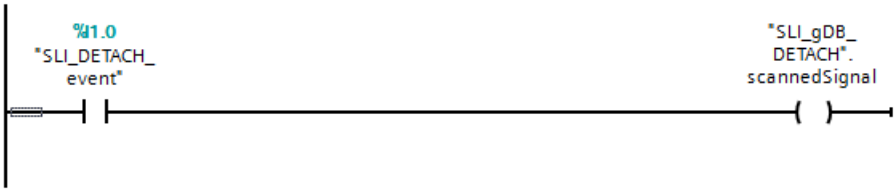
SLI_Var_DETACH

	Name	Data type	Address
1	SLI_DETACH_event	Bool	%I1.0

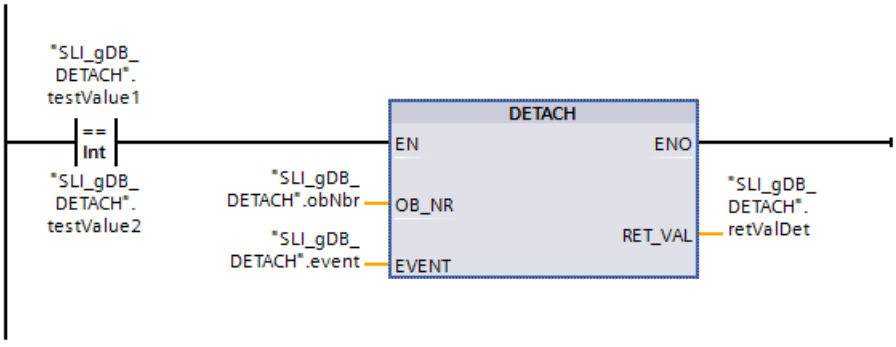


Interconnection:

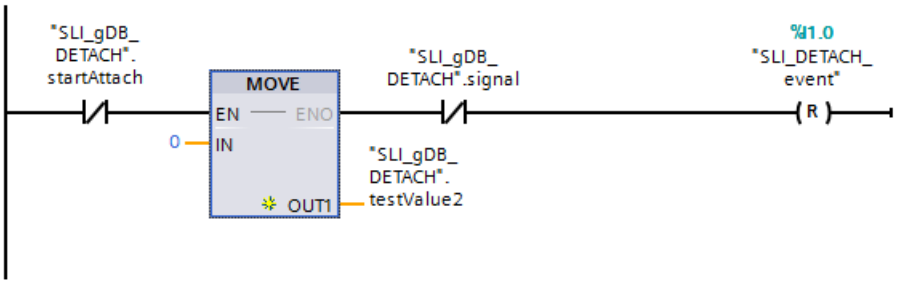
To call the instructions, create an FB ("SLI_FB_DETACH").



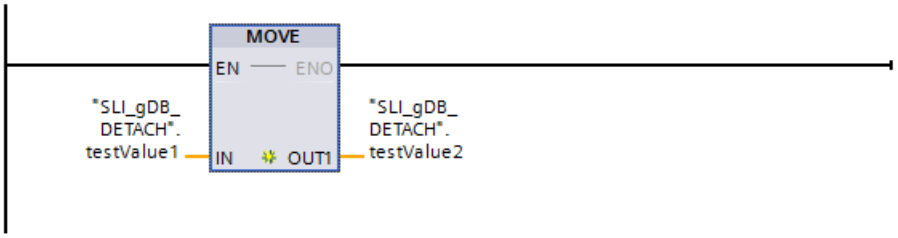
Network 1: Interconnect the parameters of the "ATTACH" instruction as follows.



Network 2: Interconnect the PLC tag as follows to call the hardware interrupt event.

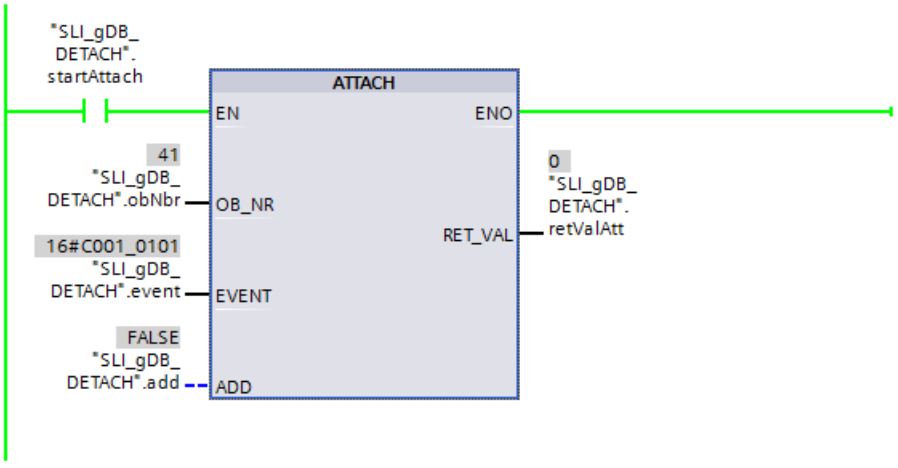


Network 3: You forward the call of the hardware interrupt event as follows.



Network 4: Interconnect the parameters of the "DETACH" instruction as follows.

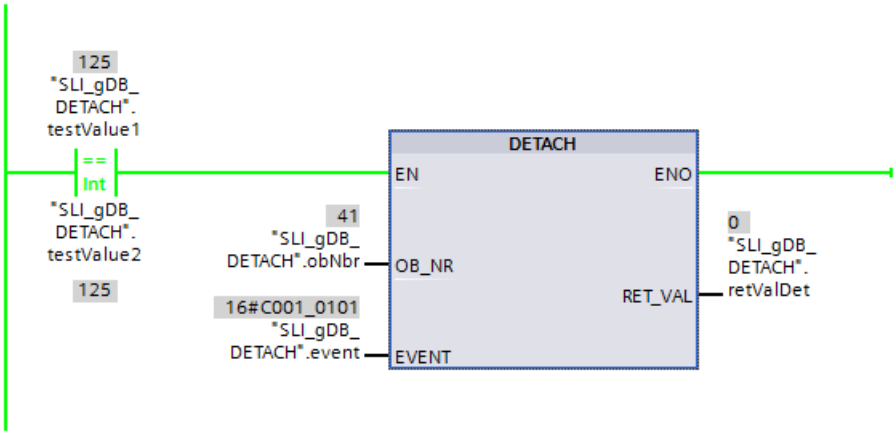
Network 5: To reset, interconnect "testValue2" and "SLI_DETACH_event" as follows.



Create the following interconnection in OB41:

Processing

When the normally open contact ("startAttach") supplies the signal state "TRUE", the "ATTACH" instruction is executed and the event is assigned to OB41. With the value "FALSE" of the input parameter ADD ("add"), the event replaces all previous event assignments for OB41. The output parameter RET_VAL ("retValAtt") indicates that processing took place without errors.



When the normally open contact ("signal") in network 2 supplies the signal state "TRUE", the hardware interrupt event ("SLI_DETACH_event") is set to "TRUE". The OB41 is called and the value of "testValue1" is transferred to "testValue2" in OB41. As long as the hardware interrupt event returns the signal state "TRUE", the OB41 is called and displayed in network 3 by the coil ("scannedSignal").

SLI_gDB_DETACH

	Name	Data type	Start value	Monitor value
1	Static			
2	startAttach	Bool	false	TRUE
3	add	Bool	0	FALSE
4	retValAtt	Int	0	0
5	obNbr	OB_ATT	41	41
6	event	EVENT_ATT	16#C0010101	16#C001_0101
7	retValDet	Int	0	0
8	testValue1	Int	125	125
9	testValue2	Int	0	125
10	signal	Bool	0	TRUE
11	scannedSignal	Bool	false	TRUE

When "testValue1" and "testValue2" supply the same value, the instruction "DETACH" is executed and the event is separated from OB41. The output parameter RET_VAL ("retValDet") indicates that processing took place without errors.

When the tag "startAttach" supplies the signal state "FALSE", the values of "testValue2" and the PLC tag are reset in network 5.

You can find additional information and the program code for the above-named example here:Sample Library for Instructions (Page 2568)

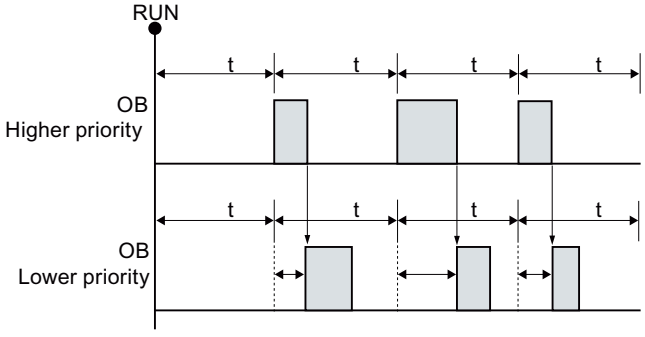
Cyclic interrupt (S7-1200, S7-1500)

SET_CINT: Set cyclic interrupt parameters (S7-1200, S7-1500)

Description

You use this instruction to set the parameters for a cyclic interrupt OB. The start time for a cyclic interrupt OB is generated from the respective time interval of the OB and the phase offset.

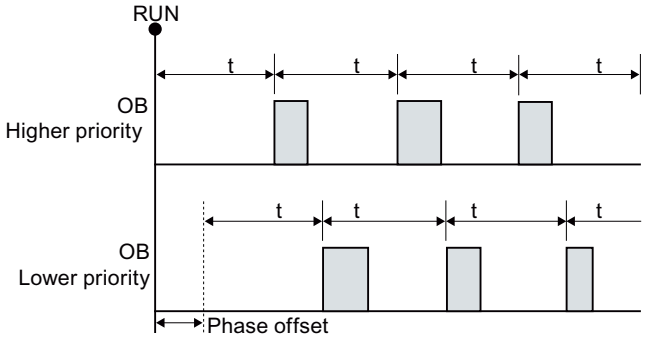
- The time interval of an OB is the interval at which the OB is periodically called. For example, if the time interval is 100 µs, the OB will be called every 100 µs during program execution.
- The phase offset is a time interval by which the call of a cyclic interrupt OB is offset. You can use the phase offset to process low priority organization blocks in a precise time base.



If the OB does not exist or if the time interval used is not supported, a corresponding error alarm is output in the RET_VAL parameter.

A time interval in the CYCLE parameter of "0" means that the OB will not be called.

Functional description



If a lower priority OB and a higher priority OB are called in the same time interval, the lower priority OB will only be called once the higher priority OB has been executed. The call time for the lower priority OB can be offset according to the length of time to execute the higher-priority OB.

OB call without phase offset

If a phase offset is configured for the lower priority OB and the phase offset is greater than the current execution time of the respective higher priority OB, then the block will be called in a fixed time base.

OB call with phase offset

Parameters

The following table shows the parameters of the "SET_CINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_CYCLIC	I, Q, M, D, L or constant	OB number (<32768)
CYCLE	Input	UDINT	I, Q, M, D, L or constant	Time interval in microseconds
PHASE	Input	UDINT	I, Q, M, D, L or constant	Phase offset
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0	No error
8090	OB does not exist or is of the wrong type
8091	Incorrect time interval
8092	Incorrect phase offset
80B2	No event assigned to OB
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for cyclic interrupt functions (Page 3808).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

QRY_CINT: Query cyclic interrupt parameters (S7-1200, S7-1500)

Description

You can use this instruction to query the current parameters of a cyclic interrupt OB. The cyclic interrupt OB is identified using the OB_NR parameter.

The values of the queried cyclic interrupt parameters correspond to those at the time the "QRY_CINT" instruction is executed.

Parameters

The following table shows the parameters of the "QRY_CINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_CYCLIC (INT)	I, Q, M, D, L or constant	OB number (<32768) or symbolic addressing via the name of the OB (e.g. OB_MyOB)
CYCLE	Output	UDINT	I, Q, M, D, L	Time interval in microseconds
PHASE	Output	UDINT	I, Q, M, D, L	Phase offset
STATUS	Output	WORD	I, Q, M, D, L	Status of the cyclic interrupt: • Bit 0 to bit 4: see parameter STATUS • Other bits: Always "0"
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Bit	Value	Meaning
0	0	Not used (always "0").
1	0	The cyclic interrupt is enabled.
	1	The cyclic interrupt is delayed.
2	0	The cyclic interrupt is not enabled or has expired.
	1	The cyclic interrupt is enabled.
3	0	Not used (always "0").
4	0	An OB with the specified number does not exist.
	1	An OB with the specified number exists.
Other bits		Not used (always "0").

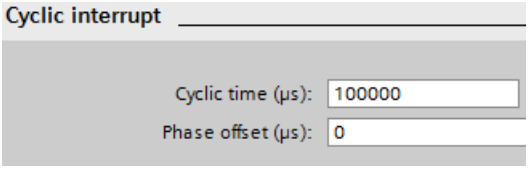
Parameter RET_VAL

If an error occurs, the relevant error code is displayed in the RET_VAL parameter and the STATUS parameter is set to "0".

Error code* (W#16#....)	Description
0	No error.
8090	OB does not exist or is of the wrong type
80B2	No result assigned to OB.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for cyclic interrupt functions (Page 3808).



You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

Program example for cyclic interrupt functions (S7-1200, S7-1500)

Introduction

In the following example, you read the phase and the cycle time of a cyclic interrupt OB (OB31) and set a new cycle time.

The OB31 has the following defaults:

Requirement

- To call, create an OB31.
- Create twelve tags in a global data block for storing the data.

SLI_gDB_SET_CINT

	Name	Data type	Start value
1	Static		
2	executeSet	Bool	false
3	obNbr	OB_CYCLIC	31
4	setCycle	UDInt	1000
5	setPhase	UDInt	0
6	returnValueSet	Int	0
7	testTime	Time	T#0ms
8	testTimeLimit	Time	T#2m
9	executeQry	Bool	false
10	returnValueQry	Int	0
11	itemiseStatus	Struct	
12	Cyclic_interrupt_enabled	Bool	false
13	Cyclic_interrupt_not_expired	Bool	false
14	OB_with_obNbr_exists	Bool	false
15	qryCycle	UDInt	0
16	qryPhase	UDInt	0

Interconnect parameters: "SLI_itemiseStatus_CINT" FC

To evaluate the status information, create an FC "SLI_itemiseStatus_CINT".

Create the following local tag in it.

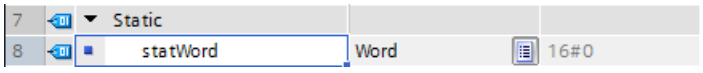
SLI_itemiseStatus_CINT

	Name	Data type
1	Input	
2	inWord	Word

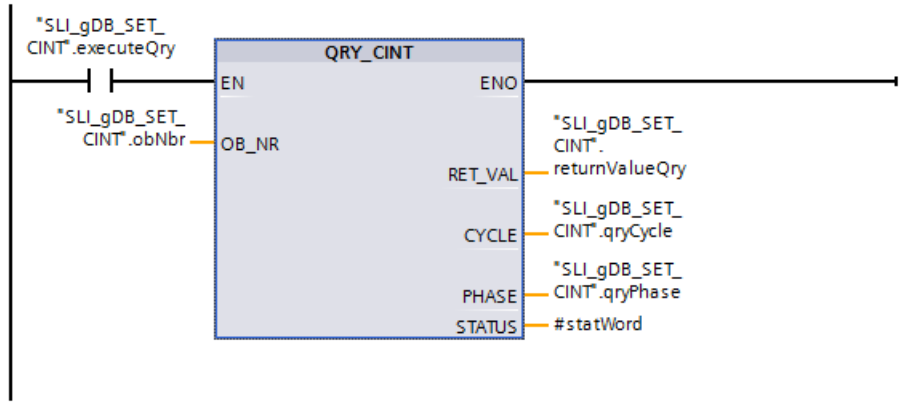
Create interconnections for all relevant bits.

Network 1:

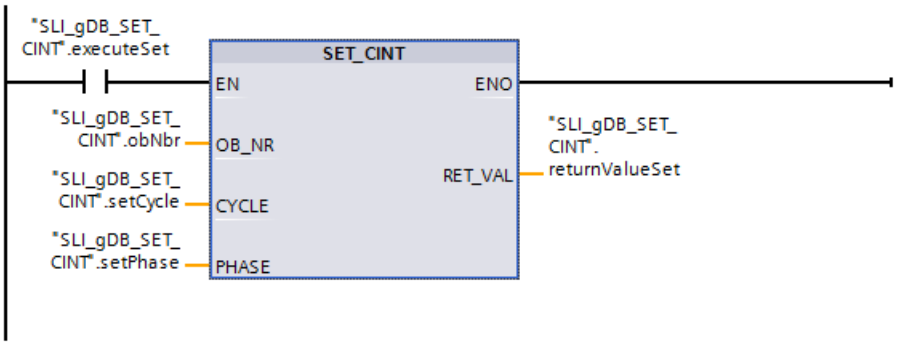
Network 2:



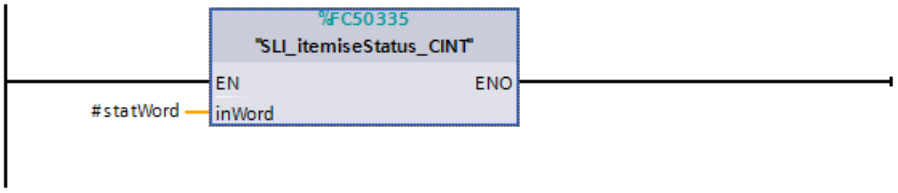
Network 3:



Interconnect parameters: "SLI_FB_SET_CINT" FB

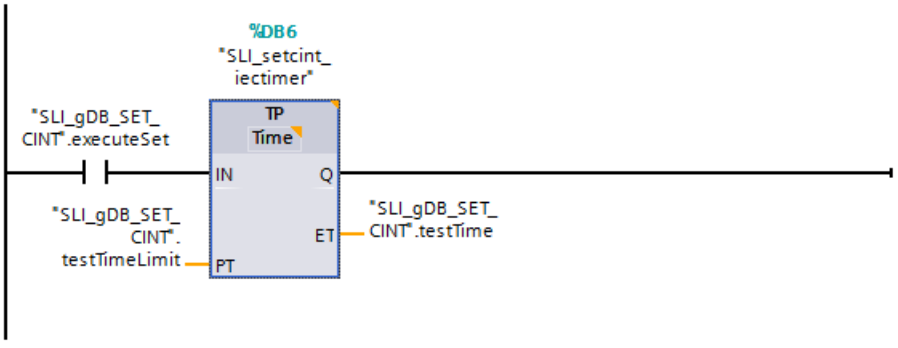


To call the instructions, create an FB ("SLI_FB_SET_CINT"). Create the following local tag in the function block "SLI_FB_SET_CINT".



Network 1: Interconnect the parameters of the "QRY_CINT" instruction as follows.

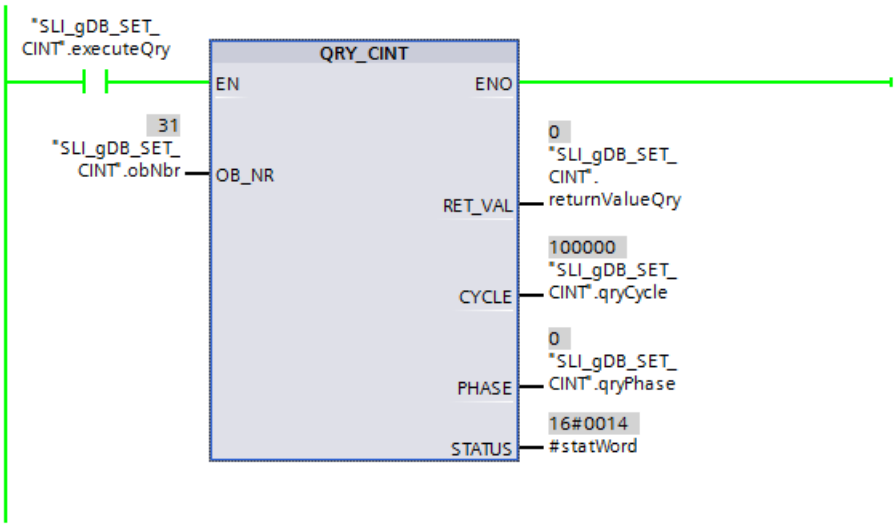
Network 2: Interconnect the parameters of the "SET_CINT" instruction as follows.



Network 3: Interconnect the parameter of the "SLI_itemiseStatus_CINT" FC as follows.

Interconnect parameters: OB31

Create the following interconnections in OB31.



Result of "QRY_CINT"

The number of the OB to be called (OB31) is stored with the input parameter OB_NR ("obNbr") of the instructions "QRY_CINT" and "SET_CINT".

When the normally open contact ("executeQry") supplies the signal state "TRUE", the "QRY_CINT" instruction is executed and the data of OB31 is read.

The cycle time is output at the output parameter CYCLE ("qryCycle"). The phase offset is output at the output parameter PHASE ("qryPhase").
The output parameter STATUS ("#statWord") displays the status of OB31. The output parameter RET_VAL ("returnValueQry") indicates that processing is taking place without errors.

Thee current status information ("#statWord") of the OB31 is interpreted in network 3 via the FC "SLI_itemiseStatus_CINT" and output via the structure "itemiseStatus".

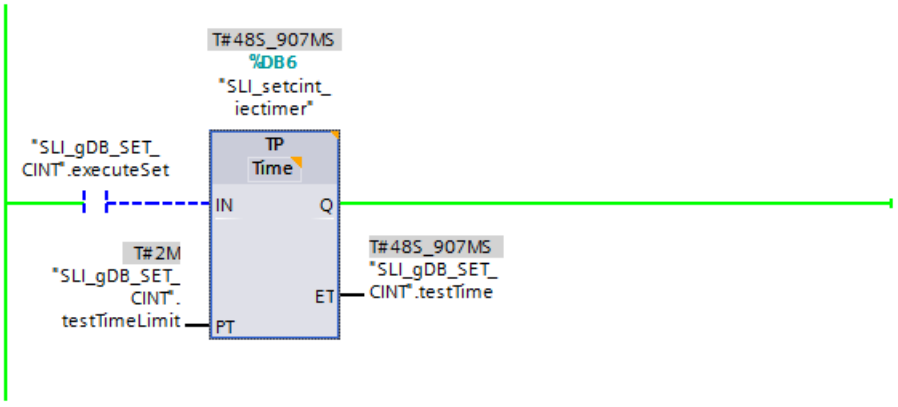
The value of the tag "#statWord" is mapped in the structure "itemiseStatus".

12		itemiseStatus	Struct		
13		Cyclic_interrupt_enabled	Bool	false	TRUE
14		Cyclic_interrupt_not_expired	Bool	false	TRUE
15		OB_with_obNbr_exists	Bool	false	TRUE

Result of "SET_CINT"

When the normally open contact ("executeSet") supplies the signal state "TRUE", the "SET_CINT" instruction is executed. A new cycle time is transferred to OB31 with the input parameter CYCLE ("setCycle") of the instruction "SET_CINT". The value "0" is stored as phase offset at the input parameter PHASE ("setPhase").

The output parameter RET_VAL ("returnValueSet") indicates that processing took place without errors.



SLI_gDB_SET_CINT

	Name	Data type	Start value	Monitor value
1	Static			
2	executeSet	Bool	false	TRUE
3	obNbr	OB_CYCLIC	31	31
4	setCycle	UDInt	1000	1000
5	setPhase	UDInt	0	0
6	returnValueSet	Int	0	0
7	testTime	Time	T#0ms	T#14S_487MS
8	testTimeLimit	Time	T#2m	T#2M
9	executeQry	Bool	false	TRUE
10	returnValueQry	Int	0	0
11	itemiseStatus	Struct		
12	Cyclic_interrupt_enabled	Bool	false	TRUE
13	Cyclic_interrupt_not_expired	Bool	false	TRUE
14	OB_with_obNbr_exists	Bool	false	TRUE
15	qryCycle	UDInt	0	1000
16	qryPhase	UDInt	0	0

After execution of the instruction "SET_CINT", OB31 retains the new cyclic interrupt data until STOP of the CPU. After the execution, you can set the normally open contact ("executeSet") to the signal state "FALSE" once again. The default properties of OB31 are not affected by the execution of "SET_CINT".

Result of the OB31

When the normally open contact ("executeSet") supplies the signal state "TRUE", an IEC timer "TP" is started in OB31. The IEC timer stops after 2 minutes.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Time-of-day interrupt (S7-1200, S7-1500)

SET_TINT: Set time-of-day interrupt (S7-1500)

Description

The instruction "SET_TINT" is used to set the start data and time of the time-of-day interrupt organization blocks from the user program, without having to make settings in the hardware configuration.

- Enter the number of the time-of-day interrupt-OBs at the parameter OB_NR for which you would like to set the start date and the time-of-day.
- Use the parameter SDT and PERIOD to specify when and how often the time-of-day interrupt OB should be called:
  - One-time call: Enter the date and the time-of-day at the parameter SDT. Use the value "0" at parameter PERIOD.
  - Repeated call: Enter the date and the time-of-day of the first call at the parameter SDT. Use the parameter PERIOD to define the time interval in which subsequent calls of the OBs should take place.

Observe the following when setting the start date and start time:

- The date and the time-of-day specification at the parameter SDT refers to the system time.
- The seconds and milliseconds specification is ignored and set to "0" at the start time.
- Only the starting date days 1, 2, ... 28 are possible if you want to specify a monthly time-of-day interrupt OBs. This restriction prevents skipping the monthly call (e.g. 30-day months or in February).
  The setting "end of the month" (W#16#2001) can be used at the parameter PERIOD as an alternative to the 29th 30th and the 31st of the month.

After setting the time-of-day interrupt with "SET_TINT" it still must be activated with the instruction "ACT_TINT".

Note

Additional information about time-of-day interrupt OBs

Other special features for the use of time-of-day interrupt OBs can be found in the descriptions of the organization blocks of the respective CPU:

For the S7-1200: AUTOHOTSPOT

For the S7-1500: AUTOHOTSPOT

The settings at the parameters SDT and PERIOD coincide with the settings for time-of-day interrupt in the properties of the time-of-day interrupt OBs.

Parameters

The following table shows the parameters of the "SET_TINT" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
SDT	Input	DT	D, L or constant	Start date and start time

Parameters	Declaration	Data type	Memory area	Description
PERIOD	Input	WORD	I, Q, M, D, L or constant	Execution intervals from the starting point SDT to: • W#16#0000 = single execution • W#16#0201 = once every minute • W#16#0401 = once hourly • W#16#1001 = once daily • W#16#1201 = once weekly • W#16#1401 = once monthly • W#16#1801 = once yearly • W#16#2001 = at month's end
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
8091	Error at the parameter SDT (invalid date and time-of-day specification).
8092	Incorrect input at the parameter PERIOD.
80A1	The set start time is in the past. This error code only occurs at PERIOD = W#16#0000.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-of-day interrupt functions (Page 3821).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

See also

ACT_TINT: Enable time-of-day interrupt (Page 3819)

SET_TINTL: Set time-of-day interrupt (S7-1200, S7-1500)

Description

The instruction "SET_TINTL" is used to set the start data and time of the time-of-day interrupt organization blocks from the user program, without having to make settings in the hardware configuration.

- Enter the number of the time-of-day interrupt-OBs at the parameter OB_NR for which you would like to set the start date and the time-of-day.
- Use the parameter SDT and PERIOD to specify when and how often the time-of-day interrupt OB should be called:
  - One-time call: Enter the date and the time-of-day at the parameter SDT. Use the value "0" at parameter PERIOD.
  - Repeated call: Enter the date and the time-of-day of the first call at the parameter SDT. Use the parameter PERIOD to define the time interval in which subsequent calls of the OBs should take place.
- Use the parameter LOCAL to select whether the time specified at the parameter SDT refers to the local time or the system time.
- With the ACTIVATE parameter, you specify when the settings made for the organization block are to be applied:
  - ACTIVATE = true: The settings made are applied directly.
  - ACTIVATE = false: The settings are applied only after "ACT_TINT (Page 3819)" is called:

Observe the following when setting the start date and start time:

- The seconds and milliseconds specification is ignored and set to "0" at the start time.
- Only the starting date days 1, 2, ... 28 are possible if you want to specify a monthly time-of-day interrupt OBs. This restriction prevents skipping the monthly call (e.g. 30-day months or in February).
  The setting "end of the month" (W#16#2001) can be used at the parameter PERIOD as an alternative to the 29th 30th and the 31st of the month.

Please observe the following during the use of local time:

- Changeover from daylight saving to standard time: When calling time-of-day interrupt organization blocks with a start time within the second hour during changeover from daylight saving time to standard time, also use a time-delay interrupt during the first hour of the time changeover.
- Changeover from standard to daylight saving time: If you specify the skipped hour as the time-of-day for the daylight saving time changeover day, the error code 16#8091 will be output at a single execution (PERIOD = W#16#0000).

Note

Additional information about time-of-day interrupt OBs

Other special features for the use of time-of-day interrupt OBs can be found in the descriptions of the organization blocks of the respective CPU:

For the S7-1200: AUTOHOTSPOT

For the S7-1500: AUTOHOTSPOT

The settings at the parameters SDT and PERIOD coincide with the settings for time-of-day interrupt in the properties of the time-of-day interrupt OBs.

Parameters

The following table shows the parameters of the "SET_TINTL" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
SDT	Input	DTL	D, L or constant	Start date and start time
LOCAL	Input	BOOL	I, Q, M, D, L or constant	• true: Use local time • false: Use system time
PERIOD	Input	WORD	I, Q, M, D, L or constant	Execution intervals from the starting point SDT to: • W#16#0000 = single execution • W#16#0201 = Once every minute • W#16#0401 = once hourly • W#16#1001 = once daily • W#16#1201 = once weekly • W#16#1401 = once monthly • W#16#1801 = once yearly • W#16#2001 = at month's end
ACTIVATE	Input	BOOL	I, Q, M, D, L or constant	• true: Set and activate the time-of-day interrupt • false: Set the time-of-day interrupt and activate only at call of "ACT_TINT (Page 3819)"
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
8091	Error at the parameter SDT (invalid date and time-of-day specification).
8092	Incorrect input at the parameter PERIOD.
80A1	The set start time is in the past. This error code only occurs at PERIOD = W#16#0000.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

CAN_TINT: Cancel time-of-day interrupt (S7-1200, S7-1500)

Description

The instruction "CAN_TINT" is used to delete the start date and time of a specified time-of-day interrupt organization block. This deactivates the time-of-day interrupt, and the organization block is no longer called.

If you want to reuse the time-of-day interrupt, the start time must be reset (instruction "SET_TINTL (Page 3816)" or "SET_TINT (Page 3813)").

After this, you must reactivate the time-of-day interrupt:

- If you use the instruction "SET_TINT (Page 3813)" or "SET_TINTL (Page 3816)" with parameter ACTIVE=false to set the time-of-day interrupt, call "ACT_TINT (Page 3819)".
- By using the instruction "SET_TINTL (Page 3816)" you can also activate the time-of-day interrupt directly with the parameter ACTIVE=true.

Parameters

The following table shows the parameters of the "CAN_TINT" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OB, whose starting date and time-of-day are to be deleted.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR.
80A0	No starting date/time-of-day defined for the affected time-of-day interrupt OB.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-of-day interrupt functions (Page 3821).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

ACT_TINT: Enable time-of-day interrupt (S7-1200, S7-1500)

Description

The instruction "ACT_TINT" is used to activate a time-of-day interrupt organization block from the user program. A prerequisite for the execution of the instruction is that the starting date and time-of-day are already set for the time-of-day interrupt OB.

Parameters

The following table shows the parameters of the "ACT_TINT" instruction:

Parameters	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OBs • The numbers 10 to 17 are available for the time-of-day interrupt OBs. • An OB number starting with 123 can also be assigned as an alternative. The OB number is displayed in the program block folder and in the system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Error at the parameter OB_NR (no time-of-day interrupt OB addressed).
80A0	Start date and time-of day not set for the relevant time-of-day interrupt OB.
80A1	The activated time is in the past. If the time-of-day interrupt is to be executed only once, only this error occurs.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-of-day interrupt functions (Page 3821).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

QRY_TINT: Query status of time-of-day interrupt (S7-1200, S7-1500)

Description

You can use this instruction to display the status of a time-of-day interrupt organization block in the STATUS output parameter.

Parameters

The following table shows the parameters of the "QRY_TINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_TOD	I, Q, M, D, L or constant	Number of the time-of-day interrupt OB whose status is queried The OB number is displayed in the program block folder and in the system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code.
STATUS	Output	WORD	I, Q, M, D, L	Status of the time-of-day interrupt (see below)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred. Exception: Status message "0" on bit 4 (no OB with this number created).
8090	Error at the parameter OB_NR. Possible causes: • The value at the parameter OB_NR is not an OB number (<1 or > 32767) supported by the CPU. • The OB number does not address a time-of-day interrupt OB.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Parameter STATUS

If an error occurs (see RET_VAL parameter), "0" is output in the STATUS parameter.

Bit	Value	Meaning
0	Always "0"	Irrelevant
1	0	The time-of-day interrupt is enabled.
	1	The time-of-day interrupt is disabled.
2	0	Time-of-day interrupt is not activated or has elapsed.
	1	The time-of-day interrupt is activated.
4	0	An OB with an OB number as specified at OB_NR parameter does not exist.
	1	An OB with an OB number as specified at OB_NR parameter does exist.
6	0	The time-of-day interrupt is based on the system time
	1	The time-of-day interrupt is based on the local time
Other		Always "0"

Example

You can find the example here: Program example for time-of-day interrupt functions (Page 3821).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

Program example for time-of-day interrupt functions (S7-1200, S7-1500)

Introduction

In the following example, you read the status of a time-of-day interrupt OB (OB10), and set a start time as well as the call frequency. Once OB10 has been started, disable OB10 once again.

The OB10 has the following defaults:

Requirement

Create 13 tags and a structure in a global data block for storing the data.

SLI_gDB_SET_TINT

		Name	Data type	Start value
1		Static		
2		obNbr	OB_TOD	10
3		executeQry	Bool	false
4		itemiseStatus	Struct	
5		T-o-d_interrupt_enabled	Bool	false
6		T-o-d_interrupt_activated	Bool	false
7		OB_with_obNbr_exists	Bool	false
8		T-o-d_interrupt_on_system_time	Bool	false
9		T-o-d_interrupt_on_local_time	Bool	false
10		returnValueQry	Int	0
11		executeSet	Bool	false
12		startDateTime	Date_And_Time	DT#1990-01-01-0
13		presetTime	Time	T#5M
14		periodOfExecute	Word	16#0201
15		returnValueSet	Int	0
16		executeAct	Bool	false
17		returnValueAct	Int	0
18		executeCan	Bool	false
19		returnValueCan	Int	0
20		testCurrCount	Int	0

Interconnect parameters: "SLI_itemiseStatus_TINT" FC

To evaluate the status information, create an FC "SLI_itemiseStatus_TINT".

Create the following local tag in it.

SLI_itemiseStatus_TINT

		Name	Data type
1		Input	
2		inWord	Word

Create interconnections for all relevant bits.

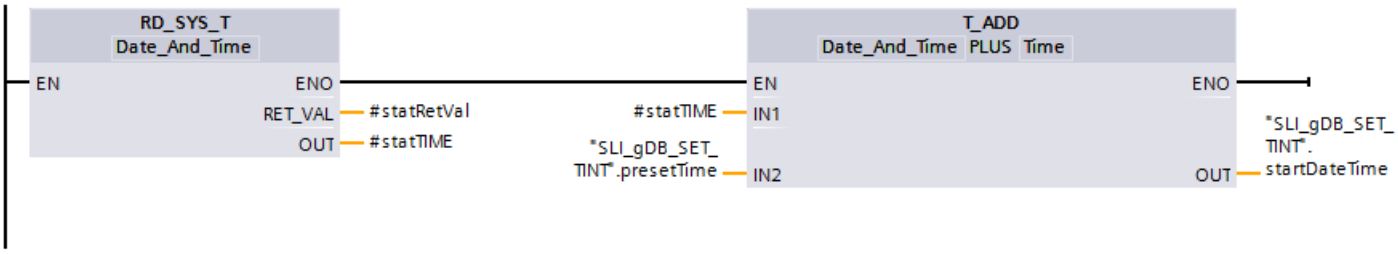
Network 1:

Network 2:

Network 3:

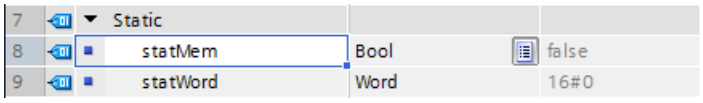
Network 4:

Network 5:

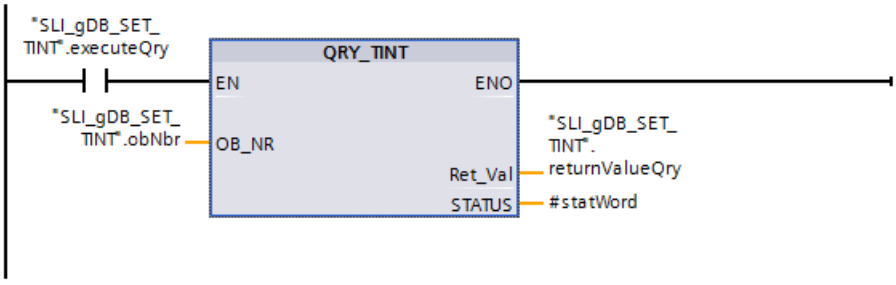


Interconnect parameters: "SLI_retrievetime_TINT" FC

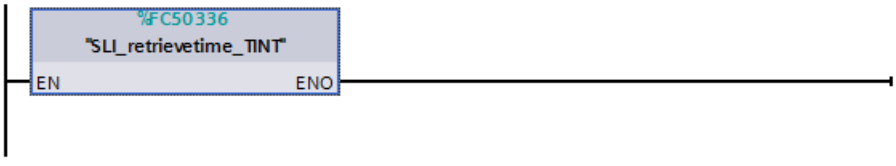
To read the date (system time) and define the start time of OB10, create an FC "SLI_retrievetime_TINT". Create the following local tags in the FC.



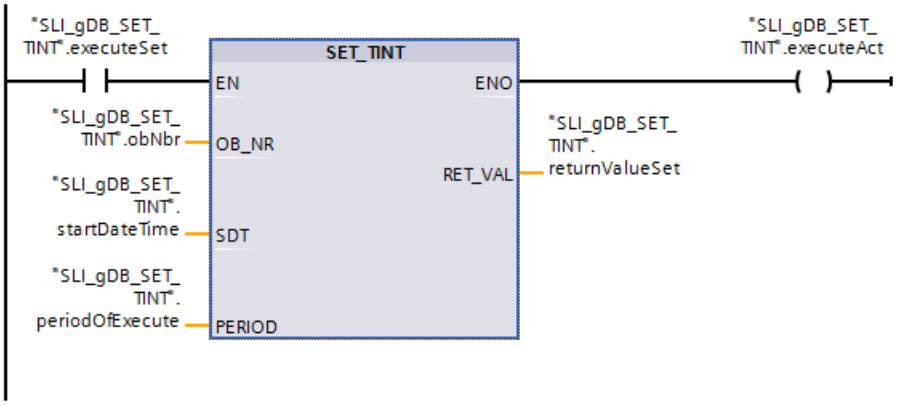
Network 1: Interconnect the parameters as follows. "RD_SYS_T" reads the system time. Use "T_ADD" to add 5 minutes to the system time.



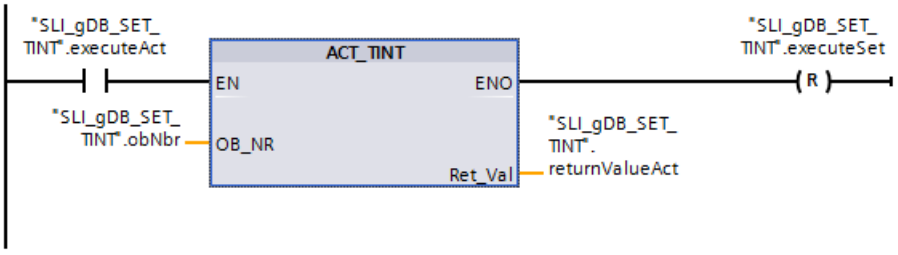
Interconnect parameters: "SLI_FB_SET_TINT" FB



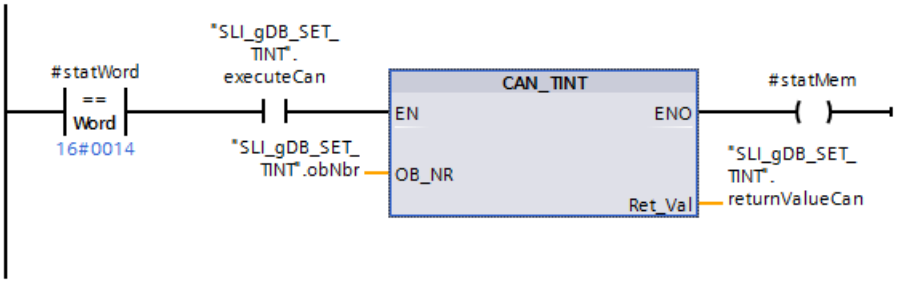
To call the instructions, create an FB ("SLI_FB_SET_TINT"). Create the following local tags in the function block "SLI_FB_SET_TINT".



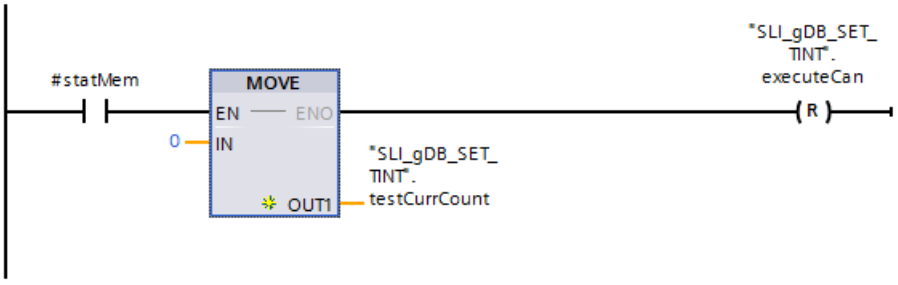
Network 1: Interconnect the parameters of the "QRY_TINT" instruction as follows.



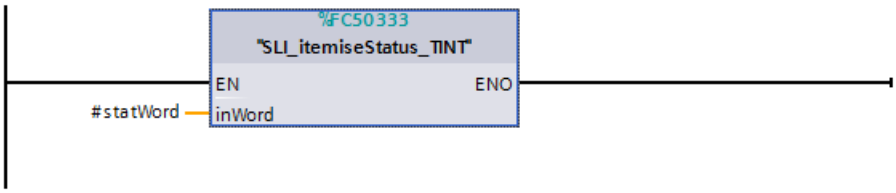
Network 2: You call the FC "SLI_retrievetime_TINT" in network 2 of the FB.



Network 3: Interconnect the parameters of the "SET_TINT" instruction as follows.

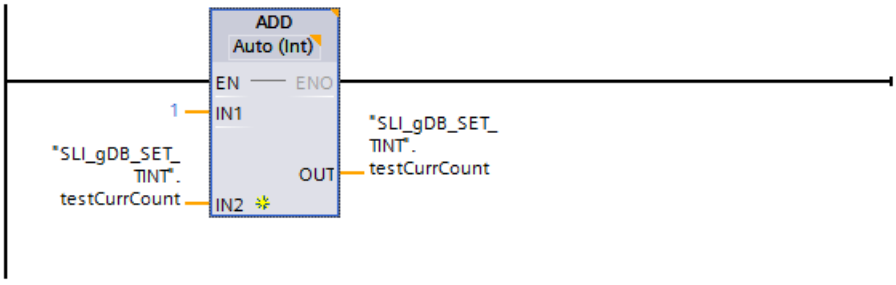


Network 4: Interconnect the parameters of the "ACT_TINT" instruction as follows.



Network 5: Interconnect the parameters of the "CAN_TINT" instruction as follows.

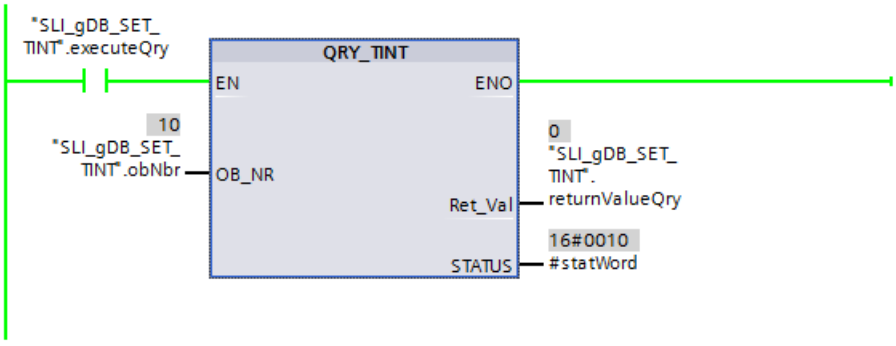
Network 6: Interconnect the parameters that are to be reset with the execution of "CAN_TINT" as follows.



Network 7: Interconnect the parameter of the "SLI_itemiseStatus_TINT" FC as follows.

Interconnect parameters: OB10

Create the following interconnections in OB10.



Result of "QRY_TINT"

The instructions receive the number of the OB to be called (OB10) with the input parameter OB_NR ("obNbr").

Network1:

When the normally open contact ("executeQry") supplies the signal state "TRUE", the "QRY_TINT" instruction is executed and the data of OB10 is read. The output parameter STATUS ("#statWord") displays the status of OB10. The output parameter RET_VAL ("returnValueQry") indicates that processing is taking place without errors.

The value of the tag "#statWord" is mapped in the structure "itemiseStatus".

4		itemiseStatus	Struct		
5		T-o-d_interrupt_enabled	Bool	false	TRUE
6		T-o-d_interrupt_activated	Bool	false	FALSE
7		OB_with_obNbr_exists	Bool	false	TRUE
8		T-o-d_interrupt_on_system_time	Bool	false	TRUE
9		T-o-d_interrupt_on_local_time	Bool	false	FALSE

Result of "SET_TINT"

Network 3: When the normally open contact ("executeSet") supplies the signal state "TRUE", the "SET_TINT" instruction is executed. The input parameter SDT ("startDateTime") transfers the defined start time (see Network 2) to OB10. "Every minute" (value "16#0201") is stored as call frequency at the input parameter PERIOD ("periodOfExecute").

The output parameter RET_VAL ("returnValueSet") indicates that processing took place without errors.

The execution of SET_TINT sets the coil ("executeAct") to "TRUE" and the instruction "ACT_TINT" is executed in network 4.

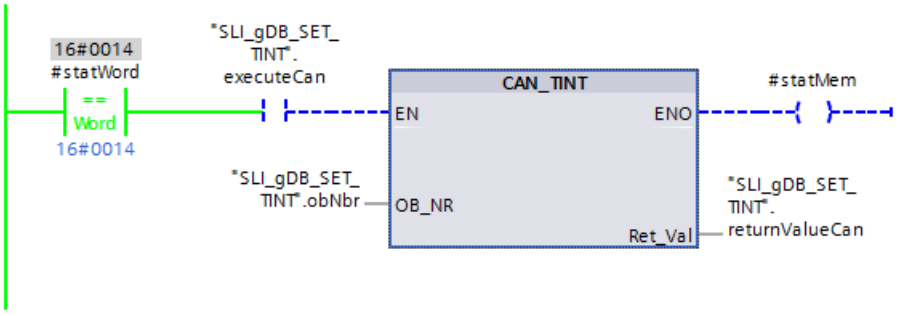
Result of "ACT_TINT"

Network 4: The instruction "ACT_TINT" activates OB10. The output parameter RET_VAL ("returnValueAct") indicates that processing took place without errors. The reset ("executeSet") in the signal state "TRUE" automatically ends the execution of the SET_TINT instruction and therefore also the execution of the ACT_TINT instruction.

Note

After execution of the instruction "SET_TINT", OB10 retains the new call data until STOP of the CPU. The default properties of OB10 are not affected by the execution of the instruction "SET_TINT".

Result of the OB10



With each call of OB10, the instruction "ADD" is executed and the tag "testCurrCount" is incremented by "1". OB10 is called (according to the value of "periodOfExecute") once every minute.

SLI_gDB_SET_TINT

	Name	Data type	Start value	Monitor value
1	Static			
2	obNbr	OB_TOD	10	10
3	executeQry	Bool	false	TRUE
4	itemiseStatus	Struct		
5	T-o-d_interrupt_enabled	Bool	false	TRUE
6	T-o-d_interrupt_activated	Bool	false	TRUE
7	OB_with_obNbr_exists	Bool	false	TRUE
8	T-o-d_interrupt_on_system_time	Bool	false	TRUE
9	T-o-d_interrupt_on_local_time	Bool	false	FALSE
10	returnValueQry	Int	0	0
11	executeSet	Bool	false	FALSE
12	startDateTime	Date_And_Time	DT#1990-01-01-0	DT#2016-11-30-17...
13	presetTime	Time	T#5M	T#5M
14	periodOfExecute	Word	16#0201	16#0201
15	returnValueSet	Int	0	0
16	executeAct	Bool	false	FALSE
17	returnValueAct	Int	0	0
18	executeCan	Bool	false	FALSE
19	returnValueCan	Int	0	0
20	testCurrCount	Int	0	5

Result of "CAN_TINT"

Network 5: When OB10 is set and enabled ("#statWord" has the value "16#0014"), the comparator supplies the signal state "TRUE" and CAN_TINT can be executed.

When the normally open contact ("executeCan") supplies the signal state "TRUE", the "CAN_TINT" instruction is executed. The instruction disables OB10 and deletes the call data of OB10 set with SET_TINT. The output parameter RET_VAL ("returnValueCan") indicates that processing took place without errors.

The execution of CAN_TINT sets the coil ("#statMem") to "TRUE" and network 6 is executed.

Result of the reset

Network 6: When the normally open contact ("#statMem") supplies the signal state "TRUE", the tag "testCurrCount" is reset to the value "0" with the instruction "MOVE". Reset ("executeCan") in the signal state "TRUE" also automatically ends the execution of the instruction "CAN_TINT".

Result of the status information "#statWord"

The FC "SLI_itemiseStatus_TINT" is called in network 7. The significant bits of the tag "#statWord" are evaluated and output as Boolean tags with plain-text name. When a tag of the structure "itemiseStatus" supplies the signal state "TRUE", its statement is correct.

Additional information

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Time-delay interrupt (S7-1200, S7-1500)

Using time-delay interrupts (S7-1200, S7-1500)

Definition

After you have called the "SRT_DINT (Page 3830)" instruction, the operating system generates an interrupt after the specified delay time has elapsed. The configured time-delay interrupt OB is called.

Prerequisites for the call

Before a time-delay interrupt can be called by the operating system, the following conditions must be met:

- The time-delay interrupt OB must be started by the "SRT_DINT (Page 3830)" instruction.
- The time-delay interrupt OB must not be deselected during configuration.
- The time-delay interrupt OB must exist in the CPU.

Purpose of the instructions "SRT_DINT", "CAN_DINT" and "QRY_DINT"

You use the instructions to

- Start time-delay interrupts ("SRT_DINT (Page 3830)")
- Cancel time-delay interrupts ("CAN_DINT (Page 3832)")
- Query time-delay interrupts ("QRY_DINT (Page 3833)")

Effects on the time-delay interrupt

The following table lists a number of different situations and explains the effect they have on a time-delay interrupt.

If ...	and ...	Then ...
A time-delay interrupt is started (by calling "SRT_DINT (Page 3830)")	The time-delay interrupt has already started,	The delay time is overwritten; the time-delay interrupt is started again.
	The time-delay interrupt OB does not exist at the time of the call,	a diagnostic buffer entry is made and the CPU continues to run.
	The interrupt is started in a startup OB and the delay time elapses before the CPU changes to RUN,	The call of the time-delay interrupt OB is delayed until the CPU is in RUN mode.
The delay time has elapsed,	A previously started time-delay interrupt OB is still being executed,	The operating system generates a time error (calls OB 80). If OB 80 does not exist, the CPU continues to run).

Response to warm restart and cold restart

During a warm restart or a cold restart, all the time-delay interrupt settings made in the user program by means of instructions are cleared.

Starting in a startup OB

A time-delay interrupt can be started in a startup OB. Two conditions must be satisfied to call the time-delay OB:

- The delay time must have elapsed.
- The CPU must be in the RUN mode.

If the delay time has elapsed and the CPU is not yet in the RUN mode, the time-delay interrupt OB call is delayed until the CPU is in RUN mode. The time-delay interrupt OB is then called before the first instruction in OB Main [OB 1] is executed.

SRT_DINT: Start time-delay interrupt (S7-1200, S7-1500)

Description

The instruction "SRT_DINT" is used to start a time-delay interrupt, which calls a time-delay interrupt OB after the expiry of the delay time specified at the parameter DTIME. The time delay interrupt OB is executed once for the time delay interrupt.

If the time-delay interrupt has not been executed yet and the instruction "SRT_DINT" is called again, the existing time-delay interrupt is deleted and a new time-delay interrupt is started.

Note

Delay time

If the delay time used is less than or equal to the currently used CPU cycle time and SRT_DINT is called cyclically, the time delay interrupt OB is executed with each CPU cycle.

Make sure that you select a delay time that is greater than the CPU cycle time.

With the SIGN parameter, you can enter an identifier that identifies the start of the time-delay interrupt. The values of the DTIME and SIGN parameters are shown in the start information of the organization blocked called.

Accuracy

The maximum time between the call of the "SRT_DINT" instruction and the start of the time-delay interrupt OB is one millisecond longer than the configured delay time, provided that no interruption events delay the call.

Parameters

The following table shows the parameters of the "SRT_DINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB to be executed after a delay time
DTIME	Input	TIME	I, Q, M, D, L or constant	Delay time (1 to 60000 ms) You can realize longer times, for example, by using a counter in a time-delay interrupt OB.
SIGN	Input	WORD	I, Q, M, D, L or constant	Identifier that appears when the time-delay interrupt OB is called in the start event information of the OB.
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
8090	Incorrect parameter OB_NR
8091	Incorrect parameter DTIME

Error code* (W#16#...)	Description
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-delay interrupt functions (Page 3834).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

CAN_DINT: Cancel time-delay interrupt (S7-1200, S7-1500)

Description

You use this instruction to cancel a started time-delay interrupt and, thus, also cancel the call of the time-delay interrupt OB that is executed after the configured delay time. You specify the number of the organization block whose call is to be canceled in the OB_NR parameter.

Parameters

The following table shows the parameters of the "CAN_DINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB whose call will be canceled
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
8090	Incorrect parameter OB_NR
80A0	Time-delay interrupt has not started.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-delay interrupt functions (Page 3834).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

QRY_DINT: Query time-delay interrupt status (S7-1200, S7-1500)

Description

The instruction "QRY_DINT" is used to query the status of the time-delay interrupt.

Parameters

The following table shows the parameters of the "QRY_DINT" instruction:

Parameter	Declaration	Data type	Memory area	Description
OB_NR	Input	OB_DELAY (INT)	I, Q, M, D, L or constant	Number of the OB whose status is being queried.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the actual parameter of RET_VAL contains an error code. The value "0" is displayed in the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status of the time-delay interrupt, see following table.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Bit	Value	Meaning
0	0	Irrelevant
1	0	Time-delay interrupt is enabled by the operating system.
	1	Time-delay interrupt is disabled.
2	0	Time-delay interrupt is not activated or has elapsed.
	1	Time-delay interrupt is activated.
3	-	-
4	0	Time-delay interrupt OB with the specified number does not exist.
	1	Time-delay interrupt OB with the specified number exists.
Other bits		Always "0"

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	Incorrect information in the OB_NR parameter
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for time-delay interrupt functions (Page 3834).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

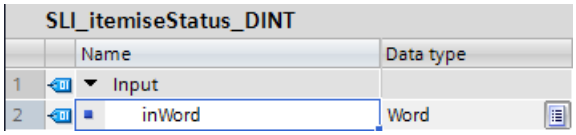
Program example for time-delay interrupt functions (S7-1200, S7-1500)

Introduction

In the following example, you read the status of a time-delay interrupt OB (OB20), and set a new delay time and start or disable OB20.

Requirement

Create 10 tags and a structure in a global data block for storing the data.



SLI_gDB_SRT_DINT

	Name	Data type	Start value
1	Static		
2	obNbr	OB_DELAY	20
3	executeQry	Bool	false
4	itemiseStatus	Struct	
5	Time-delay_interrupt_enabled	Bool	false
6	Time-delay_interrupt_activated	Bool	false
7	OB_with_obNbr_exists	Bool	false
8	returnValueQry	Int	0
9	executeSrt	Bool	false
10	delayTime	Time	T#6000ms
11	sign	Word	16#0001
12	returnValueSrt	Int	0
13	executeCan	Bool	false
14	returnValueCan	Int	0
15	testCurrCount	Int	0

Interconnect parameters: "SLI_itemiseStatus_DINT" FC

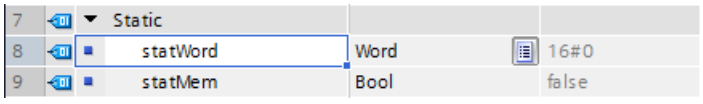
To evaluate the status information, create an FC "SLI_itemiseStatus_DINT".

Create the following local tag in it.

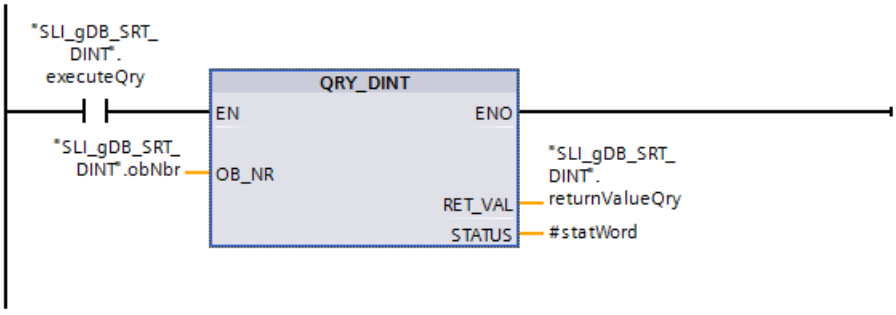
Create interconnections for all relevant bits.

Network 1:

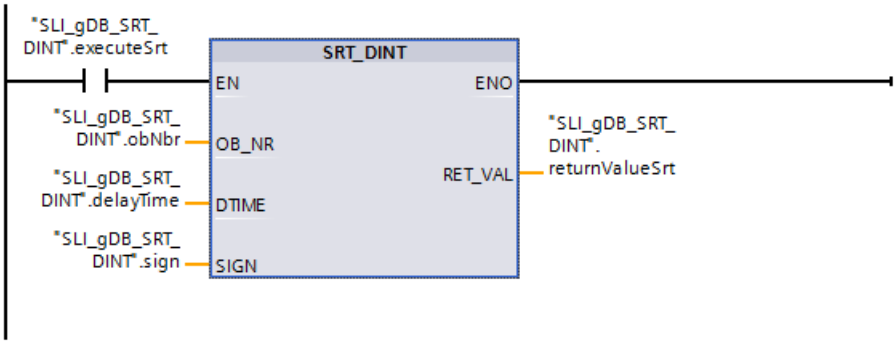
Network 2:



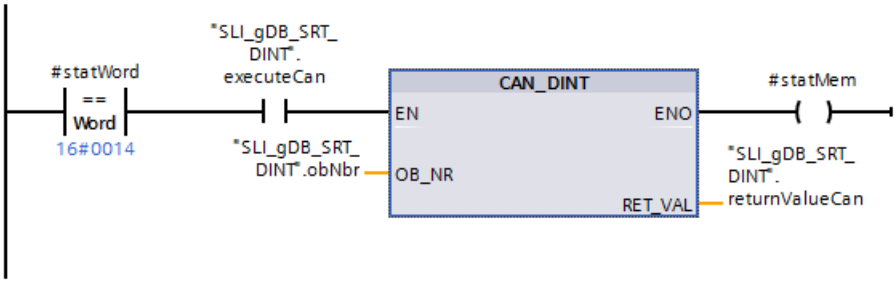
Network 3:



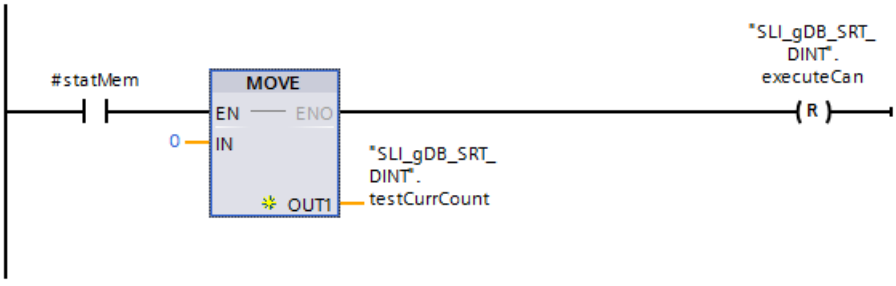
Interconnect parameters: "SLI_FB_SRT_DINT" FB



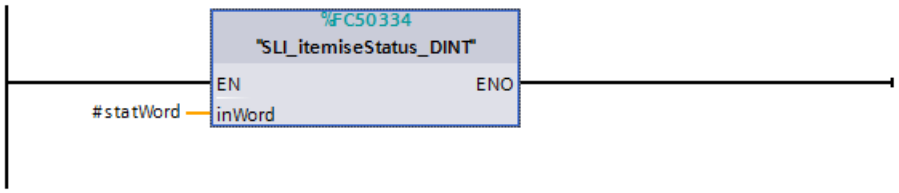
To call the instructions, create an FB "SLI_FB_SRT_DINT". Create the following local tags in the function block "SLI_FB_SRT_DINT".



Network 1: Interconnect the parameters of the "QRY_DINT" instruction as follows.

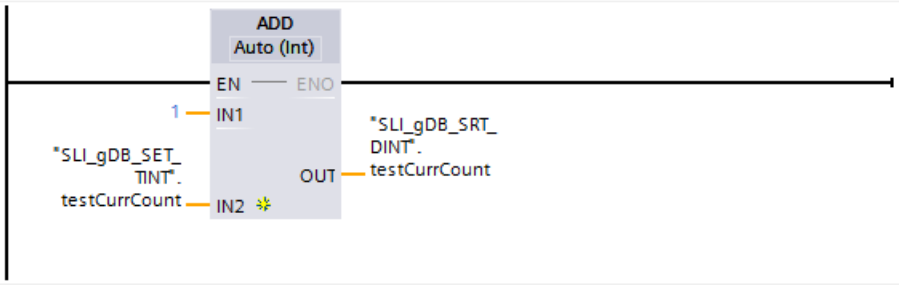


Network 2: Interconnect the parameters of the "SRT_DINT" instruction as follows.



Network 3: Interconnect the parameters of the "CAN_DINT" instruction as follows.

Network 4: Interconnect the parameters that are to be reset with the execution of "CAN_DINT" as follows.

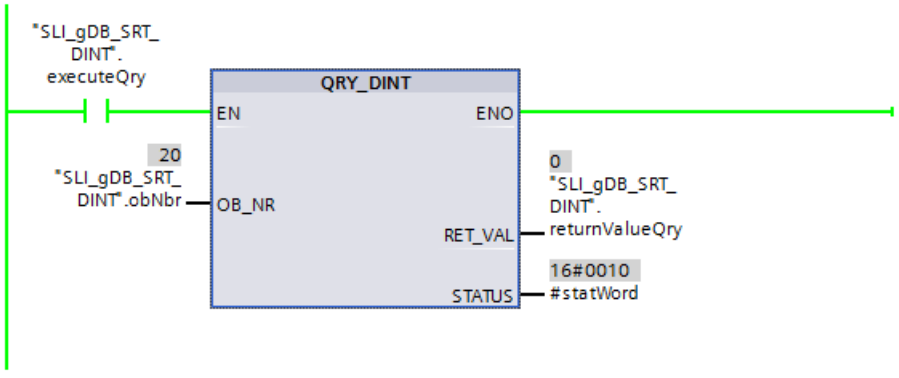


Network 5: Interconnect the parameter of the "SLI_itemiseStatus_DINT" FC as follows.

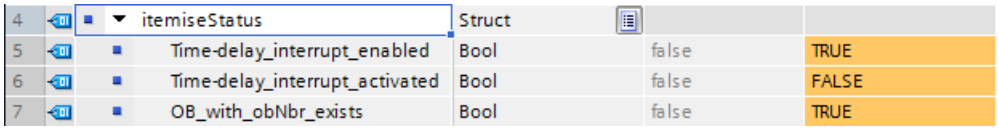
You call the FB "SLI_FB_SRT_DINT" in a cyclic OB (OB1).

Interconnect parameters: OB20

Create the following interconnections in OB20.



Result of "QRY_DINT"



The instructions receive the number of the OB to be called (OB20) with the input parameter OB_NR ("obNbr").

Network 1:

When the normally open contact ("executeQry") supplies the signal state "TRUE", the "QRY_DINT" instruction is executed and the data of OB20 is read. The output parameter STATUS ("#statWord") displays the status of OB20. The output parameter RET_VAL ("returnValueQry") indicates that processing is taking place without errors.

The value of the tag "#statWord" is mapped in the structure "itemiseStatus".

4	itemiseStatus	Struct		
5	Time-delay_interrupt_enabled	Bool	false	TRUE
6	Time-delay_interrupt_activated	Bool	false	FALSE
7	OB_with_obNbr_exists	Bool	false	TRUE

Result of "SRT_DINT"

Network 2: When the normally open contact ("executeSrt") supplies the signal state "TRUE", the "SRT_DINT" instruction is executed. The input parameter DTIME ("delayTime") transfers the delay time (6 s) to OB20 and OB20 is enabled.

Note

Its delay time starts running at the time OB20 is enabled. OB20 is then called unless it has received the delay time again beforehand in a new CPU cycle.

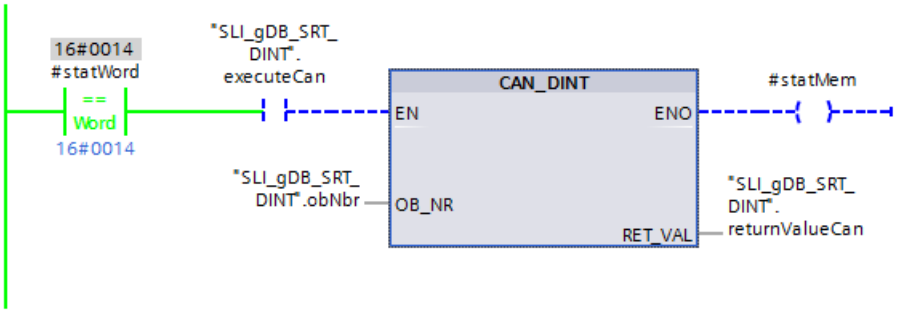
The selected identifier (value "16#0001") to be output with the execution of OB20 is stored at the input parameter SIGN ("sign"). The identifier is shown in the start event information of OB20. The output parameter RET_VAL ("returnValueSrt") indicates that processing took place without errors.

If the NO contact ("executeSrt") returns the signal state "FALSE" after successful processing of SRT_DINT, the delay time is not transferred again to the OB20. As soon as the delay time has expired, OB20 is executed once.

Note

The described reaction of the OB20 in combination with the EN parameter only applies when the currently used CPU cycle time is less than the delay time of the OB20.

Result of the OB20



With each call of OB20, the instruction "ADD" is executed and the tag "testCurrCount" is incremented by "1". OB20 is called only once after expiration of the delay time defined with SRT_DINT. After it has been called, OB20 is once again "disabled".

SLI_gDB_SRT_DINT

	Name	Data type	Start value	Monitor value
1	Static			
2	obNbr	OB_DELAY	20	20
3	executeQry	Bool	false	TRUE
4	itemiseStatus	Struct		
5	Time-delay_interrupt_enabled	Bool	false	TRUE
6	Time-delay_interrupt_activated	Bool	false	FALSE
7	OB_with_obNbr_exists	Bool	false	TRUE
8	returnValueQry	Int	0	0
9	executeSrt	Bool	false	FALSE
10	delayTime	Time	T#6000ms	T#6S
11	sign	Word	16#0001	16#0001
12	returnValueSrt	Int	0	0
13	executeCan	Bool	false	FALSE
14	returnValueCan	Int	0	0
15	testCurrCount	Int	0	1

Result of "CAN_DINT"

Network 3: As long as OB20 is set and enabled ("#statWord" has the value "16#0014"), the comparator returns the signal state "TRUE" and CAN_DINT can be executed.

When the normally open contact ("executeCan") supplies the signal state "TRUE", the "CAN_DINT" instruction is executed. The instruction disables OB20 and deletes the set call data of OB20.
The output parameter RET_VAL ("returnValueCan") indicates that processing took place without errors.

The execution of CAN_DINT sets the coil ("#statMem") to "TRUE" and network 4 is executed.

Result of the reset

Network 4: When the normally open contact ("#statMem") supplies the signal state "TRUE", the tag "testCurrCount" is reset to the value "0" with the instruction "MOVE". Reset ("executeCan") in the signal state "TRUE" also automatically ends the execution of the instruction "CAN_DINT".

Result of the status information "#statWord"

The FC "SLI_itemiseStatus_DINT" is called in network 7. The significant bits of the tag "#statWord" are evaluated and output as Boolean tags with plain-text name. When a tag of the structure "itemiseStatus" supplies the signal state "TRUE", its statement is correct.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Synchronous errors (S7-1500)

Mask synchronous error events (S7-1500)

Introduction

Synchronous errors are programming and access errors. Such errors occur as a result of programming with incorrect operand areas or numbers, or incorrect addresses. **Masking** these synchronous errors means the following:

- Masked synchronous errors do not trigger an error OB call and do not lead to a programmed alternative reaction.
- The CPU "records" the masked errors that have occurred in an error status register.

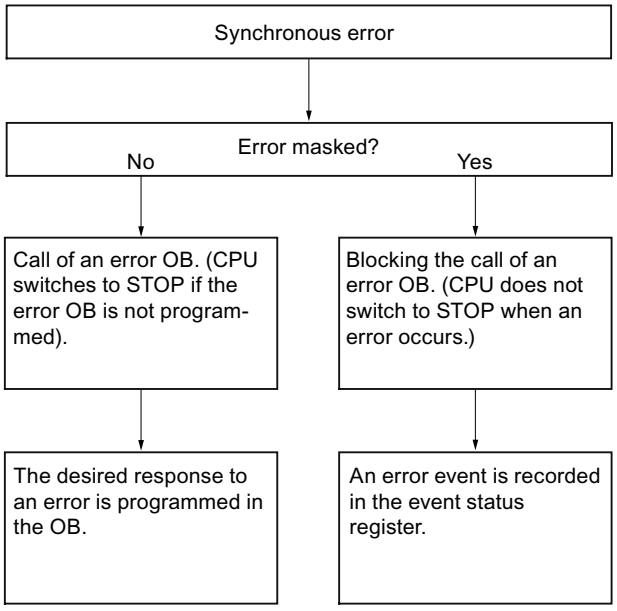
Masking is carried out by calling the "MSK_FLT (Page 3846)" instruction.

Unmasking errors means canceling a previously set mask and clearing the corresponding bit in the event status register of the current priority class. Masking is canceled as follows:

- By calling the "DMSK_FLT (Page 3847)" instruction.
- Once the current priority class has been completed.

If an error event occurs after it has been unmasked, the operating system will start the associated error OB.

You can use the "READ_ERR (Page 3848)" instruction to read the masked errors that have occurred.



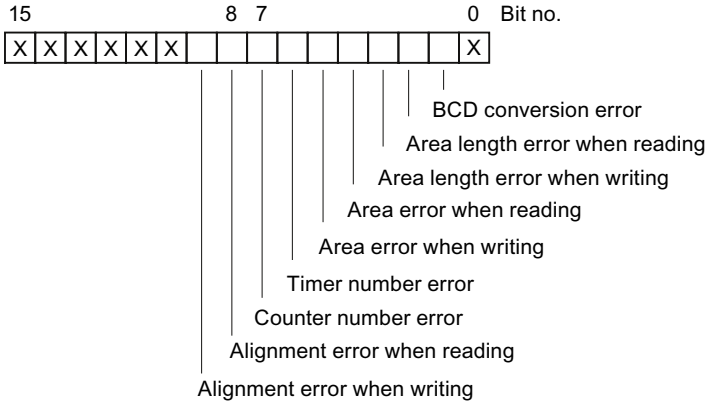
Note

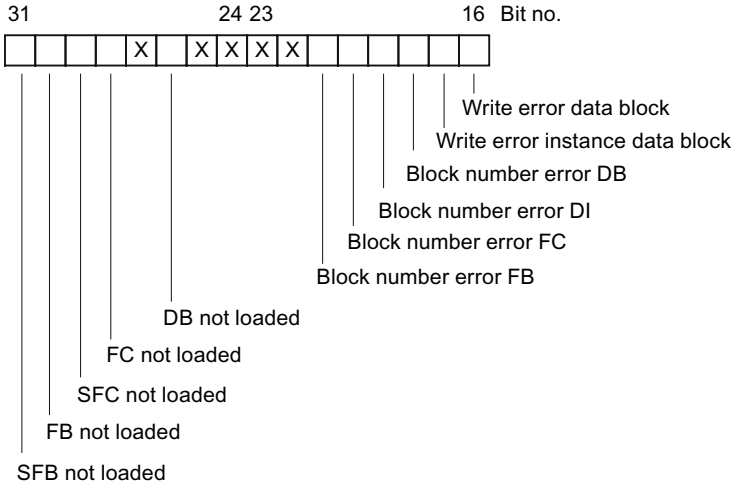
Regardless of masking or unmasking of the error events for the S7-1500, the error event is entered in the diagnostic buffer and the group error LED of the CPU lights up.

Handling errors in general

Different actions are possible if programming and I/O area access errors occur in a user program:

- You can program an error OB that is called by the operating system when the corresponding error occurs.
- You can disable the error OB call individually for each priority class. If an error of this type occurs in the priority class, the CPU does not change to STOP in this case. The CPU enters the error in an error register. From this entry, however, you do not recognize when or how often this error has occurred.



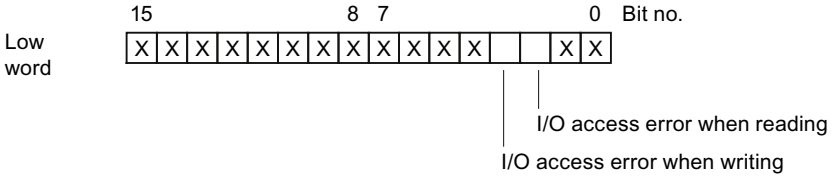


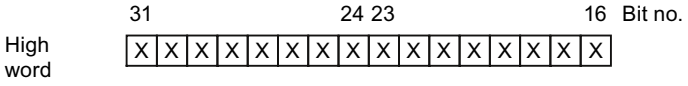
Synchronous errors are assigned to a particular bit pattern known as the **error filter**. You can find this error filter in the input and output parameters of the "MSK_FLT (Page 3846)", "DMSK_FLT (Page 3847)", and "READ_ERR (Page 3848)" instructions.

Synchronous errors are divided into **programming and access errors** which you can mask in two error masks. The error filters are illustrated in the following figures.

Programming error filter

The following figure shows the bit pattern of the error filter for programming errors. The error filter for the programming errors is available in the "PRGFLT_..." parameters (see below "Programming errors, Low-Word" or "Programming errors, High-Word").



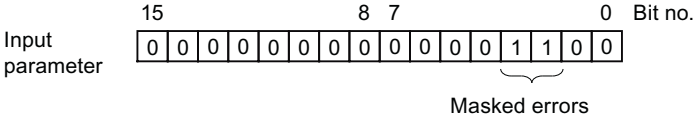


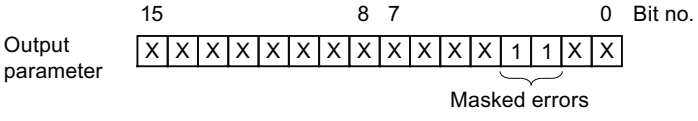
Legend: X Not relevant

The non-relevant bits "x" are set to "0" for the input and output parameters of the instructions "MSK_FLT (Page 3846)", "DMSK_FLT (Page 3847)", "READ_ERR (Page 3848)".

Access error mask

The following figure shows the bit pattern of the error mask for access errors. The error mask for access errors is located in the parameters ACCFLT_...





Legend: X Not relevant

Example: The following figure shows how the low word of the error mask for access errors appears with all masked errors.

- As input parameter for "MSK_FLT (Page 3846)"
- As output parameter for "MSK_FLT (Page 3846)"

Legend:
- X Not relevant
- 0 Not masked
- 1 Masked

Programming error low word

The following table lists the errors assigned to the low word of the error filter for programming errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
BCD conversion error	2521	The value to be converted is not a BCD number (e.g. 5E8).
Area length error when reading	2522	An addressed operand is not located entirely within the possible operand range. Example: MW 320 should be read although the memory area is only 256 bytes long.
Area length error when writing	2523	An addressed operand is not located entirely within the possible operand range. Example: A value should be written to MW 320 although the memory area is only 256 bytes long.
Area error when reading	2524	An incorrect range identifier for the operand was specified during indirect, overlapping range addressing. Example: • Correct: LAR1 P#E 12.0 L W[AR1, P#0.0] • Incorrect: LAR1 P#12.0 L W[AR1, P#0.0] The area error is reported during this operation.
Area error when writing	2525	An incorrect range identifier for the operand was specified during indirect, overlapping range addressing. Example: • Correct: LAR1 P#E 12.0 T W[AR1, P#0.0] • Incorrect: LAR1 P#12.0 T W[AR1, P#0.0] The area error is reported during this operation.
Timer number error (not implemented with the S7-1500)	2526	A non-existent timer is accessed. Example: • SI T [MW 0] with MW 0 = 129; the timer 129 should be started although there are only 128 timers available.
Counter number error (not implemented with the S7-1500)	2527	A non-existent counter is accessed. • Example: ZV Z [MW 0] with MW 0 = 600; the counter 600 is accessed although only 512 counters are available.

Error	Event ID (W#16#...)	Possible cause of error
Alignment error when reading	2528	A byte, word or double word operand with a bit address ≠ 0 is addressed. Example: • Correct: LAR1 P#M12.0 L B[AR1, P#0.0] • Incorrect: LAR1 P#M12.4 L B[AR1, P#0.0]
Alignment error when writing	2529	A byte, word or double word operand with a bit address ≠ 0 is addressed. Example: • Correct: LAR1 P#M12.0 T B[AR1, P#0.0] • Incorrect: LAR1 P#M12.4 T B[AR1, P#0.0]

Programming error high word

The following table lists the errors assigned to the high word of the error filter for programming errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
Write error data block	2530	The data block to be written to is write-protected.
Write error instance data block	2531	The instance data block to be written to is write-protected.
Block number error DB	2532	The number of the data block is greater than the highest permissible number.
Block number error DI	2533	The number of the instance data block is greater than the highest permissible number.
Block number error FC	2534	The number of a called function (FC) is greater than the highest permissible number.
Block number error FB	2535	The number of a called function block (FB) is greater than the highest permissible number.
DB not loaded	253A	The data block is not loaded.
Instruction not loaded	253C to 253F	The instruction to be called is not loaded.

Access error

The following table contains the errors that are assigned to the error mask for access errors. The possible causes of the errors are also listed.

Error	Event ID (W#16#...)	Possible cause of error
I/O access error when reading	2942	• The address in the I/O area has no assigned signal module. • Access to this I/O area was not acknowledged within the specified module monitoring time (timeout).
I/O access error when writing	2943	

MSK_FLT: Mask synchronous error events (S7-1500)

Description

You use the instruction to control the reaction of the CPU to synchronous errors. This is done by masking the respective synchronous errors (for error filters, see Mask synchronous error events (Page 3840)). When you call "MSK_FLT", you mask the synchronous errors in the current priority class.

If you set individual bits of the synchronous error filter to "1" in the input parameters, other bits that were set previously retain their value of "1". You obtain new error filters that you read out using the output parameters. The synchronous errors you have masked do not call an OB but are simply entered in an error register. You read the event status register with the instruction "READ_ERR (Page 3848)".

Parameters

The following table shows the parameters of the instruction "MSK_FLT":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_SET_MASK	Input	DWORD	I, Q, M, D, L or constant	Programming error to be masked
ACCFLT_SET_MASK	Input	DWORD	I, Q, M, D, L or constant	Access error to be masked
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_MASKED	Output	DWORD	I, Q, M, D, L	Masked programming errors
ACCFLT_MASKED	Output	DWORD	I, Q, M, D, L	Masked access errors

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	None of the errors were already masked.
0001	At least one of the errors was already masked. Nevertheless, the other errors will be masked.
-	General error information See also: Getting error ID locally with GetErrorID (Page 3409)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for synchronous error events (Page 3849).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

DMSK_FLT: Unmask synchronous error events (S7-1500)

Description

You use the instruction to unmask the errors masked with "MSK_FLT (Page 3846)". To do this, you must set the corresponding bits of the error filter to "1" in the input parameters. With the "DMSK_FLT" call, you unmask the corresponding synchronous errors of the current priority class. At the same time, the queried entries are cleared in the error register. You read out the new error filters using the output parameters.

Parameters

The following table shows the parameters of the instruction "DMSK_FLT":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_RESET_MASK	Input	DWORD	I, Q, M, D, L or constant	Programming errors to be unmasked
ACCFLT_RESET_MASK	Input	DWORD	I, Q, M, D, L or constant	Access errors to be unmasked
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_MASKED	Output	DWORD	I, Q, M, D, L	Still masked programming errors
ACCFLT_MASKED	Output	DWORD	I, Q, M, D, L	Still masked access errors

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	All specified errors were unmasked.
0001	At least one of the errors was not masked. Nevertheless, the other errors will be unmasked.
-	General error information See also: GET_ERR_ID: Get error ID locally (Page 3409)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for synchronous error events (Page 3849).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

READ_ERR: Read out event status register (S7-1500)

Description

You use the instruction to read the error register. The structure of the error register corresponds to that of the programming and access error masks, which you can program as input parameters with "MSK_FLT (Page 3846)" and "DMSK_FLT (Page 3847)".

In the input parameters, you enter the synchronous errors you want to read from the error register. When you call "READ_ERR", you read the required entries from the error register and at the same time clear these entries.

The error register contains information that tells you which of the masked synchronous errors in the current priority class occurred at least once. If a bit is set, this means that the corresponding masked synchronous error occurred at least once.

Parameters

The following table shows the parameters of the instruction "READ_ERR":

Parameter	Declaration	Data type	Memory area	Description
PRGFLT_QUERY	Input	DWORD	I, Q, M, D, L or constant	Query programming error
ACCFLT_QUERY	Input	DWORD	I, Q, M, D, L or constant	Query access error
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PRGFLT_CLR	Output	DWORD	I, Q, M, D, L	Programming errors that occurred
ACCFLT_CLR	Output	DWORD	I, Q, M, D, L	Access errors that occurred

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	All queried errors are masked.
0001	At least one of the queried errors is not masked.
-	General error information See also: Getting error ID locally with GetErrorID (Page 3409)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for synchronous error events (Page 3849).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Program example for synchronous error events (S7-1500)

Introduction

In the example below, mask the synchronous error events (program errors) with the instruction "MSK_FLT", unmask a part of the synchronous error events with the instruction "DMSK_FLT" and read out the event status register with the instruction "READ_ERR". When the program error is unmasked, call a program error OB.

Storage of data

Create the following structures and tags for storing the data in a global data block.

- Tags for MSK_FLT:

SLI_gDB_MSK_FLT			
	Name	Data type	Start value
1	Static		
2	maskedProgErrs	DWord	16#0
3	maskedAccessErrs	DWord	16#0
4	MSK_FLT	Struct	
5	execute	Bool	false
6	progErrMask_Details	Struct	
7	accessErrMask_Details	Struct	
8	progErrSetMask	DWord	16#0
9	accessErrSetMask	DWord	16#0
10	returnValue	Int	0

- MSK_FLT / content of the structure "progErrMask_Details":

6	progErrMask_Details	Struct	
7	BCD_conversion_error	Bool	false
8	Area_length_error_when_reading	Bool	1
9	Area_length_error_when_writing	Bool	1
10	Range_error_when_reading	Bool	1
11	Range_error_when_writing	Bool	1

You can find the complete organization of the structure here: Mask synchronous error events (Page 3840).

- MSK_FLT / content of the structure "accessErrMask_Details":

7	accessErrMask_Details	Struct	
8	IO_access_error_when_reading	Bool	false
9	IO_access_error_when_writing	Bool	false

- Tags for DMSK_FLT:

11	DMSK_FLT	Struct	
12	execute	Bool	false
13	progErrResetMask	DWord	16#0000_000C
14	accessErrResetMask	DWord	16#0
15	returnValue	Int	0

- Tags for READ_ERR:

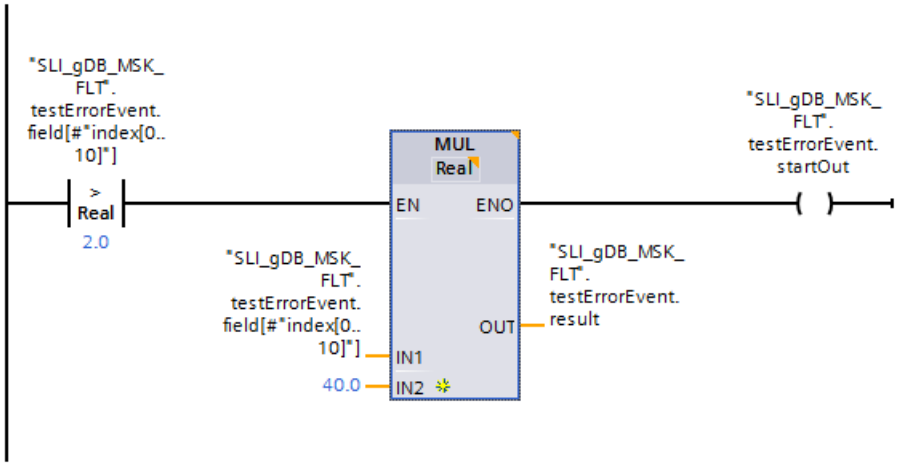
16	READ_ERR	Struct	
17	busyReading	Bool	false
18	peOB_unmasked_active	Bool	false
19	returnValue	Int	0
20	occuredMskProgErrs	DWord	16#0
21	occuredMskAccessErrs	DWord	16#0
22	occProgErrMask_Details	Struct	
23	occAccErrMask_Details	Struct	

The organization of the structures "occProgErrMask_Details" and "occAccErrMask_Details" is similar to the organization of the structures "progErrMask_Details" and "accessErrMask_Details".

- Tags for the test result:

24	testErrorEvent	Struct	
25	index	Int	0
26	field	Array[0..10] of Real	
27	result	Real	0.0
28	startOut	Bool	false

Interconnect parameters: "SLI_FB_genErr_SyncErrEv" FB



Create an "SLI_FB_genErr_SyncErrEv" FB to generate a program error.

Create the following local tag in it.

SLI_FB_genErr_SyncErrEv

	Name	Data type	Default value
1	Input		
2	index[0..10]	Int	0

Create the following interconnections in the FB.

Interconnect parameters: "SLI_itemiseDW_SyncErrEv" FC

To transfer a bit sequence in the size of a DWORD, create the FC "SLI_itemiseDW_SyncErrEv".

Create the following local tags (inputs and outputs from 1 to 31) in it.

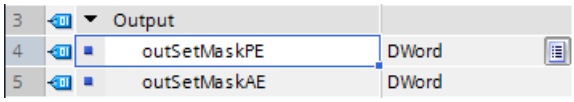
- Excerpt of the inputs:

SLI_itemiseDW_SyncErrEv		
	Name	Data type
1	Input	
2	in1	Bool
3	in2	Bool
4	in3	Bool
5	in4	Bool
6	in5	Bool
7	in6	Bool
8	in7	Bool
9	in8	Bool

- Excerpt of the outputs:

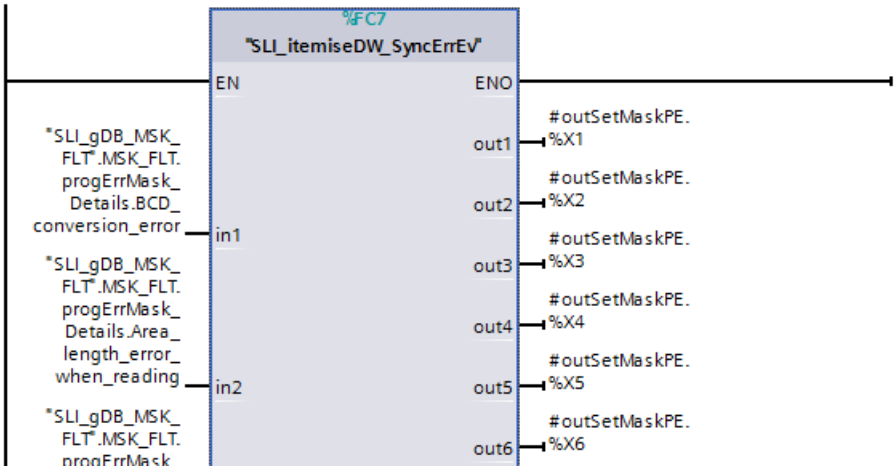
21	in31	Bool
22	Output	
23	out1	Bool
24	out2	Bool
25	out3	Bool
26	out4	Bool
27	out5	Bool
28	out6	Bool
29	out7	Bool
30	out8	Bool
39	out31	Bool

Create the following interconnections for the inputs and outputs in the FC based on the example of network 1.



Network 1:

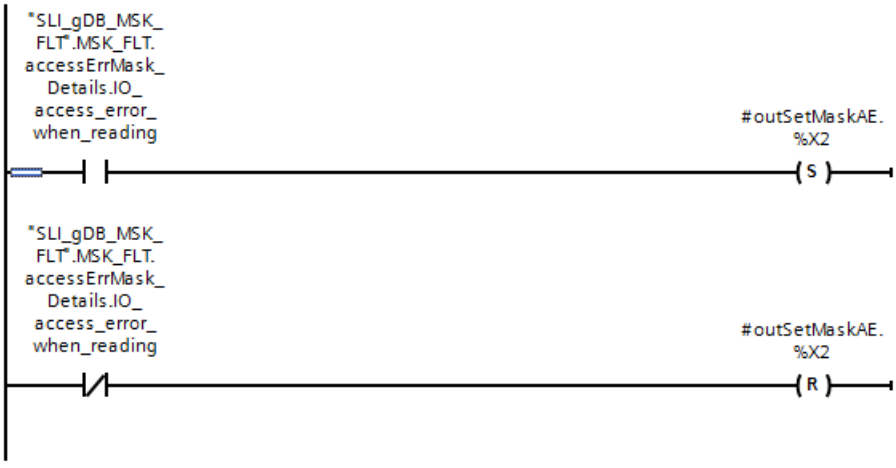
Interconnect parameters: "SLI_mask_SyncErrEv" FC



To convert the masks to be set for program and access errors, create the FC "SLI_mask_SyncErrEv".

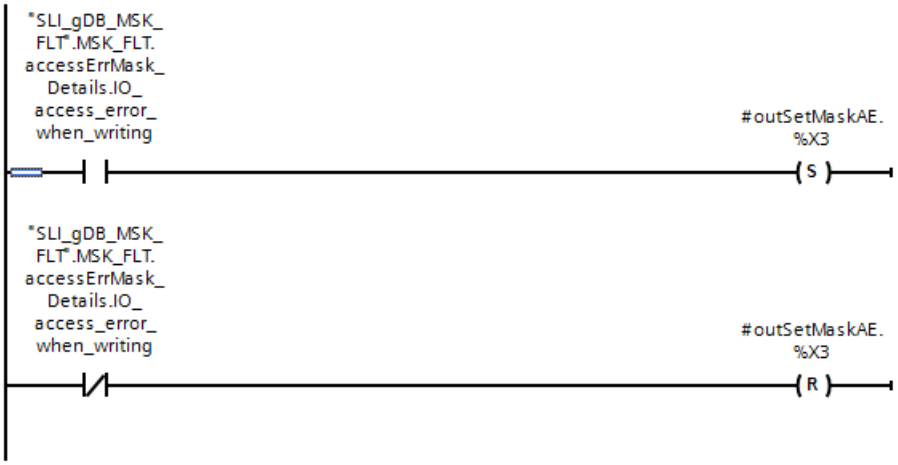
Create the following local tags in it.

Network 1:



Interconnect the parameters of the "SLI_itemiseDW_SyncErrEv" FC according to the following example.

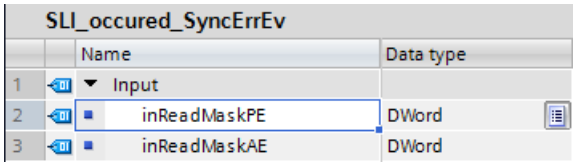
You can find the complete organization of the structure of the program errors ("progErrMask_Details") here: Mask synchronous error events (Page 3840).



Network 2:

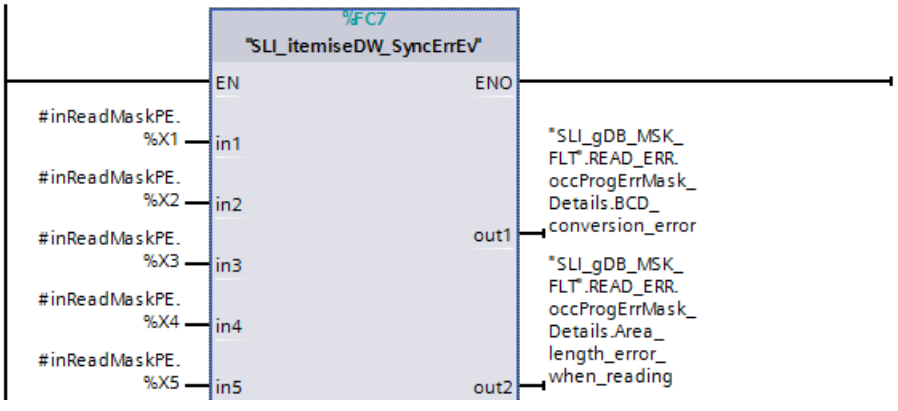
Interconnect bit 2 of the DWORD of the access errors as follows.

Network 3:



Interconnect bit 3 of the DWORD of the access errors as follows.

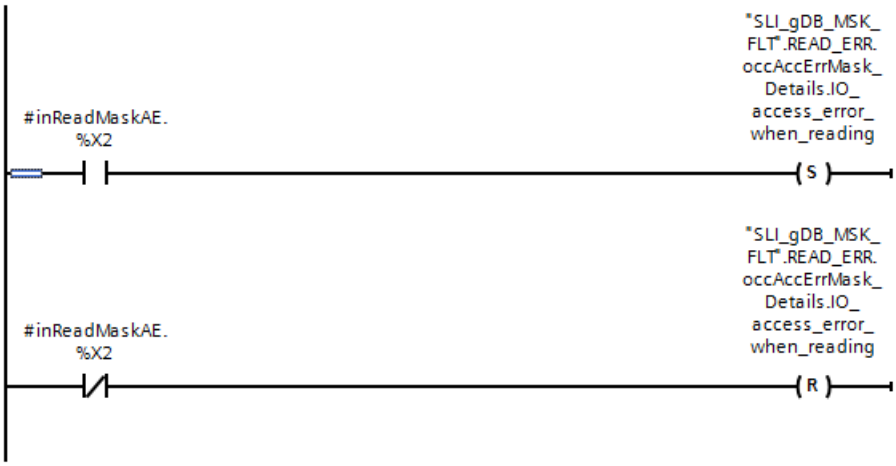
Interconnect parameters: "SLI_occured_SyncErrEv" FC



To convert read program and access errors, create the FC "SLI_occured_SyncErrEv".

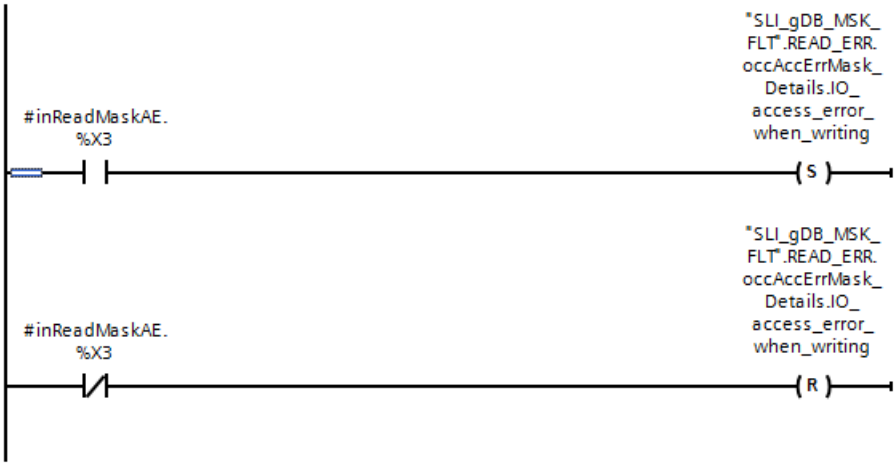
Create the following local tags in it.

Network 1:



Interconnect the parameters of the "SLI_itemiseDW_SyncErrEv" FC according to the following example.

You can find the complete organization of the structure of the program errors ("occProgErrMask_Details") here: Mask synchronous error events (Page 3840).



Network 2:

Interconnect bit 2 of the DWORD of the access errors as follows.

Network 3:

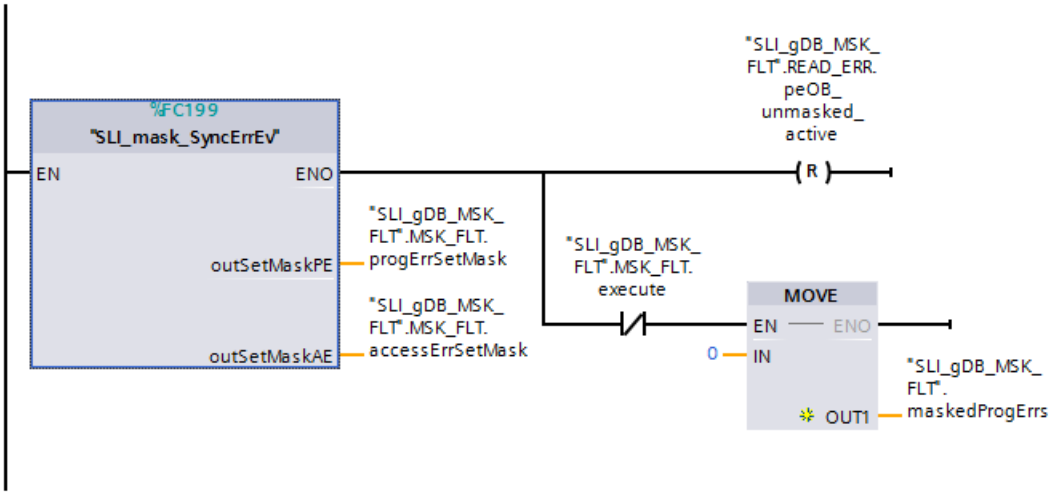
Interconnect bit 3 of the DWORD of the access errors as follows.

Interconnect parameters: "SLI_peOB_SyncErrEV" OB

Create the OB "SLI_peOB_SyncErrEV" in case of a program error in the unmasked state.

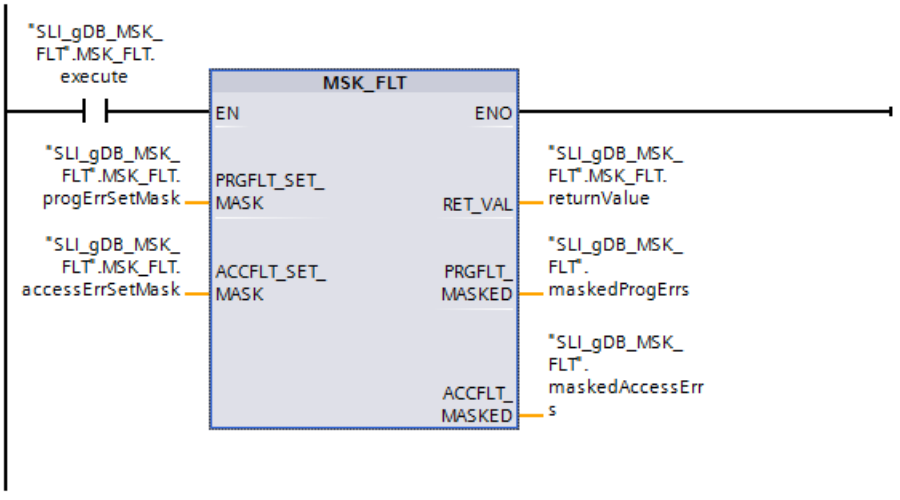
Network 1:

Create the following interconnection in the OB.



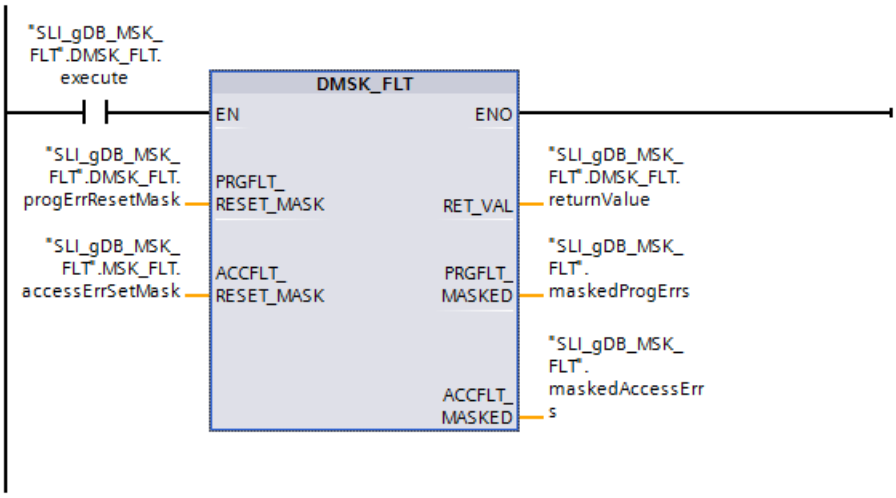
Interconnect parameters: "SLI_FC_MSK_FLT" FC

To call the program parts, create the FC "SLI_FC_MSK_FLT".



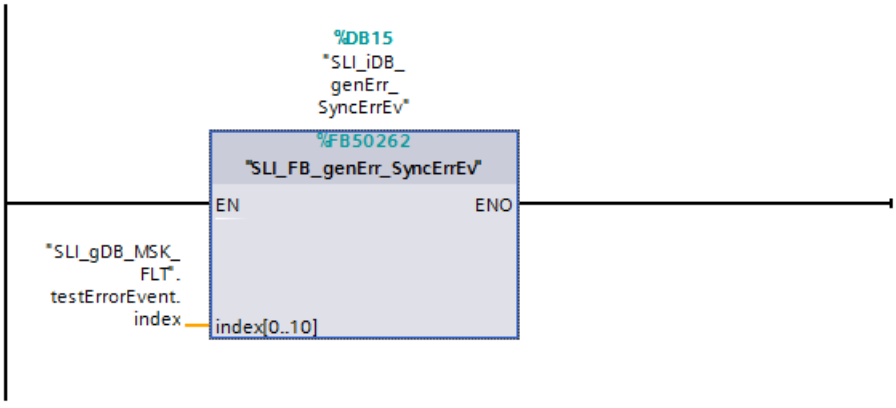
Network 1:

Interconnect the parameters of the FC "SLI_mask_SyncErrEv" as well as the tags "peOB_unmased_active", "MSK_FLT.execute" and "maskedProgErrs" as follows.



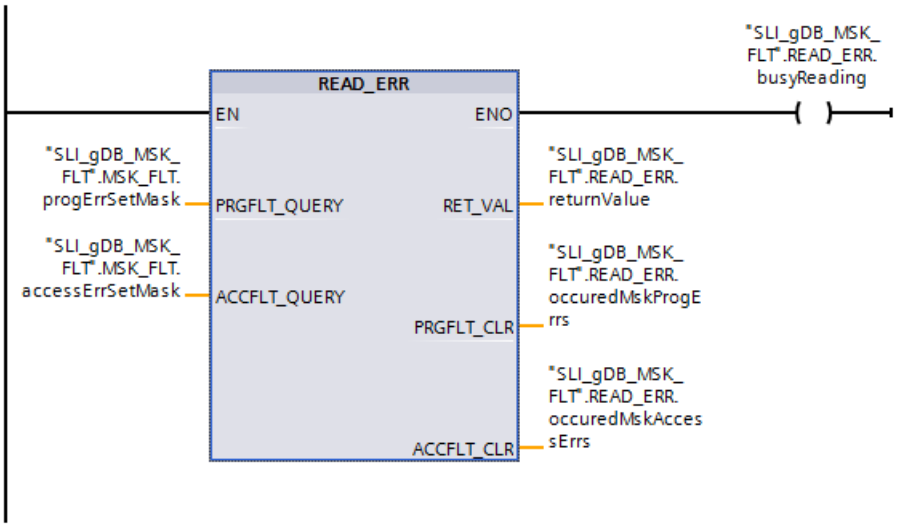
Network 2:

Interconnect the parameters of the "MSK_FLT" instruction as follows.



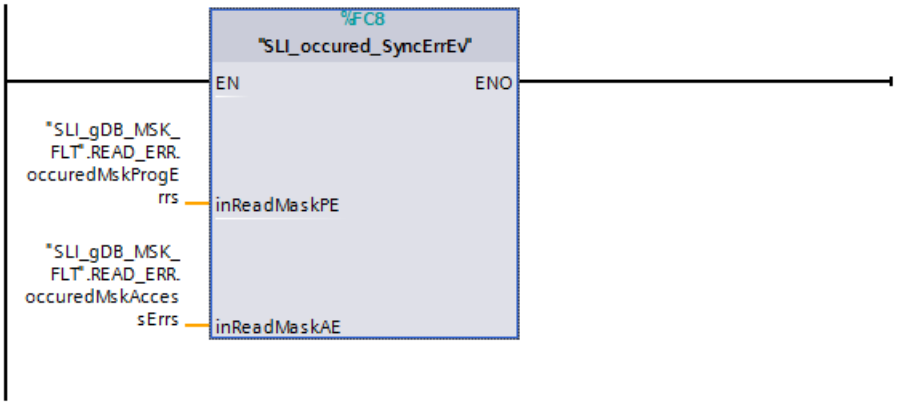
Network 3:

Interconnect the parameters of the "DMSK_FLT" instruction as follows.



Network 4:

Interconnect the parameters of the "SLI_FB_genErr_SyncErrEv" FC as follows.



Network 5:

Interconnect the parameters of the "READ_ERR" instruction as follows.

Network 6:

Interconnect the parameters of the "SLI_occured_SyncErrEv" FC as follows.

Result of OB "SLI_peOB_SyncErrEv"

When a program error was triggered and is not masked by a filter, the program error OB "SLI_peOB_SyncErrEv" is executed.

The tag "READ_ERR.peOB_unmasked_active" is then set to "TRUE" in network 1 of the OB.

Result of FC "SLI_FC_MSK_FLT"

Network 1 (FC "SLI_mask_SyncErrEv"):

By calling the FC "SLI_mask_SyncErrEv", the structures for program errors and access errors are converted into the data type DWORD ("progErrSetMask" and "accessErrSetMask").

Reset the value because the value "TRUE" of the tag "READ_ERR.peOB_unmasked_active" is still displayed even after calling the program error OB. If the instruction "MSK_FLT" is not executed successfully ("MSK_FLT.execute" has the value "FALSE"), the tag "maskedProgErrs" is reset.

Network 2 ("MSK_FLT"):

When the normally open contact ("MSK_FLT.execute") supplies the signal state "TRUE", the "MSK_FLT" instruction is executed.

The synchronous error events that have to be controlled are specified according to the tags "progErrMask_Details" and "accessErrMask_Details":

- You specify the program errors you want to mask with "progErrMask_Details".
- No access errors ("accessErrMask_Details") were masked in the example.

The synchronous error events that have to be controlled are stored in the data type DWORD with the input parameters PRGFLT_SET_MASK ("MSK_FLT.progErrSetMask") and ACCFLT_SET_MASK ("MSK_FLT.accessErrSetMask").

The output parameter RET_VAL ("MSK_FLT.returnValue") indicates that none of the errors was already masked. The currently masked synchronous error events are displayed at the output parameters "PRGFLT_MASKED" ("maskedProgErrs") and ACCFLT_MASKED ("maskedAccessErrs").

2		maskedProgErrs	DWord	16#0	16#0000_003C
3		maskedAccessErrs	DWord	16#0	16#0000_0000
4		MSK_FLT	Struct		
5		execute	Bool	false	TRUE
6		progErrMask_Details	Struct		
7		accessErrMask_Details	Struct		
8		progErrSetMask	DWord	16#0	16#0000_003C
9		accessErrSetMask	DWord	16#0	16#0000_0000
10		returnValue	Int	0	0

Network 3 ("DMSK_FLT"):

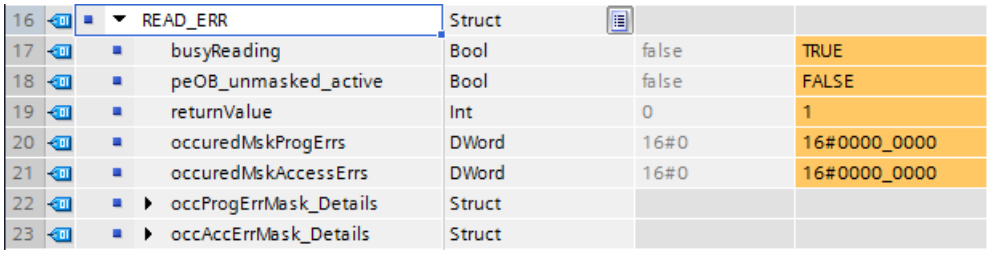
When the normally open contact ("DMSK_FLT.execute") supplies the signal state "TRUE", the "DMSK_FLT" instruction is executed. The synchronous error events that have to be unmasked are stored in the data type DWORD with the input parameters PRGFLT_RESET_MASK ("DMSK_FLT.progErrResetMask") and ACCFLT_RESET_MASK ("DMSK_FLT.accessErrResetMask").

Output parameter RET_VAL ("DMSK_FLT.returnValue") indicates that all specified errors were unmasked.

11		DMSK_FLT	Struct		
12		execute	Bool	false	TRUE
13		progErrResetMask	DWord	16#0000_000C	16#0000_000C
14		accessErrResetMask	DWord	16#0	16#0000_0000
15		returnValue	Int	0	0

The currently masked synchronous error events are displayed at the output parameters "PRGFLT_MASKED" ("maskedProgErrs") and ACCFLT_MASKED ("maskedAccessErrs").

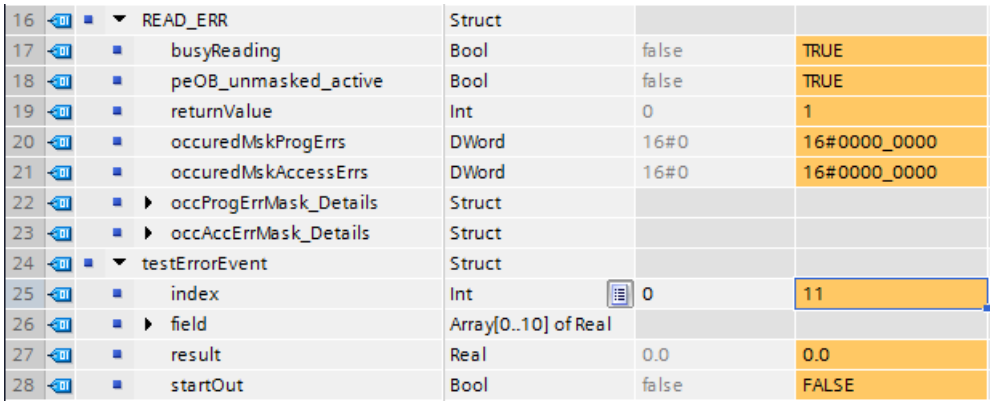
2		maskedProgErrs	DWord	16#0	16#0000_0030
3		maskedAccessErrs	DWord	16#0	16#0000_0000



Network 4 (FB "SLI_FB_genErr_SyncErrEv"):

When the tag "testErrorEvent.index" returns a value greater than "10", a program error is triggered.

Network 5 ("READ_ERR"):



The instruction "READ_ERR" reads the event status register. The synchronous error events that are to be read are stored in the data type DWORD with the input parameters PRGFLT_QUERY ("READ_ERR.progErrSetMask") and ACCFLT_QUERY ("READ_ERR.accessErrSetMask").

- Case 1 - The program error was not triggered. No masks are set:
  The output parameter RET_VAL ("READ_ERR.returnValue") indicates that at least one of the queried errors is not masked.
  The currently occurring error events are displayed at the output parameters "PRGFLT_CLR" ("READ_ERR.occuredMskProgErrs") and ACCFLT_CLR ("READ_ERR.occuredMskAccessErrs").

16	READ_ERR	Struct		
17	busyReading	Bool	false	TRUE
18	peOB_unmasked_active	Bool	false	FALSE
19	returnValue	Int	0	1
20	occuredMskProgErrs	DWord	16#0	16#0000_0000
21	occuredMskAccessErrs	DWord	16#0	16#0000_0000
22	occProgErrMask_Details	Struct		
23	occAccErrMask_Details	Struct		

- Case 2 - The program error was triggered and is not masked:
  MSK_FLT, DMSK_FLT are inactive. The program error OB is executed.

16	READ_ERR	Struct		
17	busyReading	Bool	false	TRUE
18	peOB_unmasked_active	Bool	false	TRUE
19	returnValue	Int	0	1
20	occuredMskProgErrs	DWord	16#0	16#0000_0000
21	occuredMskAccessErrs	DWord	16#0	16#0000_0000
22	occProgErrMask_Details	Struct		
23	occAccErrMask_Details	Struct		
24	testErrorEvent	Struct		
25	index	Int	0	11
26	field	Array[0..10] of Real		
27	result	Real	0.0	0.0
28	startOut	Bool	false	FALSE

- Case 3 - The triggered program error is masked:
  MSK_FLT is active. DMSK_FLT and the program error OB are inactive.

16	READ_ERR	Struct		
17	busyReading	Bool	false	TRUE
18	peOB_unmasked_active	Bool	false	FALSE
19	returnValue	Int	0	0
20	occuredMskProgErrs	DWord	16#0	16#0000_0004
21	occuredMskAccessErrs	DWord	16#0	16#0000_0000
22	occProgErrMask_Details	Struct		
23	occAccErrMask_Details	Struct		
24	testErrorEvent	Struct		
25	index	Int	0	11
26	field	Array[0..10] of Real		
27	result	Real	0.0	0.0
28	startOut	Bool	false	FALSE

  The following program error occurred according to the structure "occProgErrMask_Details":

22	occProgErrMask_Details	Struct		
23	BCD_conversion_error	Bool	false	FALSE
24	Area_length_error_when_reading	Bool	false	TRUE
25	Area_length_error_when_writing	Bool	false	FALSE
26	Range_error_when_reading	Bool	false	FALSE
27	Range_error_when_writing	Bool	false	FALSE

- Case 4 - The triggered program error is unmasked:
  MSK_FLT, DMSK_FLT and the program error OB are active.

16	READ_ERR	Struct		
17	busyReading	Bool	false	TRUE
18	peOB_unmasked_active	Bool	false	TRUE
19	returnValue	Int	0	1
20	occuredMskProgErrs	DWord	16#0	16#0000_0000
21	occuredMskAccessErrs	DWord	16#0	16#0000_0000
22	occProgErrMask_Details	Struct		
23	occAccErrMask_Details	Struct		
24	testErrorEvent	Struct		
25	index	Int	0	11
26	field	Array[0..10] of Real		
27	result	Real	0.0	0.0
28	startOut	Bool	false	FALSE

Network 6 (FC "SLI_occured_SyncErrEv"):

By calling the FC "SLI_occured_SyncErrEv", the read program errors ("occuredMskProgErrs") and access errors ("occuredMskAccessErrs") are converted into the structures "occProgErrMask_Details" and "occAccErrMask_Details".

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

MSK_FLT: Mask synchronous error events (Page 3846)

DMSK_FLT: Unmask synchronous error events (Page 3847)

READ_ERR: Read out event status register (Page 3848)

Asynchronous error event (S7-1200, S7-1500)

DIS_IRT: Disable interrupt event (S7-1500)

Description

The instruction "DIS_IRT" is used to disable the processing of new interrupts and asynchronous error events. Disabling means that if an interrupting event occurs, the operating system of the CPU reacts as follows:

- It **neither** calls an interrupt OB nor an asynchronous error OB,
- **nor** does it trigger the normal reaction if an interrupt OB or asynchronous error OB is not programmed.

If you disable interrupts and asynchronous error events, this remains in effect for all priority classes. The disable is only canceled with the instruction "EN_IRT (Page 3863)" or by a warm or a cold restart.

Note

Remember that when you program the "DIS_IRT" instruction, all interrupts that occur will be discarded.

Parameters

The following table shows the parameters of the "DIS_IRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Specifies which interrupts and asynchro-nous errors are disabled.
OB_NR	Input	INT	I, Q, M, D, L or constant	OB number
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter MODE

MODE (B#16#...)	Meaning
00	All newly occurring interrupts and asynchronous error events are disabled (with the exception of the programming error and the error during direct access to I/O data and the Motion Control OBs). Assign the value "0" to the OB_NR parameter. Entries continue to be made in the diagnostics buffer.
01	All newly occurring events belonging to a specified interrupt class are disabled. Identify the interrupt class by specifying it as follows: • Time-of-day interrupts: 10 • Time-delay interrupts: 20 • Cyclic interrupts: 30 • Process interrupts: 40 • Interrupts for DPV1: 50 • Synchronous cycle interrupt: 60 • Redundancy error interrupts: 70 • Asynchronous error interrupts: 80 Entries continue to be made in the diagnostics buffer.
02	All new occurrences of a specified interrupt are disabled. You designate the interrupt using the OB number. Entries continue to be made in the diagnostics buffer.

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	The OB_NR input parameter contains an invalid value.
8091	The MODE input parameter contains an invalid value.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for DIS_IRT & EN_IRT (Page 3864).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

EN_IRT: Enable interrupt event (S7-1500)

Description

You use the instruction to enable the processing of new interrupts and asynchronous error events that you have previously disabled with the "DIS_IRT (Page 3861)" instruction. This means that if an interrupt event occurs, the CPU operating system reacts in one of the following ways:

- It calls an interrupt OB or asynchronous error OB.
  or
- it triggers the specified reaction if an interrupt OB or asynchronous error OB is not programmed.

Parameters

The following table shows the parameters of the "EN_IRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Specifies which interrupts and asynchronous error events will be enabled.
OB_NR	Input	INT	I, Q, M, D, L or constant	OB number
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter MODE

MODE	Meaning
0	All newly occurring interrupts and asynchronous error events are enabled with the exception of the programming error and the error during direct access to I/O data and the Motion Control OBs.
1	All newly occurring events belonging to a specified interrupt class are enabled. Identify the interrupt class by specifying it as follows: • Time-of-day interrupts: 10 • Time-delay interrupts: 20 • Cyclic interrupts: 30 • Process interrupts: 40 • Interrupts for DPV1: 50 • Synchronous cycle interrupt: 60 • Redundancy error interrupts: 70 • Asynchronous error interrupts: 80
2	All newly occurring events of a specified interrupt are enabled. You designate the interrupt using the OB number.

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error occurred.
8090	The OB_NR input parameter contains an invalid value.
8091	The MODE input parameter contains an invalid value.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for DIS_IRT & EN_IRT (Page 3864).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

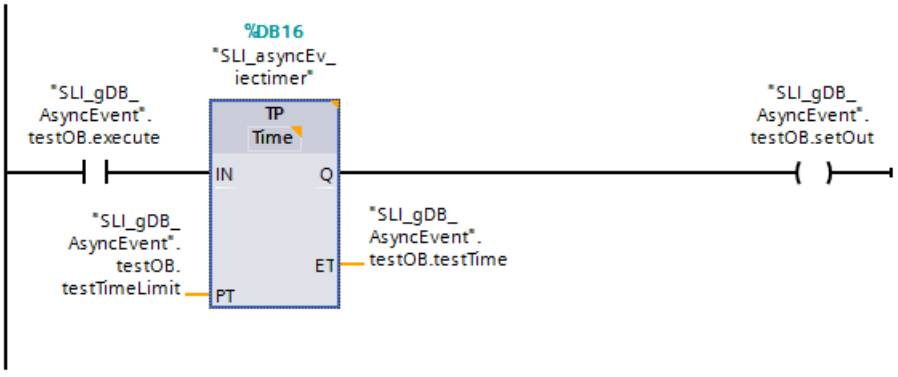
Program example for DIS_IRT & EN_IRT (S7-1200, S7-1500)

Introduction

In the following example you disable processing of a cyclic interrupt OB (OB33) with the help of the "DIS_IRT" instruction and enable OB33 once again with the instruction "EN_IRT".

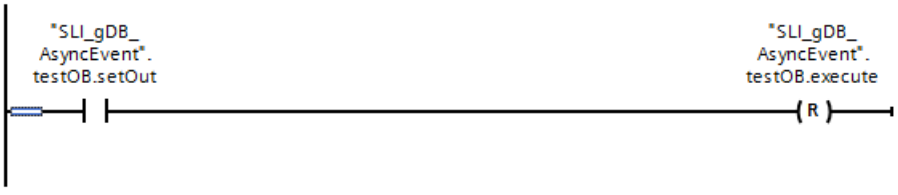
Storage of data

Create the following structures and tags for storing the data in a global data block.



SLI_gDB_AsyncEvent

	Name	Data type	Start value
1	Static		
2	DIS_IRT	Struct	
3	execute	Bool	false
4	done	Bool	false
5	mode	Byte	16#02
6	obNbr	Int	33
7	returnValue	Int	0
8	EN_IRT	Struct	
9	execute	Bool	false
10	done	Bool	false
11	mode	Byte	16#02
12	obNbr	Int	33
13	returnValue	Int	0
14	testOB	Struct	
15	execute	Bool	false
16	testTime	Time	T#0ms
17	testTimeLimit	Time	T#2m
18	setOut	Bool	false

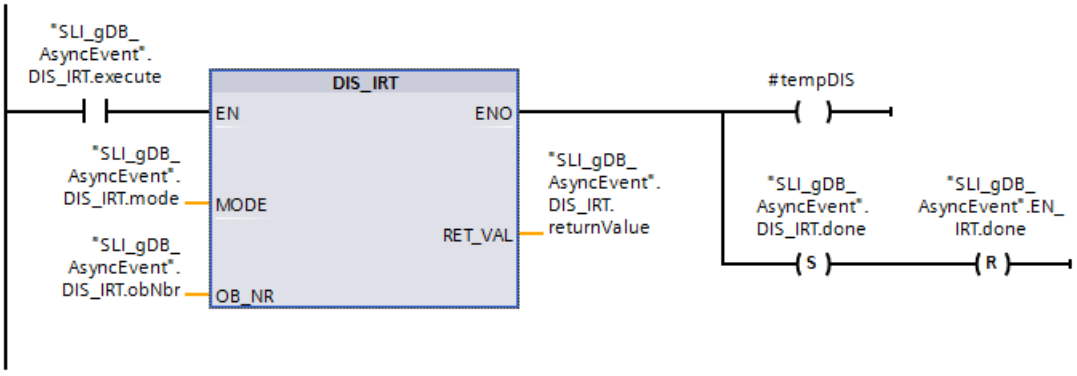


"SLI_ciOB_AsyncEvent" OB

You create an "SLI_ciOB_AsyncEvent" OB and monitor its behavior during disabling/enabling.

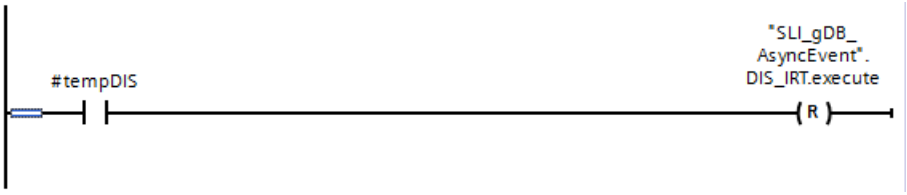
Network 1: You now call the instruction "TP" in the OB and create the following interconnections.

Network 2: Reset the tag "testOB.execute" as follows:



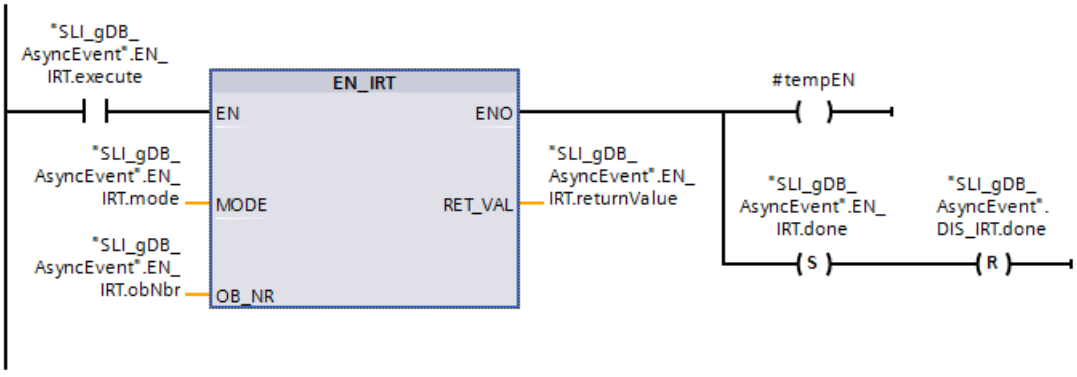
"SLI_FC_AsyncEvent" FC

To call the program parts, create the FC "SLI_FC_AsyncEvent".

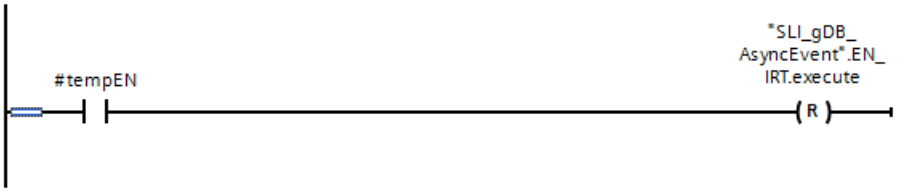


Create the following local tags in the FC.

7	Temp	
8	tempDIS	Bool
9	tempEN	Bool



Network 1: Interconnect the parameters of the "DIS_IRT" instruction as follows.



Network 2: Reset the tag "DIS_IRT.execute" as follows:

Network 3: Interconnect the parameters of the "EN_IRT" instruction as follows.

Network 4: Reset the tag "EN_IRT.execute" as follows:

Result of OB "SLI_ciOB_AsyncEvent"

If the normally open contact ("testOB.execute") supplies the signal state "TRUE" once, the "TP" instruction is executed. The tag "testOB.execute" is automatically reset to the signal state "FALSE". The value for the "testTime" tag is incremented until it corresponds to the value of the "testTimeLimit" tag.

SLI_gDB_AsyncEvent

	Name	Data type	Start value	Monitor value
1	Static			
2	DIS_IRT	Struct		
3	execute	Bool	false	FALSE
4	done	Bool	false	FALSE
5	mode	Byte	16#02	16#02
6	obNbr	Int	33	33
7	returnValue	Int	0	0
8	EN_IRT	Struct		
9	execute	Bool	false	FALSE
10	done	Bool	false	FALSE
11	mode	Byte	16#02	16#02
12	obNbr	Int	33	33
13	returnValue	Int	0	0
14	testOB	Struct		
15	execute	Bool	false	FALSE
16	testTime	Time	T#0ms	T#19S_100MS
17	testTimeLimit	Time	T#2m	T#2M
18	setOut	Bool	false	TRUE

Result of FC "SLI_FC_AsyncEvent"

Network 1:

If the normally open contact ("DIS_IRT.execute") supplies the signal state "TRUE", the "DIS_IRT" instruction is executed. The operating mode "2" to be used is specified according to the input parameter MODE ("DIS_IRT.mode"). OB33 is addressed and its processing disabled according to the input parameter OB_NR ("DIS_IRT.obNbr").

The output parameter RET_VAL ("DIS_IRT.returnValue") indicates that processing in the example is taking place without errors. You save the processing of "DIS_IRT" in the tag "DIS_IRT.done". You also reset the "EN_IRT.done" tag.

The value of the "testOB.testTime" tag is no longer incremented. Nevertheless, the IEC timer of the "TP" instruction continues to count in the background.

SLI_gDB_AsyncEvent

	Name	Data type	Start value	Monitor value
1	Static			
2	DIS_IRT	Struct		
3	execute	Bool	false	FALSE
4	done	Bool	false	TRUE
5	mode	Byte	16#02	16#02
6	obNbr	Int	33	33
7	returnValue	Int	0	0
8	EN_IRT	Struct		
9	execute	Bool	false	FALSE
10	done	Bool	false	FALSE
11	mode	Byte	16#02	16#02
12	obNbr	Int	33	33
13	returnValue	Int	0	0
14	testOB	Struct		
15	execute	Bool	false	FALSE
16	testTime	Time	T#0ms	T#28S_500MS
17	testTimeLimit	Time	T#2m	T#2M
18	setOut	Bool	false	TRUE

Network 2:

If the normally open contact ("#tempDIS") supplies the signal state "TRUE", the "DIS_IRT.execute" tag is reset.

Network 3:

If the normally open contact ("EN_IRT.execute") supplies the signal state "TRUE", the "EN_IRT" instruction is executed. The operating mode "2" to be used is specified according to the input parameter MODE ("EN_IRT.mode"). OB33 is addressed and its processing enabled once again according to the input parameter OB_NR ("EN_IRT.obNbr").

The output parameter RET_VAL ("EN_IRT.returnValue") indicates that processing in the example is taking place without errors. You save the processing of "EN_IRT" in the tag "EN_IRT.done". You also reset the "DIS_IRT.done" tag.

The value of the "testOB.testTime" tag is still incremented or changed according to the IEC timer of the "TP" instruction.

SLI_gDB_AsyncEvent

	Name	Data type	Start value	Monitor value
1	Static			
2	DIS_IRT	Struct		
3	execute	Bool	false	FALSE
4	done	Bool	false	FALSE
5	mode	Byte	16#02	16#02
6	obNbr	Int	33	33
7	returnValue	Int	0	0
8	EN_IRT	Struct		
9	execute	Bool	false	FALSE
10	done	Bool	false	TRUE
11	mode	Byte	16#02	16#02
12	obNbr	Int	33	33
13	returnValue	Int	0	0
14	testOB	Struct		
15	execute	Bool	false	FALSE
16	testTime	Time	T#0ms	T#1M_40S_800MS
17	testTimeLimit	Time	T#2m	T#2M
18	setOut	Bool	false	TRUE

Network 4:

If the normally open contact ("#tempEN") supplies the signal state "TRUE", the "EN_IRT.execute" tag is reset.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

DIS_AIRT: Delay execution of higher priority interrupts and asynchronous error events (S7-1200, S7-1500)

Description

You use "DIS_AIRT" to delay the processing of interrupt OBs whose priority are higher than the priority of the current organization block.

You can call "DIS_AIRT" multiple times in an organization block. The "DIS_AIRT" calls are counted by the operating system. Processing is delayed more and more each time "DIS_AIRT" is executed. To cancel a delay, you must execute the "EN_AIRT (Page 3870)" instruction. The processing delay applies until the number of executions of "EN_AIRT (Page 3870)" matches the number of calls of "DIS_AIRT" or the current OB has been worked through.

You query the number of delays in the RET_VAL parameter of the "DIS_AIRT instruction". If the value in the RET_VAL parameter is "0", there are no delays.

Parameters

The following table shows the parameters of the "DIS_AIRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Number of delays

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Return value	Description
n	"n" shows the number of processing delays, i.e., the number of DIS_AIRT calls, after the instruction is completed. If n = 0, interrupt handling is first enabled again; see EN_AIRT (Page 3870).

Example

You can find the example here: Program example for DIS_AIRT & EN_AIRT (Page 3871).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

EN_AIRT: Enable execution of higher priority interrupts and asynchronous error events (S7-1200, S7-1500)

Description

You use "EN_AIRT" to enable processing of organization blocks when interrupts occur that have been delayed by the "DIS_AIRT (Page 3869)" instruction.

When "EN_AIRT" is executed, you cancel a processing delay that was registered by the operating system when "DIS_AIRT (Page 3869)" was called. To cancel all delays, the number of "EN_AIRT" executions must be equal to the number of "DIS_AIRT (Page 3869)" calls. Example: You have called "DIS_AIRT (Page 3869)" five times. As a result, the processing is also delayed five times. After this, you must call the "EN_AIRT" instruction five times in order to cancel all five delays.

In the EN_AIRT parameter of the "EN_AIRT" instruction, you query the number of interrupt delays that have not yet been enabled after the execution of "RET_VAL". The value "0" in the RET_VAL parameter means that all delays enabled by "DIS_AIRT (Page 3869)" have been cancelled.

Parameters

The following table shows the parameters of the "EN_AIRT" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Number of configured delays

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Return value/ Error code* (W#16#...)	Description
n	"n" shows the number of processing delays that are not yet enabled after the instruction is completed. If n = 0, interrupt handling is first enabled again.
8080	Although the interrupt processing was already enabled, the function was called again.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

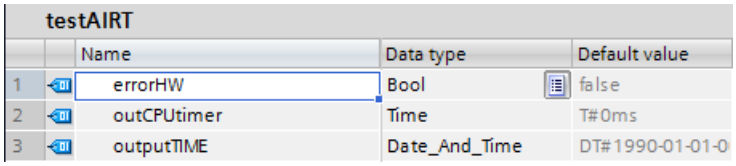
Example

You can find the example here: Program example for DIS_AIRT & EN_AIRT (Page 3871).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Program example for DIS_AIRT & EN_AIRT (S7-1200, S7-1500)

Introduction



In the following example you delay processing of a cyclic interrupt OB or of interrupt OBs with a higher priority with the help of the instructions "DIS_AIRT" and "EN_AIRT". A test program is not interrupted by an interrupt when you call the instructions.

You use the test program to save the time and diagnostics data in a data memory.

- To do this, you read out the CPU time with the instruction "TIME_TCK" and the diagnostics data with the instruction "GET_DIAG" in a cyclic interrupt OB.
- In a cyclic OB (OB1), you also read out the system time of the CPU clock with the instruction "RD_SYS_T".

Storage of data

Create the PLC data type "testAIRT" for the data memory.

testAIRT

		Name	Data type	Default value
1		errorHW	Bool	false
2		outCPUtimer	Time	T#0ms
3		outputTIME	Date_And_Time	DT#1990-01-01-0

Create the following structures and tags for storing the data in a global data block.

- For DIS_AIRT, EN_AIRT, and time recording:

SLI_gDB_delayAIRT			
	Name	Data type	Start value
1	Static		
2	startOB1	Bool	false
3	startOB_ci	Bool	false
4	delay	Struct	
5	executeDel	Bool	false
6	executeEn	Bool	false
7	nbrOfDelays	Int	0
8	timeData	Struct	
9	retValRDsys	Int	0
10	outCPUtimer	Time	T#0ms

- For diagnostics:

Note

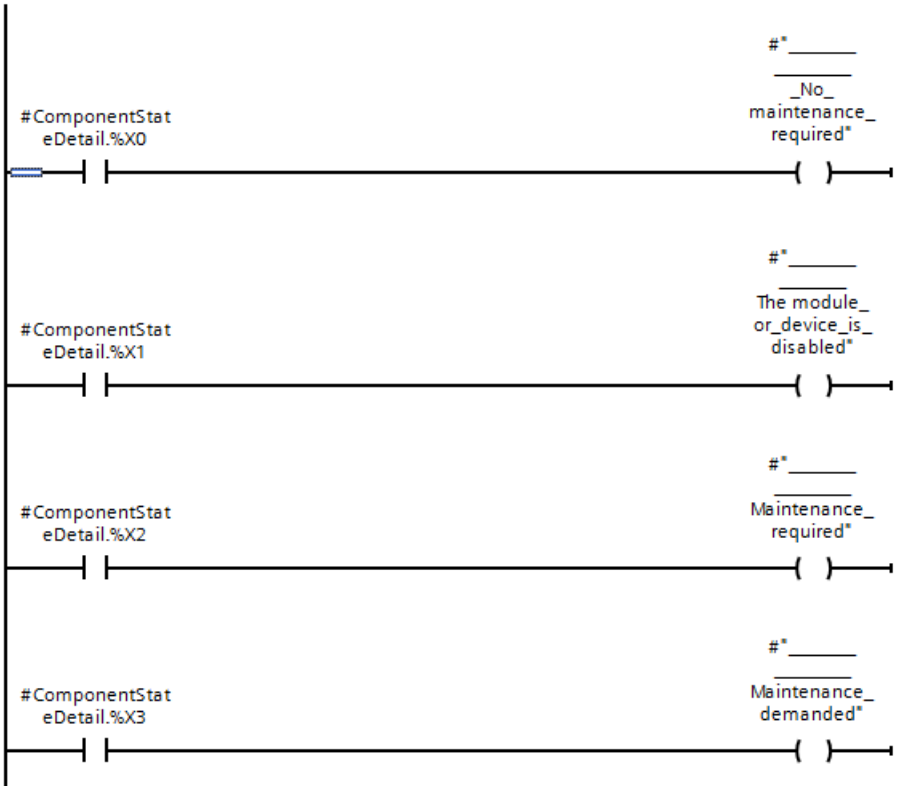
Find hardware identifier ("laddr")

Use "PLC tags > System constants" to find the hardware identifier. For an S7-1500 CPU: Find the entry "Local~Common" with the data type "HW_Submodule". The associated cell "value" contains the hardware identifier.

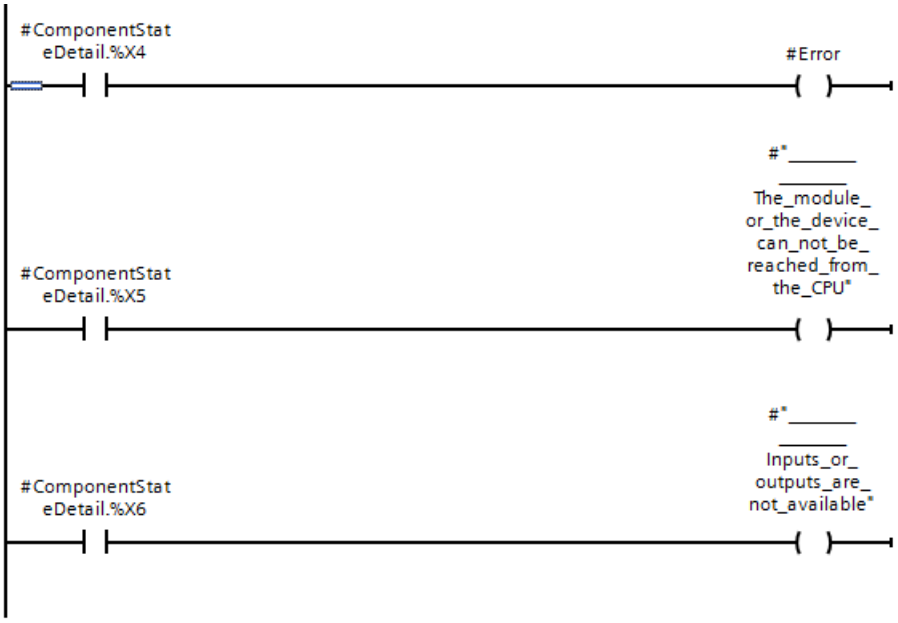
11	diag	Struct	
12	mode	UInt	2
13	laddr	HW_ANY	50
14	returnValue	Int	0
15	countDiagDetails	UInt	0
16	getDIAG	DNN	
17	SubordinateState	UInt	0
18	SubordinateIOState	Word	16#0
19	DNNmode	Word	16#0
20	itemiseIOState	Struct	
21	No_maintenance_required	Bool	false
22	The module_or_device_is_disabled	Bool	false
23	Maintenance_required	Bool	false
24	Maintenance_demanded	Bool	false
25	Error	Bool	false
26	The_module_or_the_device_can_not_be_reached_from_the_CPU	Bool	false
27	Inputs_or_outputs_are_not_available	Bool	false

- For the data memory:

28	dataStorage	Array[0..3] of "testAIRT"	
29	pos	Int	0



Interconnect parameters: in the FC "SLI_FC_itemise_IOState_AIRT"

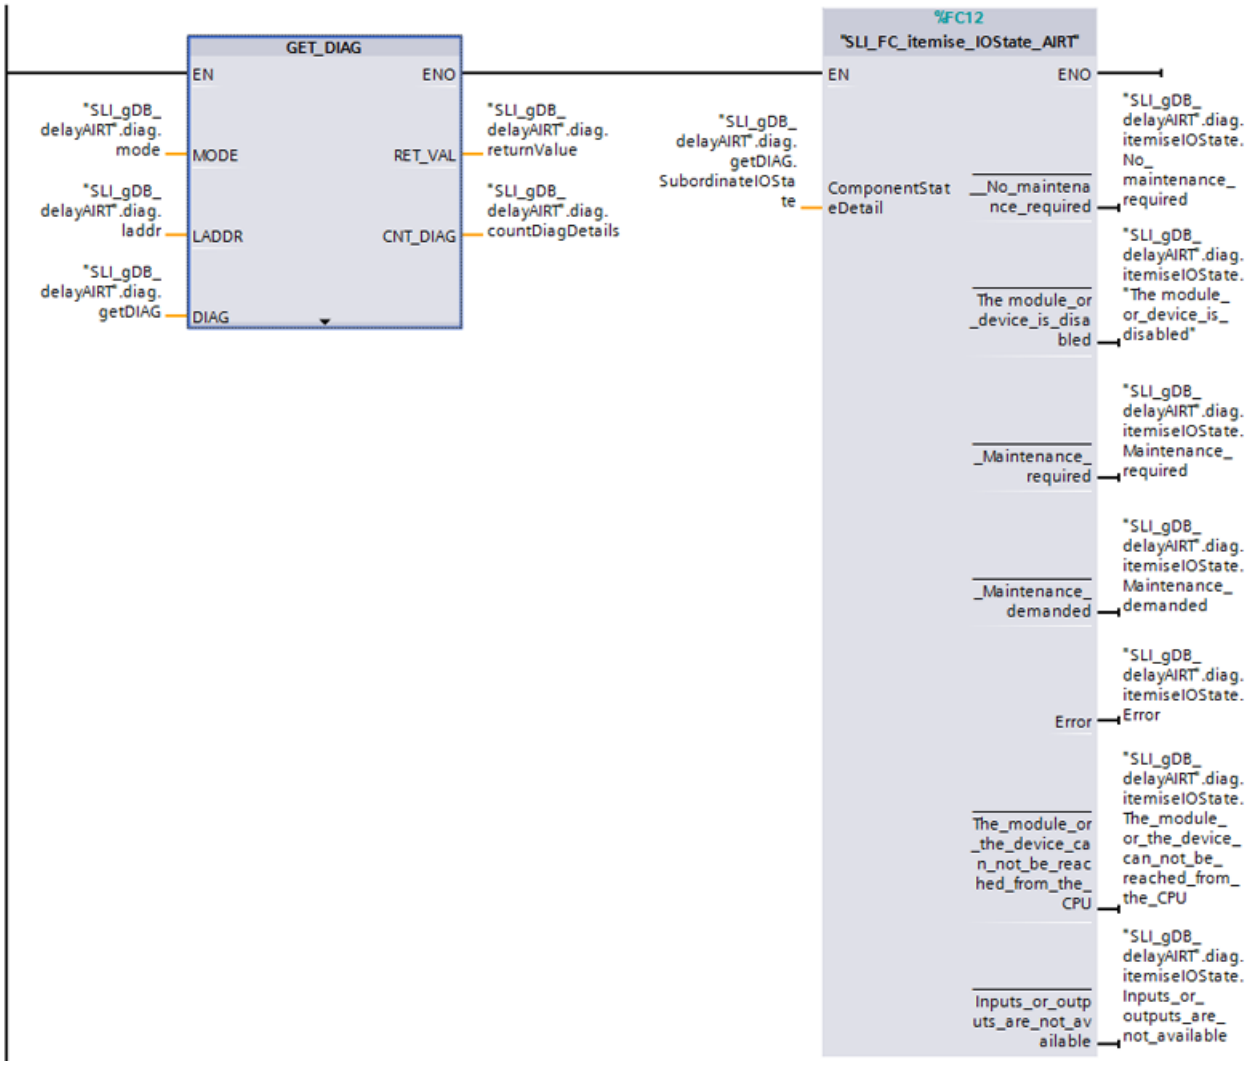


To further evaluate the diagnostics data of the "GET_DIAG" instruction, create an FC "SLI_FC_itemise_IOState_AIRT".

Create the following local tags in the FC.

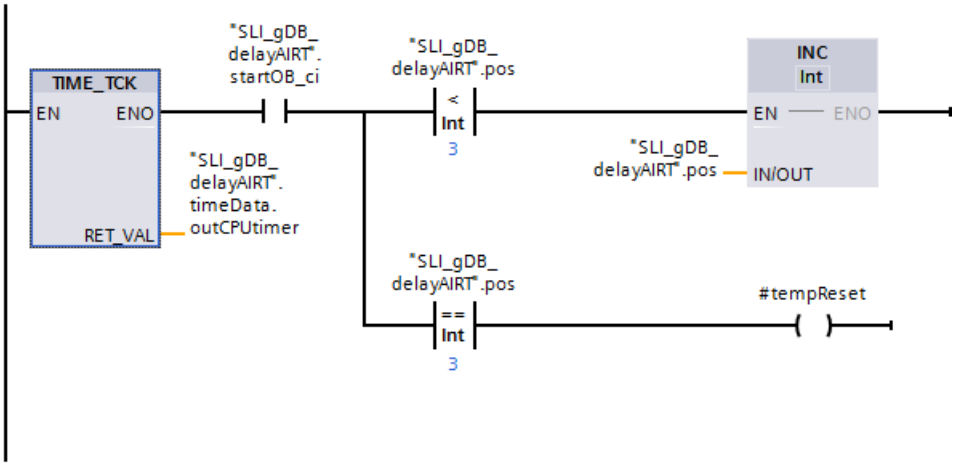
SLI_FC_itemise_IOState_AIRT		
	Name	Data type
1	Input	
2	ComponentStateDetail	Word
3	Output	
4	_____No_maintenance_required	Bool
5	_____The module_or_device_is_disabled	Bool
6	_____Maintenance_required	Bool
7	_____Maintenance_demanded	Bool
8	Error	Bool
9	_____The_module_or_the_device_can_not_be_reached_from_the_CPU	Bool
10	_____Inputs_or_outputs_are_not_available	Bool

Network 1: You create the following interconnections.

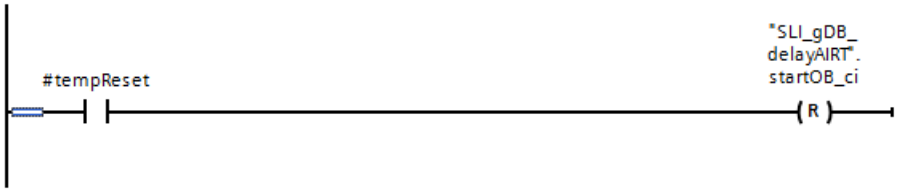


Interconnect parameters: in the "SLI_ciOB_diagProg_AIRT" OB

You create a cyclic interrupt OB "SLI_ciOB_diagProg_AIRT" and monitor its behavior during the delay.



You create the following local tag in the OB.

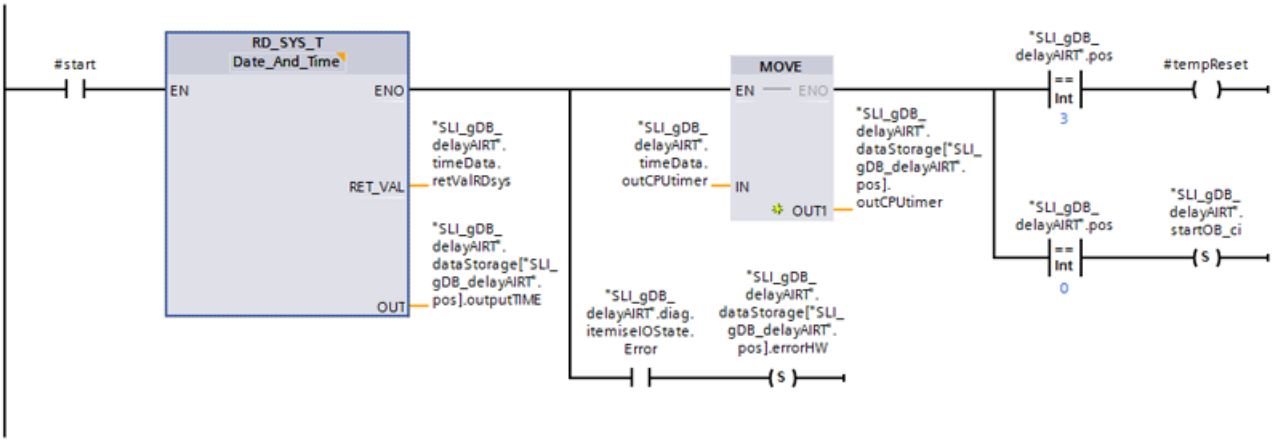


Network 1: You now call the instruction "GET_DIAG" in the OB and create the following interconnections.

Network 2: You record the CPU time as follows and increment the "pos" tag according to the following condition.

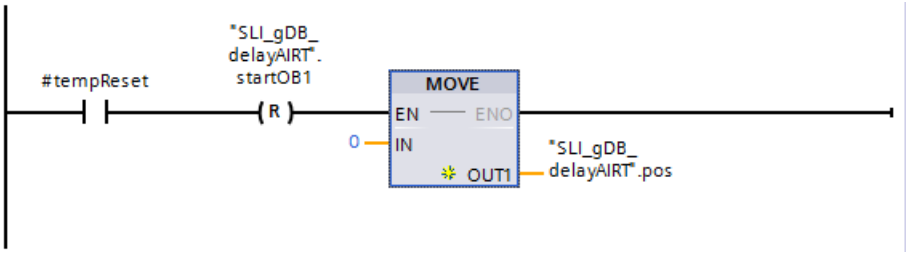
Network 3: Reset the tag "startOB_ci" as follows:

Interconnect parameters: in the FC "SLI_FC_saveDiag_AIRT"



To read the system time and merge the time and diagnostics data, create the FC "SLI_FC_saveDiag_AIRT".

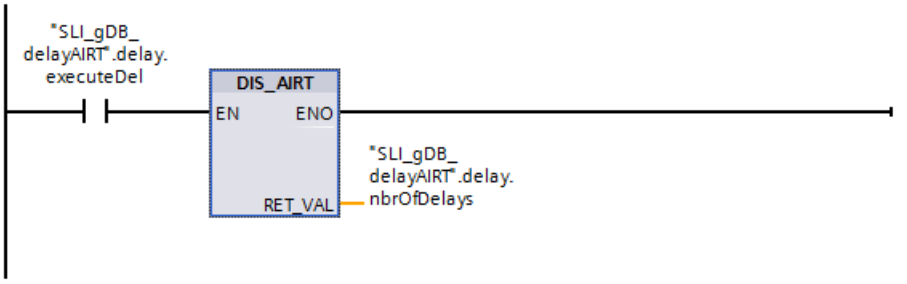
Create the following local tags in the FC.



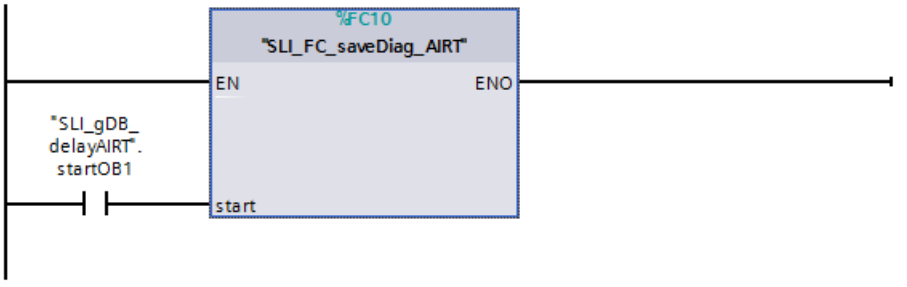
SLI_FC_saveDiag_AIRT

	Name	Data type
1	Input	
2	start	Bool
3	Output	
4	<Add new>	
5	InOut	
6	<Add new>	
7	Temp	
8	tempReset	Bool

Network 1: You create the following interconnections.

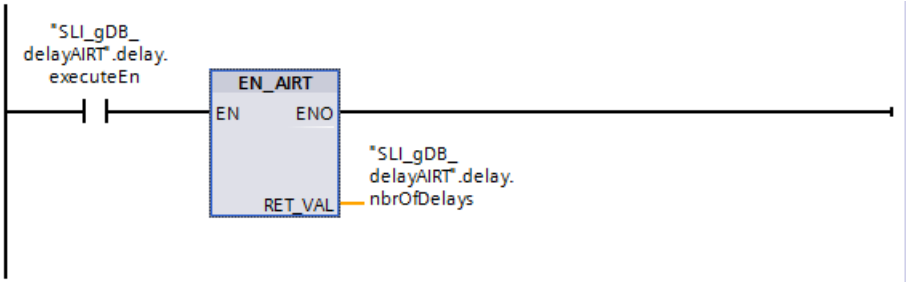


Network 2: Reset the tag "startOB1" as follows:



Interconnect parameters: in the FC "SLI_FC_delayAIRT"

To call the test program, create the FC "SLI_FC_delayAIRT".



Network 1: Interconnect the parameters of the "DIS_AIRT" instruction as follows.

Network 2: Interconnect the FC "SLI_FC_saveDiag_AIRT" as follows.

Network 3: Interconnect the parameters of the "EN_AIRT" instruction as follows.

Procedure for starting the test scenario

To start the test program, follow these steps:

Note

If you do not want to delay processing of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT"), skip steps 1 and 2.

1. Set the tag "delay.executeDel" to "TRUE".
2. Set the tag "delay.executeEn" to "TRUE".
3. Set the tag "startOB1" to "TRUE". Afterwards, the tag "startOB_ci" is set automatically. The "startOB1" tag and the "startOB_ci" tag are automatically reset after filling the data memory.

Procedure for stopping the processing of DIS_AIRT and EN_AIRT

To stop the delayed processing of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT"), follow these steps:

1. Set the tag "delay.executeEn" to "FALSE".
2. Set the tag "delay.executeDel" to "FALSE".

Result of OB "SLI_ciOB_diagProg_AIRT"

The cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT") is called every 100 ms. It reads the diagnostics data with the instruction "GET_DIAG" and outputs the CPU time.

If the normally open contact ("startOB_ci") supplies the signal state "TRUE" and the "pos" tag returns a value greater than "3", the "pos" tag is incremented. If the "pos" tag returns the value "3", the "startOB_ci" tag is reset.

SLI_gDB_delayAIRT

	Name	Data type	Start value	Monitor value
1	Static			
2	startOB1	Bool	false	FALSE
3	startOB_ci	Bool	false	FALSE
4	delay	Struct		
5	executeDel	Bool	false	FALSE
6	executeEn	Bool	false	FALSE
7	nbrOfDelays	Int	0	0
8	timeData	Struct		
9	retValRDsys	Int	0	0
10	outCPUtimer	Time	T#0ms	T#5M_26S_588MS

If execution of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT") is not delayed, the values of the data memory appear as below.

28	dataStorage	Array[0..3] o...		
29	dataStorage[0]	"testAIRT"		
30	errorHW	Bool	false	FALSE
31	outCPUtimer	Time	T#0ms	T#2M_9S_388MS
32	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-09:58:24.384
33	dataStorage[1]	"testAIRT"		
34	errorHW	Bool	false	FALSE
35	outCPUtimer	Time	T#0ms	T#2M_9S_488MS
36	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-09:58:24.484
37	dataStorage[2]	"testAIRT"		
38	errorHW	Bool	false	FALSE
39	outCPUtimer	Time	T#0ms	T#2M_9S_588MS
40	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-09:58:24.585
41	dataStorage[3]	"testAIRT"		
42	errorHW	Bool	false	FALSE
43	outCPUtimer	Time	T#0ms	T#2M_9S_688MS
44	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-09:58:24.587
45	pos	Int	0	0

Result of FC "SLI_FC_delayAIRT"

Network 1:

If the normally open contact ("delay.executeDel") supplies the signal state "TRUE", the "DIS_AIRT" instruction is executed. Processing of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT") or of an interrupt OB with higher priority is delayed. The output parameter RET_VAL ("delay.nbrOfDelays") indicates that a delay is active in the calling OB (OB1).

Network 2:

If the normally open contact ("startOB1") supplies the signal state "TRUE", the test program of the FC "SLI_FC_saveDiag_AIRT" is executed.

In the FC "SLI_FC_saveDiag_AIRT":

The system time is read with the instruction "RD_SYS_T" and stored in the data memory "dataStorage". The cell of the data memory that is to be used is determined by the "pos" tag.

The CPU time ("outCPUtimer") is also stored in the data memory. If the "diag.itemiseIOState.Error" tag has the signal state "TRUE", the "errorHW" tag is set to "TRUE" in the data memory.

The following is decided in the next steps:

- If "pos" has the value "0": The value of the "startOB_ci" tag is set to "TRUE". This means the "pos" tag can be incremented in the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT").
- If "pos" has the value "3": The tags "startOB1" and "pos" are reset.

If execution of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT") is delayed, the values of the data memory appear as below.

28	dataStorage	Array[0..3] o...		
29	dataStorage[0]	"testAIRT"		
30	errorHW	Bool	false	FALSE
31	outCPUtimer	Time	T#0ms	T#25M_52S_688MS
32	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-10:22:07.684
33	dataStorage[1]	"testAIRT"		
34	errorHW	Bool	false	FALSE
35	outCPUtimer	Time	T#0ms	T#25M_52S_788MS
36	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-10:22:07.784
37	dataStorage[2]	"testAIRT"		
38	errorHW	Bool	false	FALSE
39	outCPUtimer	Time	T#0ms	T#25M_52S_888MS
40	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-10:22:07.884
41	dataStorage[3]	"testAIRT"		
42	errorHW	Bool	false	FALSE
43	outCPUtimer	Time	T#0ms	T#25M_52S_988MS
44	outputTIME	Date_And_Time	DT#1990-01-01-0	DT#2017-01-20-10:22:07.887
45	pos	Int	0	0

Network 3:

If the normally open contact ("delay.executeEn") supplies the signal state "TRUE", the "EN_AIRT" instruction is executed. Processing of the cyclic interrupt OB ("SLI_ciOB_diagProg_AIRT") or of an interrupt OB with higher priority is enabled once again. The output parameter RET_VAL ("delay.nbrOfDelays") indicates that a delay is not active in the calling OB (OB1). Processing in the example takes place without errors.

SLI_gDB_delayAIRT

	Name	Data type	Start value	Monitor value
1	Static			
2	startOB1	Bool	false	FALSE
3	startOB_ci	Bool	false	FALSE
4	delay	Struct		
5	executeDel	Bool	false	TRUE
6	executeEn	Bool	false	TRUE
7	nbrOfDelays	Int	0	0
8	timeData	Struct		
9	retValRDsys	Int	0	0
10	outCPUtimer	Time	T#0ms	T#27M_36S_988MS

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

EN_AIRT: Enable execution of higher priority interrupts and asynchronous error events (Page 3870)

11.4.4.8 Alarms (S7-1200, S7-1500)

Program_Alarm: Generate program alarm with associated values (S7-1500)

Description

The instruction "Generate program alarm with associated values" monitors a signal and on a signal change at the parameterSIG generates a program alarm (for definition, see also: AUTOHOTSPOT). An incoming program alarm is generated with a signal change from 0 to 1 and an outgoing program alarm is generated with a signal change from 1 to 0. The program alarm is triggered synchronously to program execution.

You can append up to ten associated values to the program alarm at the parametersSD_i (0 ≤ i ≤10). The associated values are detected at the time of signal change at parameter SIG and assigned to the program alarm. For more information on configuring associated values, refer to the following sections: AUTOHOTSPOT, AUTOHOTSPOT.

Each incoming or outgoing alarm is assigned a time stamp:

- The current system time of the PLC when the signal change occurs is used by default (default value at the TIMESTAMP parameter).
- If you wish to specify a different time stamp, you can create one at the parameter TIMESTAMP.
  The time value must always be specified in system time (i.e. UTC) as this is the time used for time synchronization throughout the plant.
- If an alarm is to be time-stamped with a local time, a conversion module, which converts the local time to system time, must be connected in series. This is the only way to make sure that the time stamp is shown properly in the alarm display.

To use the current system time of the CPU, set the TIMESTAMP parameter to its default value (LDT#1970-01-01-00:00:00.0).

Call of the instruction "Generate program alarm with associated values"

Call the instruction only in a function block (FB). The block is processed synchronously. An alarm is triggered as soon as the block is exited. If there is an error during processing, an error code is output.

Once the instruction has been inserted in the FB, a multi-instance of the data type "Program_Alarm" is created in the "Static" section of the block interface. Choose any name for this multi-instance in the dialog which appears. It is also the name of the program alarm.

Finally, add the parameters of the instruction in line with your requirements (see the "Parameters" table).

Configuring the program alarm

The program alarm settings are displayed in the "Properties" window when you select the name of the program alarm in the "Static" section or in the network of the FB. Select the alarm class, priority, etc. and edit the alarm text.

The settings that are made here can be edited in the project tree. To do this, open the "Alarms" tab under "PLC supervisions & alarms"; in it open the "Program alarms" tab. All existing program alarms are then displayed in the "Alarm types" table.

Parameters

The following table shows the parameters of the instruction "Generate program alarm with associated values":

Parameter	Declaration	Data type	Memory area	Description
SIG	Input	BOOL	I, Q, M, D, L, T, C or constant	The signal to be monitored. • Positive signal edge: An incoming program alarm is generated • Negative signal edge: An outgoing program alarm is generated
TIMESTAMP	Input	LDT	M, D, L or constant	This parameter is used to assign an alarm a time stamp, for example, from an input signal with a distributed stamp. The time value must always be specified in system time (i.e. UTC), as this is the time used for time synchronization throughout the plant. • "Not assigned" means that the system time of the CPU will be used as the interrupt time stamp when a signal change occurs (default). • Any system time input will be used as the interrupt time stamp when a signal change occurs. Note: If an interrupt is to be time-stamped with a local time, a conversion module must be connected in series to convert the local time to system time. This is the only way to make sure that the time stamp is shown correctly in the interrupt display.

Parameter	Declaration	Data type	Memory area	Description
SD_i	Input	VARIANT	I, Q, M, D, L	i-th associated value (1 ≤ i ≤ 10) You can use binary numbers, integers, floating-point numbers, or character strings as associated values.
Error	Output	BOOL	I, Q, M, D, L	Status parameter Error Error = TRUE indicates that an error has occurred during processing. The possible error cause is displayed at the Status parameter.
Status	Output	WORD	I, Q, M, D, L	Status parameter Status Display of error information (see "Error and Status parameters").

You can find additional information on valid data types under "See also".

Error and Status parameters

The following table contains all specific error information that is output via the Error and Status parameters.

Error	Status*	Explanation
0	0000	No error, or the instruction was not processed because there was no signal edge at the parameter SIG.
1	0085	"Only information" alarm type
1	8001	Invalid static alarm information
1	8002	No valid static alarm information
1	8004	Maximum size of 512 bytes reached for the associated values of the alarm.
1	8005	A positive signal edge is pending at parameter SIG and there is still an alarm pending which has not yet been acknowledged.
1	8007	Outgoing alarm which was not preceded by an incoming alarm.
1	8087	Static alarms are deactivated.
1	8089	Alarm is too long.
1	80Ax	The SD_i parameter has an invalid value.
1	80C1	The CPU does not generate any alarms at this time because initialization routines are running (this is the case after download in RUN, for example). Try again later.
1	80C2	The maximum number of alarms per time unit has been sent. Try again later.
1	80C3	All dynamic alarm instances are being used. Try again later.
1	80C4	Alarm is output and is not overwritten. Try again later.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

Example

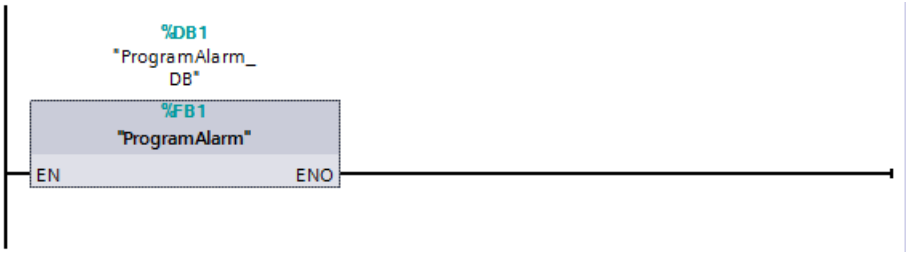
In the following example, you generate a program alarm with associated value for a signal change.

Create one tag in a global data block for storing the signal value to be monitored.

Program_Alarm_Tags

		Name	Data type	Start value
1		Static		
2		CreateAlarm	Bool	false

The instruction is called in a function block. Create four parameters for the function block for interconnection of the instruction.

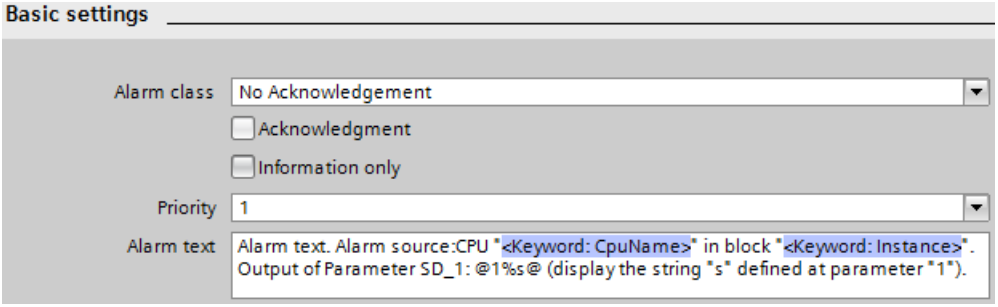


ProgramAlarm

		Name	Data type	Default value
1		Input		
2		<Add new>		
3		Output		
4		<Add new>		
5		InOut		
6		<Add new>		
7		Static		
8		MyStaticText	String	'MyStaticText'
9		Program_Alarm_1	Program_Alarm	
10		Temp		
11		OUTPUT_Error	Bool	
12		OUTPUT_Status	Word	

Interconnect the parameters of the instruction as follows.

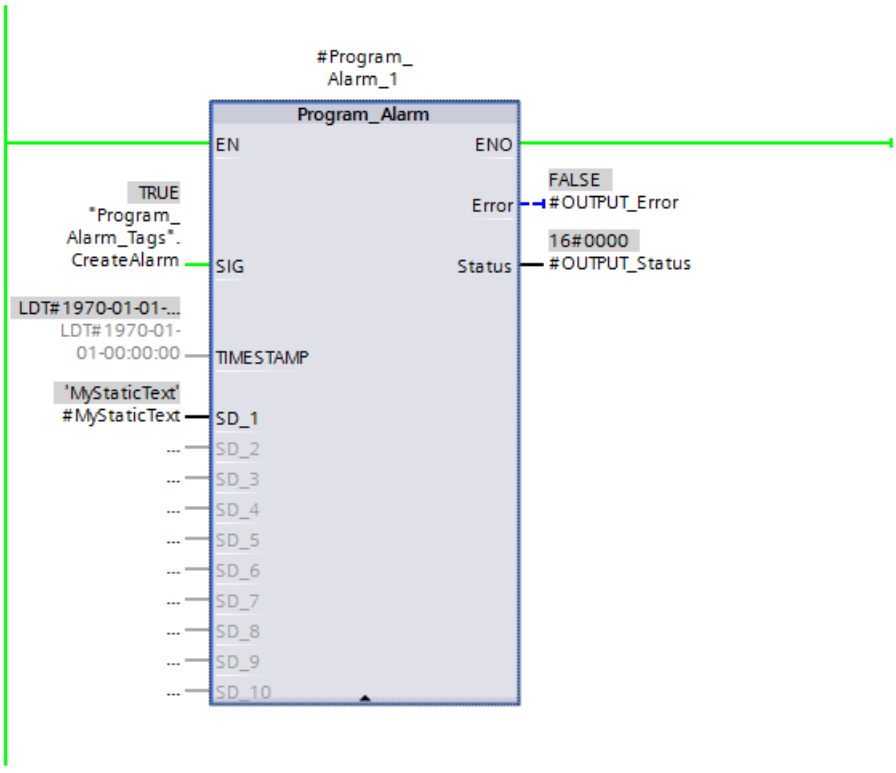
Call the function block in an OB.



A PLC alarm is generated automatically when the instruction is created. Open the PLC supervisions & alarms dialog and select the alarm to be edited in the Alarms > Program alarms tab. Create the alarm text, including two key words in the Properties > Basic settings of the alarm.

Note: If you right-click in the text box, you can insert a key word, tag, or text list.

As a result of the character sequence "@1%s@", the value of parameter SD_1 ("#MyStaticText") is read out and output as a character string.



See also:

- AUTOHOTSPOT
- AUTOHOTSPOT
- Keywords for alarm texts

If parameter SIG ("CreateAlarm") has the signal state "TRUE", the PLC alarm is output. At output parameter STATUS ("OUTPUT_Status"), the value "0001" indicates that a signal change has occurred. Then, it is indicated that no further processing is taking place (the value is "0000"). At parameter SD_1 ("#MyStaticText"), the associated value of the PLC alarm is output.

A time stamp can be transferred to parameter TIMESTAMP. If not interconnected, parameter TIMESTAMP outputs the local time of the CPU clock. At output parameter ERROR ("OUTPUT_Error"), it is indicated that the processing of the instruction was error-free.

Use the web server of the CPU, for example, to output the PLC alarm. The following is necessary in order to use the web server:

- The web server must be activated in the CPU settings.

Use the Internet browser to open the Web server (via the IP address of the CPU) and log on in the Web server menu. The CPU outputs the alarm text as long as the signal being monitored ("CreateAlarm") supplies the value "TRUE".

Time	Message text
02:32:09.226 pm	Alarm text. Alarm source:CPU "PLC_2" in block "ProgramAlarm_DB". Output of Par

Program code

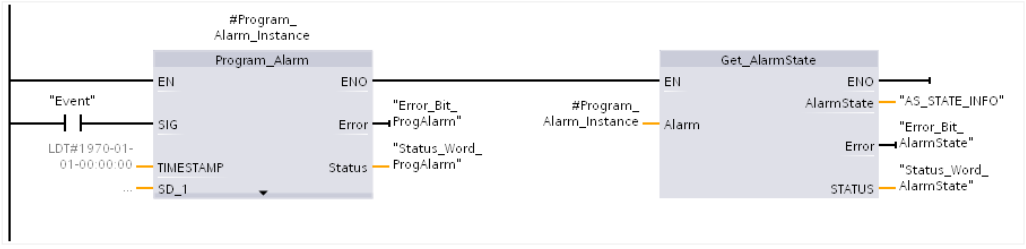
Overview of the valid data types (Page 2239)

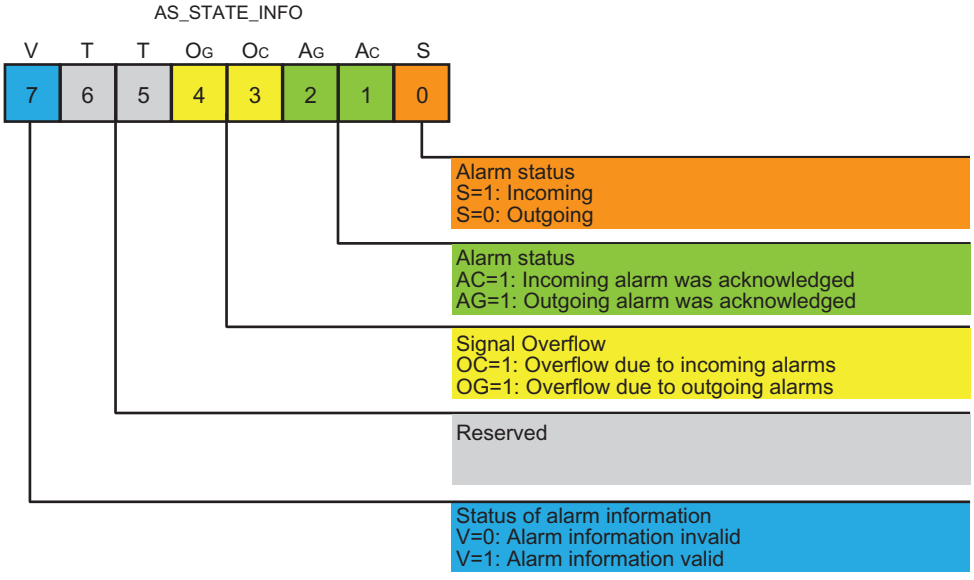
Get_AlarmState: Output alarm status (S7-1500)

Description



Use the instruction "Output alarm status" to output the alarm status of a program alarm.

There are three possible alarm statuses:



- Incoming
- Outgoing
- Acknowledged

The output of the alarm status always refers to a program alarm that was created using the instruction "Generate program alarm with associated values".

The program alarm is selected with the Alarm input parameter. Specify the instance DB of the instruction "Generate program alarm with associated values" at the parameter Alarm.

The alarm status is returned in a byte via the AlarmState output parameter. The meaning of the individual bits is shown in the following figure:

The execution status of the instruction is shown with the output parameters Error and STATUS.

Parameters

The following table lists the parameters of the instruction "Output alarm status":

Parameter	Declaration	Data type	Memory area	Description
Alarm	Input	ALARM_BASE	D	Instance of the instruction "Generate program alarm with associated values" • Alarm.Messagetype = Alarm_AP, the the bit Ac has either the signal status 0 or 1 and the bit Ag has the signal status 1 – not active: 0x86 (1000 0110) – active/not acknowledged: 0x85 (1000 0101) – active/acknowledged: 0x87 (1000 0111) – outgoing/not acknowledged: 0x84 (1000 0100) • Alarm.Messagetype = Notify_AP, the bits Ac and Ag both have the signal state 1. – not active: 0x86 (1000 0110) – active: 0x87 (1000 0111) • Alarm.Messagetype = Inforeport_AP, the bits Ac and Ag both have the signal status 1 – not active: 0x86 (1000 0110) – (temporarily) active: 0x87 (1000 0111) If the alarm is not active, bit S always has the signal state 0.
AlarmState	Output	BYTE	I, Q, M, D, L	Status of the alarm as a bit array

Parameter	Declaration	Data type	Memory area	Description
Error	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.

You can find additional information on valid data types under "See also".

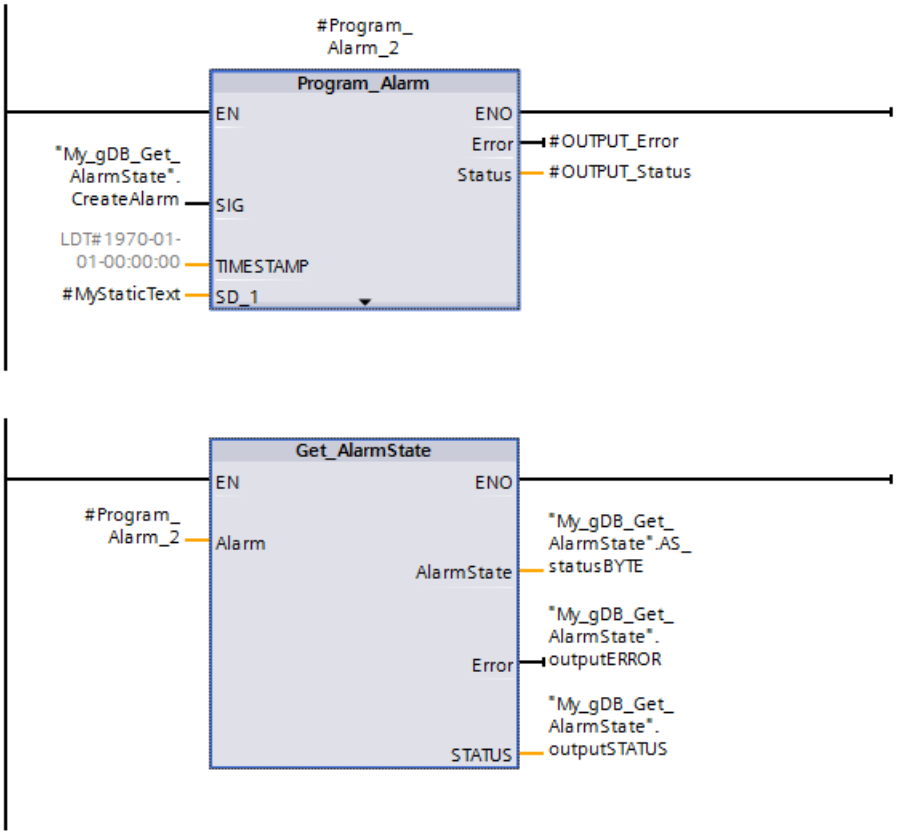
Parameter STATUS

Error code* (W#16#...)	Explanation
8001	Invalid static alarm instance
8002	ID of the alarm is invalid
8003	No active alarms within the alarm class • Alarm_AP: The alarm is outgoing and acknowledged. • Notify_AP: The alarm is outgoing. • Inforeport Bit V is set to signal status 0.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, you output the alarm status of a program alarm.

Create four tags in a global data block for storing the data.

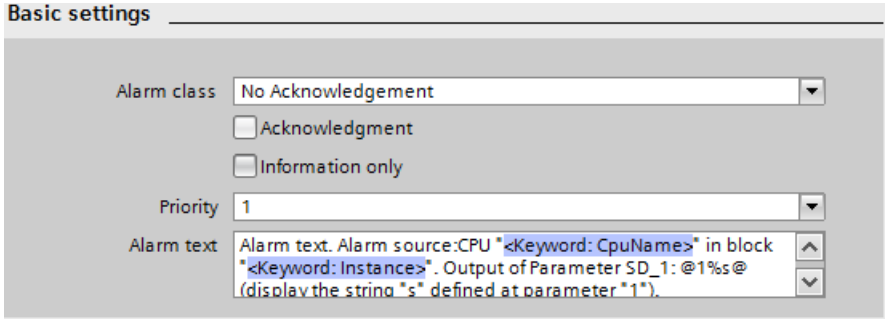


My_gDB_Get_AlarmState

	Name	Data type	Start value
1	Static		
2	AS_statusBYTE	Byte	16#0
3	outputERROR	Bool	false
4	outputSTATUS	Word	16#0
5	CreateAlarm	Bool	false

The "Get_AlarmState" instruction is called together with the "Program_Alarm" instruction in a function block. Create four parameters for the function block for interconnection of the instructions.

7		Static	
8		MyStaticText	String	'MyStaticText'
9		Program_Alarm_2	Program_Alarm	
10		Temp	
11		OUTPUT_Error	Bool	
12		OUTPUT_Status	Word	



Interconnect the parameters of the instructions as follows.

Call the function block in an OB.

A PLC alarm is generated automatically when the "Program_Alarm" instruction is created. Open the PLC supervisions & alarms dialog and select the alarm to be edited in the Alarms > Program alarms tab. Create the alarm text, including two key words.

Select the following settings for the alarm.

If input parameter SIG ("CreateAlarm") of the "Program_Alarm" instruction has the signal state "TRUE", the PLC alarm is output.

In the case of the "Get_AlarmState" instruction, the following occurs: The PLC alarm is communicated to the "Get_AlarmState" instruction using input parameter ALARM. At output parameter AlarmState ("AS_statusBYTE"), it is indicated that the alarm corresponding to the alarm class "No Acknowledgement" is active.

At output parameters ERROR ("outputERROR") and STATUS ("outputSTATUS"), it is indicated that the processing of the instruction is proceeding error-free.

My_gDB_Get_AlarmState

		Name	Data type	Start value	Monitor value
1		Static			
2		AS_statusBYTE	Byte	16#0	16#85
3		outputERROR	Bool	false	FALSE
4		outputSTATUS	Word	16#0	16#0000
5		CreateAlarm	Bool	false	TRUE

For the output of the PLC alarm, use the web server of the CPU.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Example

ou can find a detailed application example in the Siemens Industry Online Support. (https://support.industry.siemens.com/cs/document/98210758?dti=0&lc=en-WW)

See also

Overview of the valid data types (Page 2239)

Program_Alarm: Generate program alarm with associated values (Page 3882)

Gen_UsrMsg: Generate user diagnostic alarms (S7-1200, S7-1500)

Description

You use the "Gen_UsrMsg" instruction to generate an alarm that is entered in the diagnostic buffer.

You use the Mode parameter to select whether an incoming or an outgoing alarm is to be generated:

- When Mode = 1: Create an incoming alarm.
- When Mode = 2: Create an outgoing alarm.
- Regardless of whether an incoming or outgoing alarm is generated, the alarm always has the attribute "Information only".

The entry in the diagnostic buffer is created synchronously. Alarm transmission is asynchronous.

If an error occurs during the execution of an instruction, it is output via the parameter RET_VAL.

Content of the alarm

The content of the alarm is defined with a text list:

- Specify the text list you want to use with the parameter TextListID. For this purpose, open the dialog "PLC alarm text lists" in the project navigation. Show the column "ID" in the dialog "Text lists". Apply the ID at the parameter TextListID.
- Use the parameter TextID to select the text list entry you want to write in the diagnostic buffer. For this purpose select an entry from the "Text lists entries" dialog by applying a number from the columns "Range from / range to" at the parameter TextID. The same number must be used from both the "Range from" and "Range to" columns for the text list entry.
- Additional information about text lists can be found here: Text lists (Page 417)

Defining associated values

New associated values to be added to the alarm are defined in the text list entry:

- Associated values are defined by adding the following information in the text list entry: @<No. of the associated value><Element type><Format specification>@
- Use the system data type AssocValues to specify which associated value is added when generating the alarm.
- Additional information on the structure of associated values can be found here: AUTOHOTSPOT

Parameters

The following table shows the parameters of the "Gen_UsrMsg" instruction:

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	UInt	I, Q, M, D, L or constant	Parameters for selecting the status of the alarm: • 1: incoming alarm • 2: outgoing alarm
TextID	Input	UInt	I, Q, M, D, L or constant	ID of the text list entry that should be used for the alarm text.
TextListID	Input	UInt	I, Q, M, D, L or constant	ID of the text list that contains text list entry.
Ret_Val	Return	Int	I, Q, M, D, L	Error code of the instruction.
AssocValues	InOut	VARIANT	D, L	Pointer to the system data type AssocValues that allows you to define the associated values.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter AssocValues

Use the system data type AssocValues to define which associated values will be sent. A maximum of 8 associated values are possible. The structure of the system data type is created by entering the data type "AssocValues" as a data block.

The associated values are selected by entering the numbers of the associated values for the parameters Value[x]. Note the following:

- The values for TextID and TextListID are treated by the instruction as the associated values to be sent. As a result, "1" and "2" are already assigned as numbers for addressing associated values. Do not use the numbers "1" or "2" to address associated values.
- Address the associated value at parameter Value [1] as number "3", at parameter Value [2] as number "4", and so forth.

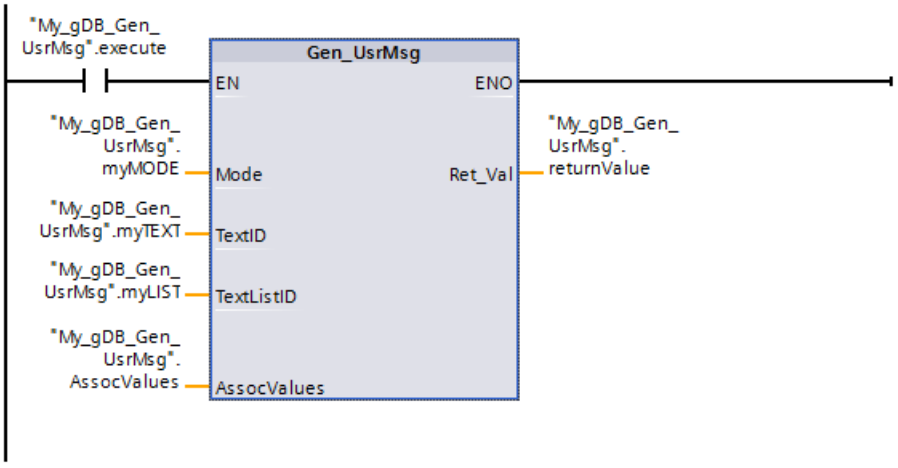
Byte	Parameter	Data type	Start value	Description	Number of the associated value
0..1	Value[1]	UINT	0	First associated value of the alarm.	3
2..3	Value[2]	UINT	0	Second associated value of the alarm.	4
4..5	Value[3]	UINT	0	...	5
6..7	Value[4]	UINT	0	...	6
8..9	Value[5]	UINT	0	...	7
10..11	Value[6]	UINT	0	...	8
12..13	Value[7]	UINT	0	...	9
14..15	Value[8]	UINT	0	Eighth associated value of the alarm.	10

Parameter RET_VAL

The following table contains all specific error information that is output via the RET_VAL parameter.

Error code* (W#16#...)	Explanation
0000	No error
8080	Value in the Mode parameter is not supported.
80C1	Resource bottleneck due to too many parallel calls.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you generate an alarm that is entered in the diagnostic buffer.

Create five tags and an "AssocValues" structure (with the AssocValues data type) in a global data block for storing the data.

My_gDB_Gen_UsrMsg

	Name	Data type	Start value
1	Static		
2	myMODE	UInt	1
3	myTEXT	UInt	3
4	myLIST	UInt	512
5	returnValue	Int	0
6	execute	Bool	false
7	AssocValues	AssocValues	
8	Value	Array[1..8] of UInt	
9	Value[1]	UInt	33
10	Value[2]	UInt	411
11	Value[3]	UInt	578
12	Value[4]	UInt	6122
13	Value[5]	UInt	722
14	Value[6]	UInt	8111
15	Value[7]	UInt	9829
16	Value[8]	UInt	10457

Interconnect the parameters of the instruction as follows.

Use the "Text lists" entry to create a Text list and a Text list entry for the alarm. Apply the ID of the text list at parameter TextListID ("myLIST"). Apply the ID (Range ...) of the text list entry at parameter TextID ("myTEXT"). Assign the alarm parameters as follows.

Text lists

Name	Id	Selection	Comment
USER_1	512	Decimal	

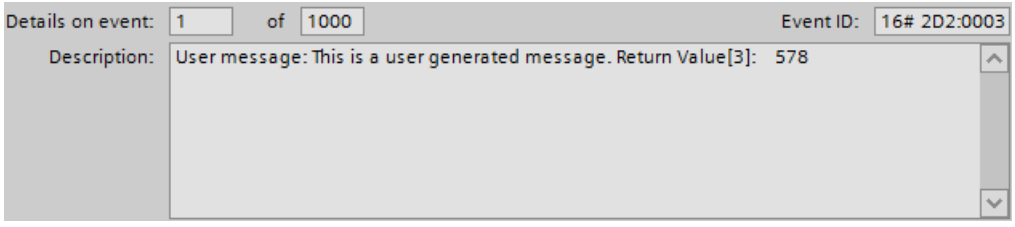
Text list entries of USER_1

Range from	Range to	Entry
3	3	This is a user generated message. Return Value[3]: @5I%6d@

If the normally open contact ("execute") supplies the signal state "TRUE", the "Gen_UsrMsg" instruction is executed. According to the value of parameter Mode ("myMODE"), an incoming

alarm is generated. The alarm to be output is made known to the instruction using parameters TextListID ("myLIST") and TextID ("myTEXT"). The associated values of the alarm are transferred using parameter AssocValues ("AssocValues").

When the alarm is generated, the character string "@5I%6d@" contained in the alarm text is interpreted as follows:



- The associated value with the number "5" is read out in the INT data type. The number corresponds to parameter Value[3] of the "AssocValues" structure.
- The associated value is output as a decimal number. The decimal number is limited to six places.

At output parameter Ret_Val ("returnValue"), it is indicated that the processing of the instruction was error-free.

My_gDB_Gen_UsrMsg

	Name	Data type	Start value	Monitor value
1	Static			
2	myMODE	UInt	1	1
3	myTEXT	UInt	3	3
4	myLIST	UInt	512	512
5	returnValue	Int	0	0
6	execute	Bool	false	FALSE
7	AssocValues	AssocValues		
8	Value	Array[1..8] of UInt		
9	Value[1]	UInt	33	33
10	Value[2]	UInt	411	411
11	Value[3]	UInt	578	578
12	Value[4]	UInt	6122	6122
13	Value[5]	UInt	722	722
14	Value[6]	UInt	8111	8111
15	Value[7]	UInt	9829	9829
16	Value[8]	UInt	10457	10457

For the output of the alarm, for a CPU of the S7-1500 series, open the entry "Online & Diagnostics > Diagnostic buffer".

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Example

You will find a detailed application example in the Siemens Industry Online Support (https://support.industry.siemens.com/cs/document/98210758?dti=0&lc=en-WW).

Get_Alarm: Read pending alarm (S7-1500)

Description

Using the "Read pending alarms" instruction, you can log on for alarms generated in the user program and copy an incoming or outgoing alarm to a referenced data block. This allows you to pass on for example alarms as a STRING to a master computer.

When you call the instruction with the "OperateMode = 1" and log on with this, you have to specify at least one or more display classes at the input "DispClassNr". After logging on no more alarms are lost either incoming or outgoing.

The alarms are processed sequentially, starting with the oldest alarm. They are read out and stored in a data block in the CPU. You can then forward the data, e.g. using the instruction "TSEND_C", to a master computer.

The instruction operates asynchronously and therefore avoids long runtimes of the function block "Get_Alarm [FB702]" that could lead to a cycle overflow. The instruction must be called recurrently in a cycle organization block and in a period of 100 ms up to maximum 1 second; otherwise, the instruction is logged off after 3 minutes. As a result of the logoff, no more alarms can be read out.

In the following cases, you need to log on the instruction again using the input "OperateMode = 1":

- After automatic logoff because the function block "Get_Alarm [FB702]" is called too rarely.
- When the operating mode changes from "STOP" > "RUN".
- As soon as you change existing alarm configurations, such as the Program_Alarm or ProDiag, the instruction automatically logs off.

You can use the instruction for alarms from the following areas:

- ProDiag
- System diagnostics
- GRAPH
- Program_Alarm
- Motion Control

Note

CPU property "Central alarm management in the PLC"

If you do not enable the CPU property "Central alarm management in the PLC" in the device configuration, only the IDs of the alarm text fields are output instead of the alarm texts (alarm text, information text and additional alarm texts 1 - 9).

Parameter

The following table shows the parameters of the instruction Read pending alarm":

Parameter	Declaration	Data type	Memory area	Description
EN *)	Input	BOOL	I, Q, M, D, L	Enable input
ENO *)	Output	BOOL	I, Q, M, D, L	Enable output
Operate-Mode	Input	BYTE	I, Q, M, D, L	There are three possible values: • 1: Logon • 2: Read out data • 3: Logoff
DataMode	Input	BYTE	I, Q, M, D, L	There are four different possible values: • 0: Only the column titles are read out (Producer-ID, ID_1, ID_2, Prio, Timestamp, State) • 1: The column headers and the alarm text is read out including associated values. • 2: The column headers, the alarm text including associated values and the information text are read out. • 3: The column headers, the alarm text including associated values, the information text and the additional alarm texts are read out.
DispClassNr (Display class number)	Input	ARRAY[0..31] of UINT	I, Q, M, D, L	You can define up to 32 different display classes: • 0 ... 16: User-defined display classes that can be set on the HMI device • 257: System diagnostics • 259: Security If you do not use the parameter, all display classes are reported. A change of the display class is only taken into consideration if mode 1 is set at the parameter mode.
Lcid (Local ID)	Input	UDINT	I, Q, M, D, L	There are different possible values: • 0: All languages • 1: First language with the lowest LC number • 2: First language plus second language with the second lowest LC number • 3: All languages • or: Enter the exact LC number to select a specific language.
Data	InOut	"AlarmData"	I, Q, M, D, L	Target range for the alarm data that was read. Alarm text structure from the PLC data type "AlarmData" according to the value at the "DataMode" parameter.

Parameter	Declaration	Data type	Memory area	Description
Data-Ready	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No data is available. • 1: The data is available. The data is valid until the next call of the instruction. Therefore, it must be processed in the same program cycle, e.g. using a move instruction.
Busy	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: The execution of the instruction has not yet been started or the asynchronous processing was completed. Additional information on the processing status can be found in the STATUS parameter. • 1: Execution of the instruction not yet complete Further entries exist
Error	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
Init	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No action necessary. • 1: A new logon is required. The alarm data received so far are no longer valid. This may be necessary in the following situations: • You have logged on. • The CPU changes from "STOP" mode to "RUN" mode. • Alarms were re-configured and the changes were made by means of "Download to device" in "RUN" mode, for example, a change in the alarm text structure.
Status	Output	WORD	I, Q, M, D, L	Error and status information
*): The enable input EN and the enable output ENO are only visible in the programming languages LAD and FBD.				

Parameter Status

The following table shows the meaning of the values of the Status parameter:

Status code* (W#16#...)	Explanation
0000	No error
0001	New data is available.
8001	The value at parameter OperateMode is invalid.
8002	The Data parameter has the wrong data type.
8003	The Lcid parameter is invalid or a language selected with the Lcid parameter is not loaded.
8004	You have already logged on via the OperateMode = 1 parameter in the user program to read the pending messages. You are only allowed and required to log on again if you log out using the OperateMode = 3, have re-configured alarm or performed a STOP > RUN transition.
8005	The value at parameter DataMode is invalid.
8085	• You did not specify a display class when you logged on. • The instruction was logged off during the reconfiguration of supervisions (ProDiag). • Automatic logoff because the function block "Get_Alarm [FB702]" is called too rarely.
80C5	The processing of the instruction is not yet completed. Please try again later.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

PLC data type "AlarmData"

The PLC data type "AlarmData" reflects the structure of an alarm.

Name	Data type	Default value	Description
ProducerID	UINT	0	There are different possible values: • 0: Program_Alarm • 4: System diagnostics • 5: Standard Motion Control (T-CPU) • 6: Security (for example, false login) • 7: SINUMERIK • 8: GRAPH • 9: ProDiag
ID_1	UINT	0	Alarm ID This ID is also displayed in the alarm editor.
ID_2	UINT	0	ID of the alarm runtime instance This ID is an internal range ID that is significant for ProDiag and sequencers: • In ProDiag, it is the supervision ID. • In a sequencer, it is the step number. For the "Program_Alarm" instruction the ID is 0, and it has no significance for system diagnostics.

Name	Data type	Default value	Description
PRIO	UINT	0	Priorities: 0 to 16
TimeStamp	LDT	DT#1970-01-01-0:0:0.000000000	Time stamp
State	BYTE	16#0	Status parameter: • 0: Outgoing • 1: Incoming
LC_ID	ARRAY[0..2] of UINT	-	Returns the value that is specified at the input "Lcid": • 0: All languages • 1: First language with the lowest LC number • 2: First language plus second language with the second lowest LC number • 3: All languages or: Enter the exact LC number to select a specific language.
AlarmText	ARRAY[0..2] of WSTRING	-	Alarm text with up to 254 characters (508 bytes). If the text is longer, it is truncated at 251 characters, for example WSTRING#'Meld... .
InfoText	ARRAY[0..2] of WSTRING	-	Information text
AddText_1 - 9	ARRAY[0..2] of WSTRING	-	Additional text 1 - 9

Example

You can find the example here: Program example for Get_Alarm & Ack_Alarms - Part 1 (Page 3903).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Overview of the valid data types (Page 2239)

Ack_Alarms: Acknowledge alarms (S7-1500)

Description

You can use the "Acknowledge alarms" instruction to acknowledge all incoming and outgoing alarms in your program code with a single command.

The instruction is called as soon as there is a positive signal edge either at the enable input EN (LAD / FBD) or as a preceding logic operation (STL / SCL), and the value = 1 is set at the MODE parameter. The instruction operates asynchronously and therefore avoids long runtimes of the function block "Ack_Alarms [FB701]" that could lead to a cycle overflow. The

CPU acknowledges all incoming and outgoing alarms and informs all HMI devices about this acknowledgment. Any pending alarms on the displays disappear as soon as they "went out".

In each case, only one acknowledgment (max. 100 alarms requiring acknowledgment) can be carried out at the same time. If additional alarms are pending, the next 100 alarms requiring acknowledgment will be confirmed automatically.

The instruction can also be used for ProDiag supervision alarms.

Parameters

The following table shows the parameters of the instruction "Acknowledge alarms":

Parameter	Declaration	Data type	Memory area	Description
EN *)	Input	BOOL	I, Q, M, D, L	Enable input
ENO *)	Output	BOOL	I, Q, M, D, L	Enable output
MODE	Input	BYTE	I, Q, M, D, L	There are two different possible values: • 0: The instruction is not executed. • 1: Confirm all alarms. All active alarms that can be confirmed are confirmed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Error and status information
*): The enable input EN and the enable output ENO are only visible in the programming languages LAD and FBD.				

Parameter STATUS

The following table shows the meaning of the values of the STATUS parameter:

Status code* (W#16#...)	Explanation
0000	No error
7001	No error occurred and the next 100 alarms requiring acknowledgment will be confirmed.
8001	The value at parameter MODE is invalid.
80C5	A confirmation process is already running. Please try again later.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Program example for Get_Alarm & Ack_Alarms - Part 1 (Page 3903).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Overview of the valid data types (Page 2239)

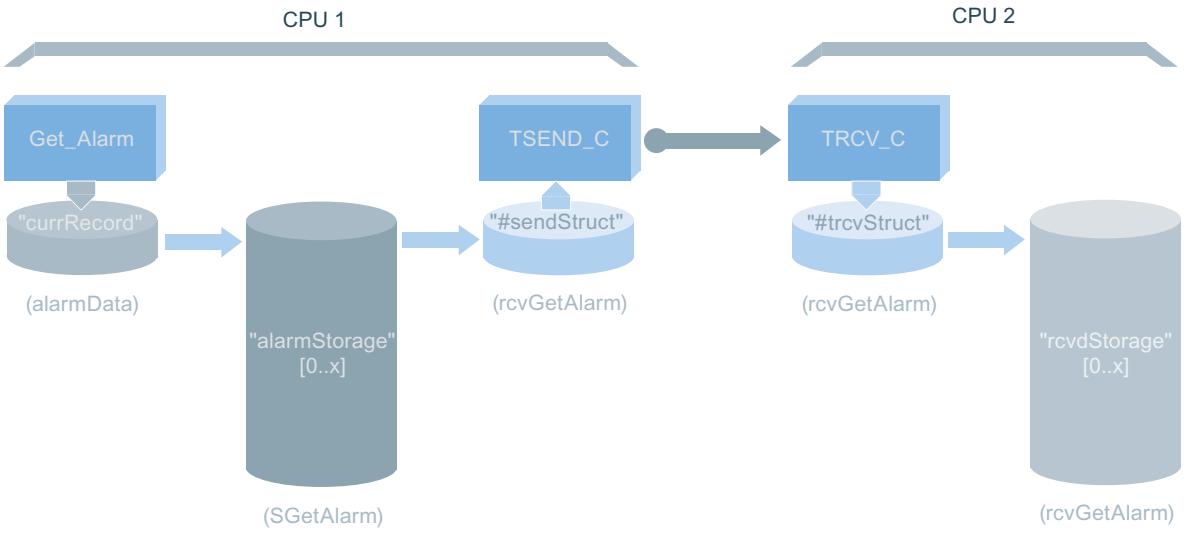
Program example for Get_Alarm & Ack_Alarms (S7-1200, S7-1500)

Program example for Get_Alarm & Ack_Alarms - Part 1 (S7-1200, S7-1500)

Introduction

In the following example, you collect all alarms of the CPU 1 (S7-1500 as of firmware V2.0) and save the alarms. You then use a programmed connection to the CPU 2 (S7-1500) to send the alarms (in abbreviated form; in PLC data type "rcvGetAlarm") from CPU 1 to CPU 2. You also save the alarms on CPU 2.

In the first part of the programming example for Get_Alarm and Ack_Alarms, you deal with the requirements and interconnection of the parameters.



The results and the procedure for the connection are described here: Program example for Get_Alarm & Ack_Alarms - Part 2 (Page 3921).

Note

Size of the memory arrays for the alarms

The memory arrays for the alarms ("alarmStorage" and "rcvdStorage") can hold up to 16 alarms when configured as described.

If you want to change the memory size, you must change the array size and the maximum value "maxPosition".

Requirements for a programmed connection

You create two CPUs (S7-1500) and connect the CPUs with each other over PROFINET. You do not assign parameters to the connection.

Note

Using Get_Alarm and Ack_Alarms

The CPU 1 (for the call of Get_Alarm and Ack_Alarms) must have firmware v2.0 or higher. In addition, the CPU property "Central alarm management in the PLC (Page 3897)" must be activated for the CPU 1.

Note

Permitting read and write access

By setting a low protection level under Properties > Protection of the CPU, you ensure that read and write access is permitted.

CPU 1: Program requirements

Creating PLC data types

You need the following PLC data types for the transfer and storage of alarms:

- You need "SGetAlarm" to save the alarms, including information about the current read loss

SGetAlarm

	Name	Data type	Default value
1	countReadLoss	UDInt	0
2	alarm	AlarmData	

- You need "rcvGetAlarm" to transfer the alarms over TSEND_C.

rcvGetAlarm

	Name	Data type	Default value
1	countReadLoss	UDInt	0
2	ProducerID	UInt	0
3	ID_1	UInt	0
4	ID_2	UInt	0
5	PRIO	UInt	0
6	TimeStamp	LDT	LDT#1970-01-01-(
7	State	Byte	16#0
8	LCID	Array[0..2] of UInt	
9	AlarmText	WString[254]	WSTRING#''

Storage of data

Create the following structures and tags for storing the data in a global data block ("SLI_gDB_GAalarm").

- For parameter assignment of TSEND_C:

SLI_gDB_GAalarm

	Name	Data type	Start value
1	Static		
2	TSEND_C	Struct	
3	start	Bool	false
4	stop	Bool	false
5	comControl	Bool	false
6	done	Bool	false
7	busy	Bool	false
8	error	Bool	false
9	status	Word	16#0
10	memErrStatus	Word	16#0

- For parameter assignment of Get_Alarm:

SLI_gDB_GAalarm

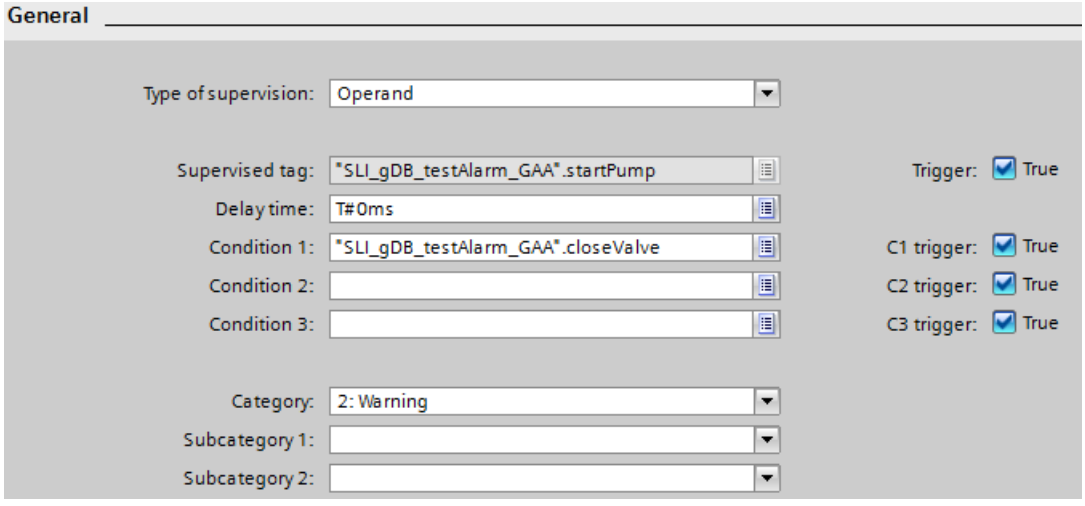
	Name	Data type	Start value
11	GetAlarm	Struct	
12	start	Bool	false
13	stop	Bool	false
14	check	Struct	
15	anew	Bool	false
16	operateMode	Struct	
17	value	Byte	16#0
18	Logon_done	Bool	false
19	ReadData_ready	Bool	false
20	ReadData_active	Bool	false
21	Logoff_done	Bool	false
22	outputMode	Byte	16#3
23	languageCodeID	UDInt	0
24	currRecord	AlarmData	
25	currReadLoss	UDInt	0
26	dataReady	Bool	false
27	initiateLogin	Bool	false
28	busy	Bool	false
29	status	Word	16#0
30	memError	Bool	false
31	memErrStatus	Word	16#0

- As part of the "GetAlarm" structure for saving the alarms in the memory array:

32	maxPosition	UInt	15
33	alarmStorage	Array[0..15] of "SGetAlarm"	
34	limitReach	Bool	false
35	savingDone	Bool	false
36	initiateSending	Bool	false
37	countAlarms	UInt	0
38	posForAlarm	UInt	0

- For parameter assignment of Ack_Alarms:

40	AckAlarm	Struct	
41	executeAck	Bool	false
42	error	Bool	false
43	status	Word	16#0



ProDiag alarm

Create three tags in a global data block ("SLI_gDB_testAlarm_GAA") for a test scenario.

SLI_gDB_testAlarm_GAA

	Name	Data type	Start value
1	Static		
2	startPump	Bool	false
3	closeValve	Bool	false
4	valveOut	Bool	false

Create the following rule in the global data block ("SLI_gDB_testAlarm_GAA") to trigger a ProDiag alarm. To do so, open the global data block > the properties of the tag "startPump" > Supervisions > Add new supervision.

CPU 2: Program requirements

Creating PLC data type

Create the PLC data type "rcvGetAlarm" as described for CPU 1.

Storage of data

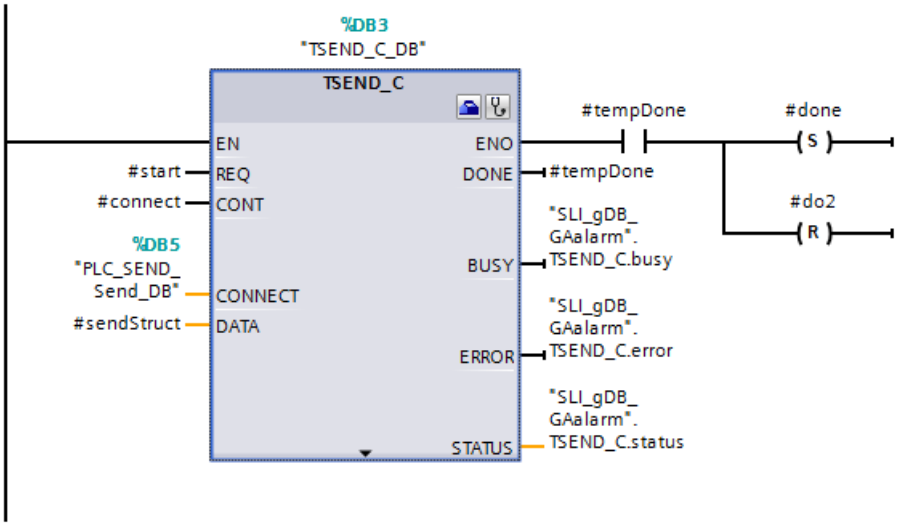
Create the following structures and tags for storing the data in a global data block ("SLI_gDB_trcv_GAA").

SLI_gDB_trcv_GAA

	Name	Data type	Start value
1	Static		
2	TRCV_C	Struct	
3	start	Bool	false
4	comControl	Bool	false
5	done	Bool	false
6	busy	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStatus	Word	16#0
10	rcvLen	UDInt	0
11	dataReceived	Bool	false
12	GetAlarm	Struct	
13	maxPosition	UInt	15
14	rcvdStorage	Array[0..15] of "rcvGetAlarm"	
15	limitReach	Bool	false
16	savingDone	Bool	false
17	countAlarms	UInt	0
18	posForAlarm	UInt	0

CPU 1: FB "SLI_FB_send_GAA" - Interconnect parameters

Create the FB "SLI_FB_send_GAA" to set up the connection between CPU 1 and CPU 2 and data transfer.



Create the following local tags in the FB.

SLI_FB_send_GAA

	Name	Data type	Default value	Retain
1	Input			
2	start	Bool	false	Non-ret...
3	connect	Bool	false	Non-retain
4	Output			
5	<Add new>			
6	InOut			
7	done	Bool	false	Non-retain
8	Static			
9	posForAlarm	UInt	0	Set in IDB
10	sendStruct	"rcvGetAlarm"		Non-retain
11	initiateSending	Bool	false	Set in IDB
12	do	Bool	false	Non-retain
13	do2	Bool	false	Non-retain
14	Temp			
15	tempDone	Bool		
16	Constant			
17	<Add new>			

In the FB, you use:

- Interconnections for canceling ("TSEND_C.stop") the data transfer.
- Interconnections for starting ("#do2") the data transfer.
- Interconnections to initiate a new data transfer ("#initiateSending", "#do").
- The instruction "TSEND_C" for connection establishment and data transfer.

Note

Interconnection of the input parameter CONNECT of the "TSEND_C" instruction

To interconnect the input parameter CONNECT, open the wizard of the "TSEND_C" instruction with "Properties > Configuration".

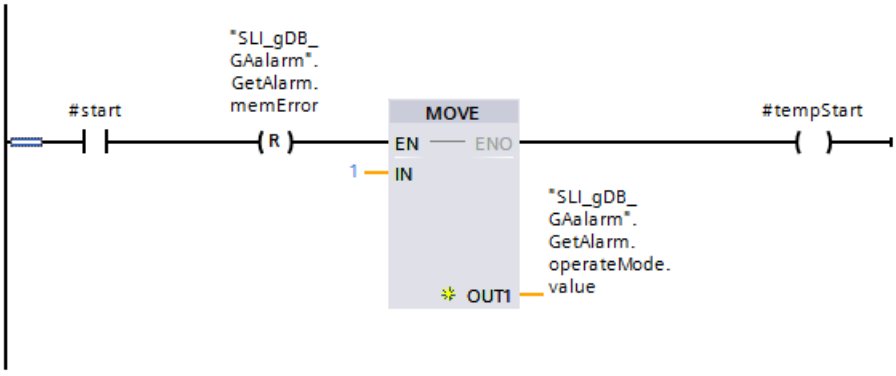
Make the following settings for the connection of TSEND_C:

- End point Select the CPUs using the drop-down list. Interface, subnet and address are entered automatically.
- Connection data: Use the drop-down list and the selection "New" to create one data block per CPU. This data block is required for storing the connection data. The name of the data block can be freely selected for each CPU (communication partner).
- Select the connection type "TCP" and the configuration type "Use program block". These settings set up an Ethernet connection with the "TCP" protocol and as programmed connection.
- You enter a freely selected connection ID. Use a connection ID that has not already been assigned.
- You enter a value for the partner port. The value must be >=2000.

Additional information on the configuration of TSEND_C (Page 4423) is available here: Program example for send functions (Page 4446).

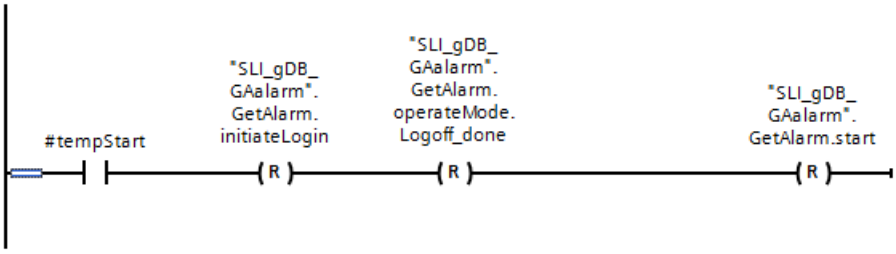
Additional information on setup and interconnections of the FB "SLI_FB_send_GAA" is available in the program code of the example in the Sample Library for Instructions (Page 2568).

CPU 1: FC "SLI_FC_switchMode_GAA" - Interconnect parameters



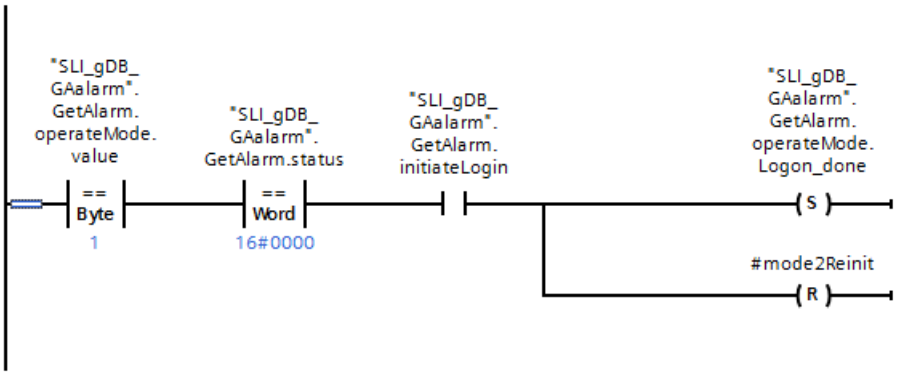
You use the FC "SLI_FC_switchMode_GAA" to control the "Get_Alarm" instruction.

Create the following local tags in the FC.

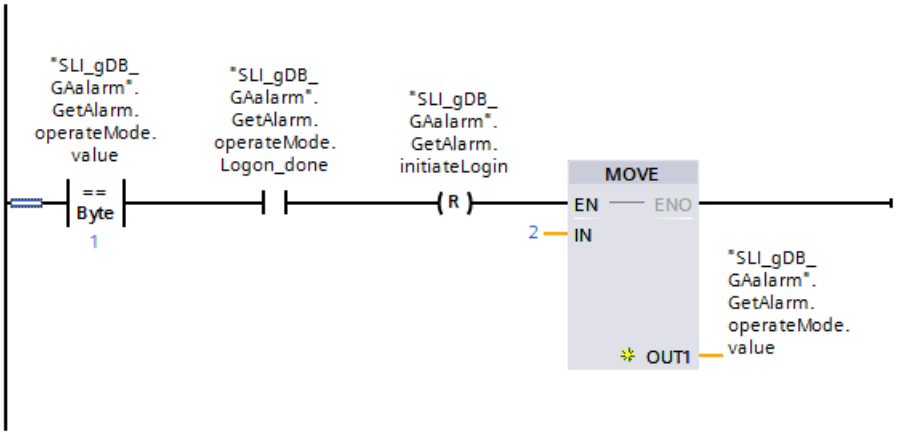


SLI_FC_switchMode_GAA		
	Name	Data type
1	Input	
2	start	Bool
3	stop	Bool
4	Output	
5	<Add new>	
6	InOut	
7	mode2Reinit	Bool
8	Temp	
9	tempStart	Bool
10	tempStop	Bool
11	Constant	
12	<Add new>	
13	Return	
14	SLI_FC_switchMode_GAA	Void

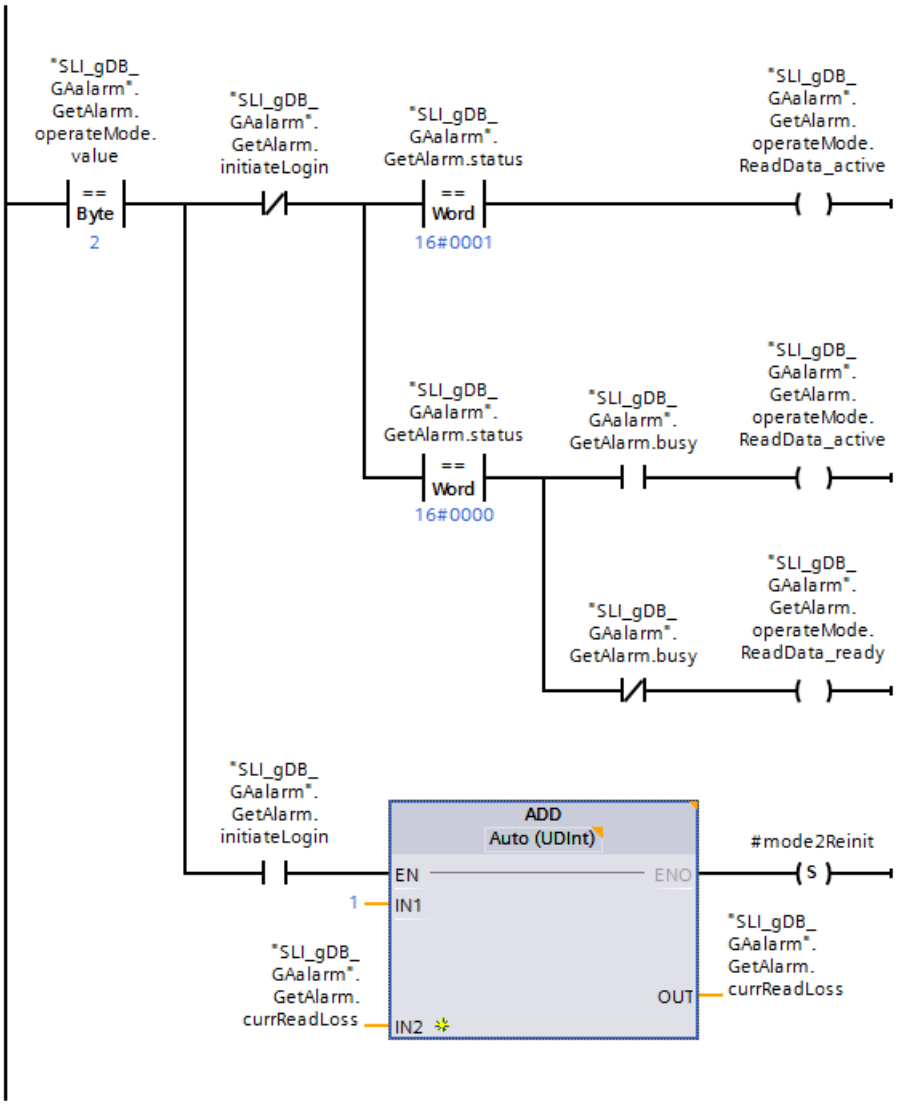
Create the following interconnections in the FC.



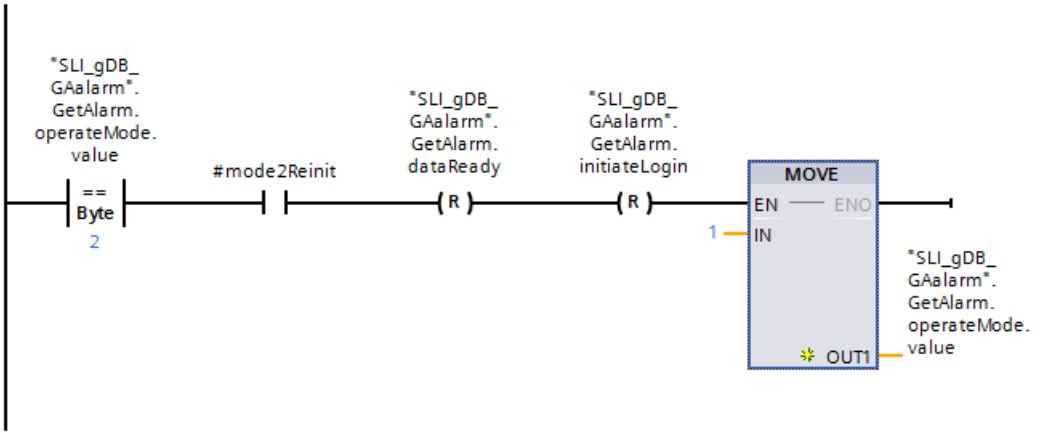
Network 1: To start the processing of Get_Alarm, create the following interconnections.



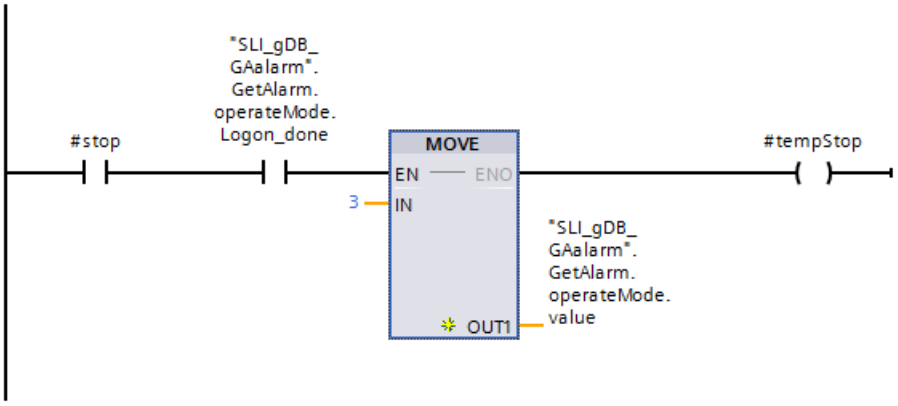
Network 2: To start the processing of Get_Alarm, create the following interconnections (Part 2).



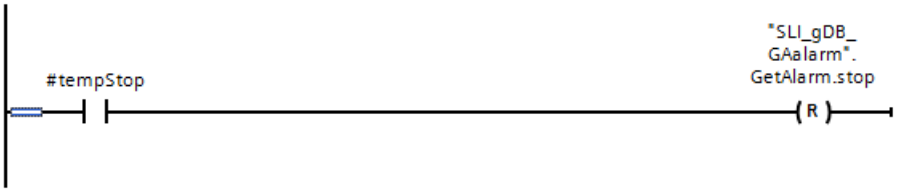
Network 3: For login of Get_Alarm, create the following interconnections.



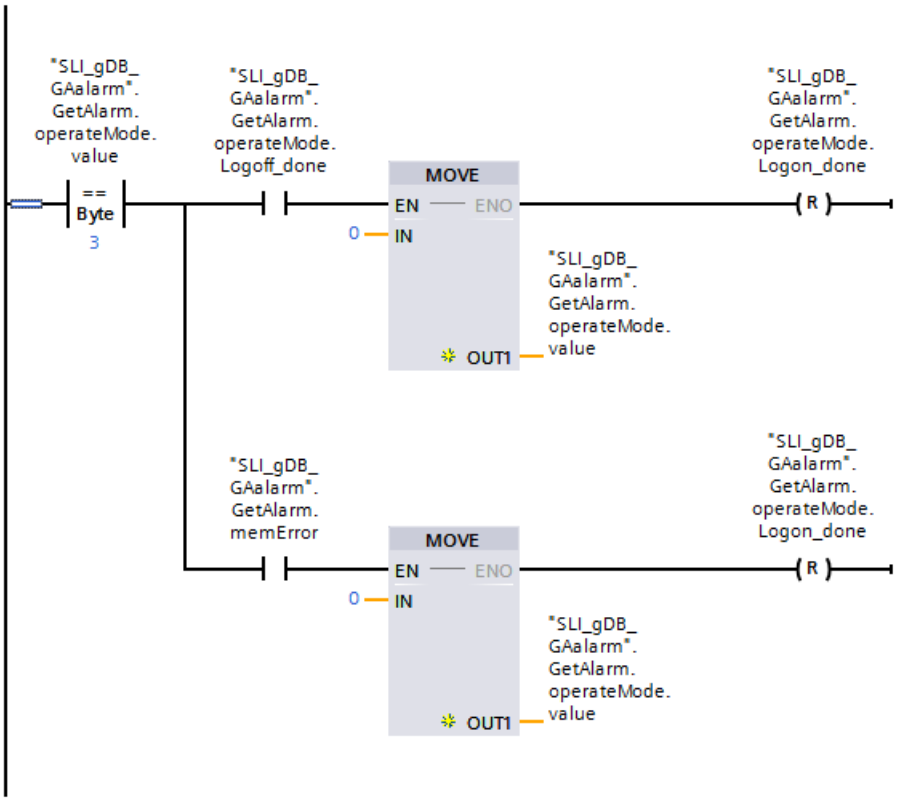
Network 4: To switch to the "Read" mode of Get_Alarm, create the following interconnections.



Network 5: To process the "Read" mode of Get_Alarm, create the following interconnections.



Network 6: To process the "Read" mode of Get_Alarm, create the following interconnections (Part 2).

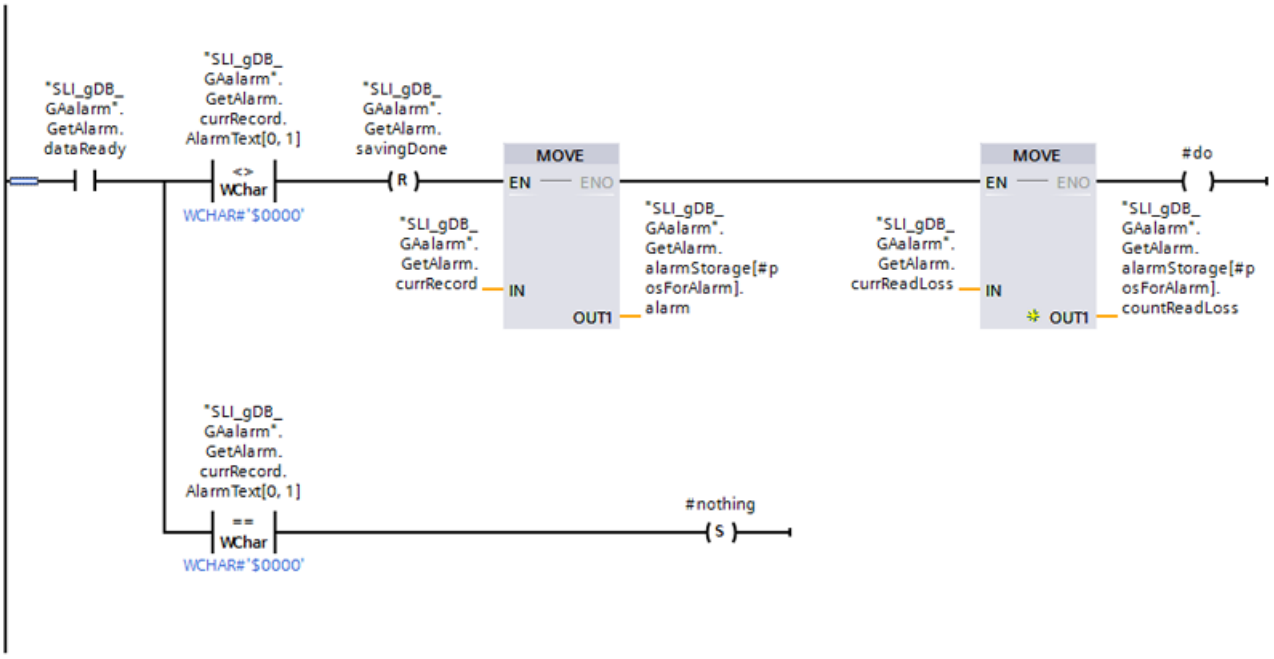


Network 7: To end the processing of Get_Alarm, create the following interconnections.

Network 8: To end the processing of Get_Alarm, create the following interconnections (Part 2).

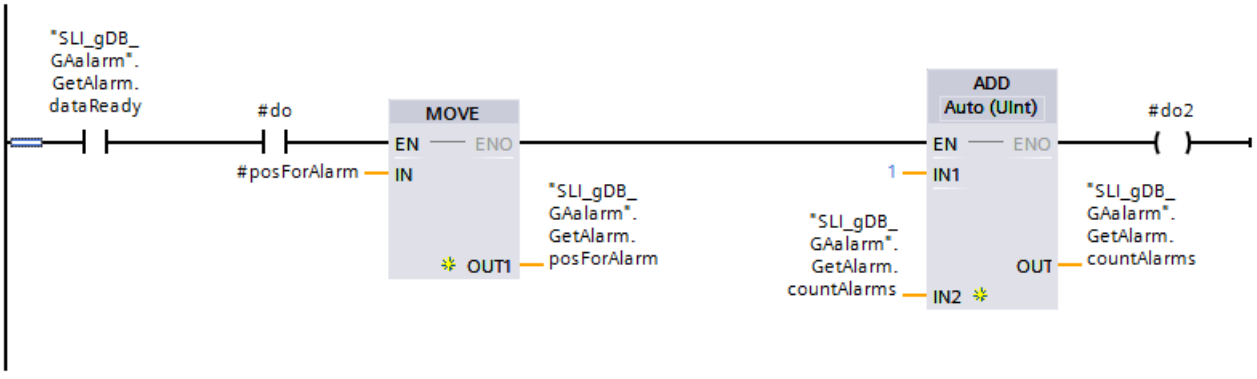
Network 9: To end the processing of Get_Alarm, create the following interconnections (Part 3).

CPU 1: FB "SLI_FB_saveAlarms_GAA" - Interconnect parameters



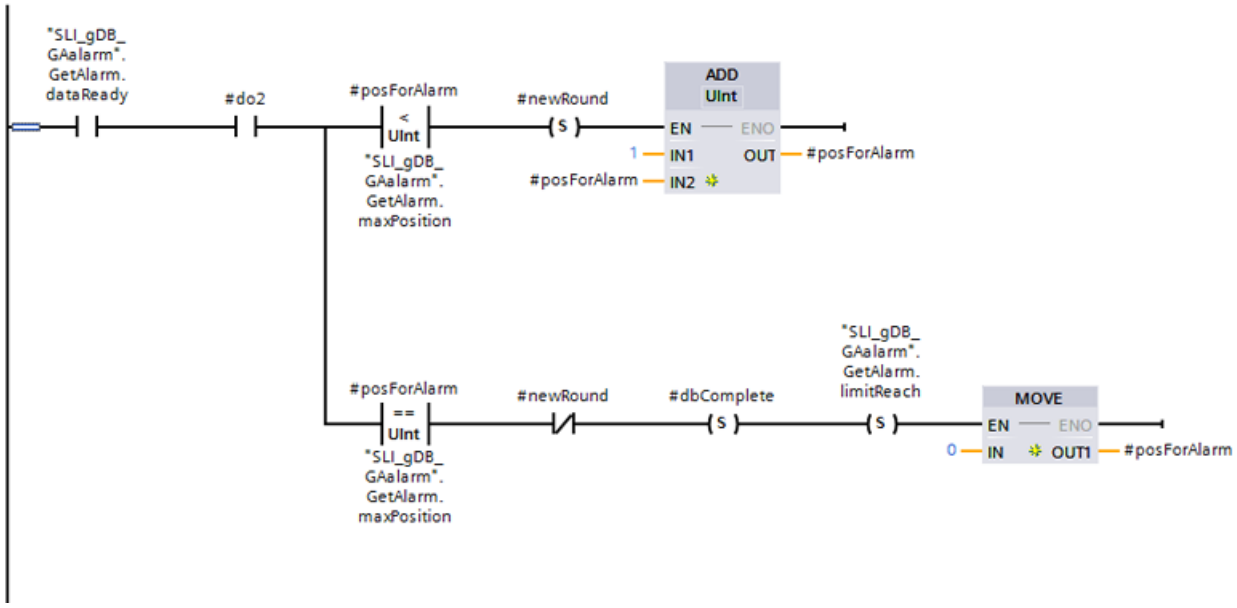
You create the FB "SLI_FB_saveAlarms_GAA" to copy the alarms to the memory array "GetAlarm.alarmStorage".

Create the following local tags in the FB.

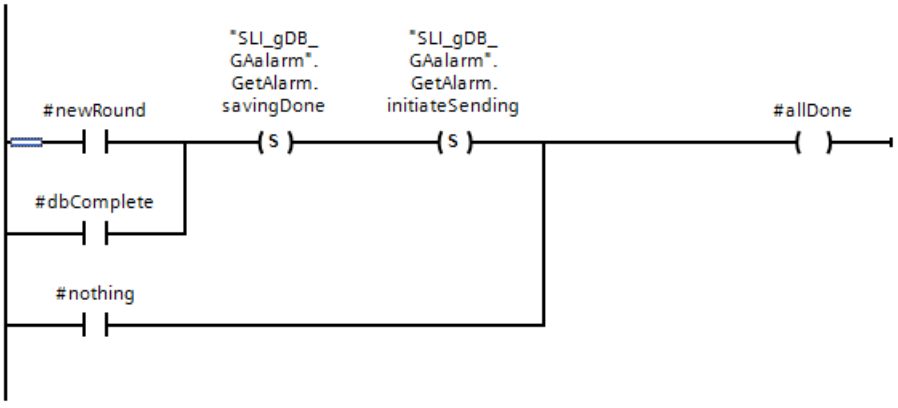


7		Static			
8		posForAlarm	UInt	0	Set in IDB
9		do	Bool	false	Set in IDB
10		do2	Bool	false	Set in IDB
11		nothing	Bool	false	Set in IDB
12		newRound	Bool	false	Set in IDB
13		dbComplete	Bool	false	Set in IDB
14		allDone	Bool	false	Set in IDB

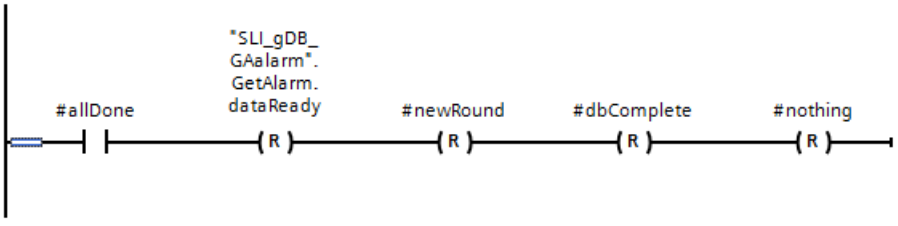
Create the following interconnections in the FB.



Network 1: The copying of alarms to the memory array "GetAlarm.alarmStorage" is decided as follows:



Network 2: To save the cell number of the memory array used last and to count the alarms, create the following interconnections.



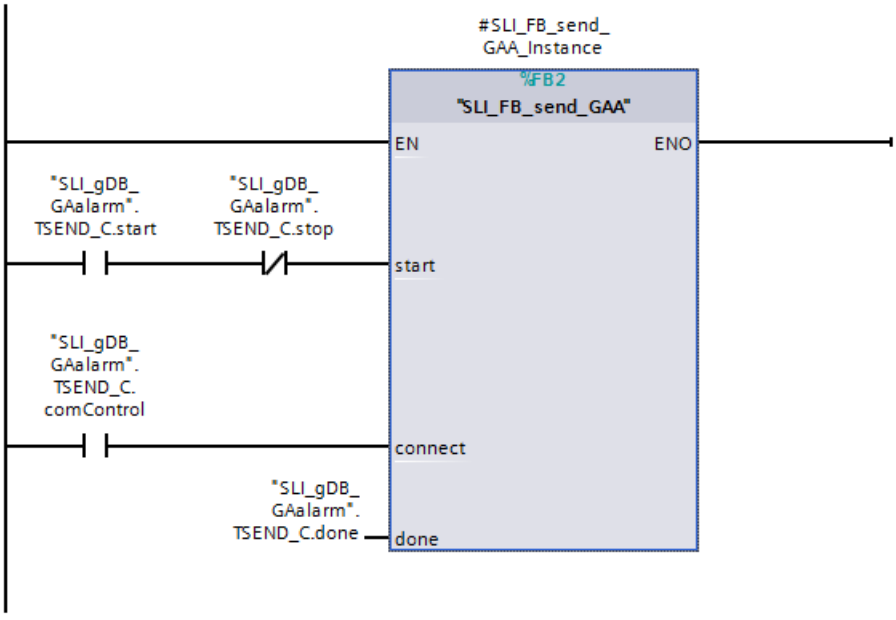
Network 3: Incrementing or resetting the cell number of the memory array is decided as follows:

Network 4: To save the success when copying to the memory array, create the following interconnections.

Network 5: To end the processing of SLI_FB_saveAlarms_GAA, create the following interconnections.

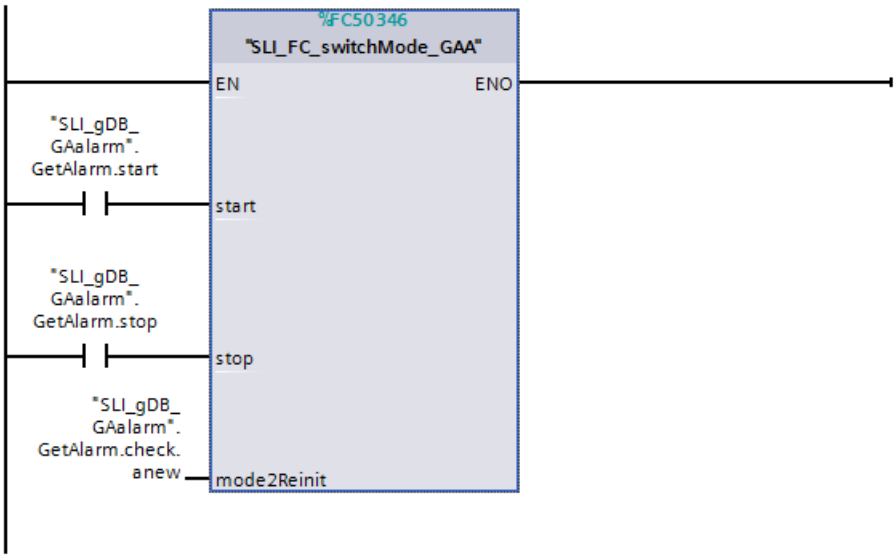
CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Interconnect parameters

You create the FB "SLI_FBCall_GetAlarm_AckA" for the following purposes:



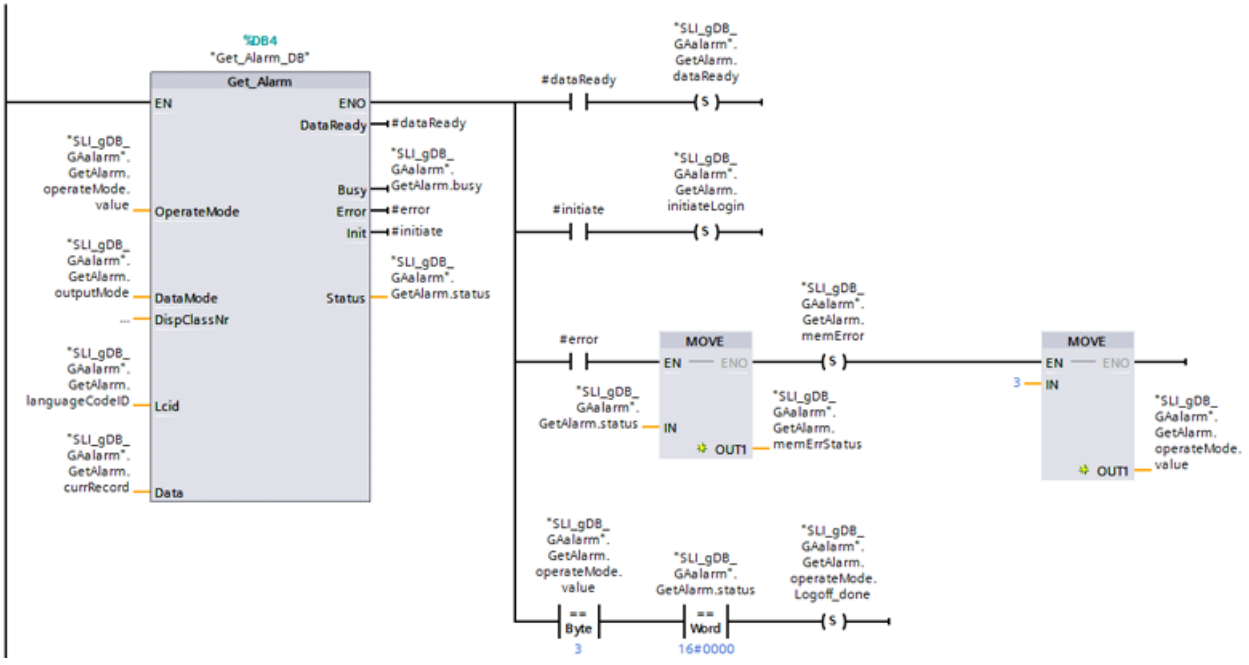
- To call and modify Get_Alarm
- To call the blocks for copying and send processes.
- To call Ack_Alarms.

Create the following local tags in the FB.

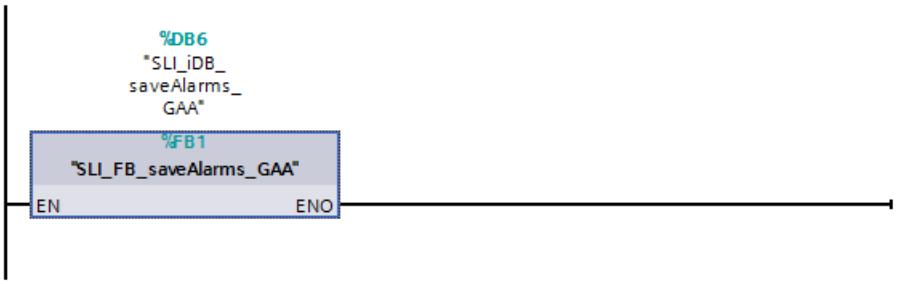


7		Static		
8		acknowledge	UInt	1	Non-ret...
9		dataReady	Bool	false	Non-retain
10		initiate	Bool	false	Non-retain
11		error	Bool	false	Non-retain
12		SLI_FB_send_GAA_Instance	"SLI_FB_send_GAA"		

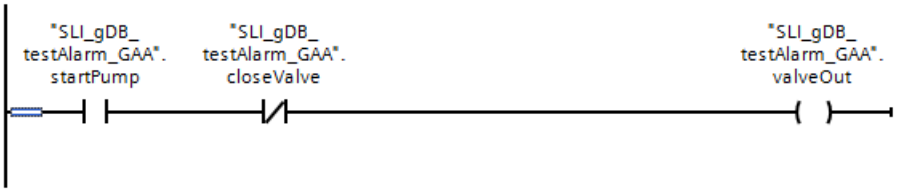
Create the following interconnections in the FB.



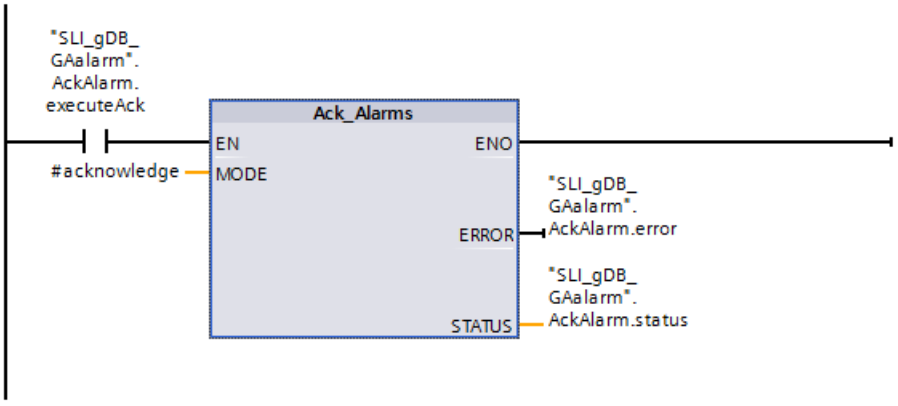
Network 1: Interconnect the parameters of the "SLI_FB_send_GAA" function block as follows.



Network 2: Interconnect the parameters of the "SLI_FC_switchMode_GAA" FC as follows.



Network 3: Interconnect the parameters of the "Get_Alarm" instruction as follows.



Network 4: Interconnect the parameters of the "SLI_FB_saveAlarms_GAA" function block as follows.

Network 5: Create the following interconnections to test the ProDiag alarms.

Network 6: Interconnect the parameters of the "Ack_Alarms" instruction as follows.

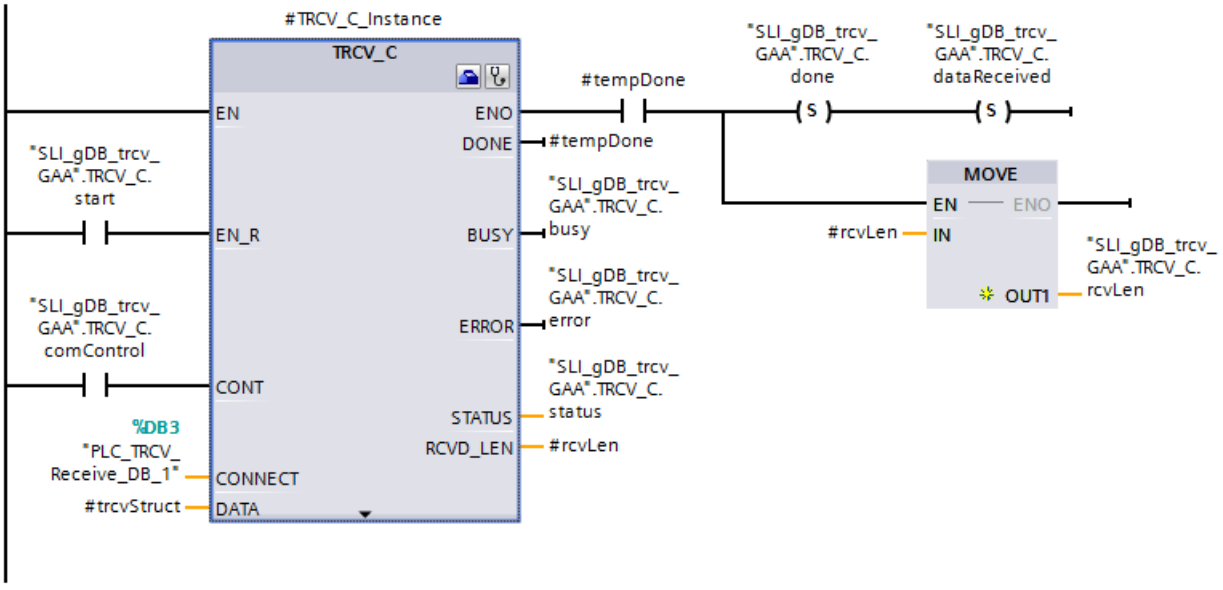
CPU 2: FB "SLI_FB_rcvdAlarms_GAA" - Interconnect parameters

You create the FB "SLI_FB_rcvdAlarms_GAA" to copy the alarms to the memory array "GetAlarm.rcvdStorage". The setup and interconnections are similar to those of the FB "SLI_FB_saveAlarms_GAA".

Additional information on setup and interconnections of the FB "SLI_FB_rcvdAlarms_GAA" is available in the program code of the example in the Sample Library for Instructions (Page 2568).

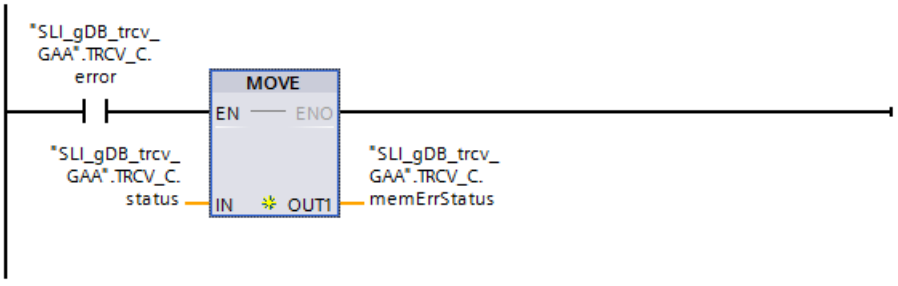
CPU 2: FB "SLI_FBCall_trcv_GAA" - Interconnect parameters

You create the FB "SLI_FBCall_trcv_GAA" to call and process TRCV_C as well as all subsequent processes.



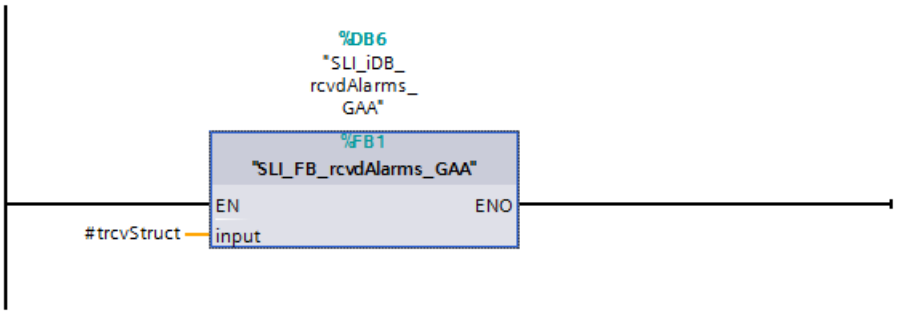
Create the following local tags in the FB.

7		Static		
8		TRCV_C_Instance	TRCV_C	
9		trcvStruct	"rcvGetAlarm"	Non-retain



Create the following interconnections in the FB.

Network 1: Interconnect the parameters of the "TRCV_C" instruction as follows. Configure the CONNECT parameter of TRCV_C using the TRCV_C wizard.



Additional information on the configuration of TRCV_C (Page 4437) is available here: Program example for send functions (Page 4446).

Network 2: To save the status if a TRCV_C error occurs, interconnect the parameter as follows.

Network 3: Interconnect the parameters of the "SLI_FB_rcvdAlarms_GAA" function block as follows.

Results and procedure

The results and the procedure for the communication connection are described here: Program example for Get_Alarm & Ack_Alarms - Part 2 (Page 3921).

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

Ack_Alarms: Acknowledge alarms (Page 3901)

Program example for Get_Alarm & Ack_Alarms - Part 2 (S7-1200, S7-1500)

Introduction

In the second part of the program example for Get_Alarm and Ack_Alarms, you will become familiar with the results of the configuration and the ProDiag alarm.

The requirements and the interconnection of the parameters are available here: Program example for Get_Alarm & Ack_Alarms - Part 1 (Page 3903).

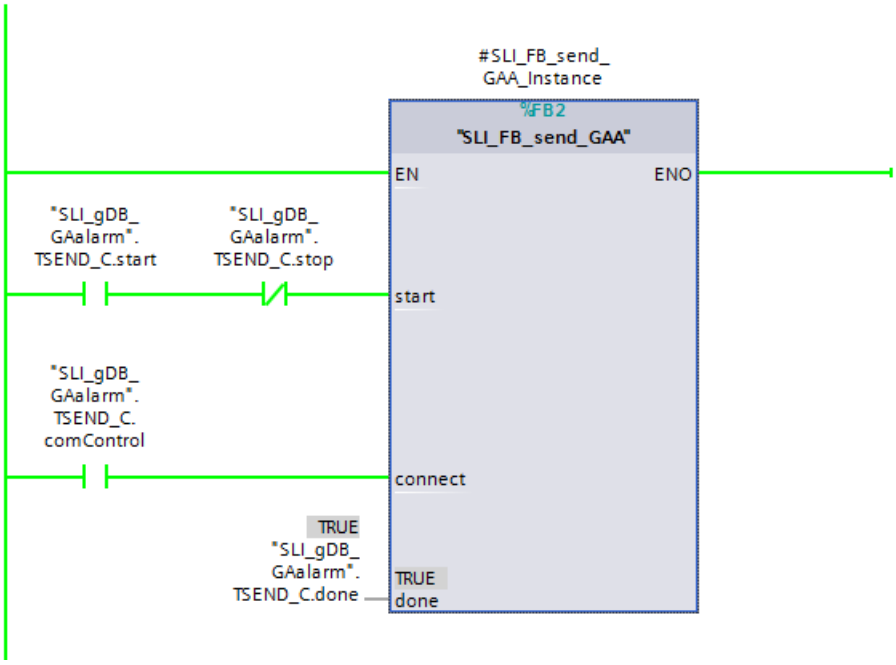
Procedure for connection setup between CPU 1 and CPU 2

Observe the order of the action steps:

1. For CPU 2, change the tag "TRCV_C.start" to "TRUE".
2. For CPU 2, change the tag "TRCV_C.comControl" to "TRUE".
3. For CPU 1, change the tag "TSEND_C.start" to "TRUE".
4. For CPU 1, change the tag "TSEND_C.comControl" to "TRUE".

Procedure for disconnection of CPU 1 and CPU 2

Observe the order of the action steps:



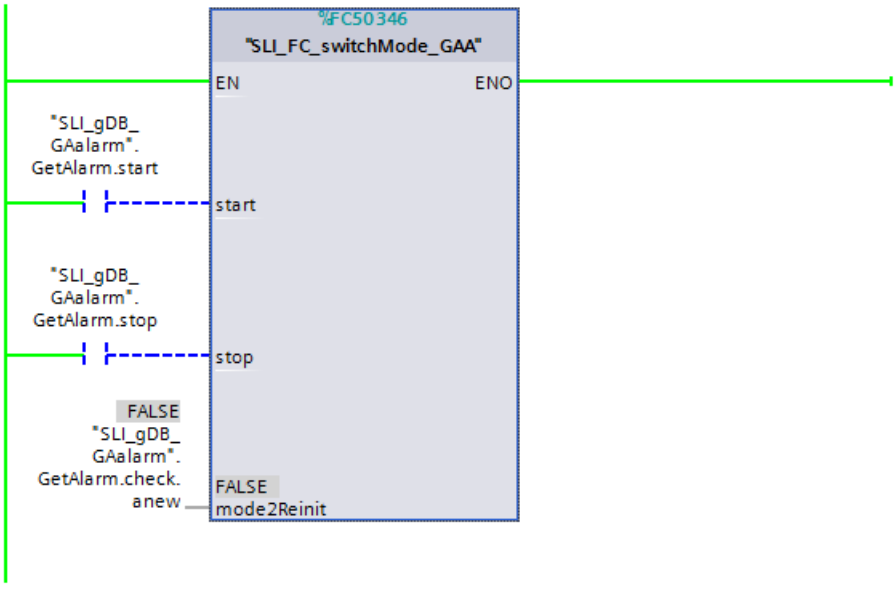
1. For CPU 1, change the tag "TSEND_C.stop" to "TRUE".
2. For CPU 2, change the tag "TRCV_C.start" to "FALSE".
3. For CPU 2, change the tag "TRCV_C.comControl" to "FALSE".
4. For CPU 1, change the tag "TSEND_C.start" to "FALSE" and the tag "TSEND_C.stop" to "FALSE".
5. For CPU 1, change the tag "TSEND_C.comControl" to "FALSE".

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 1

If the normally open contact ("TSEND_C.start") supplies the signal state "TRUE", the "TSEND_C" instruction is started. When the input parameter CONNECT ("TSEND_C.comControl") supplies the signal state "TRUE", the "TSEND_C" instruction creates a communication connection between CPU 1 and CPU 2.

Successful transfer of the data record (#sendStruct) is indicated by the output parameter DONE ("TSEND_C.done") with the signal state "TRUE" ("TSEND_C.status has the value "0000"). After transmitting the data record (#sendStruct) to CPU 2, the communication connection continues to be monitored (status "7004").

If the normally open contact ("TSEND_C.stop") supplies the signal state "TRUE", the "TSEND_C" instruction is stopped.



Additional information on the operating principle of TSEND_C (Page 4423) and TRCV_C (Page 4437) is available here: Program example for send functions (Page 4446).

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 2

If the normally open contact ("GetAlarm.start") supplies the signal state "TRUE", the "Get_Alarm" instruction is started. For this purpose, the "Get_Alarm" instruction is called in mode 1 ("GetAlarm.operateMode.value") and then changes to mode 2. After it has been processed, the tag "GetAlarm.start" is automatically reset to "FALSE".

If the normally open contact ("GetAlarm.stop") supplies the signal state "TRUE", the "Get_Alarm" instruction is stopped. For this purpose, the "Get_Alarm" instruction is called in mode 3 ("GetAlarm.operateMode.value") and then changes to inactivity (mode 0). A requirement for the stop command is successful logon of Get_Alarm ("GetAlarm.operateMode.Logon_done" is "TRUE"). After it has been processed, the tag "GetAlarm.stop" is automatically reset to "FALSE".

The success state of the processed mode of Get_Alarm is recorded:

- "GetAlarm.operateMode.Logon_done" is "TRUE" = mode 1 was completed successfully.
- "GetAlarm.operateMode.ReadData_ready" is "TRUE" = mode 2 is set. Get_Alarm is ready to read.
- "GetAlarm.operateMode.ReadData_active" is "TRUE" = Get_Alarm is in mode 2 and busy reading the data.
- "GetAlarm.operateMode.Logoff_done" is "TRUE" = mode 3 was completed successfully.

Note

Unintentional log off of Get_Alarm

When Get_Alarm is logged off in mode 2, the output parameter INIT ("GetAlarm.initiateLogin") returns the signal state "TRUE". This event is counted as read loss ("GetAlarm.currReadLoss") in FC "SLI_FC_switchMode_GAA" and the (INOUT) parameter MODE2REINIT ("GetAlarm.check.anew") of "SLI_FC_switchMode_GAA" is set to "TRUE". This results in a reset of the tags "GetAlarm.dataReady" and "GetAlarm.initiateLogin" and the "Get_Alarm" instruction is automatically restarted in mode 1. Afterwards Get_Alarm is once again ready to read in mode 2.

18		currReadLoss	UDInt	0	0
19		dataReady	Bool	false	FALSE
20		initiateLogin	Bool	false	FALSE
21		busy	Bool	false	FALSE
22		status	Word	16#0	16#0000
23		memError	Bool	false	FALSE
24		memErrStatus	Word	16#0	16#0000

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 3

When the input parameter OPERATEMODE ("GetAlarm.operateMode.value") shows the value "2", the "Get_Alarm" instruction reads all alarms of CPU 1. For this purpose, the respective alarm is recorded at the input parameter DATA ("GetAlarm.currRecord").

SLI_gDB_GAalarm

	Name	Data type	Start value	Monitor value
1	Static			
2	TSEND_C	Struct		
3	GetAlarm	Struct		
4	start	Bool	false	FALSE
5	stop	Bool	false	FALSE
6	check	Struct		
7	anew	Bool	false	FALSE
8	operateMode	Struct		
9	value	Byte	16#0	16#02
10	Logon_done	Bool	false	TRUE
11	ReadData_ready	Bool	false	TRUE
12	ReadData_active	Bool	false	FALSE
13	Logoff_done	Bool	false	FALSE
14	outputMode	Byte	16#3	16#03
15	languageCodeID	UDInt	0	0
16	currRecord	AlarmData		

The signal state "TRUE" at the output parameter DATAREADY ("#dataReady") indicates a new alarm. Because the value of "#dataReady" (as well as that of "#initiate") is only set for one cycle, the status is saved with the tag "GetAlarm.dataReady".

When the output parameter INIT ("#initiate") returns the signal state "TRUE" in mode 2, Get_Alarm was logged off and must be logged on again. See the note on network 2. In mode 1, "#initiate" / "GetAlarm.initiateLogin" shows the successful logon.

In case of an error, the status of Get_Alarm ("GetAlarm.status") is saved with the tags "GetAlarm.memErrStatus" and "GetAlarm.memErr", and Get_Alarm is set to mode 3 to log off. When Get_Alarm is to be logged off and no error occurs ("GetAlarm.status" has the value "16#0000"), logoff is saved through "GetAlarm.operateMode.Logoff_done" with the value "TRUE".

3	GetAlarm	Struct		
4	start	Bool	false	FALSE
5	stop	Bool	false	FALSE
6	check	Struct		
7	anew	Bool	false	FALSE
8	operateMode	Struct		
9	value	Byte	16#0	16#00
10	Logon_done	Bool	false	FALSE
11	ReadData_ready	Bool	false	FALSE
12	ReadData_active	Bool	false	FALSE
13	Logoff_done	Bool	false	TRUE
14	outputMode	Byte	16#3	16#03

The input parameter DATAMODE ("GetAlarm.outputMode") with the value "16#03" specifies that the alarms are read out completely (with all information). The input parameter DISPCLASSNR is not connected. This means Get_Alarm reads all display classes. The input parameter LCID ("GetAlarm.languageCodeID") with the value "0" specifies that all language versions of alarms should be read.

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 4

Under the following conditions, the currently read alarm ("GetAlarm.currRecord") as well as the read losses counted until then ("GetAlarm.currReadLoss") are saved as a combined data record in the memory array "GetAlarm.alarmStorage":

- "GetAlarm.dataReady" returns the signal state "TRUE". This means Get_Alarm has read a new alarm.
- In addition, the data record of the read alarm ("GetAlarm.currRecord") is not empty. Its alarm text is checked for this reason.

26	alarmStorage	Array[0..15] of "SG...		
27	alarmStorage[0]	"SGetAlarm"		
28	countReadL...	UDInt	0	0
29	alarm	AlarmData		
30	Produce...	UInt	0	9
31	ID_1	UInt	0	53
32	ID_2	UInt	0	1
33	PRIO	UInt	0	0
34	TimeSta...	LDT	LDT#1970-01-01-(	LDT#2016-06-22-0...
35	State	Byte	16#0	16#01
36	LCID	Array[0..2] of UInt		
37	LCID...	UInt	0	0
38	LCID...	UInt	0	0
39	LCID...	UInt	0	0
40	AlarmText	Array[0..2] of WStri...		
41	Alar...	WString[254]	WSTRING#''	WSTRING#'Warning ...

Next, the position used ("#posForAlarm") is saved in the memory array "GetAlarm.alarmStorage" in the global tag "GetAlarm.posForAlarm". In addition, the alarms are counted and the current value is recorded with the global tag "GetAlarm.countAlarms".

The position information ("#posForAlarm") is incremented so that a new alarm can be saved in a different cell in the memory array. A requirement for incrementing is that the limit of the memory array ("GetAlarm.maxPositon") is not exceeded. When the limit is exceeded, this fact is noted ("GetAlarm.limitReach") and the position information ("#posForAlarm") is set to the value "0". Any subsequent alarms would therefore overwrite old alarm entries in the memory array with this setting.

Successful copying is noted in the tag "GetAlarm.savingDone". The "GetAlarm.initiateSending" tag is set to initiate subsequent sending of the alarm.

At the end of processing of "SLI_FB_saveAlarms_GAA", the tag "GetAlarm.dataReady" (and local tags) is reset to "FALSE". The program of "SLI_FB_saveAlarms_GAA" is only processed again when "GetAlarm.dataReady" returns the value "TRUE".

25		maxPosition	UInt	15	15
26		alarmStorage	Array[0..15] of "SG...		
27		limitReach	Bool	false	FALSE
28		savingDone	Bool	false	TRUE
29		initiateSending	Bool	false	FALSE
30		countAlarms	UInt	0	1
31		posForAlarm	UInt	0	0

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 5

When the normally open contact ("startPump") and the normally closed contact ("closeValve") return the signal state "TRUE", the configured ProDiag alarm is triggered.

Get_Alarm reads the alarm and saves it in the assigned tag ("GetAlarm.currRecord"). In network 4, the alarm is subsequently copied to the memory array ("GetAlarm.alarmStorage").

17		currRecord	AlarmData		
18		ProducerID	UInt	0	9
19		ID_1	UInt	0	53
20		ID_2	UInt	0	1
21		PRIO	UInt	0	0
22		TimeStamp	LDT	LDT#1970-01-01-0	LDT#2016-06-22-0...
23		State	Byte	16#0	16#01
24		LCID	Array[0..2] of UInt		
25		LCID[0]	UInt	0	0
26		LCID[1]	UInt	0	0
27		LCID[2]	UInt	0	0
28		AlarmText	Array[0..2] of WStri...		
29		AlarmText[0]	WString[254]	WSTRING#''	WSTRING#'Warning ...
30		AlarmText[1]	WString[254]	WSTRING#''	WSTRING#''
31		AlarmText[2]	WString[254]	WSTRING#''	WSTRING#''

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 1 (data transmission)

When the tag "GetAlarm.initiateSending" returns the signal state "TRUE", the saved position ("GetAlarm.posForAlarm") is transferred in the memory array of a local tag with the same name ("#posForAlarm") and the command is forwarded for a new data transfer. The "#initiateSending" tag is set to "TRUE".

If, in addition, no error is signaled and TSEND_C is signaled as busy ("TSEND_C.error" and "TSEND_C.busy" are "FALSE"), the respective alarm ("GetAlarm.alarmStorage[..]") is transferred in abbreviated form to the structure "#sendStruct". If no stop command ("TSEND_C.stop" to "TRUE") was given, the tag "TSEND_C.start" is set to "TRUE".

The start command for data transmission ("TSEND_C.start" is "TRUE") sends the abbreviated alarm ("#sendStruct") to CPU 2 over multiple cycles.

Result of CPU 1: FB "SLI_FBCall_GetAlarm_AckA" - Network 6

If the normally open contact ("AckAlarm.executeAck") supplies the signal state "TRUE", the "Ack_Alarms" instruction is started. According to the value "1" of the input parameter MODE ("#acknowledge"), Ack_Alarms acknowledges all active alarms. Processing in the example takes place without errors ("AckAlarm.error" is "FALSE" and "AckAlarm.status" has the value "16#0000").

To view the confirmations, use an HMI device or the Web server of the CPU.

Result of CPU 2: FB "SLI_FBCall_trcv_GAA" - Network 1

If the normally open contact ("TRCV_C.start") supplies the signal state "TRUE", the "TRCV_C" instruction is started. When the input parameter CONNECT ("TRCV_C.comControl") supplies the signal state "TRUE", the "TRCV_C" instruction creates a communication connection between CPU 2 and CPU 1.

Successful transfer of the data record (#trcvStruct) is indicated by the output parameter DONE ("TRCV_C.done" and "TRCV_C.dataReceived") with the signal state "TRUE" ("TRCV_C.status has the value "0000"). After transmitting the data record (#trcvStruct) to CPU 2, the communication connection continues to be monitored and TRCV_C is ready to receive (status

"7006"). The length in Byte of the actually transmitted data record is detected with the output parameter RCVD_LEN ("TRCV_C.rcvLen").

SLI_gDB_trcv_GAA

	Name	Data type	Start value	Monitor value
1	Static			
2	TRCV_C	Struct		
3	start	Bool	false	TRUE
4	comControl	Bool	false	TRUE
5	done	Bool	false	TRUE
6	busy	Bool	false	TRUE
7	error	Bool	false	FALSE
8	status	Word	16#0	16#7006
9	memErrStatus	Word	16#0	16#0000
10	rcvLen	UDInt	0	540
11	dataReceived	Bool	false	FALSE
12	GetAlarm	Struct		
13	maxPosition	UInt	15	15
14	rcvdStorage	Array[0..15] of "rcv...		
15	limitReach	Bool	false	FALSE
16	savingDone	Bool	false	FALSE
17	countAlarms	UInt	0	0
18	posForAlarm	UInt	0	0

Additional information on the operating principle of TSEND_C (Page 4423) and TRCV_C (Page 4437) is available here: Program example for send functions (Page 4446).

Result of CPU 2: FB "SLI_FBCall_trcv_GAA" - Network 2

If the normally open contact ("TRCV_C.error") returns the signal state "TRUE", the status ("TRCV_C.status") of the error is saved ("TRCV_C.memErrStatus").

Result of CPU 2: FB "SLI_FBCall_trcv_GAA" - Network 3

An alarm is saved in the memory array "GetAlarm.rcvdStorage" under the following conditions:

- "TRCV_C.dataReceived" returns the signal state "TRUE". This means a new data record was sent to TRCV_C.
- In addition, the new received data record (#trcvStruct) is not empty.

12	GetAlarm	Struct		
13	maxPosition	UInt	15	15
14	rcvdStorage	Array[0..15] of "rcv...		
15	rcvdStorage[0]	"rcvGetAlarm"		
16	countReadL...	UDInt	0	0
17	ProducerID	UInt	0	9
18	ID_1	UInt	0	53
19	ID_2	UInt	0	1
20	PRIO	UInt	0	0
21	TimeStamp	LDT	LDT#1970-01-01-(	LDT#2016-06-22-0...
22	State	Byte	16#0	16#01
23	LCID	Array[0..2] of UInt		
24	AlarmText	WString[254]	WSTRING#''	WSTRING#'Warning ...

Next, the position used ("#posForAlarm") is saved in the memory array "GetAlarm.rcvdStorage" in the global tag "GetAlarm.posForAlarm". In addition, the alarms are counted and the current value is recorded with the global tag "GetAlarm.countAlarms".

The position information ("#posForAlarm") is incremented so that a new alarm can be saved in a different cell in the memory array. A requirement for incrementing is that the limit of the memory array ("GetAlarm.maxPositon") is not exceeded. When the limit is exceeded, this fact is noted ("GetAlarm.limitReach") and the position information ("#posForAlarm") is set to the value "0". Any subsequent alarms would therefore overwrite old alarm entries in the memory array with this setting.

Successful copying is noted in the tag "GetAlarm.savingDone".

At the end of processing of "SLI_FB_rcvdAlarms_GAA", the tag "TRCV_C.dataReceived" (and local tags) is reset to "FALSE". The program of "SLI_FB_rcvdAlarms_GAA" is only processed again when "TRCV_C.dataReceived" returns the value "TRUE".

SLI_gDB_trcv_GAA

	Name	Data type	Start value	Monitor value
1	Static			
2	TRCV_C	Struct

14	rcvdStorage	Array[0..15] of "rcv...		
15	limitReach	Bool	false	FALSE
16	savingDone	Bool	false	TRUE
17	countAlarms	UInt	0	1
18	posForAlarm	UInt	0	0

Part 1 of the program example

The requirements and the interconnection of the parameters are available here: Program example for Get_Alarm & Ack_Alarms - Part 1 (Page 3903).

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

11.4.4.9 Diagnostics (S7-1200, S7-1500)

RD_SINFO: Read current OB start information (S7-1200, S7-1500)

Description

You use the instruction "RD_SINFO" to read the start information

- of the last OB called that has not yet been completely executed, and
- of the last startup OB started.

There is no time stamp in either case. If the call is in OB 100, OB 101 or OB 102, two identical start information messages will be returned.

Parameter

The following table shows the parameters of the "RD_SINFO" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	INT	I, Q, M, D, L	Error information
TOP_SI	Output	VARIANT	D, L	Start information of the current OB
START_UP_SI	Output	VARIANT	D, L	Start information of the startup OB last started

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

SDTs of the TOP_SI parameter

The following table shows the possible SDTs for the TOP_SI parameter:

Organization blocks (OB)	System data types (SDT)	System data type numbers
Any	SI_classic	592
	SI_none	593
ProgramCycleOB	SI_ProgramCycle	594
TimeOfDayOB	SI_TimeOfDay	595

SDTs of the START_UP_SI parameter

The following table shows the possible SDTs for the START_UP_SI parameter:

System data types (SDT)	System data type numbers
SI_classic	592
SI_none	593
SI_Startup	613

Structures

The following tables set out the meaning of the structure elements of the individual structures:

Table 11-46 SI_classic structure

Structure element	Data type	Description
EV_CLASS	BYTE	• Bits 0 to 3: Event ID • Bits 4 to 7: Event class
EV_NUM	BYTE	Event number
PRIORITY	BYTE	Priority class number (Meaning of B#16#FE: OB not available or disabled or cannot be started in current operating mode)
NUM	BYTE	OB number
TYP2_3	BYTE	Data ID 2_3: Identifies the information entered in ZI2_3
TYP1	BYTE	Data ID 1: Identifies the information entered in ZI1
ZI1	WORD	Additional information 1
ZI2_3	DWORD	Additional information 2_3

Table 11-47 SI_none structure

Structure element	Data type	Description
SI_Format	USINT	• 16#FF = No information • 16#FE = Optimized start information
OB_Class	USINT	OB class for "No information" or "Optimized start information"
OB_Nr	UINT	OB number (1 ... 32767)

Table 11-48 SI_ProgramCycle structure

Structure element	Data type	Description
SI_Format	USINT	• 16#FF = No information • 16#FE = Optimized start information
OB_Class	USINT := 1	OB class for "No information" or "Optimized start information"
OB_Nr	UINT	OB number (1 ... 32767)

Width	USINT	For OB_Class = 121, 122

Note

If this was created with the block property "Standard, the structure elements specified for the SI_classic structure are identical in content to the temporary tags of an OB.

Note, however, that temporary tags of the individual OBs can have different names and different data types. Also note that the call interface of each OB includes additional information regarding the date and the time of the OB request.

Bits 4 to 7 of the EV_CLASS structure element contain the event class. The following values are possible here:

- 1: Start events from standard OBs
- 2: Start events from synchronous error OBs
- 3: Start events from asynchronous error OBs

The PRIORITY structure element supplies the priority class belonging to the current OB.

Apart from these two elements, NUM is also relevant. NUM contains the number of the current OB or the startup OB that was started last.

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
8081	Start information of the current OB does not correspond to the specified system data type
8083	Start information of the last startup OB started does not correspond to the specified system data type

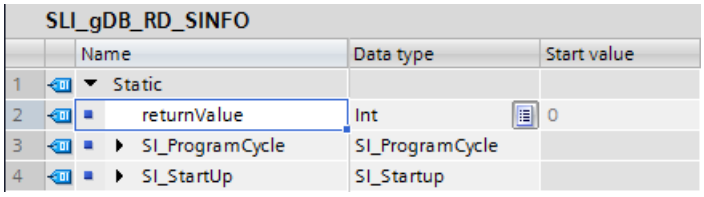
Example

OB 80 is the OB that was called last and that has not yet been completely processed and OB 100 is the start-up OB that was started last.

The following table shows the assignment between the structure elements of the TOP_SI parameter of the "RD_SINFO" instruction and the associated local tags of OB 80.

TOP_SI structure element	Data type	OB 80 - Associated local tag	Data type
EV_CLASS	BYTE	OB80_EV_CLASS	BYTE
EV_NUM	BYTE	OB80_FLT_ID	BYTE
PRIORITY	BYTE	OB80_PRIORITY	BYTE
NUM	BYTE	OB80_OB_NUMBR	BYTE
TYP2_3	BYTE	OB80_RESERVED_1	BYTE
TYP1	BYTE	OB80_RESERVED_2	BYTE
ZI1	WORD	OB80_ERROR_INFO	WORD
ZI2_3	DWORD	OB80_ERR_EV_CLASS	BYTE
		OB80_ERR_EV_NUM	BYTE
		OB80_OB_PRIORITY	BYTE
		OB80_OB_NUM	BYTE

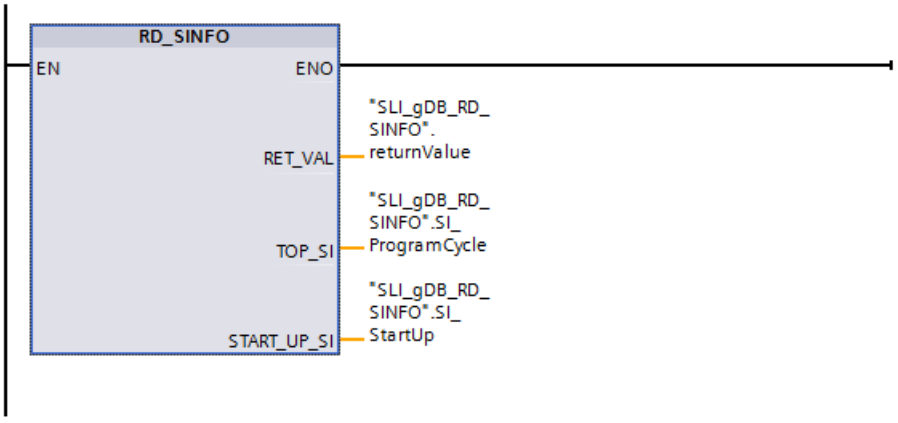
The following table shows the assignment between the structure elements of the START_UP_SI parameter of the "RD_SINFO" instruction and the associated local tags of OB 100.



START_UP_SI structure element	Data type	OB 100 - Local tag	Data type
EV_CLASS	BYTE	OB100_EV_CLASS	BYTE
EV_NUM	BYTE	OB100_STRTUP	BYTE
PRIORITY	BYTE	OB100_PRIORITY	BYTE
NUM	BYTE	OB100_OB_NUMBR	BYTE
TYP2_3	BYTE	OB100_RESERVED_1	BYTE
TYP1	BYTE	OB100_RESERVED_2	BYTE

START_UP_SI structure element	Data type	OB 100 - Local tag	Data type
ZI1	WORD	OB100_STOP	WORD
ZI2_3	DWORD	OB100_STRT_INFO	DWORD

Example



In the following example, you read out the start information of the program cycle OB that was last called and the startup OB of the CPU that was last started.

Create three tags in a global data block for storing the data.

Call the "RD_SINFO" instruction in an OB1. Interconnect the parameters of the "RD_SINFO" instruction as follows.

Use only one OB for the CPU, for the example.

When the input parameter EN returns the signal state "TRUE", the "RD_SINFO" instruction is started. The instruction "RD_SINFO" reads the start information of the last called program cycle OB (OB1) and outputs this at the output parameter TOP_SI ("SI_ProgrammCycle"). Start information of the startup OB that was
last started is output at the output parameter START_UP_SI ("SI_Startup").

According to the value of the parameter "SI_Format", OB1 uses optimized start information. In addition, the class of the OB ("OB_Class") and the assigned number of the OB ("OB_Nr") are read out. No number ("OB_Nr" with the value "0") is read out for the startup OB ("SI_Startup"), because no startup OB is used by the CPU. In addition, standard values ("SI_Format", "OB_Class") are displayed for the startup OB.

The output parameter RET_VAL ("returnValue") indicates that the processing of the example is taking place without errors (the value is "0").

SLI_gDB_RD_SINFO

	Name	Data type	Start value	Monitor value
1	Static			
2	returnValue	Int	0	0
3	SI_ProgramCycle	SI_ProgramCycle		
4	SI_Format	USInt	0	254
5	OB_Class	USInt	1	1
6	OB_Nr	UInt	0	1
7	Initial_Call	Bool	false	FALSE
8	Remanence	Bool	false	TRUE
9	SI_StartUp	SI_Startup		
10	SI_Format	USInt	0	254
11	OB_Class	USInt	100	100
12	OB_Nr	UInt	0	0
13	LostRetentive	Bool	false	FALSE
14	LostRTC	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

RT_INFO: Read out runtime statistics (S7-1500)

Description

Use the "RT_INFO" instruction to generate statistics on the runtime of specific organization blocks, communication or the user program.

Use the MODE parameter to select the information to be output:

- MODE 1 to 3 return the data on the runtime of a specific organization block whose number was specified at the OB parameter.
- MODE 10 and 11 measure over a time period of 1 s and return the mean value of the percentage of total runtime used by higher-priority OBs (MODE 10) or mean value of the percentage of total runtime used by communication (MODE 11).
- MODE 20 and 21 return the percentages of the runtime allotted to communication and the user program for the last program cycle.
- MODE 23 to 25 output the shortest, longest, and current cycle time of the user program.
- MODE 30 to 32 return data on configured settings of the user program.

All measurements are started once again when the CPU transitions from startup to RUN.

Parameters

The following table shows the parameters of the "RT_INFO" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	Use the MODE parameter to select the information you want to read out (see table "MODE parameter").
OB	Input	OB_ANY	I, Q, M, D, L or constant	Use the OB parameter to select the OB for which you want to read out information.
RET_VAL	Return	INT	I, Q, M, D, L	Error information (see " RET_VAL parameter").
INFO	InOut	VARIANT	I, Q, M, D, L	Pointer to the area to which the read data is to be written. The data type required for INFO depends on the MODE parameter (see table "MODE parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter MODE

The following table shows which information is returned for the values at the MODE parameter.

MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
1	Runtime of a specific OB	The runtime information always refers to the specified OB. Processes, such as interruptions by OBs of a higher priority or communication, are not included. You can use the instruction "RUNTIME" to measure the runtime of the entire program.	OB number	LTIME	S7-1500 V1.5
2	Maximum runtime of a specific OB		OB number	LTIME	S7-1500 V1.5
3	Minimum runtime of a specific OB		OB number	LTIME	S7-1500 V1.5

MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
10	Mean value of the percentage of total runtime used by higher-priority OBs The runtime of all OBs used in the user program with a higher priority than cyclical program OBs is output (ProgramCycle). These usually include all OB types except startup OBs. The CPU determines which OBs can be used and their priority. This information is included in the basic chapters on programming.	Averaging takes place over a time period of 1 s.	Not relevant	UINT	S7-1500 V1.5
11	Mean value of the percentage of total runtime used by communication The percentage of communication processes in the total runtime of the user program is output.		Not relevant	UINT	S7-1500 V1.5
20	Identical to MODE 10 except that the evaluation is based on the last program cycle executed.	• If the cycle time is too high (> 1 second), the calculation is not performed. The instruction outputs the value 65535 (0xFFFF). • If the cycle time is too low (< 1 millisecond), the calculation cannot be performed. In this case, the last cycle with a duration of at least one millisecond is evaluated. By assigning a minimum cycle time in the CPU properties, you can prevent cycle times from falling below 1 ms.	Not relevant	UINT	S7-1500 V1.7
21	Identical to MODE 11 except that the evaluation is based on the last program cycle executed.		Not relevant	UINT	S7-1500 V1.7
23	Longest cycle time Duration of the longest cycle since the last transition from STOP to RUN.	The times correspond to the "Cycle times measured" values in the "Cycle time" dialog of the TIA Portal. You open the dialog using Online & Diagnostics > Diagnostics > Cycle time.	Not relevant	LTIME	S7-1500 V1.7
24	Shortest cycle time Duration of the shortest cycle since the last transition from STOP to RUN.		Not relevant	LTIME	S7-1500 V1.7
25	Current/last cycle time Duration of the last cycle.		Not relevant	LTIME	S7-1500 V1.7

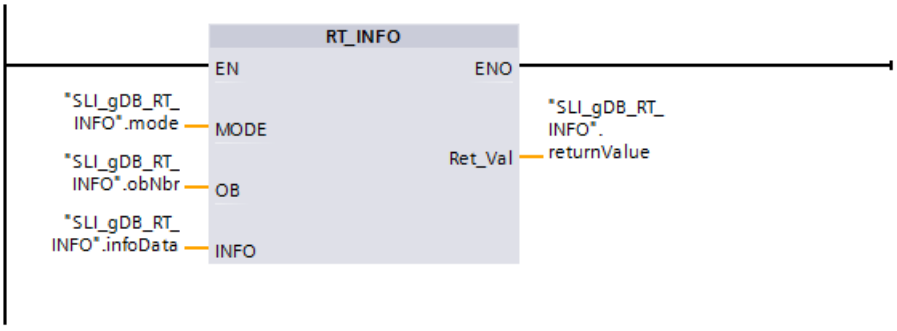
MODE (decimal)	Description	Note	Value at OB parameter	Data type of INFO	Available as of CPU version
30	Cycle monitoring time Maximum permitted duration of the CPU program. If the cycle time exceeds the cycle monitoring time, the CPU goes to STOP or calls a time error OB.	The times correspond to the "Configured cycle time" values in the "Cycle time" dialog of the TIA Portal. You open the dialog using Online & Diagnostics > Diagnostics > Cycle time.	Not relevant	LTIME	S7-1500 V1.5
31	Output of the configured minimum cycle time for the user program. If a minimum cycle time has been assigned in the CPU properties, the operating system delays the start of the new cycle until the minimum cycle time has been reached.		Not relevant	LTIME	S7-1500 V1.5
32	Output of the configured maximum communication load as a percentage	The specification of the percentage of the cycle load allotted to communication is made in the CPU properties under "Communication load".	Not relevant	UINT	S7-1500 V1.5

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0	No error
8080	Value at the MODE parameter is not supported.
8081	Organization block selected at OB parameter does not exist in the user program.
8092	Selected MODE parameter is not supported by this CPU version.
80C3	Insufficient resources. Try to call the instruction again at a later time.
8452	Data type at INFO parameter is incorrect. Check whether the correct data type was selected depending on the MODE parameter.

Example



In the following example, you read out the runtime of a cycle organization block.

Create four tags in a global data block for storing the data.

SLI_gDB_RT_INFO

	Name	Data type	Start value
1	Static		
2	mode	UInt	1
3	obNbr	OB_ANY	123
4	infoData	LTime	LT#0ns
5	returnValue	Int	0

Interconnect the parameters of the instruction as follows.

- Create a new block of type "Program cycle". Specify the OB number at the OB parameter.
- Enter "1" (read out runtime of a particular OB) at the MODE parameter.
- Specify a tag with the data type LTIME at the INFO parameter ("infoData" in this case).
- Specify a tag with the data type INT at the RET_VAL parameter to output the error messages of the instruction.

After calling the instruction, the currently measured runtime is written to the "infoData" tag.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

LED: Read LED status (S7-1200, S7-1500)

Description

You can use the "LED" instruction to read out the status (e.g., "On" or "Off") of a particular module LED.

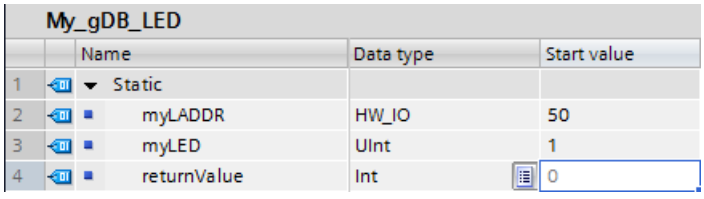
- With the LADDR parameter, you address the CPU or the interface.
- With the LED parameter, you select the module LED whose current status is read out using the instruction.
- The RET_VAL parameter outputs the status of the selected LED when the instruction is called. Depending on the LED selected, only certain status information can be displayed. For example, some LEDs have only one color. Refer to the hardware documentation of the respective module for information on the possible statuses of a particular LED.

Parameters

The following table shows the parameters of the "LED" instruction:

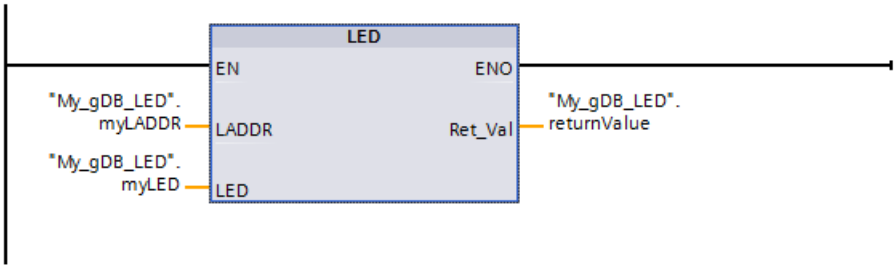
Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware identifier of the CPU or interface The number is assigned automatically and is stored in the properties of the CPU or interface in the hardware configuration (*CPU name* + *~Common*).
LED	Input	UINT	I, Q, M, D, L or constant	Identification number of the LED: • 1: STOP/RUN • 2: ERROR • 3: MAINT (maintenance) • 4: Redundant • 5: Link (green) • 6: Rx/Tx (yellow)
RET_VAL	Return	INT	I, Q, M, D, L	Status of LED

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Parameter RET_VAL

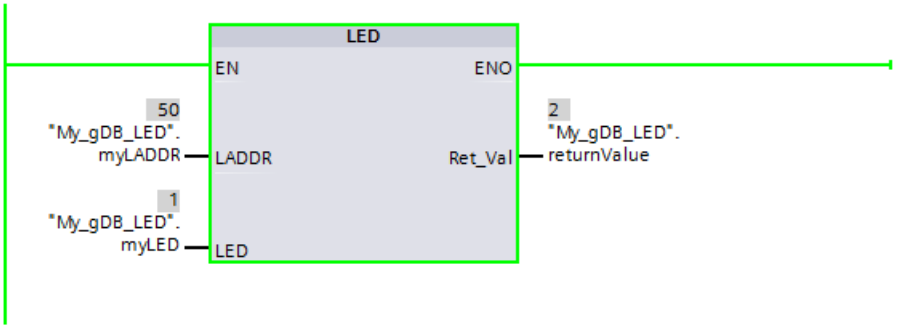
RET_VAL	Description
0 to 9	LED status: • 0 = LED does not exist or status information not available • 1 = Permanently switched off • 2 = Color 1 (e.g., for LED STOP/RUN: green) permanently ON • 3 = Color 2 (e.g., for LED STOP/RUN: orange) permanently ON • 4 = Color 1 flashing at 2 Hz • 5 = Color 2 flashing at 2 Hz • 6 = Colors 1 and 2 flashing alternately at 2 Hz • 7 = LED is active, color 1 • 8 = LED is active, color 2 • 9 = LED does not exist or status information not available For reasons of compatibility, ENO is set to FALSE for this value of RET_VAL.
8091	Hardware component addressed using the LADDR parameter is not available.
8092	A hardware component was addressed with the LADDR parameter that does not return the required information.
8093	The identification number specified at the LED parameter is not defined.
80Bx	The CPU specified in the LADDR parameter does not support the "LED" instruction.



Example

In the following example, you read out the status of the CPU LED.

Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows.

The HW identifier of the CPU is made known to the "LED" instruction through parameter LADDR ("myLADDR"). The CPU LED to be monitored is made known through parameter LED ("myLED"). The status of the CPU LED (STOP/RUN) is queried. If the CPU is placed in RUN operating mode from STOP, the value "6" (green and orange alternating) is indicated at output

parameter RET_VAL ("returnValue"). Then, the value "2" (permanently green) is indicated as the LED status ("returnValue").

Note: The meaning of the colors for the STOP/RUN LED are as follows:

Color	Meaning
Red	STOP
Green	RUN
Alternating green and orange	The CPU is loading
Alternating red and green	Program processing is running

Additional information on the meaning of the LED colors can be found in the hardware description of the CPU.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Get_IM_Data: Reading identification and maintenance data (S7-1200, S7-1500)

Description

The "Get_IM_Data" instruction reads the identification and maintenance data (I&M) data from a device. Use the LADDR parameter to select the device from which you want to read the I&M via the hardware identifier.

The IM_TYPE parameter is used to select the data that is read out via the instruction:

- IM_TYPE = 0: I&M 0 data
  The I&M 0 data are the device-specific basic information of a device and contain information such as the manufacturer ID, order number, serial number and the hardware and firmware version. Only read access is possible to the I&M 0 data. The information is also displayed in the TIA Portal with the "Online & Diagnostics" view of a device.
- IM_TYPE = 11: I&M 1 data from the parameter assignment data of the CPU
  The I&M 1 data contain a functional description of the device and the location designation. i.e. the information about how the device is designated within the plant.

- IM_TYPE = 12: I&M 2 data from the parameter assignment data of the CPU
  The I&M 2 data includes the date of installation, i.e. the information about when the device was installed in the plant.
- IM_TYPE = 13: I&M 3 data from the parameter assignment data of the CPU
  The I&M 3 data contains additional information about the installed device. The additional information is free text and is assigned as desired.

The I&M data read is written to the addressed area defined at the DATA parameter.

The execution status of the read job is displayed via the BUSY, DONE, ERROR output parameters and the two middle bytes of the STATUS output parameter.

Definition: Identification and maintenance data (I&M)

Identification and maintenance (I&M) data refers to information stored in a module, which assists you in checking the plant configuration, locating hardware changes in a plant and eliminating errors.

- Identification data (I-data) is static information about a device that can only be read.
- Maintenance data (M-data) refers to plant-dependent information, such as the installation location or date. Maintenance data are created during configuration and written to the module.

Parameters

The following table shows the parameters of the "Get_IM_Data" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware ID of the device The number is assigned automatically and is stored in the properties of the device or in the hardware configuration.
IM_TYPE	Input	UINT	I, Q, M, D, L or constant	Identification and maintenance data number Possible values: • 0: I&M 0 data • 11: I&M 1 data from the parameter assignment data of the CPU • 12: I&M 2 data from the parameter assignment data of the CPU • 13: I&M 3 data from the parameter assignment data of the CPU
DATA	InOut	VARIANT	I, Q, M, D, L	Area for storing the read identification and maintenance data (see below).
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. The I&M data were transferred to the DATA parameter.

Parameter	Declaration	Data type	Memory area	Description
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction completed or not yet started. • 1: Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display it, therefore, copy STATUS to a free data area.

You can find more information on the data types in "Overview of the valid data types (Page 2239)".

Parameter DATA for I&M 0 data

Use an array (ARRAY of BYTE) or a special data structure to store the I&M 0 data:

- If you address an array (ARRAY of BYTE) at parameter DATA, the read I&M 0 data is copied as a byte sequence to DATA. If the addressed array is longer than the read data, the unneeded bytes are filled with zeros.
- The following "IM0_Data" structure can also be used at the DATA parameter for I&M 0 data:

Parameter		Data type	Bytes	Description
Manufacturer_ID		UINT	2	Manufacturer ID (e.g. "42" for SIEMENS)
Order_ID		CHAR[20]	20	Order number
Serial_Number		CHAR[16]	16	Serial number
Hardware_Revision		UNIT	2	Hardware revision
Software_Revision		STRUCT	4	Firmware revision
	Type	CHAR	1	-
	Functional	USInt	1	-
	Bugfix	USInt	1	-
	Internal	USInt	1	-
Revision_Counter		UINT	2	Revision counter
Profile_ID		UNIT	2	Profile
Profile_Specific_Type		UNIT	2	Device class
IM_Version		UNIT	2	I&M version
I&M_Supported		UNIT	2	I&M data (I&M 0-I&M 4) supported at the device end

If a different data type is used at the DATA parameter, the STATUS parameter outputs error code 8093.

DATA parameter for I&M 1, I&M 2, and I&M 3 data

Use a string (STRING), an array (ARRAY of CHAR/BYTE) or a data structure (STRUCT) to store the I&M data:

- If you address a string (STRING data type) at the the DATA parameter, the length of the string automatically adjusts the length of the read I&M data (up to 254 characters).
- If you address a data structure (ARRAY of CHAR/BYTE or STRUCT) a the DATA parameter, the I&M data read are written to the individual components of the data type used. If the addressed data structure is longer than the read data, the remaining components are filled with zeros.
- If you crate a data structure with a STRUCT data type at the DATA parameter, use a data block without optimized block access (see category "Attributes" of the block properties).

If a data type other than STRING, ARRAY of BYTE/CHAR or STRUCT is used at the DATA parameter, the STATUS parameter generates error code 8093.

Note

Additional information about I&M data

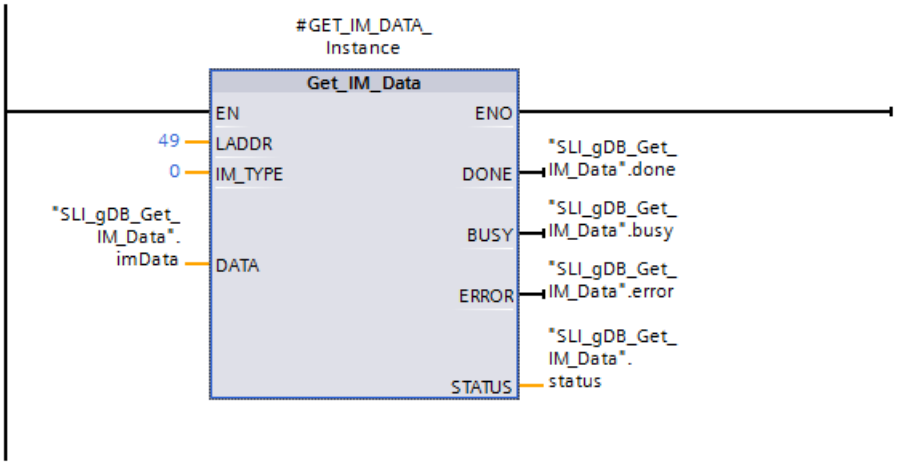
You can find more information about I&M data, for example, on the PROFIBUS & PROFINET International websites (link: http://www.profibus.com (http://www.profibus.com)).

Parameter STATUS

Error code* (W#16#...)	Description
0	No error
7001	First call of the asynchronous instruction "Get_IM_Data". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "Get_IM_Data". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
8091	The device addressed at the LADDR parameter does not exist.
8092	LADDR addresses a device that does not support the output of the I&M data.
8093	Data type at the DATA parameter is not supported.
80A1	LADDR addresses a device that does not support the output of I&M 1, I&M 2 or I&M 3 data.
80B1	No valid data available. (Either the I&M data is not supported by the (sub)module or you have not configured I&M data for this device.)
80B2	Invalid value at the IM_TYPE parameter or the selected IM_TYPE is not supported by the CPU or the addressed device.
80C3	Maximum of 10 parallel executions of the instances exceeded: • Avoid more than 10 parallel calls. • Repeat the call at a later time, as this is a temporary error.

Error code* (W#16#...)	Description
8752	The memory area specified at the DATA parameter is too small to store all the I&M data. The read I&M data are stored only up to the maximum length of the specified memory area.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you read out the IM0 data of an S7-1500 CPU. The IM0 data are the basic information of a device and contain information such as the manufacturer ID, order number, serial number and the hardware and firmware version.

Create four tags and a structure with the IM0_Data data type in a global data block for storing the IM0 data. You can assign any name to the structure ("MyPLC_IM_Data") in this case.

SLI_gDB_Get_IM_Data

	Name	Data type	Start value
1	Static		
2	imData	IM0_Data	
3	done	Bool	false
4	busy	Bool	false
5	error	Bool	false
6	status	Word	16#0

Enter the hardware identifier of the CPU at the LADDR parameter. The hardware identifier uniquely identifies the product. To determine the hardware identifier of your CPU, open the PLC tag table and the System constants tab. Then, search for the CPU in the Name column. The associated value is the hardware identifier that you enter at the LADDR parameter.

Once the instruction is successfully executed, the IM0 data is written to the data block.

SLI_gDB_Get_IM_Data

		Name	Data type	Start value	Monitor value
1		Static			
2		imData	IM0_Data		
3		Manufacturer_ID	UInt	0	42
4		Order_ID	String[20]	''	'6ES7 511-1AK00-0...
5		Serial_Number	String[16]	''	'S C-DOS710132013'
6		Hardware_Revision	UInt	0	3
7		Software_Revision	IM0_Version		
8		Type	Char	' '	'V'
9		Functional	USInt	0	1
10		Bugfix	USInt	0	5
11		Internal	USInt	0	0
12		Revision_Counter	UInt	0	0
13		Profile_ID	UInt	0	0
14		Profile_Specific_Ty...	UInt	0	0
15		IM_Version	Word	16#0	16#0101
16		IM_Supported	Word	16#0	16#001E
17		done	Bool	false	TRUE
18		busy	Bool	false	FALSE
19		error	Bool	false	FALSE
20		status	Word	16#0	16#0000

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Difference between synchronous and asynchronous instructions (Page 2571)

GET_NAME: Read out name of an IO device or a DP slave (S7-1200, S7-1500)

Description

The instruction "GET_NAME" reads out the name of an IO device or a DP slave. The name is displayed in the network view and in the properties of the IO device or the DP slave. The following screenshot shows this using an IO device as example.

You select the IO device or the DP slave by using the hardware identifier of the PROFINET IO system or the DP master system (at the LADDR parameter) and the device number of the IO device or the PROFIBUS address of the DP slave (STATION_NR parameter).

After the instruction has been executed successfully, the name of the IO device or the DP slave is written to the area addressed with the DATA parameter.

The name that is read depends on the type of IO device:

- For a DP slave or IO device, the name of the head module is output.
- For an I-slave or I-device, the name of the interface module is output.
- The name of the interface is output for an HMI panel.
- The name of the interface module is output for a PC station.
- The name of the Device Access Point (DAP) is displayed (name of the interface or head module) for GSD devices.

The length of the name is output at the LEN parameter. If the name is longer than the area specified at the DATA parameter, only that section which corresponds to the maximum length of the addressed area will be written.

The maximum length for a name is 128 characters.

Note

Name of the CPU readout (Version 1.1)

If you assign a "0" at each of the parameters LADDR and STATION_NR the instruction will output the name of the CPU.

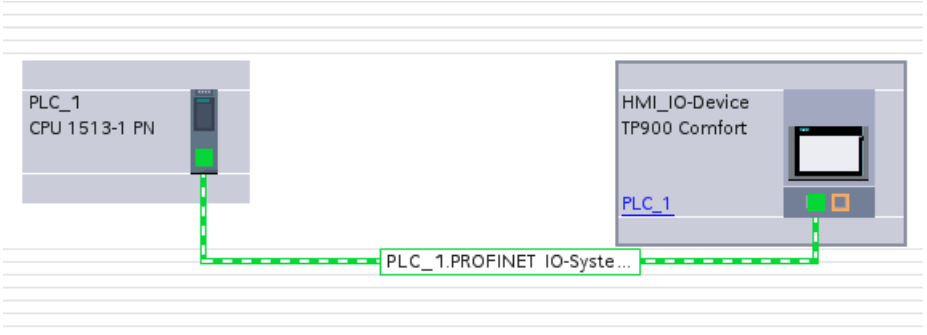
Parameters

The following table shows the parameters of the "GET_NAME" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IOSYSTEM	I, Q, M, D, L or constant	Hardware identifier of the PROFINET IO or DP master system. The number is taken from the system constants or the properties of the PROFINET IO system or DP master system.
STATION_NR	Input	UINT	I, Q, M, D, L or constant	Device number of the PROFINET IO device or PROFIBUS address of the DP slave. This number is displayed in the network view and in the properties of the IO device or the DP slave.
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the area to which the name is written.
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. The name of the IO device or the DP slave was transferred to the area at the DATA parameter.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
LEN	Output	DINT	I, Q, M, D, L	Length of the name of the IO device or the DP slave (number of characters).
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, therefore, copy STATUS to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS



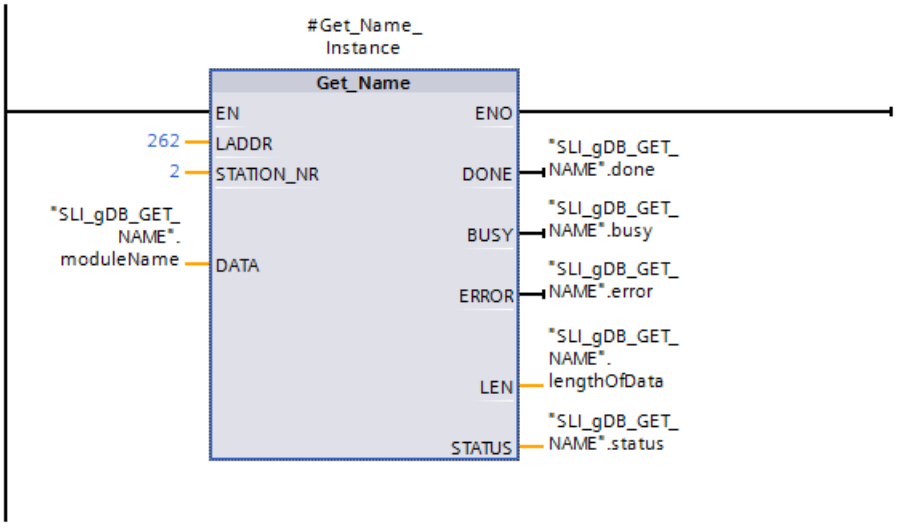
Error code* (W#16#...)	Explanation
0	No error
7001	First call of the asynchronous instruction "GET_NAME". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "GET_NAME". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
8090	The hardware identifier specified at the LADDR parameter does not exist in the project.
8092	The value at the LADDR parameter does not address a PROFINET IO system or a DP master system.
8093	Instruction does not support data type at the DATA parameter.
8095	• Device number (STATION_NR parameter) does not exist in the selected PROFINET IO system or does not address an IO device. • PROFIBUS address (STATION_NR parameter) does not exist in the selected DP master system.
80B1	The CPU used does not support the instruction.
80C3	Temporary resource error: The CPU is currently processing the maximum possible number of simultaneous block calls. "GET_NAME" cannot be executed until at least one of the block calls is finished.
8852	The area specified at the DATA parameter is too short for the full name of the IO device or the DP slave. The name will be written up to the maximum possible length. To read the full name, use a longer data area at the DATA parameter. The area must have at least as many characters as there are at the LEN parameter.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

The following example shows how you can read out the station name of a HMI panel.

Configuration of the HMI panel:

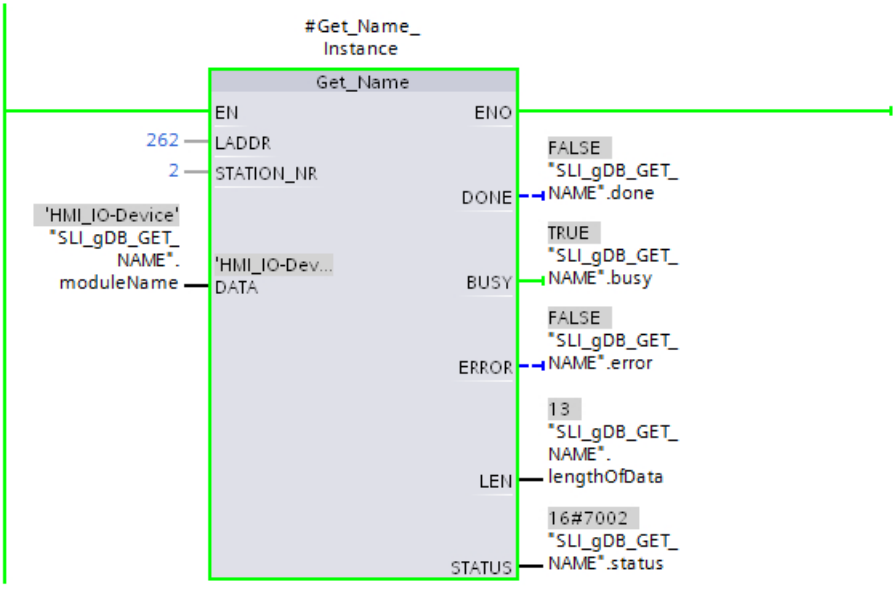
- The HMI panel with the station name "HMI_IO-Device" is created in the network view and assigned to the same PROFINET IO system as the CPU.
- The operating mode "IO device" was activated in the properties of the hardware configuration for the HMI panel and the CPU was assigned as the IO controller.
- The device number "20" assigned in the properties under "Ethernet addresses".



Create the following tags for storing the data in a global data block:

SLI_gDB_GET_NAME

	Name	Data type	Start value
1	Static		
2	moduleName	String	''
3	done	Bool	false
4	busy	Bool	false
5	error	Bool	false
6	lengthOfData	DInt	0
7	status	Word	16#0



Assigning parameters to the instruction "GET_NAME":

- Enter the hardware identifier of the IO system (262) at the input parameter LADDR.
- Enter the device number of the HMI panel (2) at the input parameter STATION_NR.
- Interconnect the remaining parameters of the "GET_NAME" instruction as follows.

Execution of the instruction:

- After execution of the instruction, the name of the station of the HMI panel (HMI_IO-Device) is stored at parameter DATA ("moduleName").
- The number of characters of the name is output (13) at the parameter LEN.
- As GET_NAME was not stopped after the successful reading of the IO device, output parameter BUSY ("busy") shows the value "TRUE" and output parameter STATUS ("status") shows the value "16#7002".

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

GetStationInfo: Read information of an IO device (S7-1200, S7-1500)

Description

You can use the "GetStationInfo" instruction to read information of a PROFINET IO device. The instruction also enables you to read the information of an IO device located in a lower-level IO system (connected via CP/CM).

The IO device is addressed via the hardware identifier of the station at the LADDR parameter. The hardware identifier is displayed in the "Devices & Networks" view in the station properties.

Use the MODE parameter to select the information to be read.

At the DATA parameter, specify the data area to which the read address data will be written. For storing the IP address, use the "IF_CONF_v4" structure. For storing the MAC address, use the "IF_CONF_MAC" structure.

Enable reading of the address data using the REQ control parameter. This requires the IO device to be accessible.

The execution status of the read job is displayed via the BUSY, DONE, ERROR output parameters and the STATUS output parameter.

Note

Address the IO device using only the hardware identifier of the station

The station, the IO device and PROFINET interface have their own hardware identifier. Use only the hardware identifier of the station for the "GetStationInfo" instruction.

If a PROFINET interface is addressed via the LADDR parameter, for example, the address data is not read and the 8092 error code is generated.

To read the address data of an integrated PROFINET interface or a CM/CP in the central configuration, use the "RDREC" instruction.

Parameters

The following table shows the parameters of the "GetStationInfo" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Control parameter Request Activates the reading of the information with REQ = "1".
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the station of the IO device The number is taken from the properties of the station in the Network view or from the "System constants" tab of the default tag table.
DETAIL	Input	HW_SUBMODULE	I, Q, M, D, L or constant	The DETAIL parameter is not used. Leave the parameter unconnected.
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of address data to be read: • MODE = 1: Address parameter according to IPv4 (S7-1500 CPUs as of firmware version V1.1) • MODE = 2: MAC address (S7-1500 CPUs as of firmware version V1.5)
DATA	InOut	VARIANT	D, L	Pointer to the area to which the address data of the IO device is written. Use the "IF_CONF_v4" structure for MODE = 1 and the "IF_CONF_MAC" structure for MODE = 2.
DONE	Output	BOOL	I, Q, M, D, L	The instruction was executed successfully. The address data was transferred to the DATA parameter.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.

You can find more information on the data types in "Overview of the valid data types (Page 2239)".

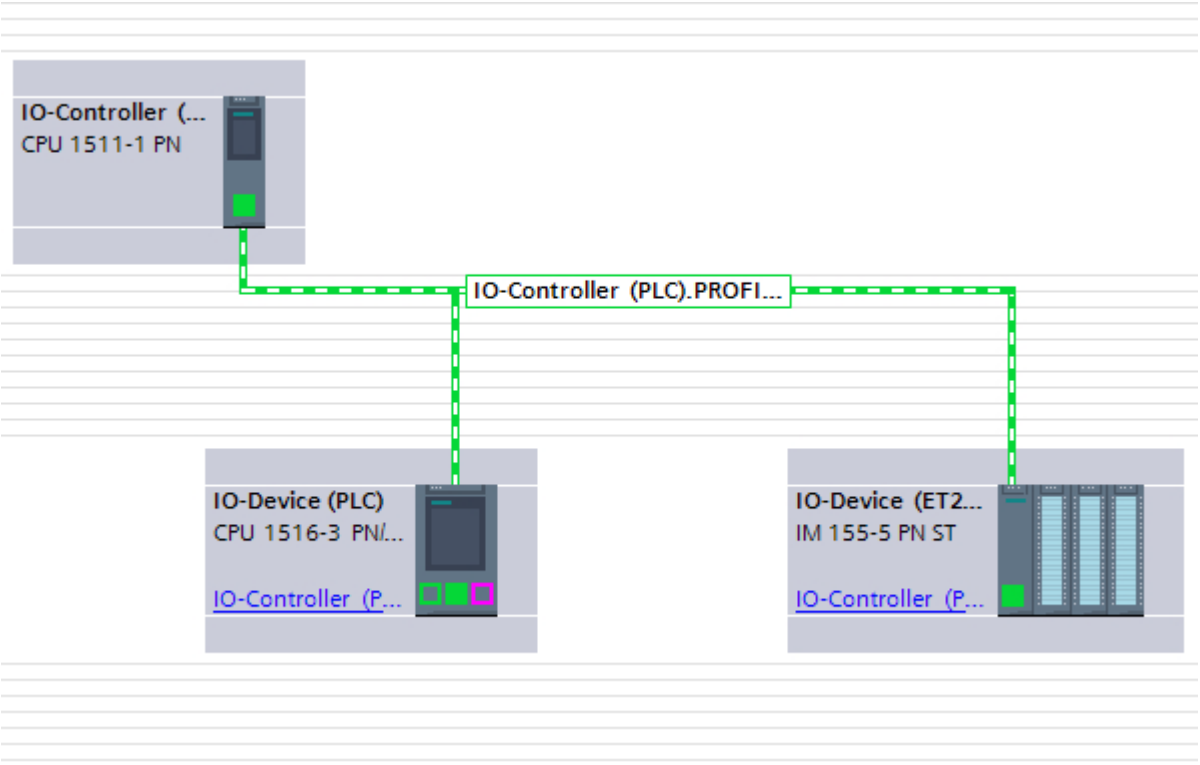
Parameter DATA

- Use the "IF_CONF_v4" structure at the DATA parameter to store the address parameter according to IPv4.

Byte	Parameter	Data type	Start value	Description
0 … 1	Id	UINT	30	ID of the "IF_CONF_v4" structure.
2 … 3	Length	UNIT	18	Length of data read in BYTE.
4 ... 5	Mode	UNIT	0	Not relevant for the "GetStationInfo" instruction (left at "0").
6 ... 9	InterfaceAddress	ARRAY [1..4] of BYTE	-	IP address of the IO device in the format IP_V4, e.g. for 192.168.3.10: • addr[1] = 192 • addr[2] = 168 • addr[3] = 3 • addr[4] = 10
10 … 13	SubnetMask	ARRAY [1..4] of BYTE	-	Subnet mask of the IO device in the format IP_V4, e.g. for 255.255.255.0: • addr[1] = 255 • addr[2] = 255 • addr[3] = 255 • addr[4] = 0
14 ... 17	DefaultRouter	ARRAY [1..4] of BYTE	-	IP address of the router in the format IP_V4, e.g. for 192.168.3.1: • addr[1] = 192 • addr[2] = 168 • addr[3] = 3 • addr[4] = 1

- Use the "IF_CONF_MAC" structure at parameter DATA for storing the MAC address.

Byte	Parameter	Data type	Start value	Description
0 … 1	Id	UINT	3	ID of the "IF_CONF_MAC" structure.
2 … 3	Length	UNIT	12	Length of data read in BYTE.
4 ... 5	Mode	UNIT	0	Not relevant for the "GetStationInfo" instruction (left at "0").
6 ... 11	MACAddress	ARRAY [1..6] of BYTE	-	MAC address of the IO device, e.g. for 08-00-06-12-34-56 • Mac[1] = 8 • Mac[2] = 0 • Mac[3] = 6 • Mac[4] = 12 • Mac[5] = 34 • Mac[6] = 56



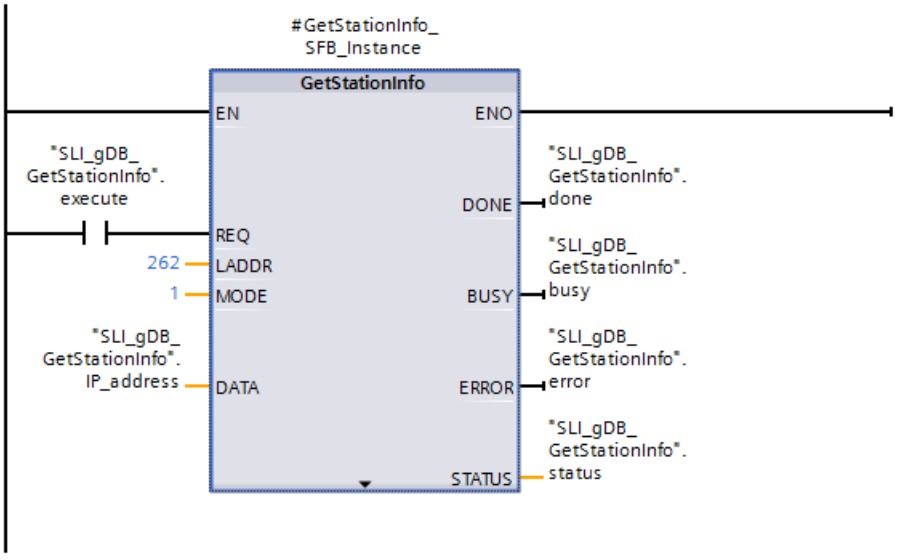
Parameter STATUS

Error code* (W#16#...)	Explanation
0	No error
7000	No job in progress.
7001	First call of the asynchronous instruction "GetStationInfo". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
7002	Additional call of the asynchronous instruction "GetStationInfo". Execution of the instruction not yet complete (BUSY = 1, DONE = 0).
8080	Value at the MODE parameter is not supported.
8090	The hardware identifier specified at the LADDR parameter is not configured.
8092	The LADDR parameter does not address a PROFINET IO device.
8093	Invalid data type at the DATA parameter.
80A0	Requested information is not read.
80C0	Addressed IO device is not reachable.
80C3	The maximum number of simultaneous calls of the "GetStationInfo" instruction (10 instances) has been reached.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

Below, you use the „GetStationInfo“ instruction to read the IP address data of an IO device and write the information to a data block. The IP address data includes the IP address, subnet mask and (if used) the address data of the router.

The instruction is executed on the IO controller and reads the IP address information of a lower-level IO device (an ET200MP in this example).



Create five tags and a structure with the IF_CONF_v4 data type in a global data block for storing the address data. Assign any name to the structure (in this case "IP_Address").

SLI_gDB_GetStationInfo

		Name	Data type	Start value
1		Static		
2		execute	Bool	false
3		IP_address	IF_CONF_v4	
4		done	Bool	false
5		busy	Bool	false
6		error	Bool	false
7		status	Word	16#0

Then call the "GetStationInfo" instruction:

- You use the IF_CONF_v4 structure at the DATA parameter.
- Enter the hardware identifier of the IO device at the LADDR parameter. The hardware identifier uniquely identifies the product. To determine the hardware identifier of your IO device, open the PLC tag table and the System constants tab. Then, search for the device in the Name column and for the „Hw_Device“ in the Data type column. The associated value is the hardware identifier that you enter at the LADDR parameter.
- Select "1" (read address parameters according to IPv4) for the MODE parameter.

You start reading the address data with REQ= 1 (TRUE). Once the instruction is successfully executed, the IP address data is written to the data block.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

GetChecksum: Read out checksum (S7-1200, S7-1500)

Description

The "GetChecksum" instruction reads the checksum of a group of objects. The objects are selected with the parameter "Scope".

Note

Generation of the checksum for blocks

There are differences between standard and safety blocks in terms of the generation of the checksum. You can find additional information in the help for the STEP 7 Safety option package.

Parameter

The following table shows the parameters of the "GetChecksum" instruction:

Parameter	Declaration	Data type	Description
Scope	Input	UINT	With the Scope parameter, you select the objects for which you want to read out the checksum: • 1: Standard blocks (i.e. no safety blocks) • 2: Safety blocks • 3: Text lists
Range (hidden)	Input	UINT	"Range" must have the value 0.
Subrange (hidden)	Input	UINT	"Subrange" must have the value 0.
Done	Output	BOOL	The instruction was executed successfully. The checksum was transferred to the Checksum parameter.
Busy	Output	BOOL	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.
Error	Output	BOOL	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the "Status" parameter.

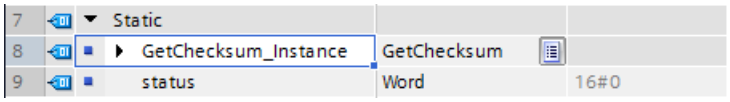
Parameter	Declaration	Data type	Description
Status	Output	WORD	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy STATUS to a free data area.
Checksum	InOut	VARIANT	Checksum The "Checksum" parameter must point to a tag of the data type ARRAY[0..7] of BYTE; unused bytes are set to 0.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter "Status"

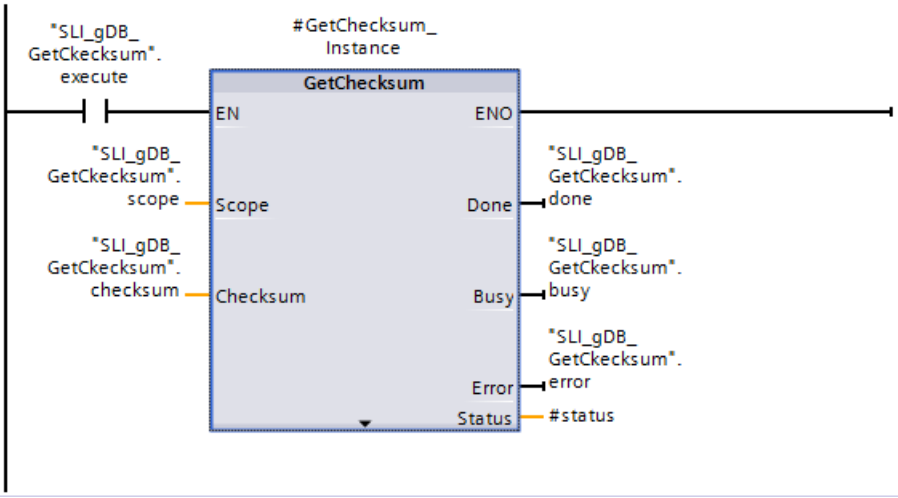
Error code* (W#16#...)	Explanation
0	No error
7001	First call: Generation of the checksum initiated
7002	Intermediate call: Generation of the checksum already active
8080	Invalid value of the "Scope" parameter
8081	The "Range" parameter is not supported in this firmware version and must have the value 0.
8082	The "Subrange" parameter is not supported in this firmware version and must have the value 0.
8091	The "GetChecksum" instruction is not supported by the CPU.
8852	The tag to which the "Checksum" parameter points has the wrong data type.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



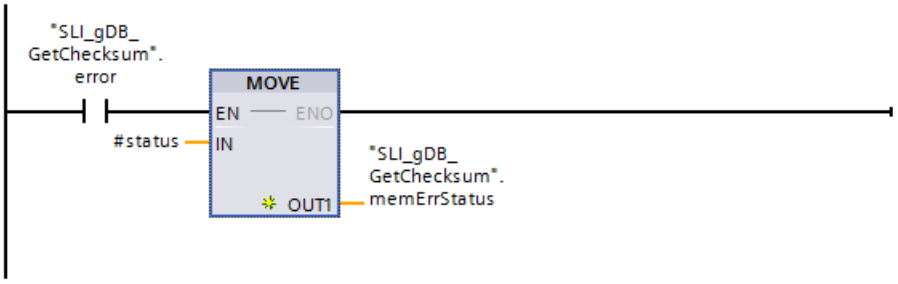
In the following example, you read out the checksum of the standard blocks of a S7-1500 CPU.

Create the following tags for storing the data in a global data block:



SLI_gDB_GetChecksum

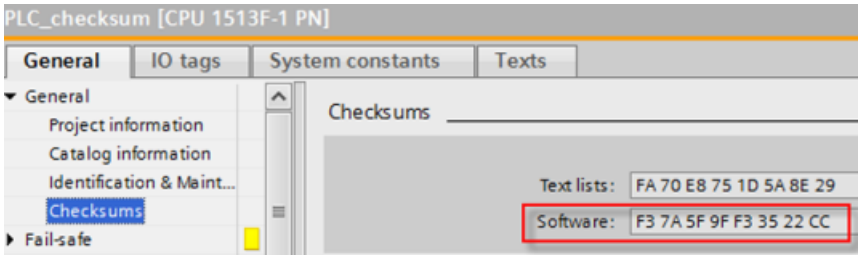
	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	scope	UInt	1
4	checksum	Array[0..7] of Byte	
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	memErrStatus	Word	16#0



Create an FB. Create the following local tags in the FB.

Network 1: Interconnect the parameters of the "GetChecksum" instruction as follows.

Network 2: If an error occurs, save the status as follows.



If the normally open contact ("execute") supplies the signal state "TRUE", the "GetChecksum" instruction is executed. The checksum of the standard blocks is read according to the value "1" of the input parameter SCOPE ("scope"). The checksum is output at the CHECKSUM ("checksum") parameter. The success status of GetChecksum is displayed at the output parameter DONE ("done").

Output parameters STATUS ("#status" and "memErrStatus") and ERROR ("error") indicate that the processing in the example was completed without error.

SLI_gDB_GetCkecksum

	Name	Data type	Start value	Monitor value
1	Static			
2	execute	Bool	false	TRUE
3	scope	UInt	1	1
4	checksum	Array[0..7] of Byte		
5	checksum[0]	Byte	16#0	16#F3
6	checksum[1]	Byte	16#0	16#7A
7	checksum[2]	Byte	16#0	16#5F
8	checksum[3]	Byte	16#0	16#9F
9	checksum[4]	Byte	16#0	16#F3
10	checksum[5]	Byte	16#0	16#35
11	checksum[6]	Byte	16#0	16#22
12	checksum[7]	Byte	16#0	16#CC
13	busy	Bool	false	FALSE
14	done	Bool	false	TRUE
15	error	Bool	false	FALSE
16	memErrStatus	Word	16#0	16#0000

You can also find the checksum in the CPU properties.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

Comparison of PLC programs based on checksums (Page 5086)

GetSMCinfo: Reading out information about the SIMATIC memory card (S7-1200, S7-1500)

Description

Use the instruction "GetSMCinfo" to retrieve information about the inserted SIMATIC memory card. The information to be read out is selected with the parameter "Mode".

Enable reading of the address data via the REQ control parameter. The output parameters Done, Busy, Error and Status indicate the status of the job.

Parameter

The following table shows the parameters of the instruction "GetSMCinfo":

Parameter	Declaration	Data type	Description
REQ	Input	BOOL	Control parameter Request Activates the reading of the information with REQ = "1".
Mode	Input	UINT	Use the Mode parameter to select the information about the SIMATIC memory card that you want to read out: • 0: Memory size in KB (1 KB = 1024 bytes) • 1: Assigned memory space in KB • 2: Maintenance information: Previously used up portion of the service life in % Note: – With the S7-1500 software controllers and S7-PLCSIM, 0x00 is always entered in Info for Mode=2 (no maintenance information available). – With SIMATIC Memory Cards, which do not generally support this information or which cannot supply this information with the current firmware of your CPU, 0xFF is entered in Info. • 3: Set proportion of the service life as a percentage after which the CPU creates a diagnostics buffer entry and activates the maintenance LED and a diagnostics interrupt. Note: This information is read from the memory card, but instead from the planning data. If you have disabled the generation of diagnostics interrupt, 0xFF is entered in Info.
Done	Output	BOOL	1: The instruction has been executed successfully. The information that was read is transferred to the Info parameter.
Busy	Output	BOOL	Status parameter • 0: Execution of the instruction complete. • 1: Execution of the instruction not yet complete.
Error	Output	BOOL	Status parameter • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the Status parameter.
Status	Output	INT	Error code
Info	InOut	UDINT	Buffer for the information that was read.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Determining the I&M 0 data

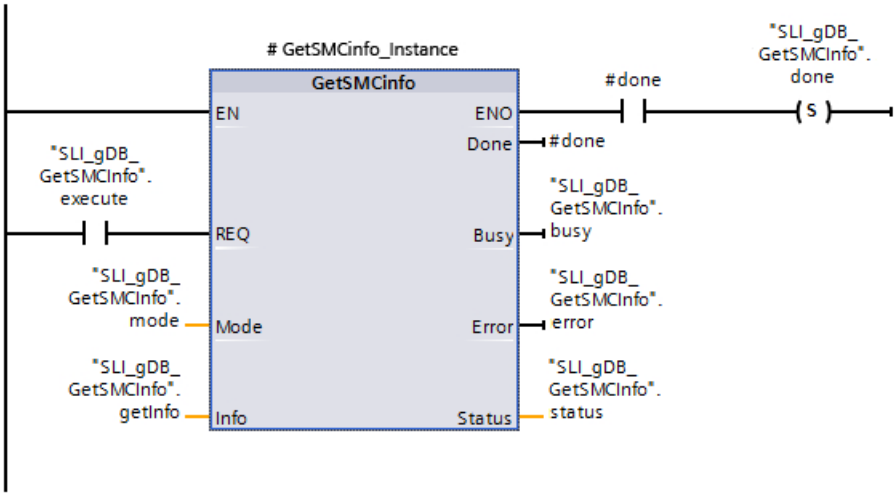
The I&M 0 data of the SIMATIC memory card cannot be determined with the GetSMCinfo instruction. For this use the instruction "Get_IM_Data (Page 3947)".

Parameter Status

Error code* (W#16#...)	Explanation
0	No error.
7000	No job in progress.
7001	First call: Trigger job (Busy = 1, Done = 0).
7002	Intermediate call: Job already active (Busy = 1, Done = 0).
8080	Invalid value of the "Mode" parameter
8081 (only S7-1200)	No SIMATIC memory card inserted.
8092	No data available, for example, because "GetSMCinfo" is not supported by the CPU.
80C3	The maximum number of simultaneous calls of the "GetSMCinfo" instruction has been reached.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, you determine the memory size of the SIMATIC memory card used.



Create the following tags for storing the data in a global data block:

SLI_gDB_GetSMCinfo

	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	mode	UInt	0
4	getInfo	UDInt	0
5	done	Bool	false
6	busy	Bool	false
7	error	Bool	false
8	status	Word	16#0

Create an FB. In the status area of the FB, create a local tag"#done" with the Bool data type.

Interconnect the parameters of the "GetSMCinfo" instruction as follows.

The GetSMCinfo instruction is executed only when the input parameter REQ ("execute") returns the signal state "TRUE". The mode to be used for reading out the SIMATIC Memory Card is stored in the input parameter MODE ("mode"). The memory size of the SIMATIC memory card is read according to the value "0" and displayed in KB at parameter INFO ("getInfo"). The success status of GetSMCinfo is displayed at the output parameter DONE ("#done") and stored in the tag "done".

Output parameters STATUS ("status") and ERROR ("error") indicate that the processing in the example was completed without error.

SLI_gDB_GetSMCinfo

	Name	Data type	Start value	Monitor value
1	Static			
2	execute	Bool	false	TRUE
3	mode	UInt	0	0
4	getInfo	UDInt	0	2025008
5	done	Bool	false	TRUE
6	busy	Bool	false	FALSE
7	error	Bool	false	FALSE
8	status	Word	16#0	16#0000

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

DeviceStates: Read module status information in an IO system (S7-1200, S7-1500)

Description

You use the instruction "DeviceStates" to query specific status information for all modules in an IO system, which means:

- Either for all IO devices in a PROFINET IO system
- Or for all DP slaves in a DP master system

The Boolean value that is output indicates the modules to which the selected status applies. For example, read out which IO devices are currently disabled in a PROFINET IO system.

Information is also displayed as to whether the status information to be read applies to at least one of the IO devices or DP slaves.

The instruction can be called in a cyclic OB as well as in an interrupt OB (e.g. OB82 - diagnostic interrupt).

Parameters

The following table shows the parameters of the "DeviceStates" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IOSYSTEM	I, Q, M, L or constant	Hardware identifier of the PROFINET IO or DP master system (see description below)
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of status information to be read (see description below)
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction (see description below)
STATE	InOut	VARIANT	I, Q, M, D, L	Buffer for status of the IO devices or the DP slaves (see description below)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter LADDR

You select the PROFINET IO or DP master system at the LADDR parameter by means of the hardware identifier.

The hardware identifier is available:

- Either in the Network view of the properties of the PROFINET IO or DP master system.
- Or in the PLC tag table in the listed system constants with the data type HW_IOSYSTEM.

Parameter MODE

You use the MODE parameter to read out status information. You can read out one of the following status information items for the entire PROFINET IO or DP master system:

- 1: IO devices/DP slaves are configured
- 2: IO devices/DP slaves are faulty
- 3: IO devices/DP slaves are disabled
- 4: IO devices/DP slaves exist
- 5: IO devices/DP slaves for which a problem has occurred. For example:
  - Maintenance demanded or recommended
  - Not accessible
  - Not available
  - Error occurred

Parameter STATE

With the STATE parameter, the status of the IO devices/DP slaves that was selected with the MODE parameter is output.

If the status selected using MODE applies to an IO device/DP slave, the following bits are set to "1" at the STATE parameter:

- Bit 0 = 1: Group display. The bit n of at least one IO device/DP slave was set to "1".
- Bit n = 1: The status selected with MODE applies to the IO device/DP slave.
  - With a PROFINET IO system, bit n corresponds to the device number of the respective IO device (see properties of the PROFINET interface in the device view and network view)
  - With a PROFIBUS DP system, bit n corresponds to the PROFIBUS address of the DP slave (see properties of the DP slave in the device view and network view)

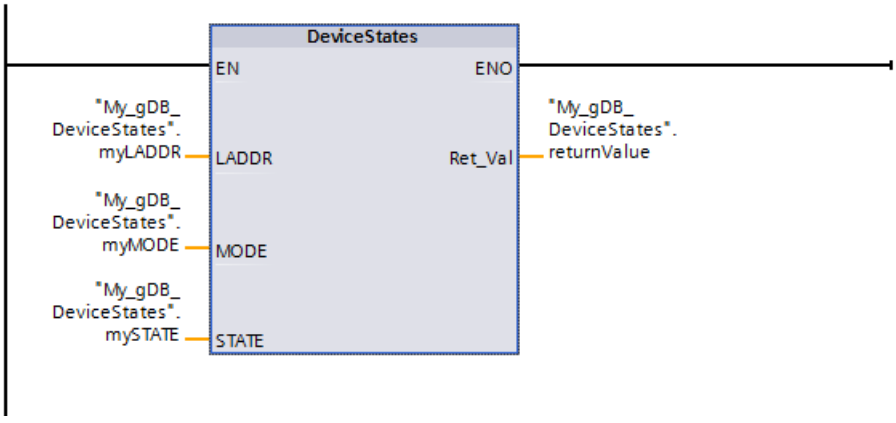
Use "BOOL" or "Array of BOOL" as data type:

- To only output the bit for group display of the status information, you can use the data type BOOL at the STATE parameter.
- To output the status information for all IO devices/DP slaves, use Array of BOOL with the following length:
  - With PROFINET IO system: 1024 bits
  - With DP master system: 128 bits

Parameter RET_VAL

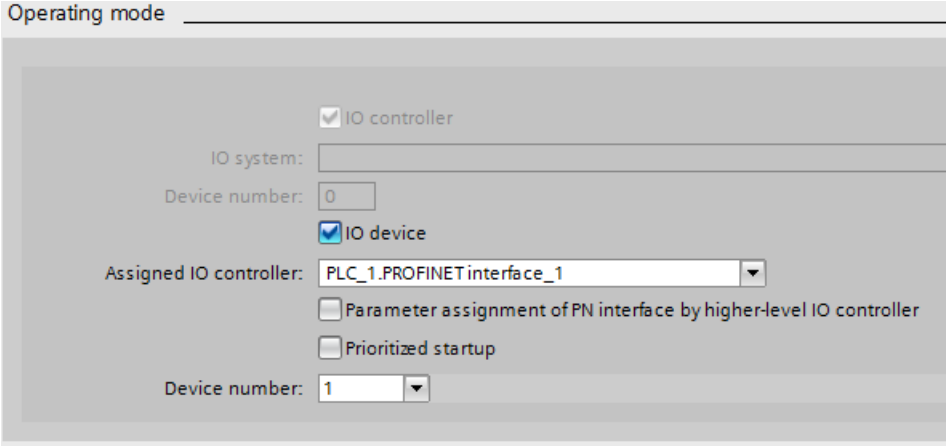
Error code* (W#16#...)	Description
0	No error
8091	Hardware identifier of the LADDR parameter does not exist. Check (for example, in the system constants) whether the value for LADDR exists in the project.
8092	LADDR does not address a PROFINET IO or DP master system.
8093	Invalid data type at the STATE parameter.
80B1	Instruction "DeviceStates" is not supported by the CPU.
80B2	The selected MODE parameter is not supported by the used CPU for the IO system specified in the LADDR parameter.
8452	The complete status information does not fit in the tag configured in the STATE parameter. Note: When the tag configured at STATE is checked for adequate field length, the CountOfElements instruction is called. This counts the fill elements when the data type VARIANT points to an Array of BOOL; with an Array [0...120] of BOOL e.g. 128 is determined as the field length. This has the consequence that the error code W#16#8452 is only returned by DeviceStates when the number of field elements you have set plus the number of fill elements created by the CPU falls below the value 1024 or 128
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example - Reading out the presence of IO devices in the PROFINET IO master system



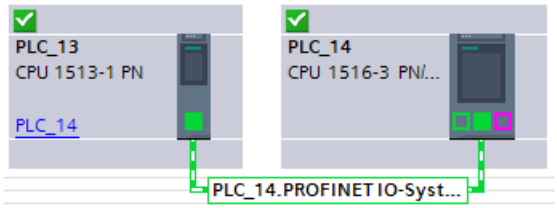
In the following example, you query the existence of IO devices in an IO system. The IO system consists of two CPUs of the S7-1500 series. The "PLC_14" CPU will contain the program, including the "DeviceStates" instruction. The "PLC_13" CPU will be configured as an IO device.

In the "PLC_14" CPU: Create three tags and a "mySTATE" structure (with the Array of BOOL data type) in a global data block for storing the data.



My_gDB_DeviceStates

		Name	Data type	Start value
1		Static		
2		myLADDR	HW_IOSYSTEM	258
3		myMODE	UInt	4
4		returnValue	Int	0
5		mySTATE	Array[0..1023] ...	
6		mySTATE[0]	Bool	false
7		mySTATE[1]	Bool	false
8		mySTATE[2]	Bool	false
9		mySTATE[3]	Bool	false
10		mySTATE[4]	Bool	false
11		mySTATE[5]	Bool	false
12		mySTATE[6]	Bool	false



In the "PLC_14" CPU: The instruction is called in a cyclic OB. Interconnect the parameters of the instruction as follows.

In the "PLC_13" CPU: Set up this CPU "PLC_13" as an IO device using the CPU properties. The IO device receives the device number 1.

An IO system is displayed in the Network view.

In the "PLC_14" CPU: The HW identifier of the IO system is made known to the "DeviceStates" instruction through parameter LADDR ("myLADDR"). According to the value "4" of parameter MODE ("myMODE"), the IO system is searched for IO devices.

At parameter STATE ("mySTATE"), the presence is output for the IO devices (based on the value of parameter MODE). Bit 0 serves as a group value and indicates that IO devices are present. Bit 1 indicates that the IO device with the device number 1 is present.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

My_gDB_DeviceStates

	Name	Data type	Start value	Monitor value
1	Static			
2	myLADDR	HW_IOSYSTEM	258	16#0102
3	myMODE	UInt	4	4
4	returnValue	Int	0	0
5	mySTATE	Array[0..1023] ...		
6	mySTATE[0]	Bool	false	TRUE
7	mySTATE[1]	Bool	false	TRUE
8	mySTATE[2]	Bool	false	FALSE
9	mySTATE[3]	Bool	false	FALSE
10	mySTATE[4]	Bool	false	FALSE
11	mySTATE[5]	Bool	false	FALSE
12	mySTATE[6]	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Example - Reading the faulty stations of a PROFINET IO master system

A PROFINET IO system consists of 4 IO devices with the device numbers 1, 2, 3 and 4. The IO device with number 2 is faulty.

The instruction "DeviceStates" is executed for the PROFINET IO system with MODE = 2 (faulty/ not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one of the IO devices.
- Bit 1 = 0: IO device with device number 1 is not faulty.
- Bit 2 = 1: IO device with device number 2 is faulty.
- Bit 3 = 0: IO device with device number 3 is not faulty.
- Bit 4 = 0: IO device with device number 4 is not faulty.

- Bit 5 = 0: Irrelevant
- Bit 6 = 0: Irrelevant
- ...

Example - Reading the faulty stations of a PROFIBUS DP master system

A DP master system consists of 4 DP slaves with the PROFIBUS addresses 3, 4, 5 and 6. The DP slave with address 4 is faulty.

The instruction "DeviceStates" is executed for the DP master system with MODE = 2 (faulty/ not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one of the DP slaves.
- Bit 1 = 0: Irrelevant
- Bit 2 = 0: Irrelevant
- Bit 3 = 0: DP slave with address 3 is not faulty.
- Bit 4 = 1: DP slave with address 4 is faulty.
- Bit 5 = 0: DP slave with address 5 is not faulty.
- Bit 6 = 0: DP slave with address 6 is not faulty.
- Bit 7 = 0: Irrelevant
- Bit 8 = 0: Irrelevant
- ...

ModuleStates: Read module status information of a module (S7-1200, S7-1500)

Description

You can use the "ModuleStates" instruction to read the status information of the modules of a PROFINET IO device or PROFIBUS DP slave.

The Boolean value that is output indicates the modules to which the selected status applies. You can, for example, read which modules are currently disabled in a PROFINET IO device.

Information is also displayed as to whether the status information to be read applies to at least one of the modules.

The instruction can be called in a cyclic OB as well as in an interrupt OB (e.g. OB82 - diagnostic interrupt).

Parameters

The following table shows the parameters of the "ModuleStates" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the station (see description below)
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of module status information to be read (see description below)
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction (see description below)
STATE	InOut	VARIANT	I, Q, M, D, L	Buffer for the module status (see description below)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter LADDR

You select the IO device or the DP slave at the LADDR parameter by means of the hardware identifier of the station.

The hardware identifier is available:

- Either in the network view of the properties of the IO device station or DP slave station.
- Or in the PLC tag table for the listed system constants with the data type HW_DEVICE (for an IO device) or with the data type HW_DPSLAVE (for a DP slave).

Parameter MODE

You use the MODE parameter to read out status information. One of the following status information items can be read for the modules:

- 1: Modules are configured
- 2: Modules are faulty
- 3: Modules are disabled
- 4: Modules exist
- 5: There is a problem in the modules. For example:
  - Maintenance demanded or recommended
  - Not accessible
  - Not available
  - Error occurred

Parameter STATE

The STATE parameter outputs the status of the modules selected with the MODE parameter.

If the status selected using MODE applies to a module, the following bits are set to "1":

- Bit 0 = 1: Group display. The bit n of at least one module was set to "1".
- Bit n = 1: The status selected with MODE applies to the module in slot n-1 (example: bit 3 = slot 2).

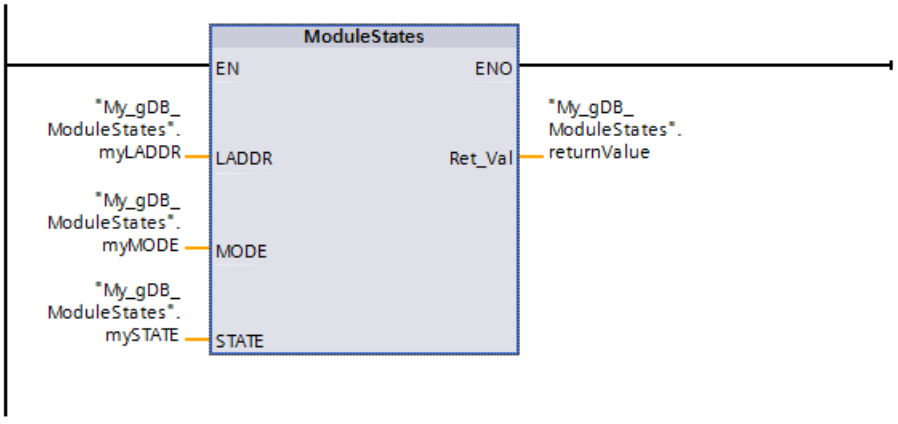
Use "BOOL" or "Array of BOOL" as data type:

- To only output the bit for group display of the status information, use the BOOL data type at the STATE parameter.
- To output the status information for all modules, use Array of BOOL with a length of 128 bits.

Parameter RET_VAL

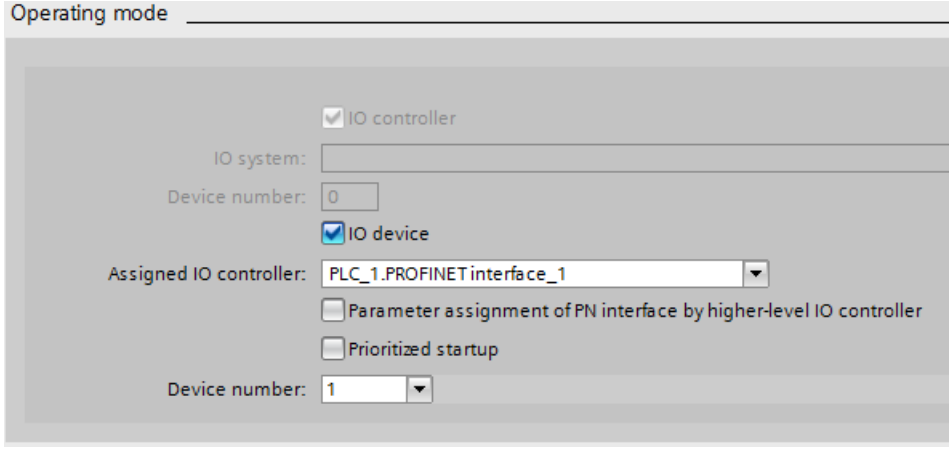
Error code* (W#16#...)	Description
0	No error
8091	Hardware identifier of the LADDR parameter does not exist. Check (for example, in the system constants) whether the value for LADDR exists in the project.
8092	LADDR does not address an IO device or DP slave.
8093	Invalid data type at the STATE parameter.
80B1	The instruction "ModuleStates" is not supported by the CPU.
80B2	The selected MODE parameter is not supported by the used CPU for the IO device/the DP slave in the LADDR parameter.
8452	The complete status information does not fit in the tag configured in the STATE parameter. Note: When the tag configured at STATE is checked for adequate field length, the CountOfElements instruction is called. This counts the fill elements when the data type VARIANT points to an Array of BOOL; with an Array [0...120] of BOOL e.g. 128 is determined as the field length. This has the consequence that the error code W#16#8452 is only returned by ModuleStates when the number of field elements you have set plus the number of fill elements created by the CPU falls below the value 128
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



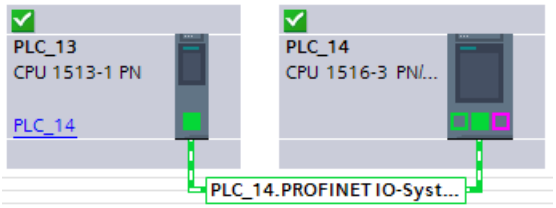
In the following example, you query the existence of modules of a PROFINET IO device. The IO system consists of two CPUs of the S7-1500 series. The "PLC_14" CPU will contain the program, including the "ModuleStates" instruction. The "PLC_13" CPU will be configured as an IO device.

In the "PLC_14" CPU: Create three tags and a "mySTATE" structure (with the Array of BOOL data type) in a global data block for storing the data.



My_gDB_ModuleStates

	Name	Data type	Start value
1	Static		
2	myLADDR	HW_DEVICE	260
3	myMODE	UInt	4
4	returnValue	Int	0
5	mySTATE	Array[0..127] of Bool	
6	mySTATE[0]	Bool	false
7	mySTATE[1]	Bool	false
8	mySTATE[2]	Bool	false
9	mySTATE[3]	Bool	false
10	mySTATE[4]	Bool	false
11	mySTATE[5]	Bool	false
12	mySTATE[6]	Bool	false



In the "PLC_14" CPU: The instruction is called in a cyclic OB. Interconnect the parameters of the instruction as follows.

In the "PLC_13" CPU: Set up this CPU "PLC_13" as an IO device using the CPU properties.

An IO system is displayed in the Network view.

In the "PLC_14" CPU: A module is located in slot 1 of the IO device.

In the "PLC_14" CPU: The HW identifier of the IO device is made known to the "ModuleStates" instruction through parameter LADDR ("myLADDR"). According to the value "4" of parameter MODE ("myMODE"), the IO device is searched for modules.

At parameter STATE ("mySTATE"), the presence is output for the modules (based on the value of parameter MODE) . Bit 0 serves as a group value and indicates that modules are present. Bit 2 indicates that a module is present in slot 1.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

My_gDB_ModuleStates

		Name	Data type	Start value	Monitor value
1		Static			
2		myLADDR	HW_DEVICE	260	16#0104
3		myMODE	UInt	4	4
4		returnValue	Int	0	0
5		mySTATE	Array[0..127] of Bool		
6		mySTATE[0]	Bool	false	TRUE
7		mySTATE[1]	Bool	false	FALSE
8		mySTATE[2]	Bool	false	TRUE
9		mySTATE[3]	Bool	false	FALSE
10		mySTATE[4]	Bool	false	FALSE
11		mySTATE[5]	Bool	false	FALSE
12		mySTATE[6]	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Example

An IO device contains 4 modules in slots 1 to 4. The module in slot 2 is faulty.

The instruction "ModuleStates" is executed for the IO device with MODE = 2 (faulty/not faulty).

The following bits are set in the STATE parameter:

- Bit 0 = 1: A fault exists for at least one module.
- Bit 1 = 0: Slot number 0 (used by IO device)
- Bit 2 = 0: Module in slot number 1 is not faulty.
- Bit 3 = 1: Module in slot number 2 is faulty.
- Bit 4 = 0: Module in slot number 3 is not faulty.
- Bit 5 = 0: Module in slot number 4 is not faulty.
- Bit 6 = 0: Irrelevant
- Bit 7 = 0: Irrelevant

GEN_DIAG: Generate diagnostics information (S7-1500)

Description

The "GEN_DIAG" instruction generates diagnostics information for hardware components from other manufacturers for use in TIA Portal diagnostics. The GSD(GSDL/GSDML) file supplied by the manufacturer must first be installed before the instruction can be used.

The instruction generates all diagnostic events (including those for maintenance).

- Use the LADDR parameter to select the hardware component for which you want to generate a diagnostic event.
- Use the MODE parameter to specify whether the event is to be outgoing or incoming.
- Use the DiagEvent parameter to define the diagnostic event in the DiagnosticDetail structure. When you define a tag at the DiagEvent parameter, the structure is created automatically in the local interface of the block.

The diagnostics information is provided synchronously. Diagnostics information transfer and alarm output are asynchronous.

NOTICE
Failsafe-specific errors messages are not valid If you define failsafe-specific diagnostics information at the DiagEvent parameter, the instruction will check this information and output the error code 80A1.

Parameters

The following table shows the parameters of the "GEN_DIAG" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Identification number of the hardware component
MODE	Input	UINT	I, Q, M, D, L or constant	Selection of incoming/outgoing information: • 1: The diagnostic event specified is an incoming event • 2: The diagnostic event specified is an outgoing event • 3: All diagnostic events are outgoing. There are therefore no hardware component faults (green diagnostics symbol). The DiagEvent parameter is not evaluated when MODE = 3.
DiagEvent	InOut	DiagnosticDetail	L, D	Specifies the diagnostic event (see "DiagEvent parameter").
RET_VAL	Return	INT	I, Q, M, D, L	Status of instruction / error message (see "RET_VAL parameter")

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter DiagEvent

The structure DiagnosticDetail is a system data type for specifying the diagnostic event. Its structure is as follows:

Parameter		Data type	Description
DiagnosticDetail		Struct	
	ChannelInfo	WORD	Channel properties (0...7)
	ALID	UINT	Local ID of the alarm. The ID uniquely identifies the alarm.
	TextID	UINT	ID of an alarm text in a text list.
	ChannelNumber	UINT	Manufacturer-specific channel number (0x0000 — 0x7FFF)
	Addval_0	DWORD	Placeholder for additional information The value / list of values depends on the connection error.
	TextID2	UINT	Texts for CPU response (mode, OB calls, etc.).
	LADDR	HW_ANY	Identical to the LADDR parameter.
	TextListId	UINT	• 0: No text list • ≠0: ID of the text list
	ChannelDirection	UINT	• 0000: Irrelevant • FFF1: Input • FFF2: Output • FFF3: Input/Output
	Addval_1	DWORD	Placeholder for additional information on the channel error (depends on the GSD file). For channel error types, see also: IEC 61158 (PROFINET IO Type 10 and PROFIBUS DP Type 3).

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error
8080	Value in the MODE parameter is not supported.
8090	Identification for hardware component not available at the LADDR parameter.
8091	Diagnostics information cannot be generated for the hardware component addressed at the LADDR parameter.
80A1	• Content of the DiagnosticsDetail structure at the DiagEvent parameter is invalid or inconsistent. • Failsafe-specific diagnostics information defined at the DiagEvent parameter (not valid).
80A4	Hardware component addressed cannot be accessed.
80C1	Insufficient resources for parallel execution.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

GET_DIAG: Read diagnostic information (S7-1200, S7-1500)

Description

The "GET_DIAG" instruction is used to read the diagnostic information of a hardware component. The hardware component is selected with the parameter LADDR. With the MODE parameter, you select which diagnostic information is read.

Parameters

The following table shows the parameters of the "GET_DIAG" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	Use the MODE parameter to select which diagnostics data is output.
LADDR	Input	HW_ANY (WORD)	I, Q, M, L or constant	Hardware ID of the hardware component
RET_VAL	Return	INT	I, Q, M, D, L	Status of the instruction
CNT_DIAG	Output	UINT	I, Q, M, D, L	Reserved (always "0").
DIAG	InOut	VARIANT	I, Q, M, D, L	Diagnostic information corresponds to the selected mode, see table below
DETAIL	InOut	VARIANT	I, Q, M, D, L	Parameter is hidden. Do not use this parameter!

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter MODE

Depending on the value at the MODE parameter, different diagnostic data is output at the DIAG, CNT_DIAG and DETAIL output parameters.

MODE	Description	DIAG	CNT_DIAG
0	Output of all supported diagnostic information for a hardware component as DWORD, where Bit X=1 indicates that mode X is supported.	Bits of the DWORD data type: • Bit 0 = 1: MODE 0 is supported • Bit 1 = 1: MODE 1 is supported • Bit 2 = 1: MODE 2 is supported • Bits 3 to 31: Not relevant	0
1	Output of the diagnostic status of the addressed hardware component.	Structure DIS (see below for description): • MaintenanceState • ComponentStateDetail • OwnState • IOState • OperatingState	0
2	Output of the status of all subordinate components of the addressed hardware component.	Structure DNN (see below for description): • SubordinateState • SubordinateIOState • DNNmode	0

DIS structure

With parameter MODE = 1, the diagnostic information is output in accordance with the DIS structure. In this case, enter the system data type "DIS" as data type for the tag declaration.

Note

Determining the OperatingState

When determining the OperatingState, you need to select LADDR = 52 (hardware identifier of CPUExecUnit).

The following table shows the meaning of the individual parameter values.

Parameter	Data type	Value	Description
MaintenanceState	DWORD	Enum	
		0	Good
		1	The hardware component is disabled.
		2	-
		3	-
		4	-
		5	Maintenance required
		6	Maintenance demanded
		7	Error
		8	Status unknown / error in higher-level hardware component
		9	-
		10	Inputs/outputs are not available.

Parameter	Data type	Value	Description
ComponentState-Detail	DWORD	Bit array	Status: • Bit 0 to 15: Status of the hardware component • Bit 16 to 31: Status of the CPU
		0 to 2 (Enum)	Additional information: • 0: No additional information • 1: Transfer not permitted
		3	Bit 3 = 1 if at least one qualified diagnostics is available
		4	Bit 4 = 1: Maintenance required for at least one channel or the component
		5	Bit 5 = 1: Maintenance demanded for at least one channel or the component
		6	Bit 6 = 1: Error in at least one channel or the component
		7 to 10 (Enum)	• 0: Own - Hardware component is available • 1: Application Ready Pending - No I/O access • 2: Locked by Superordinated - No access to hardware component • 3: Locked by IOController - No access to hardware component • 4: Locked by IOSupervisor - No access to hardware component
		11 to 14 (Enum)	• 0 (bit 11 = 0, bit 12 = 0, bit 13 = 0, bit 14 = 0): OK - The correct element exists. • 1 (bit 11 = 1, bit 12 = 0, bit 13 = 0, bit 14 = 0): Substitute - The element was replaced by a compatible element. • 2 (bit 11 = 0, bit 12 = 1, bit 13 = 0, bit 14 = 0): Wrong - The element was replaced by an incompatible element (The element is reachable, but not ready for operation.). • 3 (bit 11 = 1, bit 12 = 1, bit 13 = 0, bit 14 = 0): No Submodule - The element does not exist.
		15	Reserved (always "1").
		16 to 31	Status information for modules generated by the CPU: • Bit 16 = 1: Submodule or module disabled • Bit 17 = 1: CiR operation active • Bit 18 = 1: Input not available • Bit 19 = 1: Output not available • Bit 20 = 1: Overflow diagnostics buffer • Bit 21 = 1: Diagnostics not available • Bit 22 = 1: Partial device failure (with PNIO for Shared iDevices) • Bit 23 - 31: Reserved (always 0)

Parameter	Data type	Value	Description
OwnState	UINT	Enum	Maintenance status
		0	Good
		1	Disabled
		2	Maintenance required
		3	Maintenance demanded
		4	Error
		5	Not accessible
		6	Diagnostic status unknown
		7	IO not available - Inputs/outputs are not available.
IOState	WORD	Bit array	I/O status of the hardware component
		Bit 0 = 1	Good
		Bit 1 = 1	Disabled
		Bit 2 = 1	Maintenance required
		Bit 3 = 1	Maintenance demanded
		Bit 4 = 1	Error
		Bit 5 = 1	Hardware component not reachable - Hardware component cannot be accessed.
		Bit 6 = 1:	Qualified: Bit 6 = 1 if at least one qualified diagnostics is available
		Bit 7 = 1:	I/O data not available - I/O data not available
		8 to 14	Reserved (always = 0)
		Bit 15	Network/hardware fault • S7-1200: Reserved (always = 0) • S7-1500: If bit 4 = 1 or bit 5 = 1: – Bit 15 = 0: Network error – Bit 15 = 1: Hardware error

Parameter	Data type	Value	Description
OperatingState	UINT	Enum	
		0	Not Supported - for I/O modules OperatingState always has the value 0.
		1	STOP / firmware update
		2	STOP / Memory reset
		3	STOP / self start
		4	STOP
		5	Memory reset
		6	Startup
		7	-
		8	RUN
		9	-
		10	HOLD
		11	-
		12	-
		13	DEFECTIVE
		14	-
		15	De-energized
		16	CiR
		17	STOP without ODIS
		18	RUN ODIS
		19	Resetting to factory settings
		20	STOP / no memory card

DNN structure

With parameter MODE = 2, the diagnostic information details are output in accordance with the DNN structure. In this case, enter the system data type "DNN" as data type for the tag declaration.

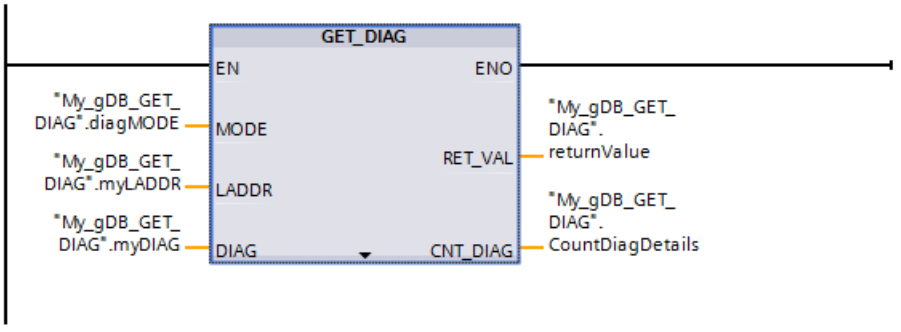
The following table shows the meaning of the individual parameter values.

Parameter	Data type	Value	Description
SubordinateState	UINT	Enum	Status of the subordinate component (see parameter OwnState of the DIS structure)
SubordinateIOState	WORD	Bitarray	Status of the inputs and outputs of the subordinate component (see parameter IO State of the DIS structure)
DNNmode	WORD	Bitarray	• Bit 0 = 0: Diagnostics enabled • Bit 0 = 1: Diagnostics disabled • Bit 1 to 15: Reserved

Parameter RET_VAL

Error code* (W#16#...)	Description
0	No error
n	The data area at the DETAIL parameter is too small. Not all details of the diagnostics data are output.
8080	Value in the MODE parameter is not supported.
8081	Type at the DIAG parameter is not supported with the selected mode (parameter MODE).
8082	Type at the DETAIL parameter is not supported with the selected mode (parameter MODE).
8090	LADDR does not exist
80C1	Insufficient resources for parallel execution.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you read out the diagnostic information of a CPU.

Create four tags and a "myDIAG" structure (with the DIS data type) in a global data block for storing the data.

My_gDB_GET_DIAG

	Name	Data type	Start value
1	Static		
2	diagMODE	UInt	1
3	myLADDR	HW_ANY	50
4	returnValue	Int	0
5	CountDiagDetails	UInt	0
6	myDIAG	DIS	
7	MaintainanceState	DWord	16#0
8	ComponentStateDetail	DWord	16#0
9	OwnState	UInt	0
10	IOState	Word	16#0
11	OperatingState	UInt	0

Interconnect the parameters of the instruction as follows.

The HW identifier of the CPU is made known to the "GET_DIAG" instruction through parameter LADDR ("myLADDR"). According to the value "1" of parameter MODE ("diagMODE"), the following applies:

- The instruction reads the status of the addressed hardware object (of the CPU).
- At parameter DIAG ("myDIAG"), the diagnostic information is output in a structure (DIS data type).

To understand the diagnostic information, the hex values must be converted to binary code. At parameter DIAG ("myDIAG"), the following is indicated:

- MaintenanceState: According to the value "0", the CPU requires no maintenance.
- ComponentStateDetail: According to the hex value "0000_8000", bit 15 is active.
- OwnState: According to the value "0", no fault has occurred.
- IOState: According to the hex value "0001", there is no maintenance required.
- OperatingState: Outputs "0".

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors. At output parameter CNT_DIAG ("CountDiagDetails"), it is indicated that "0" diagnostic details of parameter DETAIL have been output.

My_gDB_GET_DIAG

	Name	Data type	Start value	Monitor value
1	Static			
2	diagMODE	UInt	1	1
3	myLADDR	HW_ANY	50	16#0032
4	returnValue	Int	0	0
5	CountDiagDetails	UInt	0	0
6	myDIAG	DIS		
7	MaintainanceState	DWord	16#0	16#0000_0000
8	ComponentStateDetail	DWord	16#0	16#0000_8000
9	OwnState	UInt	0	0
10	IOState	Word	16#0	16#0001
11	OperatingState	UInt	0	0

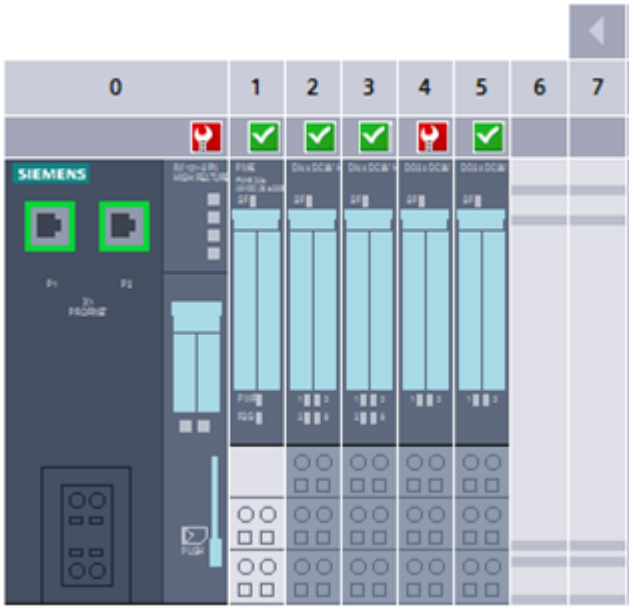
Note: For example, you could individually read out bit 3 (channel diagnostics yes/no) from the ComponentStateDetail tag.

- Address the bit as follows: ComponentStateDetail.%X3

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

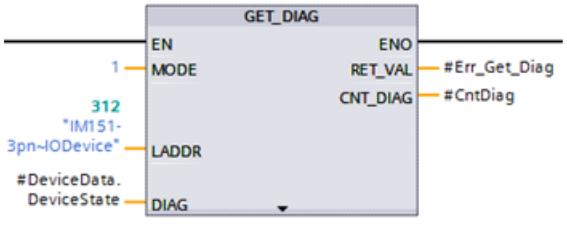
Example - Diagnostics of an IO device

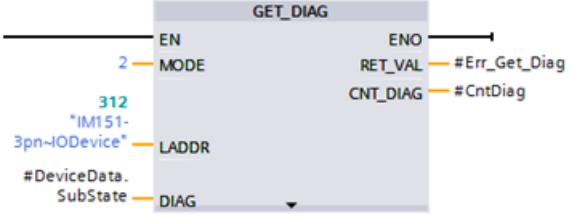


In the following example, you read out the diagnostic information of an IO device. For diagnostics, you use the device view of the IO device and the instruction GET_DIAG.

Diagnostics in the device view

One of the IO device modules signals an error. The device status changes and is displayed as follows:





The module and the head module of the IO device show a group status in the device view. An error is therefore displayed for both.

Diagnostics with the GET_DIAG instruction

To read out the diagnostic information of the IO device, address the head module of the IO device (via LADDR).

- In mode 1 (MODE has the value 1), you read out the status of the IO device.
- In mode 2 (MODE has the value 2), you read out the status of the subordinate modules.

Call MODE 1: Self-diagnostics	Call MODE 2: Summary of the subordinate diagnostics
	

LADDR (HW ID) = IM151-3pn~IODevice
DIAG (DIS structure) = #DeviceData.DeviceState
DIS.OwnState = 0 (no error)
DIS.IOState = bit sequence 0000 0000 0000 0001
	LADDR (HW ID) = IM151-3pn~IODevice
	DIAG (DNN structure) = #DeviceData.SubState
	DNN.SubordinateState = 4 (error)
	DNN.SubordianteIOState = bit sequence 1000 0000 0001 0001

Result

Unlike the device view, the GET_DIAG instruction does not return the group status of the IO device. The error in the subordinate module is not read until mode 2.

11.4.4.10 Pulse (S7-1200)

CTRL_PWM: Pulse-width modulation (S7-1200)

Description

The "CTRL_PWM" instruction is used to enable and disable a pulse output supported by the CPU using the software.

- Enter the hardware ID of the pulse generator that you want to control with the instruction at the input PWM.
- When the bit in the ENABLE input of the instruction is set, the pulse output is enabled.
  - If ENABLE has a value of TRUE the pulse generator will generate a pulse with the properties defined in the device configuration.
  - When the bit in the ENABLE input is reset or the CPU changes to STOP, the pulse output is disabled and no more pulses are generated.

BUSY always has the value of FALSE for S7-1200 since S7-1200 activates the pulse generator if the instruction "CTRL_PWM" is executed.

When the EN enable input has signal state "1" and no errors have occurred during execution of the instruction, the enable output ENO is set.

Note

Use of the force table for PWM and PTO

Digital inputs and outputs that are used for PWM and PTO cannot be forced. Digital inputs and outputs that were assigned via device configuration are not controlled by either the force table or the watch table.

Note

Process image of PTO/PWM outputs

Do not use PTO/PWM outputs in the process image (for example, for access in the user program, for online functions or in the HMI). The update rate of the process image is much slower than the rate of the signal changes. The display in the process image therefore does not reflect the signal flow.

Requirement

A prerequisite for the correct execution of the instruction is that the specified pulse generator is activated in the hardware configuration.

Open the properties of the module in the device view. Go to "Pulse generators (PTO/PWM)", open the desired PTO/PWM and activate the function the "Activate this pulse generator" under "General".

Go to "Assigning parameters" and set the Pulse options.

Note

Pulse output parameters are assigned exclusively in the device configuration and not using the "CTRL_PWM" instruction. Any change of parameters that is intended to have an effect on the CPU must therefore be made while the CPU is in STOP mode. Changing the duration of the pulse is an exception.

Changing the pulse duration from the user program

The pulse duration setting made in the dialog "Pulse options" can be changed from the user program.

The value set for "Initial pulse duration" is written in the output bytes of the pulse generator. The start address and the end address are displayed in the properties of the pulse generator under "I/O-addresses".

To change the pulse duration, write the desired values in the output word address specified in the device configuration.

Example:

- A value of 500 (decimal) is used for the "Initial pulse duration". The start address of the PTO/PWM is "1000" and the end address is "1001".
- The binary value of "0000000111110100" (=500 decimal) is written in both of the output bytes.
  - Start address (AB1000): 0000_0001 (BIN)
  - End address (AB1001): 1111_0100 (BIN)

Please note that the pulse duration always depends on the parameters set for the Pulse duration format (hundredths, thousandths, ...).

Change the cycle time from the user program.

Select the check box "Permit change to cycle time in runtime" in the "Pulse options" of the corresponding pulse generator. When this check box is selected, the first two output bytes contain the pulse duration and the third to sixth output byte contains the cycle time.

During the run time of the pulse generator, you can change the value of the double word at the end of allocated memory of the outputs. This changes the cycle time of the PWM signal.

Example: Select the check box so that the CPU assigns PWM1 six output bytes, and select AB1008 to AB1013 for this. After loading the program into the CPU and starting the pulse generator, you can change the pulse duration by writing AW1008 and the cycle time by writing AD1010.

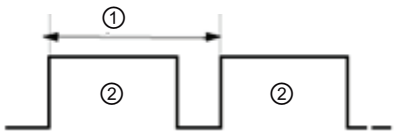


Figure 11-1 PWM_Example

① Cycle time
② Pulse duration

Parameters

The following table shows the parameters of the "CTRL_PWM" instruction:

Parameter	Declaration	Data type	Memory area	Description
PWM	Input	HW_PWM	I, Q, M, D, L or constant	Hardware ID of the pulse generator The hardware ID can be found in the properties of the pulse generator in the Device view. The hardware IDs of the pulse generators are also listed in the system constants.
ENABLE	Input	BOOL	I, Q, M, D, L or constant	The pulse output is enabled when ENABLE = TRUE and disabled when ENABLE = FALSE.
BUSY	Output	BOOL	I, Q, M, D, L	Processing status
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction (see below).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Error code* (W#16#...)	Description
0	No errors
80A1	Hardware ID of the pulse generator is invalid.
80D0	Pulse generator with the specified hardware ID is not activated. Activate the pulse generator in the CPU properties under "Pulse generators (PTO/PWM)".
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

CTRL_PTO: Output a pulse sequence with a preset frequency (S7-1200)

Description

The "CTRL_PTO" instruction makes a pulse sequence available to you with a preset frequency. For this you do not require an axis DB of a technological object.

Requirement

The use of the "CTRL_PTO" instruction does not require an activated pulse generator. You activate this in the hardware configuration as well as selecting the signal type. You need to specify the pulse generator at the "PTO" parameter and set the "REQ" parameter to TRUE.

Note

Using a PLC pulse generator

At any one time a pulse generator can only be used by one instruction.

Note

Use of the force table with PWM and PTO

Digital inputs and outputs that are used for PWM and PTO cannot be forced. Digital inputs and outputs that were assigned via the device configuration are not controlled by either the force table or the watch table.

Note

Process image of PTO/PWM outputs

Do not use PTO/PWM outputs in the process image (for example, for access in the user program, for online functions or in the HMI). The update rate of the process image is much slower than the rate of the signal changes. The display in the process image therefore does not reflect the signal flow.

Parameter

The following table shows the parameters of the "CTRL_PTO" instruction:

Parameter	Declaration	Data type	Description
REQ	Input	BOOL	• REQ=1: Sets the frequency of the pulse generator to the value of FREQUENCY REQ=1 and FREQUENCY=0: Deactivates the pulse generator • REQ=0: No change at pulse generator
PTO	Input	HW_PTO	Hardware identifier of the pulse generator This can be taken from the properties of the pulse generator in the device view or the list of system constants.
FREQUEN-CY	Input	UDINT	Frequency of the pulse sequence to be output in Hz
DONE	Output	BOOL	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	Processing status Since the S7-1200 enables the pulse generator when the "CTRL_PTO" instruction is executed, BUSY always has the value FALSE with the S7-1200.

Parameter	Declaration	Data type	Description
ERROR	Output	BOOL	Status parameter • 0: No error • 1: An error occurred during execution of the instruction.
STATUS	Output	WORD	Status of the instruction (see below)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter Status

Error code* (W#16#...)	Explanation
0	No error
8090	The pulse generator with the specified hardware ID is already being used.
8091	Range exceeded for the "FREQUENCY" parameter; for more detailed information, refer to the manual.
80A1	The PTO parameter does not address a hardware ID of a pulse generator.
80D0	The pulse generator with the specified hardware ID is not activated. Activate the pulse generator in the CPU properties under "Pulse generators (PTO/PWM)".
80D1	The pulse generator with the specified hardware ID does not have the "PTO" property. Select "PTO" in the hardware configuration.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

11.4.4.11 Recipes and data logging (S7-1200, S7-1500)

Recipe functions (S7-1200, S7-1500)

Recipe functions - overview (S7-1200, S7-1500)

Description

With the instructions "RecipeExport" and "RecipeImport" you transfer recipe data

- from a recipe data block to a CSV file on the memory card of the CPU ("RecipeExport")
- from a CSV file on the memory card of the CPU to a recipe data block ("RecipeImport")

Note

Service life of memory cards

The service life of memory cards is limited. Additional information is available here: AUTOHOTSPOT

Protection of recipe data

The instructions "RecipeExport" and RecipeImport" are not suitable for applications in which special protection is necessary for the recipe data. For higher protection of the data use the recipe functions of HMI.

Position of the recipe data block with "RecipeExport"

The data block with the recipe data exported with "RecipeExport" can be located in work or load memory. If the data block is both in the work memory and in the load memory, the values from the work memory are used.

Delimiters

You can use different delimiters to separate the row values in the recipe. Note that if you open the CSV file with the exported recipe data, for example in Excel, commas can be replaced by periods and vice versa. The reason for this is that different languages use different decimal separators. This can have an effect when importing CSV files. The following convention applies for "RecipeImport"; the first detected possible delimiter is assumed to be the delimiter for all values of a table row.

- Example 1: If a semicolon is detected as the first delimiter, during import it is assumed that the semicolon is used as the delimiter for all further values. As the decimal delimiter with a value of the type REAL, a comma is then used.
- Example 2: If a comma is detected as the first delimiter, during import it is assumed that the comma is used as the delimiter for all further values. As the decimal delimiter with a value of the type REAL, a period is then used.

If the recipe data record contains a character string, make sure that the character string does not contain the delimiter you are using. With character strings, also make sure that they do not contain any control characters that specify a line break (with ASCII: LF, CR LF, CR).

Note: Spaces and tabs are not used as delimiters. These lead to error code 80B2 during import.

Note

Asynchronous processing of the recipe functions

Because the recipe functions are executed asynchronously, you must keep the data in the source area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

RecipeExport: Exporting recipes (S7-1200, S7-1500)

Description

The "RecipeExport" instruction exports the recipe data from a data block to a CSV file in the load memory.

With S7-1500 CPUs, the DB that is to be exported can be located either in the work memory or in the load memory. If the data block is in both the work memory and the load memory, the

values from the work memory are exported. For S7-1200 CPUs, the DB to be exported must be present in the load memory.

The CSV file is created in the load memory. For S7-1500 CPUs, this is the memory card; for S7-1200 CPUs the internal or external load memory (if a memory card is present).

During the export, the CSV file is created in the "Recipes" folder in the main directory of the load memory. The name of the data block is used as file name of the created CSV file. If a CSV file with an identical name already exists, it is overwritten during the export.

Each recipe data record generates a line in the CSV file. These lines have the following structure:

- The first line contains the "Index" entry and the name of the recipe components.
- Each additional line contains the number of the recipe data record (index) and the associated components.

When you take the data types of the recipe DB, the maximum size of a data record is 5000 bytes. If this is exceeded, the error code W#16#8092 is returned. This restriction to 5000 bytes also applies to the size of the header; any characters in the DB exceeding this limit are truncated, and the process continues with the first recipe data record.

The S7-1200 CPUs also monitor the number of columns. These must not exceed 255 (whereby the index column is not counted).

Functional description

The export is triggered by the "REQ" parameter. The BUSY parameter is set to "1" during the export. After the execution of the instruction, BUSY is reset to "0" and the completion of the operation is indicated with "1" at the DONE parameter.

If an error occurs during execution, this is signaled by the parameters ERROR and STATUS.

Parameters

The following table shows the parameters of the "RecipeExport" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Control parameter REQUEST: Activates the export on a rising edge.
RECIPE_DB	InOut	VARIANT	D	Pointer to the recipe data block. For information on the structure of the data block, refer to: Structure of a recipe DB (Page 4001)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: The instruction is not executed. • 1: The instruction is executed.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See the "STATUS" parameter table.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0	No error occurred
7000	No job processing active
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8090	File name of the CSV file contains invalid characters. The file name of the CSV file is identical to the name of the data block.
8091	The data structure referenced by RECIPE_DB cannot be processed or the number of data columns in a S7-1200 CPU is greater than 255.
8092	Data structure at RECIPE_DB parameter exceeds 5000 bytes.
80B3	Insufficient memory space on the memory card or the internal load memory.
80B4	The memory card is write-protected.
80B6	With (S7-1200 CPUs only) attribute "Save only in load memory", the recipe data block is not activated.
80C0	CSV files is temporarily locked.
80C1	Recipe data block temporarily disabled.
80C3	Too few resources
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for recipe functions (Page 4004).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Difference between synchronous and asynchronous instructions (Page 2571)

RecipeImport: Importing recipes (S7-1200, S7-1500)

Description

The "RecipeImport" instruction imports the recipe data from a CSV file of the load memory into the data block at the RECIPE_DB parameter.

For S7-1500 CPUs, the CSV file is on the memory card; for S7-1200 CPUs, it is in the internal or external load memory (if a memory card is present).

The values in the data block are overwritten in the process. With S7-1500 CPUs, the DB to which the recipe data is to be imported can be located either in the work memory or in the load memory. If it is in both the work memory and the load memory, the values are imported to the data block located in the work memory. For S7-1200 CPUs, the DB into which the recipe data is to be imported must be located in the load memory.

Note the following when importing the CSV file:

- The CSV file must be located in the "Recipes" directory of the load memory.
- The name of the CSV file must match the name of the data block at the RECIPE_DB parameter.
- Each line of the CSV file corresponds to one recipe data record. The first line (header) of the CSV file contains the name of the recipe components (see also: Structure of a recipe DB (Page 4001)). The first line is ignored completely during the import. The names of the recipe components in the CSV file and the data block are not synchronized during the import, and the number of entries is also irrelevant.
- In each case the first value in each line of the CSV file is the index number of the recipe. The individual recipes are imported in the order of the index. For this, the index in the CSV file has to be in ascending order and may contain no gaps (if this is not the case, the error message 80B0 is output at the STATUS parameter.
- The CSV file may not contain more recipe data records than provided for in the data block. The maximum number of data records is indicated by the array limits in the data block.
- If a value of the CSV file does not fit in the associated data type of the DB, the import is rejected. If necessary, character strings are truncated after their maximum permissible length.
  If the data type in the DB is BOOL type, an S7-1500 CPU accepts all integer values. The value 1 is then set to TRUE and all other values are set to FALSE. An S7-1200 CPU accepts only the values 0 and 1, all other values are rejected.

Functional description

The import is triggered by the "REQ" parameter. The BUSY parameter is set to "1" during the import. After the execution of the instruction, BUSY is reset to "0" and the completion of the operation is indicated with "1" at the DONE parameter.

If an error occurs during execution, this is signaled by the parameters ERROR and STATUS.

Parameters

The following table shows the parameters of the "RecipeImport" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Control parameter REQUEST: Activates the import on a positive edge.
RECIPE_DB	InOut	VARIANT	D	Pointer to the recipe data block. For information on the structure of the data block, refer to: Structure of a recipe DB (Page 4001)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter • 0: The instruction is not executed. • 1: The instruction is executed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See the "STATUS" parameter table.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0	No error occurred
7000	No job processing active
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8090	The file name contains invalid characters.
8092	No matching CSV file found for the import. Possible cause: The name of the CSV file does not match the name of the recipe DB.
80C0	CSV file is temporarily locked.
80C1	Recipe data block is temporarily locked.
80B0	Numbering in the index of the CSV file is not continuous, not ascending or exceeds the maximum number (array limit) in the data block.
80B1	Structure of the recipe data block and the CSV file do not match: The CSV file contains too many fields.
80B2	Structure of the recipe data block and the CSV file do not match: The CSV file contains too few fields.

Error code* (W#16#...)	Explanation
80B6	With (S7-1200 CPUs only) attribute "Save only in load memory", the recipe data block is not activated.
80C3	Too few resources
80D0 +n	Structure of the recipe data block and the CSV file do not match: Data type in field n does not match (n<=46).
80FF	Structure of the recipe data block and the CSV file do not match: Data type in field n does not match (n>46).
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for recipe functions (Page 4004).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Difference between synchronous and asynchronous instructions (Page 2571)

Structure of a recipe DB (S7-1200, S7-1500)

Introduction

The following sections describes the structure of a recipe DB based on a simple example. The recipe DB consists of five data records, three of which are used. The fourth and fifth data records are left free for later expansions. Each data record contains one recipe, which is made up of the recipe name and eight ingredients.

product-name	water	barley	wheat	hops	yeast	wa-terTmp	mashTmp	mash-Time	QTest
Pils	10	9	3	280	39	40	30	100	0
Lager	10	9	3	150	33	50	30	120	0
BlackB-eer	10	9	3	410	47	60	30	90	1
Not_used	0	0	0	0	0	0	0	0	0
Not_used	0	0	0	0	0	0	0	0	0

Structure of the recipe data block

The recipe data are implemented as follows in a global data block:

- The template for all recipes is the PLC data type "Beer_Recipe" with the recipe components "procutname", "water", etc. with the corresponding data types.
- In a global data block, the PLC data type is used as Array [1.. 5] of "Beer_Recipe". The array limits (1 to 5 in this case) indicate the maximum number of recipes that the DB may contain.
- The values for the recipe components are added as start value in the data block.
- The global DB is interconnected with the instruction via the InOut parameter RECIPE_DB.

Recipe_DB

	Name	Data type	Offset	Start value
1	Static			
2	Products	Array [1 .. 5] of "Beer_Recipe"	...	
3	Products[1]	"Beer_Recipe"	...	
4	Products[2]	"Beer_Recipe"	...	
5	Products[3]	"Beer_Recipe"	...	
6	productname	String[20]	...	'BlackBeer'
7	water	UInt	...	10
8	barley	UInt	...	9
9	wheat	UInt	...	3
10	hops	UInt	...	410
11	yeast	UInt	...	47
12	waterTmp	UInt	...	60
13	mashTmp	UInt	...	30
14	mashTime	UInt	...	90
15	QTest	UInt	...	1
16	Products[4]	"Beer_Recipe"	...	
17	Products[5]	"Beer_Recipe"	...	

Exporting to CSV file

After the execution of the "RecipeExport (Page 3996)" instruction the data of the DB are written to a CSV file with the following structure:

Recipe_DB.csv

```
index,productname,water,barley,wheat,hops,yeast,waterTmp,mashTmp,mashTime,QTest
1,”Pils”,10,9,3,280,39,40,30,100,0
2,”Lager”,10,9,3,150,33,50,30,120,0
3,”BlackBeer”,10,9,3,410,47,60,30,90,1
4,”Not_used”,0,0,0,0,0,0,0,0,0
5,”Not_used”,0,0,0,0,0,0,0,0,0
```

Display in Excel

The CSV file can be opened in Excel to make reading and editing easier. If the commas are not recognized as separators when you open the file, use the Excel import function to output the data in structured form:

	A	B	C	D	E	F	G	H	I	J	K
1	index	product	water	barley	wheat	hops	yeast	waterTmp	mashTmp	mashTime	QTest
2	1	"Pils"	10	9	3	280	39	40	30	100	0
3	2	"Lager"	10	9	3	150	33	50	30	120	0
4	3	"BlackBeer"	10	9	3	410	47	60	30	90	1
5	4	"Not_used"	0	0	0	0	0	0	0	0	0
6	5	"Not_used"	0	0	0	0	0	0	0	0	0

Editing the CSV file

The CSV file is uploaded to the PC/programming device by means of the Web server and edited. After editing, the modified file can be reloaded in the CPU. You must delete the existing CSV file for this.

You can use the "RecipeImport (Page 3999)" instruction to re-import the modified data from the CSV file into the data block.

Note that the modified data must still be compatible with the data block. In other words:

- No changes may be made to the structure in the table (for example, by adding ingredients in a new column).
- If you add data records to the file, make sure when importing into the data block that the array limits through which you specify the maximum number of data records correspond to at least the number of data records.
- An index is automatically generated during export to the CSV file. If you create additional data records, add consecutive index numbers accordingly.
- The values in the table cells must correspond to the data types used in the data block with respect to format as well as length.
  - Example 1: If INT data type was used in the data block, use only integers in the table.
  - Example 2: If SINT data type was used in the data block, use only integers with the values -128 to +127 in the table.

  Always keep in mind the permitted data types and data areas as listed in the table below when you make changes in the table.

Data type		Format	Note
Floating-point numbers	LReal	+9.9999999999999E+999	Always written exponentially
	Real	+9.9999999E+99	Always written exponentially
Signed integers	LInt	+9999999999999999999	Value range of signed integers: -9223372036854775808 .. +9223372036854775807
	DInt	+9999999999	Value range of integers: -2147483648 to +2147483647
	Int	+99999	Value range of integers: -32768 to +32767
	SInt	+999	Value range of integers: -128 to +127
Unsigned integers	ULInt	+99999999999999999999	Value range of integers: 0 to +18446744073709551615
	UDInt	+9999999999	Value range of integers: 0 to +4294967295
	UInt	+99999	Value range of integers: 0 to +65535
	USInt	+999	Value range of integers: 0 to +255
Binary numbers	LWord	+99999999999999999999	Value range of integers: 0 to +18446744073709551615
	DWord	+9999999999	Value range of integers: 0 to +4294967295
	Word	+99999	Value range of integers: 0 to +65535
	Byte	+999	Value range of integers: 0 to +255
	Bool	9	Value range: 0 or 1

Data type		Format	Note
Date and time	LTIME	dddddd:hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	TIME	hhh:mm:ss.999	ISO format with milliseconds
	S5TIME	hhh:mm:ss.999	ISO format with milliseconds
	LDT	YYYY-MM-DD hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DTL	YYYY-MM-DD hh:mm:ss. 999_999_999	ISO format with milliseconds, microseconds and nanoseconds
	DT	YYYY-MM-DD hh:mm:ss.999	ISO format with milliseconds
	DATE	YYYY-MM-DD	ISO format

	TOD	hh:mm:ss.999	ISO format
Characters	WString	"abcd"	• Character string inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. • Current length • A character string of data type WString consists of elements of the WChar data type. When a recipe DB is exported, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	String	"abcd"	• Character string inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. • Current length
	WChar	"a"	Individual character inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted. When a recipe DB is exported, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	Char	"a"	Individual character inside double quotation marks. When a recipe DB is imported, the double quotation marks may be omitted.

Example program for recipe functions (S7-1200, S7-1500)

In the following example, you export the recipe data from a data block (recipe DB) to a CSV file and import new recipe data into the data block.

Requirements

As the template for the recipe data create a PLC data type "Beer_Recipe" an.

Beer_Recipe

	Name	Data type	Default value
1	productname	String[20]	''
2	water	UInt	0
3	barley	UInt	0
4	wheat	UInt	0
5	hops	UInt	0
6	yeast	UInt	0
7	waterTmp	UInt	0
8	mashTmp	UInt	0
9	mashTime	UInt	0
10	QTest	UInt	0

To store all recipe data records, create a recipe DB. You will find further information on creating a recipe DB in "Structure of a recipe DB (Page 4001)".

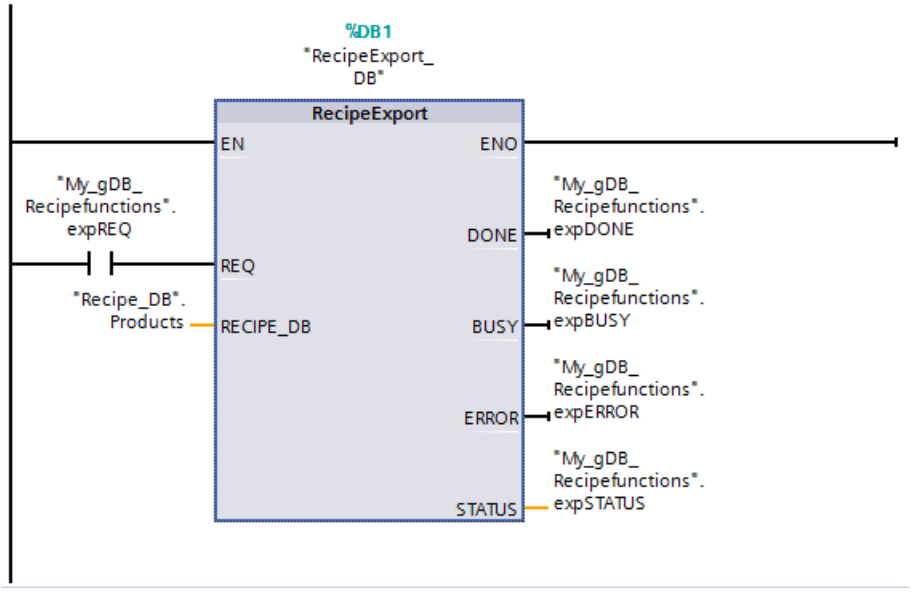
Recipe_DB

	Name	Data type	Start value
1	Static		
2	Products	Array[1..5] of "Beer_Recipe"	
3	Products[1]	"Beer_Recipe"	
4	Products[2]	"Beer_Recipe"	
5	Products[3]	"Beer_Recipe"	
6	productname	String[20]	'Blackbeer'
7	water	UInt	10
8	barley	UInt	9
9	wheat	UInt	3
10	hops	UInt	410
11	yeast	UInt	47
12	waterTmp	UInt	60
13	mashTmp	UInt	30
14	mashTime	UInt	90
15	QTest	UInt	1
16	Products[4]	"Beer_Recipe"	
17	Products[5]	"Beer_Recipe"	

To store the data for the interconnection, create twelve tags in a global data block.

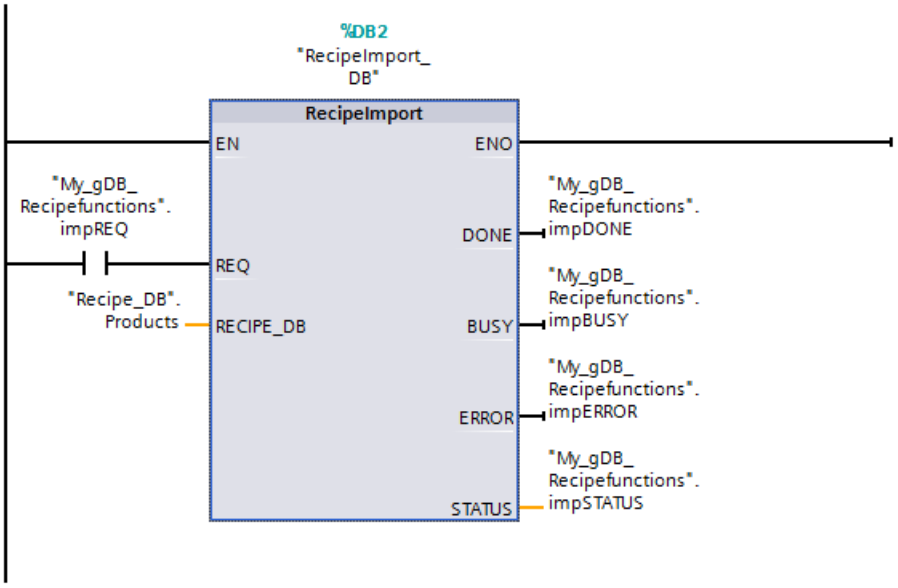
My_gDB_Recipefunctions

	Name	Data type	Start value
1	Static		
2	expREQ	Bool	false
3	expDONE	Bool	false
4	expBUSY	Bool	false
5	expERROR	Bool	false
6	expSTATUS	Word	16#0
7	impREQ	Bool	false
8	impDONE	Bool	false
9	impBUSY	Bool	false
10	impERROR	Bool	false
11	impSTATUS	Word	16#0
12	outputErr_EXP	Byte	0
13	outputErr_IMP	Byte	0



To display and store a CSV file, use the Web server of the CPU. In order to use the web server and theCSV file, the following is necessary:

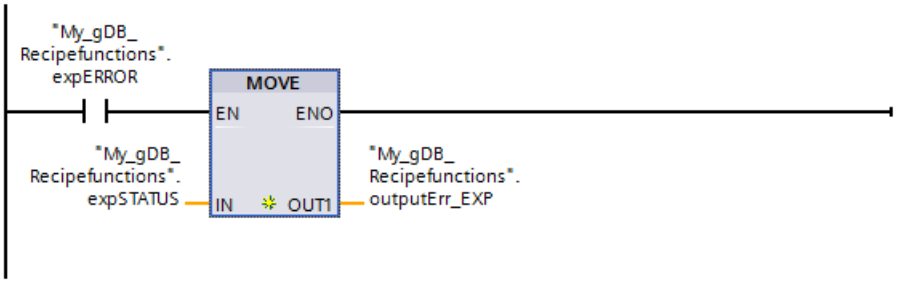
- The web server must be activated in the CPU settings.
- A user profile with the Web server properties of the CPU must be set up with the following settings:
  - The user must be able to read files.
  - The user must be able to write/delete files.



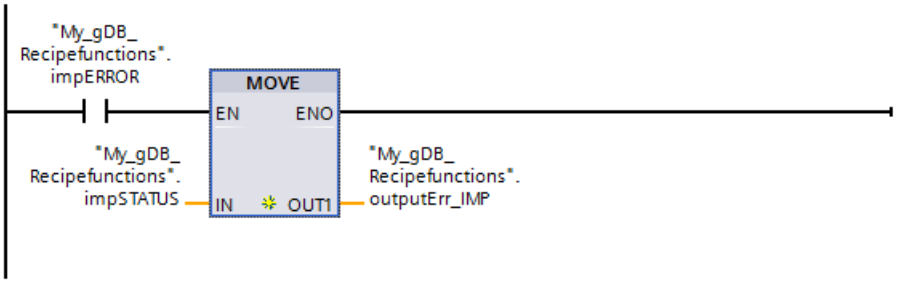
Interconnection of the parameters

The instructions are called in a function block.

Network 1: Interconnect the parameters of the "RecipeExport" instruction as follows.

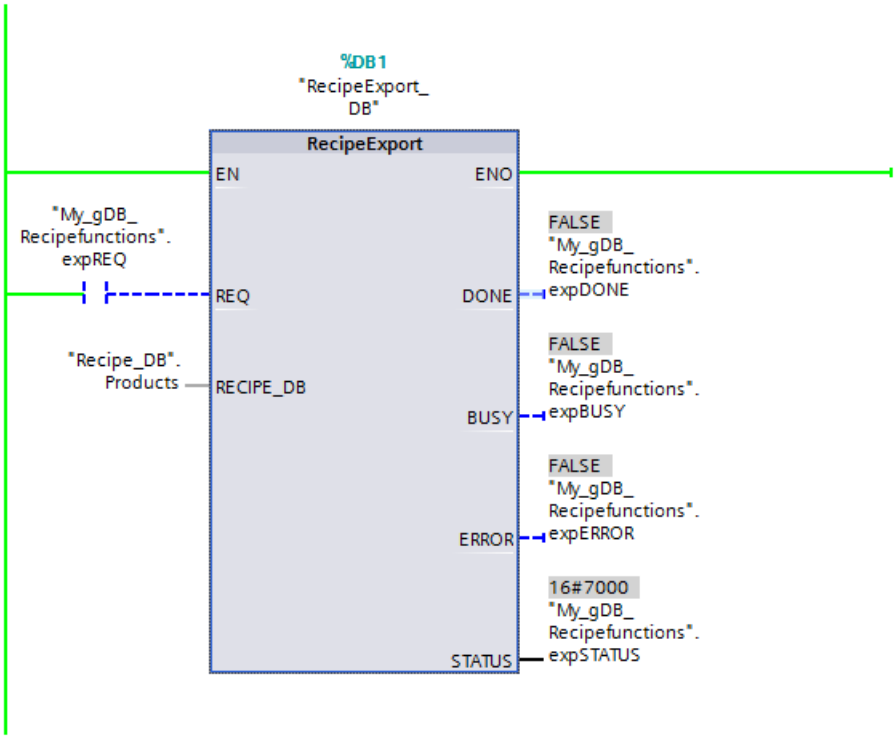


Network 3: Interconnect the parameters of the "RecipeImport" instruction as follows.



Network 2 and 4: Since the parameters STATUS ("expSTATUS" and "impSTATUS") are only valid for one cycle, record the parameters with a "MOVE" instruction. At the output parameters OUT1 ("outputErr_EXP" or "outputErr_IMP") output the status in case of an error.

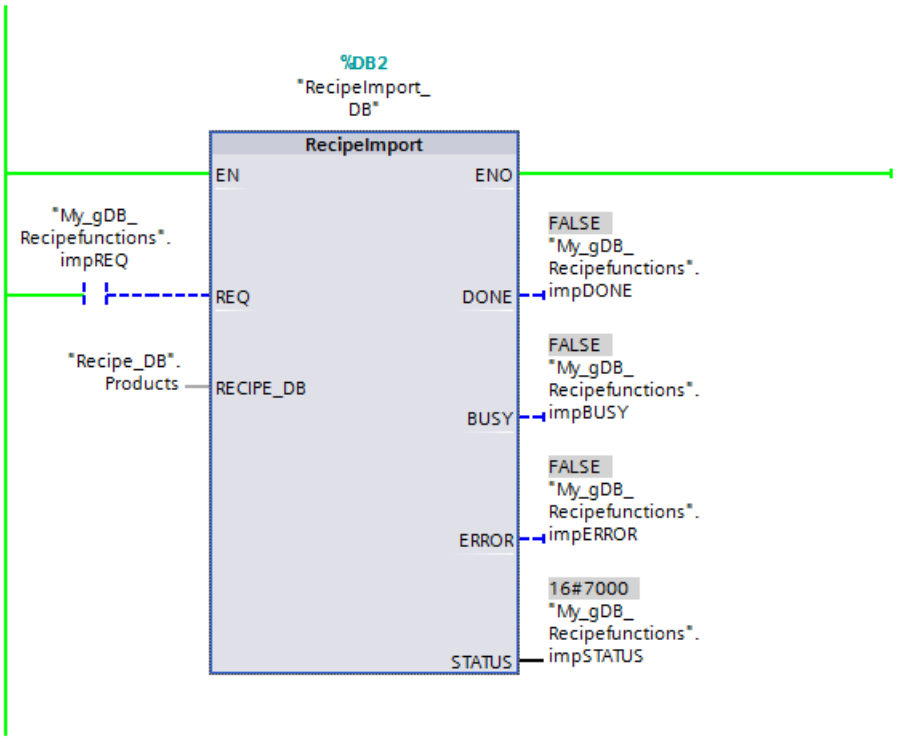
Interconnect the parameters in network 2 as follows.



Interconnect the parameters in network 4 as follows.

"RecipeExport" instruction

The recipe DB to be exported needs to be interconnected at the RECIPE_DB parameter. If the REQ ("expREQ") parameter has the signal status "TRUE" export is started. From the data of the recipe DB, a CSV file is generated and stored in the recipe folder in the CPU memory. At output parameter STATUS ("expSTATUS") it is displayed that a signal change has taken place. Then, it is indicated that no further processing is taking place (the value is "7000").



At output parameter ERROR ("expERROR"), it is indicated that the processing of the instruction was error-free.

"RecipeImport" instruction

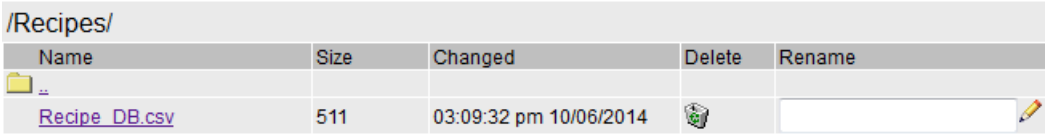
The recipe DB to be imported needs to be interconnected at the RECIPE_DB parameter. If the REQ ("impREQ") parameter has the signal status "TRUE" export is started. In the existing recipe DB, all the recipe data is loaded from the corresponding CSV file-that is located in the recipe folder of the CPU memory. At output parameter STATUS ("impSTATUS") it is displayed that a signal change has taken place. Then, it is indicated that no further processing is taking place (the value is "7000").

At output parameter ERROR ("impERROR"), it is indicated that the processing of the instruction was error-free.

Displaying and saving the CSV file

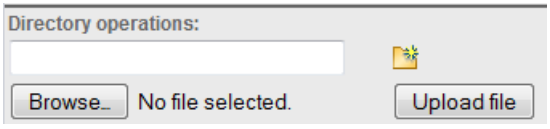
Opening the Web server

Use the Internet browser to open the Web server (via the IP address of the CPU) and log on in the Web server menu.



Via the "File browser" tab open the "Recipes" folder in the CPU memory.

The CPU outputs the CSV file as soon as the "RecipeExport" instruction executes. To have the current status of the CSV file displayed, click on the "Update automatically" button. Below the function is displayed as "On".



Editing the CSV file

To edit the CSV file, you have the following options:

- You open the CSV file in the Web server.
- You save the CSV file on the PG/PC.
  - **Note**: To be able to load the edited CSV file from the PC in the CPU memory: First delete the CSV file with the same name in the CPU memory

  - After editing, load the CSV file in the CPU memory using the Web server.

Changing component values during runtime

To change component values of the recipe DB during runtime (e.g. Recipe_DB.Product[4]) use a watch table.

	i	Name	...	Display format	Monitor value	Modify value
1		"Recipe_DB".Products[4].productname		String	'Not_used'	'Mix'
2		"Recipe_DB".Products[4].water		DEC	0	10
3		"Recipe_DB".Products[4].barley		DEC	0	2
4		"Recipe_DB".Products[4].wheat		DEC	0	2
5		"Recipe_DB".Products[4].hops		DEC	0	4
6		"Recipe_DB".Products[4].yeast		DEC	0	30
7		"Recipe_DB".Products[4].waterTmp		DEC	0	60
8		"Recipe_DB".Products[4].mashTmp		DEC	0	60
9		"Recipe_DB".Products[4].mashTime		DEC	0	10
10		"Recipe_DB".Products[4].QTest		DEC	0	0

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Data logging (S7-1200, S7-1500)

Data logging - Overview (S7-1200, S7-1500)

Saving process values

The data logging instructions are used in the user program to save process values to data logs. Data logs can be saved on the Memory Card (MC) or in the internal load memory. The data logs are saved in CSV format (Comma Separated Value).

NOTICE

Special characters in character strings

If you use character strings within the data log, it is strongly recommended that you do not use the delimiter of the CSV file within these character strings. If you ignore this recommendation, opening the CSV file e.g. with MS Excel may lead to problems. Instead of the delimiter of the CSV file, use a different character such as "-", "/" or the space " ".

Also the character that indicates the end of a character string and CR andLF are special characters in a character string. They are not handled correctly by the instructions and cause problems.

The data types are converted into a character string according to the following rules:

Data type		Format	Note
Floating-point numbers	LReal	+9.9999999999999E+999	Always written exponentially
	Real	+9.9999999E+99	Always written exponentially
Signed integers	LInt	+9999999999999999999	Value range of signed integers: -9223372036854775808 .. +9223372036854775807

	TOD	hh:mm:ss.999	ISO format
Characters	WString	"abcd"	• Character string inside double quotation marks • The current length is padded with spaces up to the maximum length. • A character string of data type WString consists of elements of the WChar data type. When a data log is saved, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	String	"abcd"	• Character string inside double quotation marks • The current length is padded with spaces up to the maximum length.
	WChar	"a"	Individual character inside double quotation marks. When a data log is saved, the contents of characters of the WChar data type are limited to 16#FF (example: 16#1255 is changed to 16#55).
	Char	"a"	Individual character inside double quotation marks

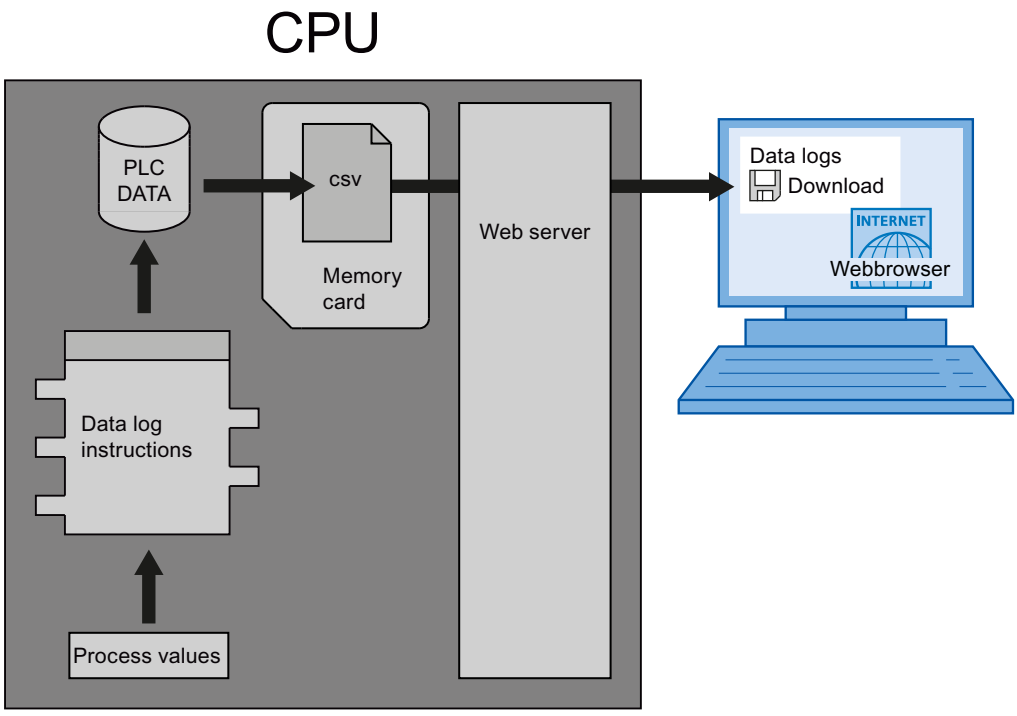
The data logging instructions are used in your program to create or open a data log, to write an entry and to close the data log file.

⚠ WARNING

Runtime of the data logging instructions

The conditions specified below slow down the data logging instructions. This effect becomes stronger with the growing size and number of data logging files.

- Large file size of the data log file
- Large number of data log files on the memory card
- Simultaneous access to a log file by the Web server



The runtime of some data logging instructions is not typically impaired by the size and number of data logs (e.g. "DataLogWrite"); the instructions "DataLogCreate", "DataLogNewFile", "DataLogClear" and "DataLogOpen", on the other hand, show the behavior described.

Note

Data logging instructions with which data is transferred

Because the data logging functions are executed asynchronously, you must keep the data in the source area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

You decide by the creation of the data buffer which program values are stored in the data log during the creation of the data buffer. The data buffer is used as a memory for new data log entries. New values have to be written to the buffer before "DataLogWrite (Page 4029)" is called. During execution of the "DataLogWrite (Page 4029)" instruction, data is written from the buffer to a data log record.

Data log files can be copied to the PC as follows:

- If the PROFINET interface is connected to the PC, you use a Web browser to access the data logs via the Web server. The CPU can be in RUN or STOP mode for this. If the CPU is in "RUN" mode, the program continues running while the Web server is transferring data.
- If there is a memory card in the CPU, you can remove this card and insert it into a standard slot for SD (Secure Digital) cards or MMC (MultiMediaCard) cards on a PC or programming device. Use File Manager to transfer the data log files from the memory card to the PC. When you remove the memory card, the CPU goes to "STOP".

Note

Service life of memory cards

The service life of memory cards is limited. Additional information is available here: AUTOHOTSPOT

Properties of the data log

Writing of the data records of a data log is carried out in accordance with the principle of a ring buffer. New data records are added until the maximum number of data records is reached (RECORD parameter). The next data record then overwrites the "oldest" data record of the data log.

If you want to prevent data records from being overwritten, use the "DataLogNewFile (Page 4034)" instruction to create a new data log file based on the current data log. New data records are then written into the new data log.

Creating data logs

With the "DataLogCreate (Page 4016)" instruction, you can create a new data log file in the ""\DataLogs" directory of the load memory.

- The name assigned at the NAME parameter is the designation for the data log and is also used as the file name for the CSV file. The file is stored in the directory "DataLogs".
- The block parameter DATA determines the data buffer for the new data log object and the columns and data types in the data log. The columns and data types of a data record in the data log are determined by the elements of the structure declaration or array declaration of this data buffer. Each element of a structure or of an array corresponds to a column in a line in the data log.
- You use the HEADER block parameter to assign a header text in the header to each column.
- The "DataLogCreate (Page 4016)" instruction returns an ID. This ID is used by the other data logging instructions as a reference for the created data log.

Opening data logs

You use the instruction "DataLogOpen" (S7-1200 and S7-1500) to open an existing data log on the memory card. A data log must be open before you can write new data records to it.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 4016)" and "DataLogNewFile (Page 4034)".

Up to 10 data logs can be open simultaneously. The data log to be opened can be selected using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the parameter NAME and specify 0 as the ID, the ID belonging to the data log will be displayed in the ID parameter when you open the data log.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

You can run a consistency check for "DataLogOpen (S7-1500).

Writing to data logs

A data log must be open ("DataLogOpen (Page 4023)" instruction) before a data record can be written to a data log. The "DataLogWrite (Page 4029)" instruction writes a data record to the data log.

Closing data logs

With the "DataLogClose (Page 4031)" instruction, you close and open data log. You select the data log using the ID parameter.

The data log is closed automatically when the CPU switches to STOP and upon restart.

Deleting data logs

You use the instruction "DataLogDelete (Page 4033)" (S7-1500) to delete a data log file from the memory card. The data log and the data records it contains can only be deleted if the log was created with the instruction "DataLogCreate (Page 4016)".

Select the data log to be deleted using the NAME and ID parameters. The ID parameter is evaluated first. If there is a data log with the relevant ID, the NAME parameter will not be

evaluated. If the value "0" is used at the ID parameter, a value with the data type STRING must be used at the NAME parameter.

Note

Deleting data logs on the memory card

You can copy data logs from a memory card using a PC card reader, but you must not change them or delete them using a PC card reader.

In addition to the data log instructions, the use of a Web server is recommended to display, download (copy) and delete data logs.

Calling the file system of the memory card in the file Explorer directly brings with it the risk that you accidentally delete or change data log or other system files so that a file becomes damaged or the memory card becomes unusable. Changes to data logs on the memory card that you made outside the PLC have the effect POWER ON time of the PLC is increased.

Clearing data logs

You use the instruction "DataLogClear (Page 4027)" (S7-1500) to delete all the data records in an existing data log. The instruction does not delete the optional header of the CSV file (see the description of the HEADER parameter of the instruction "DataLogCreate (Page 4016)").

You use the ID parameter to select the data log whose data records are to be deleted. Before you can delete data records, the data log must be open.

New file for data logs

You use the instruction "DataLogNewFile (Page 4034)" (S7-1200) or "DataLogTypedNewFile (Page 4036)" (S7-1500) to create a new data log with the same properties as an existing data log. This allows the contents of an existing data log to be retained.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

You can run a consistency check for "DataLogTypedNewFile (Page 4036)" (S7-1500).

DataLogCreate: Create data log (S7-1200, S7-1500)

Description

With the "DataLogCreate" instruction you create a data log.

The data log is saved on the memory card or in the internal load memory in the directory "\DataLogs". The amount of data that is stored in a data log is dependent on the available space on the memory card or the storage space in the internal load memory of the CPU used. The maximum size of the generated CSV file is 500,000,000 bytes for S7-1200 CPUs, 1,000,000,000 bytes for S7-1500 CPUs.

You specify the maximum number of data records that is stored in a data log in the RECORDS parameter. When the specified maximum number of data records in the data log is reached, the oldest data record is overwritten. To avoid overwriting of existing data records, use the "DataLogNewFile (Page 4034)" instruction. The instruction is used to create a new data log with the same structure when the number specified at the RECORDS parameter is reached (return value 1 at the STATUS parameter of the "DataLogWrite (Page 4029)" instruction). The data records are then saved in the new data log.

You specify the name for the data log in the NAME parameter. The data log is created in CSV (Comma Separated Value) format. With the HEADER parameter, you create an (optional) header for the data log.

Once the data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogCreate" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction The data log is created with a rising edge at the parameter REQ.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Maximum number of data records in the data log If the "DataLogWrite (Page 4029)" instruction writes more records than specified in this parameter, the oldest record is overwritten.
FORMAT	Input	UInt	I, Q, M, L, D or constant	Data format: • 0: Internal (not supported) • 1: CSV (Comma separated values)
TIMESTAMP	Input	UInt	I, Q, M, L, D or constant	Time stamp: • 0: No time stamp • 1: Date and time The extra columns in the header are automatically added if time-stamping is activated.

Parameter	Declaration	Data type	Memory area	Description
NAME	Input	VARIANT	L, D	Name of the data log The specified name is also used as a file name for the csv file. With S7-1200 CPUs. the following restrictions apply to name of the data log: • The name must not be longer than 35 characters. • All ASCII characters between 0x20 and 0x7E are permitted with the exception of \ ' / " : ; [ ] | = . * ? < > With S7-1500 CPUs. the following restrictions apply to name of the data log: • The name must not be longer than 55 characters. • The following characters are permitted: 0 ... 9, a ... z, A ... Z as well as - and _
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log (only output) The ID of the data log is required for further data logging instructions to address the created data log.
HEADER	InOut	VARIANT	D	Header of the data log (optional) The parameter is hidden after the instruction is added. The header is written as the first line in the CSV file.
DATA	InOut	VARIANT	D	Pointer to the data structure that is written as data record when executing the "DataLogWrite (Page 4029)" instruction.
DONE	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: Processing not yet complete. • 1: Processing of instruction finished successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: Processing of the instruction has not started, completed, or canceled. • 1: Processing of the instruction is in progress.
ERROR	Output	BOOL	I, Q, M, L, D	Status parameter: • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Detailed status information: Detailed error and status information is output at the parameter STATUS. The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter HEADER

The HEADER parameter is a VARIANT pointer to a data block that defines a header for the CSV file (header). The header is always the first line in the CSV file representation.

- The header preset using HEADER is transferred to the CSV file. Here there is no check as to whether it is consistent with the remainder of the data log. In particular, there is no check whether the number of columns separated by commas matches the number of data columns.
- A STRING, Array of BYTE, or Array of CHAR data type can be used for the individual column names. When the STRING data type is used, the length is limited to 254 bytes. When the Array of BYTE and Array of CHAR are used, 5000 elements are possible.

If no header is to be created, do not specify a value in the HEADER parameter.

Parameter DATA

The DATA parameter is a VARIANT pointer to an elementary data type, a structure or an array in a data block. An element of a structure or an array corresponds to a column in the data log with a specific data type.

Note the following when creating the data block:

- Normally, the number of columns matches the number of columns defined in the HEADER parameter. This is however not stipulated.
- Each element of the structure or the array corresponds to a column entry in the CSV file. Therefore, no nesting structures (STRUCT in STRUCT) may be used when using the data type STRUCT. However the use of arrays within a data type is permitted STRUCT with the following exception: Arrays whose elements are of the data type "PLC data type (UDT)" are not permitted.
- The data structure can contain up to 256 elements. If there are more than 256 elements, error code 8C52 is output at the STATUS parameter.
- The tags of the data block can be set as retentive or non-retentive tags. However, the retentivity setting must be the same for all tags of the data block.

Parameter STATUS (S7-1200)

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogCreate instructions has already been reached.
8090	Invalid file name (see description of the NAME parameter).

Error code* (W#16#...)	Description
8093	Data log already exists.
8097	The length of the file exceeds the limitation of the file system or the CPU-specific limitation.
80A2	Write error returned from file system.
80B2	Maximum number of data logs exceeded
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
80C1	Too many data logs are open.
8253	The RECORDS parameter has an invalid value.
8353	Invalid format selection
8453	Invalid time stamp
8B24	Invalid assignment at parameter HEADER (for example: points to local memory).
8B51	Impermissible data type at parameter HEADER or length exceeds the maximum size.
8C24	Invalid assignment at parameter DATA (for example: points to local memory).
8C51	Impermissible data type at parameter DATA / data structure cannot be used.
8C52	Structure at the parameter DATA contains more than 256 elements.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Parameter STATUS (S7-1500)

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	The maximum number of simultaneously active DataLogCreate instructions has already been reached.
8090	Invalid file name (see description of the NAME parameter).
8091	"NAME" parameter is not a string.
8093	Data log already exists.
8097	The length of the file exceeds the limitation of the file system or the CPU-specific limitation.
80A2	Write error returned from file system.
80B2	Maximum number of data logs exceeded or data log resources used up
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
80C1	Too many data logs are open.
8253	The RECORDS parameter has an invalid value.
8353	Invalid format selection.
8453	Invalid time stamp.
8B24	Invalid assignment at parameter HEADER (for example: points to local memory).
8B51	Impermissible data type at parameter HEADER or length exceeds the maximum size.

Error code* (W#16#...)	Description
8C24	Invalid assignment at parameter DATA (for example: points to local memory).
8C51	Impermissible data type at parameter DATA / data structure cannot be used.
8C52	Structure at the parameter DATA contains more than 256 elements.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, a simple data log is created with a time stamp and three process values.

Tags in the global data block

The values for the input parameters of the data log are stored in the global data block "DataLogDB":

- DataLogName (String): The tag contains the name of the data log which is also used as the file name for the CSV file.
- DataLogID (DInt): The ID of the data log is written in this tag when the instruction is called.
  - The ID is automatically assigned by the instruction.
  - Use the tag "DataLogID" in other DataLog instructions in order to address this data log.
- MyHeader (String): This tag contains the header of the data log, i.e. the column headings for the process values.
- MyData (Struct): The tag contains the three process values that are written in the data log. Each time a record is written (instruction "DataLogWrite (Page 4029)") the current values are written in a new record.

DataLogDB

	Name	Data type	Start value	Retain
1	Static			
2	DataLogName	String	'MyDataLog'	
3	DataLogID	DInt	0	
4	MyHeader	String	'Value1,Value2,Value3'	
5	MyData	Struct		
6	ProcessValue1	Int	2	
7	ProcessValue2	Int	3	
8	ProcessValue3	Int	4	

Calling the "DataLogCreate" instruction

The instruction is called with the following input parameters:

- REQ (BOOL): When REQ = "1" the data log is created.
- RECORD (3): A maximum of three data records can be written in the data log. Thereafter, the oldest data record is overwritten.

- FORMAT (1): The data log is created as a CSV file.
- TIMESTAMP (1): Enabled: Two additional columns are automatically created (date and time) for the data log. The current time stamp is written in the data record each time "DataLogWrite (Page 4029)" is executed.
- NAME (VARIANT): Pointer to the tag "DataLogName" in the data block "DataLogDB".
- ID (VARIANT): Pointer to the tag "DataLogID" in the data block "DataLogDB" (output only).
- HEADER (VARIANT): Pointer to the tag "MyHeader" in the data block "DataLogDB".
- DATA (VARIANT): Pointer to the tag "MyData" in the data block "DataLogDB".

Readout of the data log via the web server

You read out the created data log with the web server:

- Activate the web server in the properties of the CPU. The authorization "...to read files" must be activated for the web server in order to readout the data log.
- You can access the web server via the Internet browser by entering the IP address of the CPU as a URL.
- Under "Filebrowser" the directory "\DataLogs" was automatically created which contains the data log.
- The DataLog only contains one entry "//END" if the instruction "DataLogWrite (Page 4029)" has still not been executed. The first data record is written after the initial execution of "DataLogWrite (Page 4029)".

	A	B	C	D	E	F
1	SeqNo	Date	Time	ProcessValue1	ProcessValue2	ProcessValue3
2	1	01.07.2013	12:33:42.917	2	3	4
3						
4						
5						

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Data logging - Overview (Page 4011)

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogOpen: Open data log (S7-1200, S7-1500)

DataLogOpen: Open data log (S7-1200)

Description

You use the "DataLogOpen" instruction to open an existing data log on the memory card. To write new data records to the data log, a data log must be open.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 4016)" and "DataLogNewFile (Page 4034)".

Up to 10 data logs can be open simultaneously. The data log to be opened can be selected using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the parameter NAME and specify 0 as the ID, the ID belonging to the data log will be displayed in the ID parameter when you open the data log.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

Parameters

The following table shows the parameters of the "DataLogOpen" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D or constant	Execution of the instruction upon a rising edge.
MODE	Input	UInt	I, Q, M, L, D or constant	Mode for opening the data log: • MODE= "0" Data records of the data log are retained • MODE= "1" Data records of the data log are deleted, but the header is retained
NAME	Input	VARIANT	L, D	(File) name of the data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log.
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
0	No errors.
2	Warning: Data log file has already been opened by this application.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogOpen instructions has already been reached.
8090	There are inconsistencies between the data log definition and existing data log data.
8091	A data type other than String was used at the NAME parameter.
8092	Data log does not exist.
80B4	The memory card is write-protected.

Error code* (W#16#...)	Description
80C1	Too many files open.
The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for working with data logs (Page 4038).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Data logging - Overview (Page 4011)

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogOpen: Open data log (S7-1500)

Description

You use the "DataLogOpen" instruction to open an existing data log on the memory card. A data log must be open to write new data records to it.

Data log opens automatically when you execute the instructions "DataLogCreate (Page 4016)" and "DataLogNewFile (Page 4034)".

Up to 10 data logs can be open simultaneously. The data log to be opened can be selected using the ID or name of the data log.

- If you specify the ID and the name of the data log in the ID and NAME parameters, respectively, the data log will be identified based on the ID. The data log name will not be compared.
- If you select the data log using the parameter NAME and specify 0 as the ID, the ID belonging to the data log will be displayed in the ID parameter when you open the data log.
- If you select the data log using the ID parameter and no name is specified, the name will be displayed in the NAME parameter when the data log is opened.

You use the MODE parameter to specify whether the data records of the data log are to be deleted upon opening.

The parameter DATA enables a consistency check between the data log to be opened and the definition of the data log of the instruction "DataLogCreate (Page 4016)". A check is made as to whether the data type of the DATA parameter is identical to the data type of "DataLogCreate". If this is not the case, the error code W#16#8090 is output at the STATUS parameter.

Parameters

The following table shows the parameters of the "DataLogOpen" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
MODE	Input	UInt	I, Q, M, L, D or constant	Mode for opening the data log: • MODE= "0" Data records of the data log are retained • MODE= "1" Data records of the data log are deleted, but the header is retained
NAME	Input	VARIANT	L, D	(File) name of the data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log.
DATA	InOut	VARIANT	D	With consistency check: Pointer to the data area at the DATA parameter of the "DataLogCreate (Page 4016)" instruction.
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
0	No errors.
2	Warning: Data log file has already been opened by this application.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogOpen instructions has already been reached.

Error code* (W#16#...)	Description
8090	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
8091	A data type other than String was used at the NAME parameter.
8092	Data log does not exist.
80B4	The memory card is write-protected.
80C1	Too many files open.
The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for working with data logs (Page 4038).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

DataLogClear: Empty data log (S7-1200, S7-1500)

Description

The "DataLogClear" instruction deletes all data records in an existing data log. The instruction does not delete the optional header of the CSV file (see the description of the HEADER parameter of the instruction "DataLogCreate (Page 4016)").

You use the ID parameter to select the data log whose data records will be deleted.

Requirement

Before you can delete data records, the data log must be open (see "DataLogOpen (Page 4023) instruction").

Parameters

The following table shows the parameters of the "DataLogClear" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
ID	InOut	DWORD	I, Q, M, D, L	Object ID of the data log
DONE	Output	BOOL	I, Q, M, D, L	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output at the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

Error code* (W#16#...)	Explanation
0000	No error.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogClear instructions has already been reached.
8080	The data log file selected with the ID parameter is not processed by the "DataLogClear" instruction.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B4	The memory card is write-protected.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Data logging - Overview (Page 4011)

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogWrite: Write data log (S7-1200, S7-1500)

Description

With the "DataLogWrite" instruction you write a data record into an existing data log. With the ID parameter you select the data log into which the data record is to be written. To create a new data record, the data log must be open. The instruction creates a new data record in the format that was specified in the DATA parameter when the data log was created.

Before calling the "DataLogWrite" instruction, transfer the data to the tag that you interconnected at the DATA parameter of the "DataLogCreate" instruction. When the "DataLogWrite" instruction is executed, the transferred data is copied to the data log.

NOTICE
Data log data loss when the power supply to the CPU is interrupted If the power supply is interrupted during execution of the "DataLogWrite" instruction, the data record to be transferred is lost.

Parameters

The following table shows the parameters of the "DataLogWrite" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS (S7-1200)

Error code* (W#16#...)	Description
0	No errors
0001	Last possible data record created at the end of the file. Creating another data record will overwrite an older data record.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogWrite instructions has already been reached.
8090	Data log definition does not match the existing data log.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Parameter STATUS (S7-1500)

Error code* (W#16#...)	Description
0	No errors
0001	Last possible data record created at the end of the file. Creating another data record will overwrite an older data record.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	The maximum number of simultaneously active DataLogWrite instructions has already been reached.
8090	Data log definition does not match the existing data log.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B0	Data log is not open.
80B3	Insufficient memory space on the memory card.
80B4	The memory card is write-protected.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for working with data logs (Page 4038).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

DataLogClose: Close data log (S7-1200, S7-1500)

Description

With the "DataLogClose" instruction, you close an open data log. You select the data log using the ID parameter.

Note

Closing data logs automatically

The data log is closed automatically when the CPU goes to STOP or if there is a restart.

Parameters

The following table shows the parameters of the "DataLogClose" instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execute function on a rising edge.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS (S7-1200)

Error code* (W#16#...)	Description
0	No errors
1	Data log is not open
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogClose instructions has already been reached.
8092	Data log does not exist.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Parameter STATUS (S7-1500)

Error code* (W#16#...)	Description
0	No errors
1	Data log is not open
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
8070	The maximum number of simultaneously active DataLogClose instructions has already been reached.
8092	Data log does not exist.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Example program for working with data logs (Page 4038).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogDelete: Delete data log (S7-1200, S7-1500)

Description

You use the "DataLogDelete" instruction to delete a data log file from the memory card. The data log and the data records it contains are only deleted if they were created with the "DataLogCreate" or "DataLogNewFile" instruction.

Parameters

The following table shows the parameters of the "DataLogDelete" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
NAME	Input	VARIANT	L, D	File name of the data log
DELFILE	Input	BOOL	I, Q, M, D, L or constant	• 0: Data log is retained. • 1: Data log is deleted.
ID	InOut	DWORD	I, Q, M, D, L	Object ID of the data log
DONE	Output	BOOL	I, Q, M, D, L	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Deletion of the data log is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output at the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters NAME and ID

Select the data log to be deleted using the NAME and ID parameters. The ID parameter is evaluated first. If there is a data log with the relevant ID, the NAME parameter will not be evaluated. If the value "0" is used at the ID parameter, a value with the data type STRING must be used at the NAME parameter.

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogDelete instructions has already been reached.
8091	A data type other than STRING is being used at the NAME parameter.
8092	Data log does not exist.
80A2	Write error signaled back by the file system.
80B4	The memory card is write-protected.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

See also

DataLogCreate: Create data log (Page 4016)

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogNewFile: Data log in new file (S7-1200, S7-1500)

DataLogNewFile: Data log in new file (S7-1200)

Description

With the "DataLogNewFile" instruction you create a new data log with the same properties as an already existing data log. This allows the contents of an existing data log to be retained.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

Once the new data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogNewFile" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D or constant	Execution of the instruction upon a rising edge.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Number of data records in the data log.
NAME	Input	VARIANT	L, D	File name of the new data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log • In: ID of the existing data log • Out: ID of the new data log
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogNewFile instructions has already been reached.
8090	Invalid file name.
8091	Data type at parameter NAME is not STRING.
8092	Source data log does not exist.
8093	New data log already exists.
8097	File length exceeds the file system limit.
80A0	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
80A2	Write error signaled back by the file system.
80B2	Maximum number of data logs exceeded or data log resources used up

Error code* (W#16#...)	Description
80B3	Load memory not sufficient.
80B4	The memory card is write-protected.
80C1	Too many files open.
8253	The RECORDS parameter has an invalid value.
The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Example program for working with data logs (Page 4038).

Difference between synchronous and asynchronous instructions (Page 2571)

DataLogNewFile: Data log in new file (S7-1500)

Description

With the "DataLogNewFile" instruction you create a new data log with the same properties as an already existing data log. This allows the contents of an existing data log to be retained.

When called, the instruction creates a new data log on the memory card or in the internal load memory with the name defined at the NAME parameter. You use the ID parameter to specify the ID of the old data log whose properties you want to apply to the new data log. The ID of the new data log is then output via the ID parameter.

You specify the file size of the new data log with the RECORDS parameter of the instruction.

The parameter DATA enables a consistency check between the new data log to be created and the definition of the data log of the instruction "DataLogCreate (Page 4016)". A check is made as to whether the data type of the DATA parameter is identical to the data type of "DataLogCreate". If this is not the case, the error code W#16#80A0 is output at the STATUS parameter.

Once the new data log is created, it is opened automatically. This means that data can be written.

Parameters

The following table shows the parameters of the "DataLogNewFile" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, L, D, T, C or constant (T and C are only available in LAD and FBD with S7-1500)	Execution of the instruction upon a rising edge.
RECORDS	Input	UDInt	I, Q, M, L, D or constant	Number of data records in the data log.
NAME	Input	VARIANT	L, D	File name of the new data log.
ID	InOut	DWORD	I, Q, M, L, D	Object ID of the data log • In: ID of the existing data log • Out: ID of the new data log
DATA	InOut	VARIANT	D	Data type for consistency check
DONE	Output	BOOL	I, Q, M, L, D	Instruction was executed successfully.
BUSY	Output	BOOL	I, Q, M, L, D	Execution of the instruction not yet complete.
ERROR	Output	BOOL	I, Q, M, L, D	• 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, L, D	Status parameter The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
0	No errors.
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8070	The maximum number of simultaneously active DataLogNewFile instructions has already been reached.
8090	Invalid file name
8091	Data type at parameter NAME is not STRING.
8092	Source data log does not exist.
8093	New data log already exists.
8097	The length of the file exceeds the limitation of the file system or the CPU-specific limitations.

Error code* (W#16#...)	Description
80A0	Data types inconsistent. The data log at parameter ID uses different data types than specified at parameter DATA.
80A2	Write error signaled back by the file system.
80B2	Maximum number of data logs exceeded or data log resources used up
80B3	Load memory not sufficient.
80B4	The memory card is write-protected.
80C0	Access currently not possible.
80C1	Too many files open.
8253	The RECORDS parameter has an invalid value.
The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Difference between synchronous and asynchronous instructions (Page 2571)

Example program for working with data logs (S7-1200, S7-1500)

Introduction

The following example program shows the main functions of the data log instructions. For detailed information about individual instructions, open the corresponding help description using the corresponding links.

General notes on using data logs

- The data log created is automatically opened when the "DataLogCreate" and "DataLogNew" instructions are executed.
- Data logs are automatically closed after the CPU switches from RUN to STOP or after a restart of the CPU.
- For the "DataLogWrite" instruction to be executed, the data log must be open.
- For S7-1200 CPUs, a maximum of eight data logs can be open simultaneously. For S7-1500 CPUs, a maximum of ten data logs can be open simultaneously.

Example program

Create the following tags for storing the data in a global data block (SLI_gDB_Datalogging).

SLI_gDB_DataLogging

	Name	Data type	Start value
1	Static		
2	newName	String	'myNewDataLog1a'
3	name	String	'myDataLog1a'
4	logID	DWord	16#0
5	logHeader	String	'Count,Temperature,Pressure'
6	myData	Struct	
7	count	Int	0
8	temperature	Real	0.0
9	pressure	Real	0.0
10	executeCreate	Bool	false
11	createDone	Bool	false
12	createBusy	Bool	false
13	createError	Bool	false
14	createStatus	Word	16#0
15	createStatusMem	Word	16#0
16	dlogCreated	Bool	false

The DB ("SLI_gDB_Datalogging") is used to create a data log (DataLogCreate (Page 4016)). The three entries of the structure "myData" are used as process values: count, temerature and pressure. In the data block, these three values are stored temporarily and then transferred with the "DataLogWrite (Page 4029)" instruction to a data log as a data record.

A data record is composed later from the following entries:

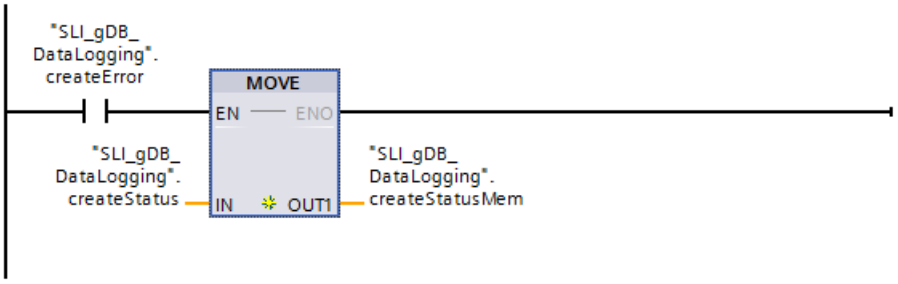
- The data record number (assigned automatically)
- The date (assigned automatically when "1" is used for DataLogCreate at the TIMESTAMP parameter).
- The time of day (assigned automatically when "1" is used for DataLogCreate at the TIMESTAMP parameter).
- The current value of "count" from the "myData" structure.
- The current value of "temperature" from the "myData" structure.
- The current value of "pressure" from the "myData" structure.

Use the global data block "SLI_gDB_DataLogW" to make available the process values for writing a data record DataLogWrite (Page 4029)).

SLI_gDB_DataLogW

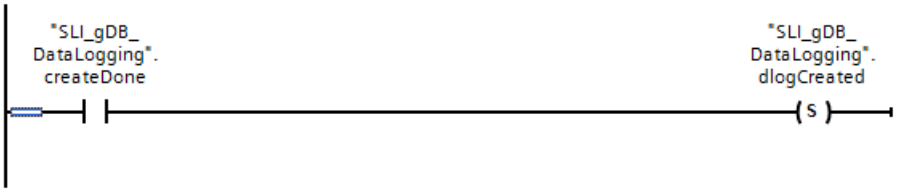
	Name	Data type	Start value
1	Static		
2	executeWrite	Bool	false
3	count	Int	5
4	scaledTemp	Real	25.7
5	scaledPressure	Real	45.0
6	writeDone	Bool	false
7	writeBusy	Bool	false
8	writeError	Bool	false
9	writeFullStatus	Word	16#0
10	closeDone	Bool	false
11	closeBusy	Bool	false
12	closeError	Bool	false
13	closeStatus	Word	16#0
14	executeOpen	Bool	false
15	openDone	Bool	false
16	openBusy	Bool	false
17	openError	Bool	false
18	openStatus	Word	16#0
19	executeNewFile	Bool	false
20	fileDone	Bool	false
21	fileBusy	Bool	false
22	fileError	Bool	false
23	fileStatus	Word	16#0

Create an FB "SLI_FB_DataLogging". Create the following local tags in the FB.



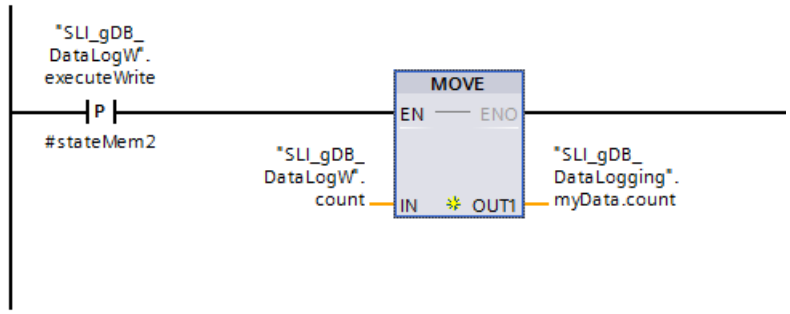
7	Static			
8	DataLogCreate_Instance	DataLogCreate		
9	stateMem	Bool	false	Non-retain
10	stateMem2	Bool	false	Non-retain
11	stateMem3	Bool	false	Non-retain
12	stateMem4	Bool	false	Non-retain
13	stateMem5	Bool	false	Non-retain
14	DataLogWrite_Instance	DataLogWrite		
15	DataLogClose_Instance	DataLogClose		
16	DataLogOpen_Instance	DataLogOpen		
17	DataLogNewFile_Instance	DataLogNewFile		

Create the following interconnections in the FB.

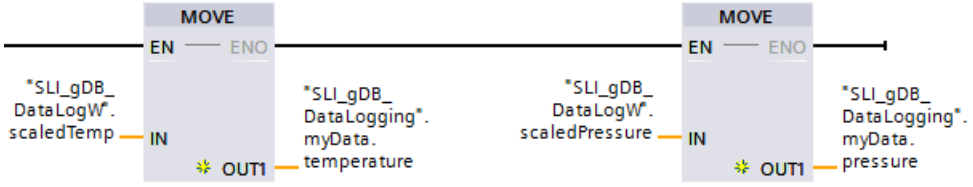


Network 1: A positive edge at the input parameter REQ (" executeCreate") of the instruction DataLogCreate (Page 4016) starts the creation of the data log.

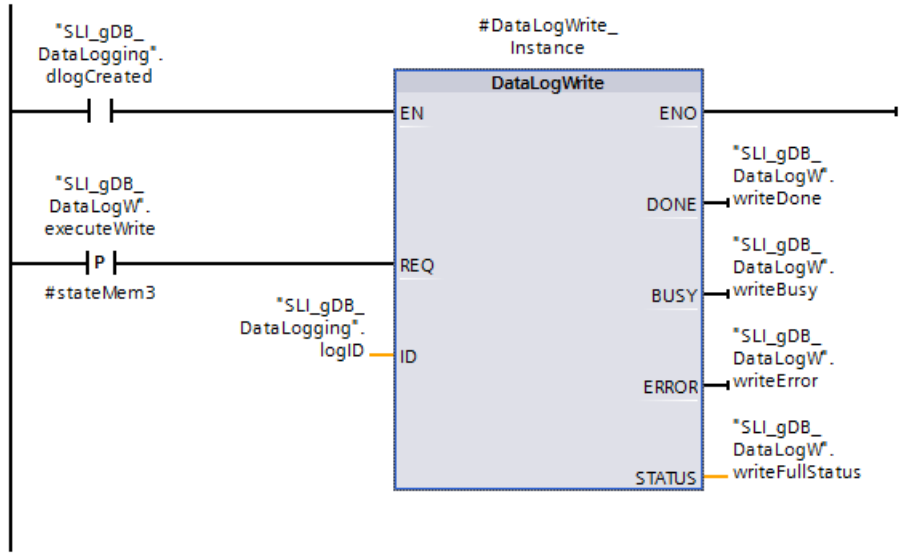
Network 2: In case of error of DataLogCreate, save the status as follows.



Network 3: The output parameter DONE ("createDone") of DataLogCreate (Page 4016) is only valid for one cycle. Therefore, save its value in the tag "dlogCreated".

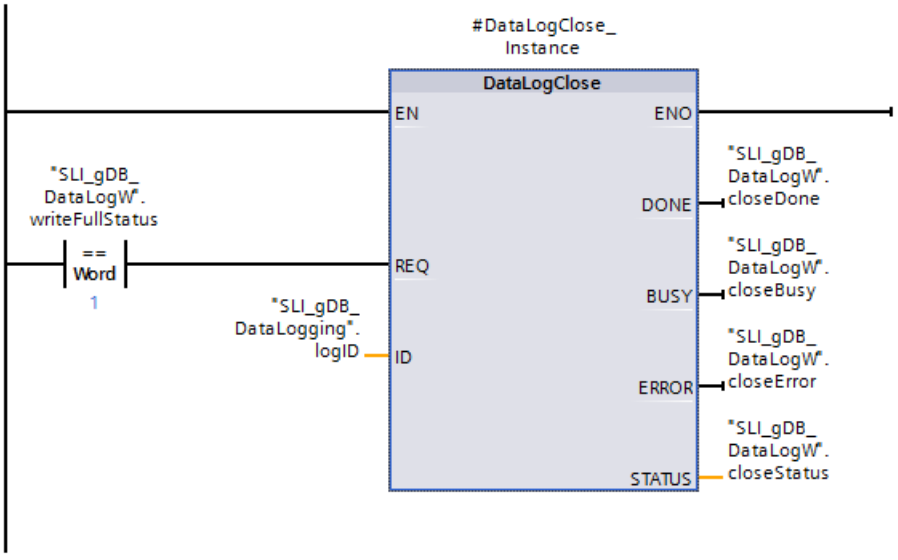


Network 4: A rising edge triggers the point in time at which new process values are stored in the myData structure. This step is used to store the desired process values temporarily in the data block.

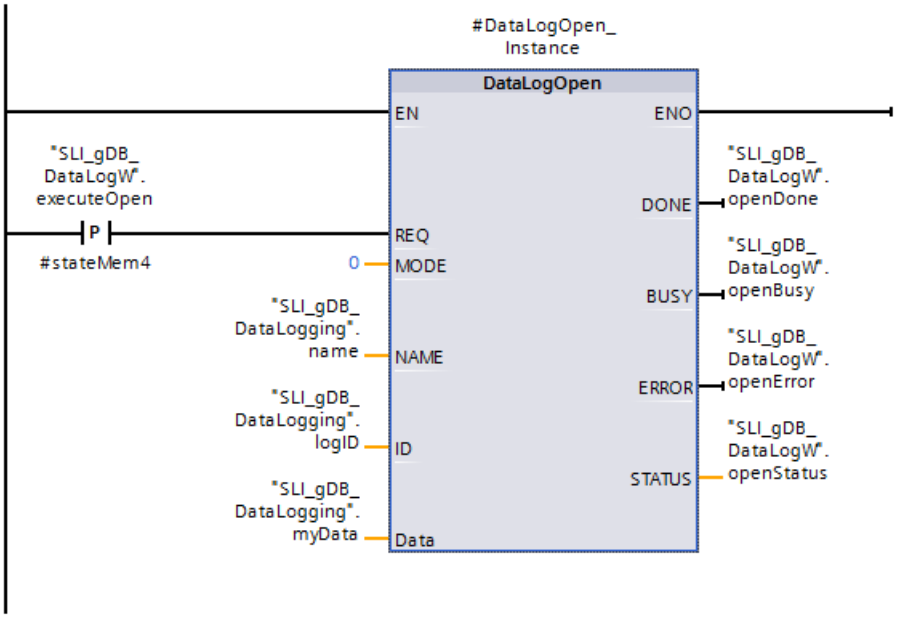


Part 1:

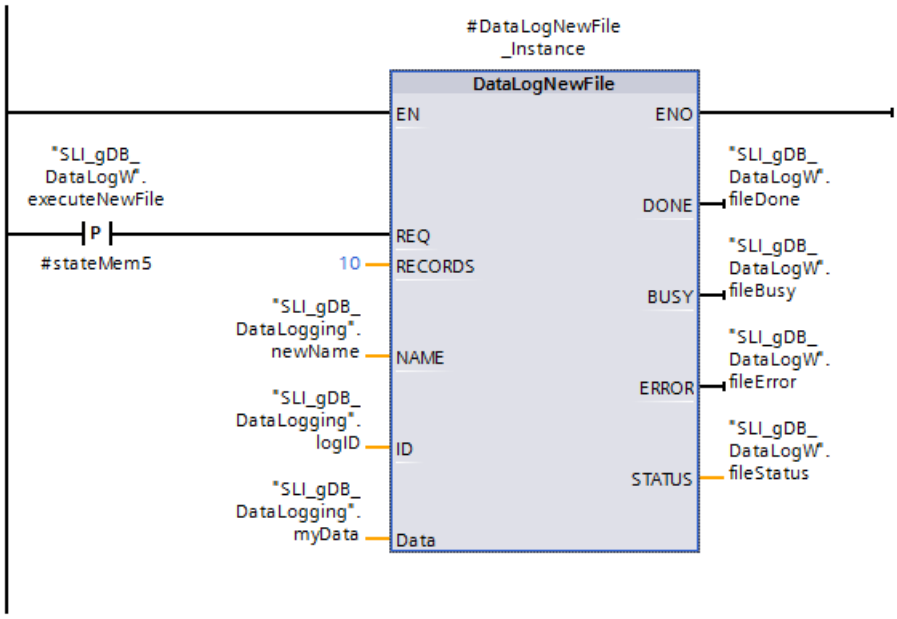
Part 2:



Network 5: Once the execution of DataLogCreate (Page 4016) is complete, ("dlogCreated" is "TRUE"), the EN input of DataLogWrite (Page 4029) is set. The reason for this is that a generation process extends over several cycles and must be completed in order for a write operation to be performed. Writing is triggered for a data record by a rising edge at the input parameter REQ ("executeWrite").



Network 6: Close the data log after the last data record has been written. The data log was created for 5 data records (see Network 1). This means that after five data records the value "0001" is output at the instruction DataLogWrite (Page 4029) at the parameter STATUS ("writeFullStatus"). (Last possible data record has been created at the end of the file. Creating another data record will overwrite an older data record.)



In this case, the input REQ is set and the instruction DataLogClose (Page 4031) is executed. When the data log is closed, no more data records are written.

Network 7: The data log must be opened again with the DataLogOpen (Page 4025) instruction in order to write a data record again at a later time. If another data record is written with DataLogWrite (Page 4029) after this, the oldest data record is overwritten.

Network 8: If you do not want to overwrite the older data records, you can use the DataLogNewFile (Page 4036) instruction to create a new data log with the same structure. To do this, enter the ID of the existing data log whose structure you want to copy at the ID parameter of the instruction. Once the DataLogNewFile (Page 4036) instruction has been executed, a new and unique ID value for the new data log is assigned.

Note that the call for DataLogNewFile (Page 4036) also extends over several cycles. Therefore, similar to the DataLogCreate (Page 4016) instruction, you should also query the DONE bit to prevent premature execution of DataLogWrite (Page 4029) (see Networks 1, 2 and 4).

Result

Opening of written data via the web server

The data logs created with the example program are displayed via the web server. To do this, open the Web server using an Internet browser and open the "\DataLogs" directory.

Contents of the CSV files

- "5" is set as the maximum number of data records when creating the data log with the DataLogCreate instruction. If this number is not exceeded, all written data records are included in the data log.

	A	B	C	D	E	F
1	Record	Date	UTC Time	Count	Temperature	Pressure
2	1	9/30/2010	20:26:56	1	9.86E+01	3.52E+01
3	2	9/30/2010	20:28:43	2	1.00E+02	3.73E+01
4	3	9/30/2010	20:29:03	3	9.99E+01	3.68E+01
5	4	9/30/2010	20:29:21	4	9.95E+01	3.64E+01
6	5	9/30/2010	20:30:19	5	9.92E+01	3.74E+01
7						

- If another data record is added to this, the oldest data record (Record 1) is overwritten.

	A	B	C	D	E	F
1	Record	Date	UTC Time	Count	Temperature	Pressure
2	6	9/30/2010	20:32:03	6	9.86E+01	3.58E+01
3	2	9/30/2010	20:28:43	2	1.00E+02	3.73E+01
4	3	9/30/2010	20:29:03	3	9.99E+01	3.68E+01
5	4	9/30/2010	20:29:21	4	9.95E+01	3.64E+01
6	5	9/30/2010	20:30:19	5	9.92E+01	3.74E+01
7						

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

11.4.4.12 Data block functions (S7-1200, S7-1500)

CREATE_DB: Create data block (S7-1200, S7-1500)

Description

The "CREATE_DB" instruction is used to create a new data block in the load and/or work memory.

The instruction "CREATE_DB" does not change the checksum of the user program.

A data block that was only generated in the work memory has the following properties:

- After a memory reset or POWER OFF / POWER ON this block no longer exists.
- When loading or when there is a STOP-RUN transition, its content remains unchanged.

Number of the data block

The data block created is assigned a number from the range defined at the LOW_LIMIT (low limit) and UP_LIMIT (high limit) parameters. "CREATE_DB" assigns the smallest possible number from the specified range to the DB. You cannot assign the numbers of the DBs already contained in the user program.

To create a DB with a specific number, enter the same number for the high and low limit of the range to be specified. If a DB with the same number already exists in the work memory and/or load memory, or if the DB exists as a copied version, the instruction will be terminated and an error message will be generated at the RET_VAL parameter.

Start values of the data block

The SRCBLK parameter is used to define start values for the DB that is to be created. The SRCBLK parameter is a pointer to a DB or a DB area from which you apply the start values. The DB addressed at the SRCBLK parameter must have been generated with standard access ("Optimized block access" attribute disabled).

- If the area specified at the SRCBLK parameter is larger than the DB generated, the values up to the length of the DB generated will be applied as start values.
- If the area specified at the SRCBLK parameter is smaller than the DB generated, the remaining values will be filled with "0".

To ensure data consistency, you must not change this data area while "CREATE_DB" is being executed (which means as long as the BUSY parameter has the value TRUE).

Note

SRCBLK points to a TEMP tag

TEMP tags of standard blocks are located in the temporary local data area. A reference in SRCBLK to a TEMP tag therefore results in the value 80A3 (the data block at the SRCBLK parameter was not created with standard access) being output as RET_VAL.

Functional description

The "CREATE_DB" instruction works asynchronously. Processing takes place across several calls. You start the job by calling "CREATE_DB" with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "CREATE_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Level-triggered control parameter "request to activate" REQ = 1: Request to generate the data block
LOW_LIMIT	Input	UINT	I, Q, M, D, L or constant	Low limit of the range for the assignment of a DB number. The smallest possible number is 60000.
UP_LIMIT	Input	UINT	I, Q, M, D, L or constant	High limit of the area used by "CREATE_DB" to assign a number to your DB (largest possible DB number: 60999)
COUNT	Input	UDINT	I, Q, M, D, L or constant	The count value specifies the number of bytes which you want to reserve for the DB generated. The number of bytes must be an even number. The maximum length is 65534 bytes.

<table>
<tr><th>Parameter</th><th>Declaration</th><th>Data type</th><th>Memory area</th><th>Description</th></tr>
<tr><td rowspan="8">ATTRIB</td><td rowspan="8">Input</td><td rowspan="8">BYTE</td><td rowspan="8">I, Q, M, D, L or constant</td><td>You use the first 4 bits of the byte at parameter ATTRIB to define the properties of the data block *:</td></tr>
<tr><td>• Bit 0 = 0: Attribute "Only store in load memory" is not set.
• Bit 0 = 1: Attribute "Only store in load memory" is set. With this setting, the DB takes up no space in the work memory and is not included in the program. The DB cannot be accessed with bit commands. When bit 0 = 1, the selection for bit 2 is irrelevant.
To ensure compatibility with STEP 7 V5.x, bits 0 and 3 must be considered together (see below).</td></tr>
<tr><td>• Bit 1 = 0: Attribute "Data block write-protected in the device" is not set.
• Bit 1 = 1: Attribute "Data block write-protected in the device" is set.</td></tr>

<tr><td colspan="5">* The properties selected here correspond to the attributes in the properties of a data block.</td></tr>
</table>

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The destination area is greater than the source area. The source area is written completely to the destination area. The remaining bytes of the destination area remain unchanged.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8081	The source area is larger than the destination area. The complete destination area is written. The remaining bytes of the source area are ignored.
8092	The "Create data block" function is currently unavailable because • The "Compress user memory" function is currently active. • The maximum number of blocks on your CPU has already been reached.
8093	No data block or a data block that is not in the work memory is specified for the SRCBLK parameter.
8094	An invalid value was specified at parameter ATTRIB.
80A1	DB number error: • The number is "0" • The number exceeds the CPU-specific high limit for DB numbers • Low limit > high limit
80A2	DB length error: • The length is "0" • The length is an odd number • The length is greater than permitted by the CPU
80A3	The data block at the SRCBLK parameter was not created with standard access.
80B1	There is no DB number free.
80B2	Insufficient free memory available.
80B4	The memory card is write-protected.
80BB	Not enough load memory.
80C3	The maximum number of simultaneously active "CREATE_DB" instructions has already been reached.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You will find the example here: Program example for CREATE functions (Page 4065).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

READ_DBL: Read from data block in the load memory (S7-1200, S7-1500)

Description

With the instruction, you copy a DB or an area of a DB in load memory (Micro Memory Card) to the data area of a destination DB. The destination data block must be runtime-relevant, which means it must not be created with the Only store in load memory attribute. The content of the load memory is not changed during the copy process.

To ensure data consistency, you must not change the destination area while "READ_DBL" is being executed (i.e., as long as the BUSY parameter has the value TRUE).

The parameters SRCBLK and DSTBLK (source and destination blocks) must both be VARIANT data type. The following restrictions hereby apply:

- Valid for standard memory areas: If you want to interconnect a parameter of VARIANT data type (source or destination area) with a tag of BOOL data type or an ARRAY of BOOL, you have the following options:
  - You can address it symbolically
    Example: Parameter SRCBLK: "Data_block".myArray
  - You can address it absolutely with help of the ANY pointer. However, you must note that the specified length of the area must be divisible by 8, or the instruction will otherwise not be executed.
    Example: Parameter SRCBLK: P#DB123.DBX456.0 BOOL 1000
- For a VARIANT pointer of type STRING, the length must be equal to 1.
- The source and destination blocks must have been created with the same block access, i.e. both must use either the "Optimized" or "Standard" access type.
- When the source and target DB blocks have optimized access, you must not use the STRUCT data type.

Note

"READ_DBL" is processed asynchronously and is therefore, it is not suitable for frequent (or cyclic) reading of tags in the load memory.

Once started, a job is always completed. If the maximum number of simultaneously active "READ_DBL" instructions is reached and you call "READ_DBL" once again at this time in a priority class having higher priority, error code W#16#80C3 will be returned. Consequently it does not make sense to restart the high-priority job right away.

Functional description

The "READ_DBL" instruction works asynchronously. Processing takes place across several calls. You start the job by calling "READ_DBL" with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "READ_DBL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
SRCBLK	Input	VARIANT	D	Pointer to data block in the load memory that is to be read from
RET_VAL	Return	INT	I, Q, M, D, L	Error information
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
DSTBLK	Output	VARIANT	D	Pointer to the data block in the work memory that is written to

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The destination area is greater than the source area. The source area is written completely to the destination area; the remaining bytes of the destination area will not be changed.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ=1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8x51	Note: This error code is only for S7-1200 CPUs. Data type error in the data block.
8081	The source area is larger than the destination area. The complete destination area is written. The remaining bytes of the source area are ignored.
8082	• Destination DB type different from source DB type (optimized/standard access). • The destination and source DB were both created with optimized access. You have, however, used structures with the destination and source DB that lead to a different arrangement of the data when compiled. (Note: Use UDTs instead.)
8093	Note: This error code is only for S7-1500 CPUs. No data block or a data block that is not in the work memory is specified for the DSTBLK parameter.
80B1	Note: This error code is only for S7-1500 CPUs. At parameter SRCBLK, only data blocks that are located in the load memory are permitted.
8xB1	Note: This error code is only for S7-1200 CPUs. No data block is specified for the SRCBLK parameter, or the data block specified there is not a load memory object.
80B4	DSTBLK points to a DB with F-attribute (that must not be written)
8xC0	Note: This error code is only for S7-1200 CPUs. The destination DB is currently being processed by another instruction or a communication function.

Error code* (W#16#...)	Description
80C3	The maximum number of simultaneously active "READ_DBL" instructions has already been reached.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, you read out the contents of a DB in the load memory to a DB in the work memory.

To store the data for the interconnection, create three tags in a global data block.

SLI_gDB_READ_DBL

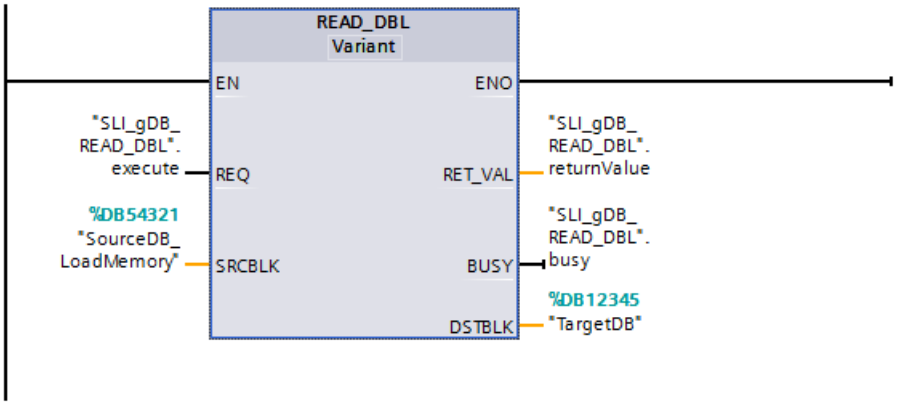
	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	busy	Bool	false
4	returnValue	Int	0

To store the send data, create two global data blocks with three tags each of the INT data type.

- For receive data in the load memory:

SourceDB_LoadMemory

	Name	Data type	Offset	Start value
1	Static			
2	MySourceValue1	Int	0.0	111
3	MySourceValue2	Int	2.0	222
4	MySourceValue3	Int	4.0	333



- For receive data in the work memory:

TargetDB

	Name	Data type	Offset	Start value
1	Static			
2	MyTargetValue1	Int	0.0	0
3	MyTargetValue2	Int	2.0	0
4	MyTargetValue3	Int	4.0	0

Create the following interconnections in an FB "SLI_FB_READ_DBL".

Network 1: Interconnect the parameters of the "READ_DBL" instruction as follows.

Network 2: You can stop the processing of READ_DBL as follows.

If the normally open contact ("execute") supplies the signal state "TRUE", the "READ_DBL" instruction is executed. The DB is stored in the load memory with the input parameter SRCBLK ("SourceDB_LoadMemory").
The DB is stored in the work memory with the output parameter DSTBLK ("TargetDB"). The instruction "READ_DBL" calls the data to be transferred in the load memory (SRCBLK) and reads the data in the work memory (DSTBLK).

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

GET_ERR_ID: Get error ID locally (Page 3409)

WRIT_DBL: Write to data block in the load memory (S7-1200, S7-1500)

Description

The instruction "WRIT_DBL" is used to transfer the contents of a DB or a DB area from the work memory to a DB or a DB area in the load memory (Micro Memory Card). The source DB must be runtime-relevant, which means it must not be created with the Only store in load memory attribute.

Note

Start value behavior during "Upload from device"

The start values that you changed with the "WRIT_DBL" instruction are lost when you perform the "Upload from device" action.

To ensure data consistency, it is not permitted to change the source range while "WRIT_DBL" is being executed (i.e., as long as the BUSY parameter has the value TRUE).

The parameters SRCBLK and DSTBLK (source and destination blocks) must both be VARIANT data type. The following restrictions hereby apply:

- For a VARIANT pointer of type BOOL, the length must be divisible by 8.
- For a VARIANT pointer of type STRING, the length must be equal to 1.
- The source and destination blocks must have been created with the same block access, i.e. both must use "Optimized block access" or optimized access must be disabled for both.
- When the source and target DB blocks have optimized access, you must not use the STRUCT data type.

The "WRIT_DBL" instruction does not change the checksum of the user program if you write a DB that was created using an instruction. However, when a loaded DB is written, the first entry in this DB changes the checksum of the user program.

Note

"WRIT_DBL" is not suitable for frequent (or cyclical) writing of tags in the load memory. This is because the memory card technology limits the number of write accesses that can be made to a memory card.

Functional description

The "WRIT_DBL" instruction works asynchronously. Processing takes place across several calls. You start the job by calling "WRIT_DBL" with REQ=1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "WRIT_DBL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Write request
SRCBLK	Input	VARIANT	D	Pointer to the DB in the work memory that is to be read from
RET_VAL	Return	INT	I, Q, M, D, L	Error information
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.
DSTBLK	Output	VARIANT	D	Pointer to the data block in the load memory that is written to

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Description
0000	No error
0081	The destination area is greater than the source area. The source area is written completely to the destination area; the remaining bytes of the destination area will not be changed.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
8051	Note: This error code is only for S7-1200 CPUs. Type error data block.
8251	Note: This error code is only for S7-1200 CPUs. Data type error in the source DB
8551	Note: This error code is only for S7-1200 CPUs. Data type error in the target DB
8081	The source area is larger than the destination area. The complete destination area is written. The remaining bytes of the source area are ignored.
8082	Note: This error code is only for S7-1500 CPUs. • Destination DB type different from source DB type (optimized/non-optimized access). • The destination and source DB were both created with optimized access. You have, however, used structures with the destination and source DB that lead to a different arrangement of the data when compiled. (Note: Use UDTs instead.)
8093	Note: This error code is only for S7-1500 CPUs. No data block or a data block that is not in the work memory is specified for the SRCBLK parameter.
80B1	Note: This error code is only for S7-1500 CPUs. At parameter DSTBLK, only data blocks that are located in the load memory are permitted.

Error code* (W#16#...)	Description
82B1	Note: This error code is only for S7-1200 CPUs. No data block is specified for the SRCBLK parameter.
85B1	Note: This error code is only for S7-1200 CPUs. For parameter DSTBLK, no data block is specified or the data block specified there is not in the load memory.
80B4	• The memory card is write-protected. • DB with F-attribute must not be read.
80BB	Insufficient load memory available.
82C0	Note: This error code is only for S7-1200 CPUs. The source DB is currently being processed by another instruction or a communication instruction.
85C0	Note: This error code is only for S7-1200 CPUs. The destination DB is currently being processed by another instruction or a communication instruction.
80C3	The maximum number of simultaneously active "WRIT_DBL" instructions has already been reached.
General error codes	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

In the following example, you transfer the contents of a DB in the work memory to a DB in the load memory. To verify successful transfer to the DB, read the contents in another DB in the work memory.

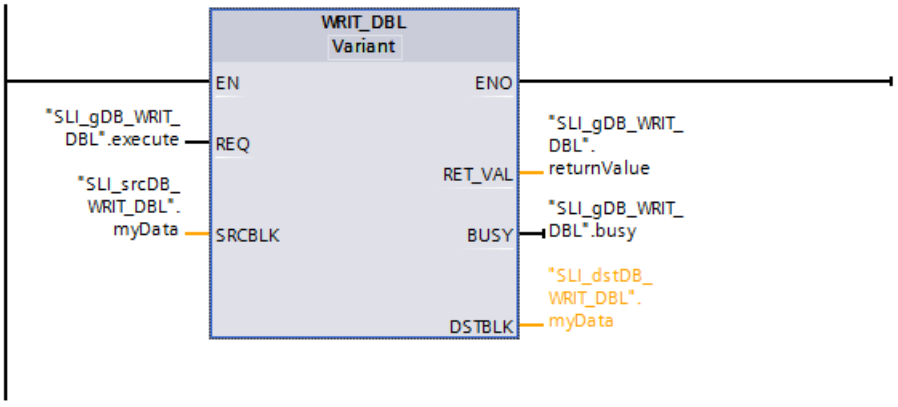
To store the data for the interconnection, create five tags in a global data block.

SLI_gDB_WRIT_DBL

	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	returnValue	Int	0
4	busy	Bool	false
5	readRetVal	Int	0
6	readBusy	Bool	false

To store the data to be transmitted, create three global data blocks with one "myData" tag each (Array of INT data type):

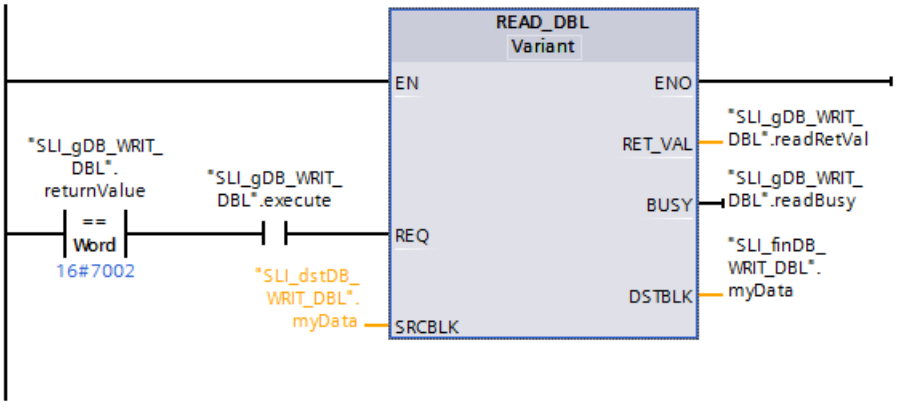
- A DB for send data in the work memory (SLI_srcDB_WRIT_DBL).



SLI_srcDB_WRIT_DBL

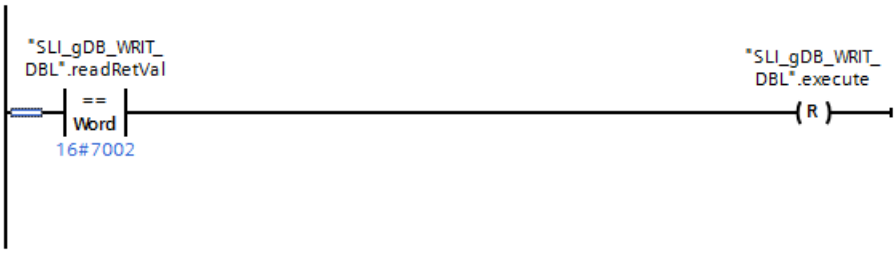
	Name	Data type	Start value
1	Static		
2	myData	Array[0..3] of Int	
3	myData[0]	Int	1
4	myData[1]	Int	2
5	myData[2]	Int	3
6	myData[3]	Int	4

- A DB for receive data in the load memory (SLI_dstDB_WRIT_DBL).
- A DB for receive data in the work memory (SLI_finDB_WRIT_DBL).



Network 1:

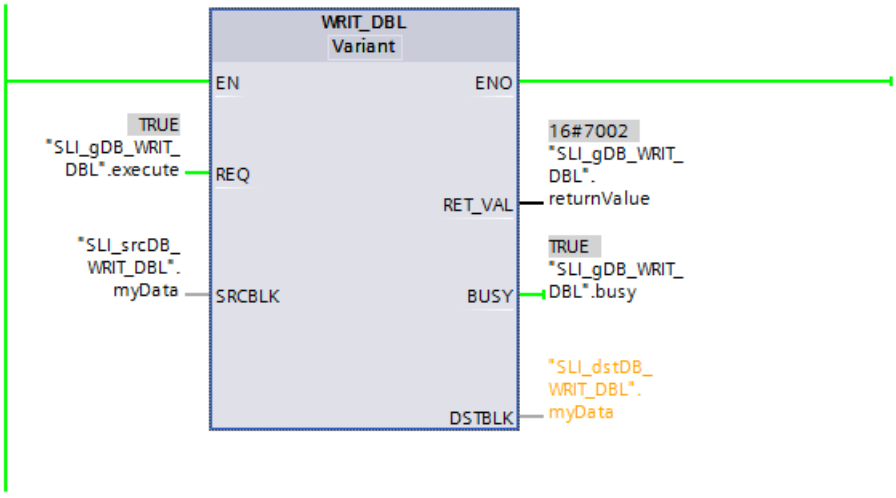
Interconnect the parameters of the "WRIT_DBL" instruction as follows.



Network 2:

Interconnect the parameters of the "READ_DBL" instruction as follows.

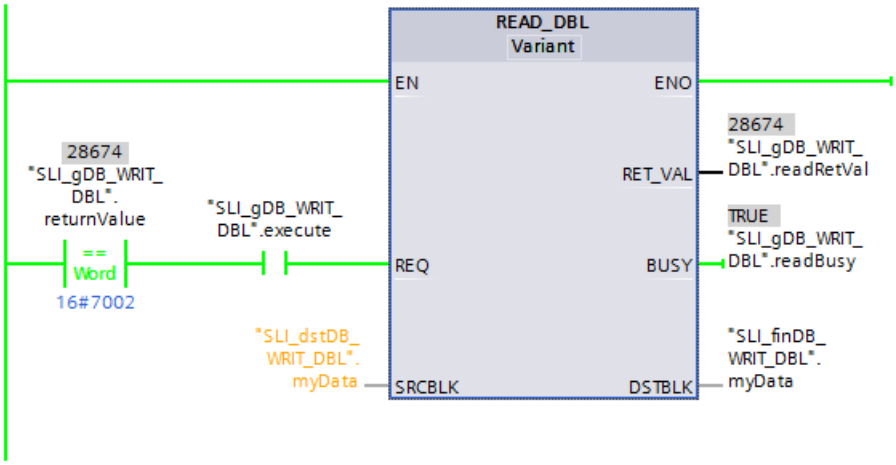
Network 3:



Reset the tag "execute" as follows:

"WRIT_DBL" instruction:

If the normally open contact ("execute") supplies the signal state "TRUE", the "WRIT_DBL" instruction is executed. The DB is stored in the work memory with the input parameter SRCBLK ("SLI_srcDB_WRIT_DBL.myData"). The DB is stored in the load memory with the output parameter DSTBLK ("SLI_dstDB_WRIT_DBL.myData").



The "WRIT_DBL" instruction calls the data to be transferred in the work memory (SRCBLK) and writes the data to the required location in the load memory (DSTBLK). The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

"READ_DBL" instruction:

When processing of WRIT_DBL took place without errors and the normally open contact ("execute") supplies the signal state "TRUE", the "READ_DBL" instruction is executed. The DB is stored in the load memory with the input parameter SRCBLK ("SLI_dstDB_WRIT_DBL.myData"). The DB for the receive data is stored with the output parameter DSTBLK ("SLI_finDB_WRIT_DBL.myData").

The "READ_DBL" instruction calls the data to be transferred in the load memory (SRCBLK) and reads the data at the required location in the work memory (DSTBLK). The output parameter RET_VAL ("readRetVal") indicates that processing took place without errors.

The DB for the receive data in the work memory (SLI_finDB_WRIT_DBL) displays the transmitted data.

SLI_finDB_WRIT_DBL

	Name	Data type	Start value	Monitor value
1	Static			
2	myData	Array[0..3] o...		
3	myData[0]	Int	0	1
4	myData[1]	Int	0	2
5	myData[2]	Int	0	3
6	myData[3]	Int	0	4

The tag "execute" is reset after the successful processing of READ_DBL (see Network 3). The processing of READ_DBL and WRIT_DBL is stopped.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

ATTR_DB: Read data block attribute (S7-1200, S7-1500)

Description

You use the instruction "ATTR_DB" to obtain information about a data block (DB) located in the work memory of the CPU. The instruction determines the attributes set at the ATTRIB parameter for the DB selected.

The length cannot be read out for data blocks with optimized access and data blocks that are only in load memory. In these cases, the DB_LENGH parameter has the value "0".

Do not apply ATTR_DB to data blocks with optimized access and activated memory reserve.

Do not read out the data blocks for Motion Control with the "ATTR_DB" instruction. The error code 80B2 is output for this.

Parameters

The following table shows the parameters of the "ATTR_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Request to read block attributes
DB_NUM-BER	Input	DB_ANY	I, Q, M, D, L or constant	Number of the DB to be tested
RET_VAL	Output	INT	I, Q, M, D, L	Error information
DB_LENGTH	Output	UDINT	I, Q, M, D, L	• Number of data bytes which the selected DB contains. • "0" for data blocks with optimized access and data blocks that are only in load memory.
ATTRIB	Output	BYTE	I, Q, M, D, L	DB properties:
				• Bit 0*= 0: Attribute "Only store in load memory" is not set. • Bit 0*= 1: Attribute "Only store in load memory" is set.
				• Bit 1 = 0: Attribute "Data block write-protected in the device" is not set. • Bit 1 = 1: Attribute "Data block write-protected in the device" is set.
				If bit 0 = 1, then bit 2 is irrelevant and gets the value 1. • Bit 2 = 0: Retentive - The DB is regarded as retentive if at least one value has been set as retentive. • Bit 2 = 1: Not retentive - The complete DB is not retentive.
				• Bit 3*= 0: The DB is either in the load memory (bit 0 = 1) or in the work memory (bit 0 = 0). • Bit 3*= 1: The DB is generated in both the load and the work memory
* The relationship between bit 0 and bit 3 is explained in the parameters of the instruction "CREATE_DB: Create data block (Page 4045)".				

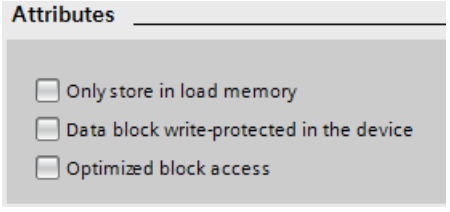
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
80A1	Error in input parameter DB_NUMBER: the actual parameter selected • Is "0" • Is greater than the maximum permitted DB number for the CPU used.
80B1	The DB with the specified number does not exist on the CPU.

Error code* (W#16#...)	Explanation
80B2	Data blocks of Motion Control technology objects cannot be read with the "ATTR_DB" instruction.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you read the status of a data block.

You create a DB with a "myData" tag (Array[0..3] of INT data type).

SLI_srcDB_ATTR_DB

	Name	Data type	Offset	Start value
1	Static			
2	myData	Array[0..3] of Int	0.0	
3	myData[0]	Int	0.0	1
4	myData[1]	Int	2.0	2
5	myData[2]	Int	4.0	3
6	myData[3]	Int	6.0	4

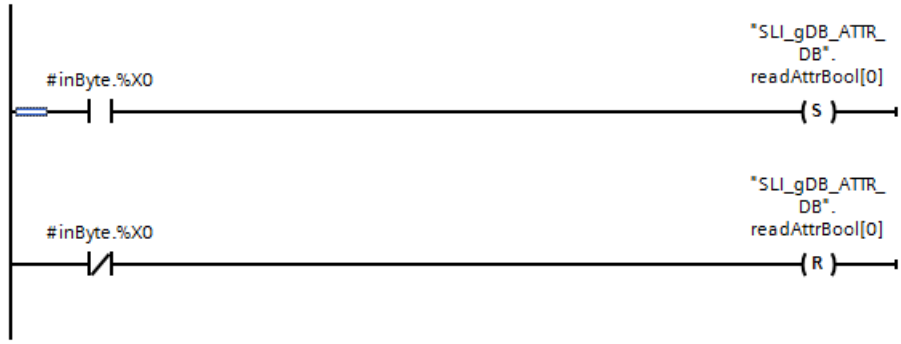
For standard access, disable optimized data access in the DB properties.

To store the data for the interconnection, create four tags in a global data block.

SLI_gDB_ATTR_DB

	Name	Data type	Start value
1	Static		
2	startAttr	Bool	false
3	attrRetVal	Int	0
4	readLenByte	UDInt	0
5	readAttrBool	Array[0..7] of Bool	

Interconnect parameters: "SLI_itemiseByte_ATTR_DB" FC



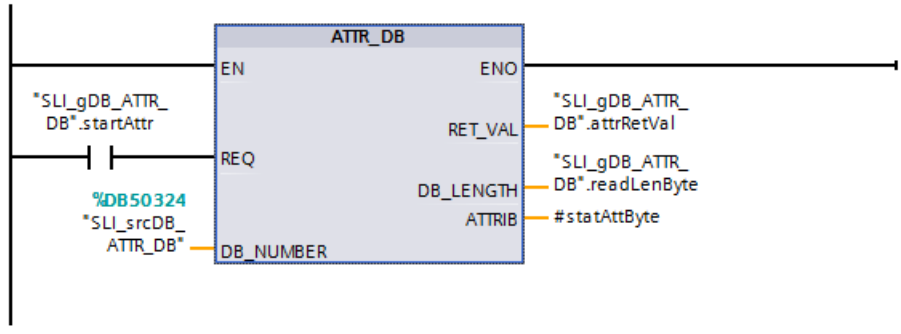
To better evaluate the value of the output parameter ATTRIB, create the FC "SLI_itemiseByte_ATTR_DB".

Create the following local tag in it.

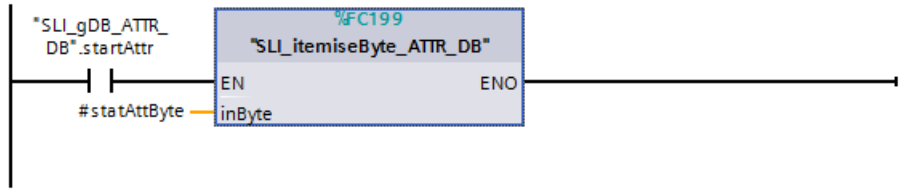
SLI_itemiseByte_ATTR_DB

	Name	Data type
1	Input	
2	inByte	Byte

Network 1: Create interconnections for all bits (0..7) of the local tag according to the example of network 1.



Interconnect parameters: "SLI_FB_ATTR_DB" FB



Create an FB "SLI_FB_ATTR_DB" for the call of ATTR_DB. Create the following local tag in it.

Network 1: Interconnect the parameters of the "ATTR_DB" instruction as follows.

Network 2: Interconnect the FC "SLI_itemiseByte_ATTR_DB" as follows.

Result of FB "SLI_FB_ATTR_DB"

If the normally open contact ("startAttr") supplies the signal state "TRUE", the "ATTR_DB" instruction is executed. The number of the DB to be evaluated is stored with the input parameter DB_NUMBER ("SLI_srcDB_ATTR_DB"). The "ATTR_DB" instruction calls the DB based on the number and outputs its status at the output parameter ATTRIB ("#statAttrByte"). The length of the read data (4 INT) of the data block in BYTE (value "8") is output at the output parameter DB_LENGTH ("readLenByte").

The hexadecimal value of the output parameter ATTRIB is converted into a bit string using FC "SLI_itemiseByte_ATTR_DB". The bit sequence "00110000" (Bit 0 to 7) means:

- The DB exists not only in the load memory.
- The DB is not write-protected.
- The DB is not retentive.
- The DB is generated in both the load and the work memory.

The output parameter RET_VAL ("attrRetVal") indicates that processing took place without errors.

SLI_gDB_ATTR_DB

	Name	Data type	Start value	Monitor value
1	Static			
2	startAttr	Bool	false	TRUE
3	attrRetVal	Int	0	0
4	readLenByte	UDInt	0	8
5	readAttrBool	Array[0..7] of Bool		
6	readAttrBool[0]	Bool	false	FALSE
7	readAttrBool[1]	Bool	false	FALSE
8	readAttrBool[2]	Bool	false	TRUE
9	readAttrBool[3]	Bool	false	TRUE
10	readAttrBool[4]	Bool	false	FALSE
11	readAttrBool[5]	Bool	false	FALSE
12	readAttrBool[6]	Bool	false	FALSE
13	readAttrBool[7]	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

DELETE_DB: Delete data block (S7-1200, S7-1500)

Description

You use the instruction "DELETE_DB" to delete a data block (DB) that was created from the user program by calling the instruction "CREATE_DB (Page 4045)".

If the data block was not created with "CREATE_DB", the error code W#16#80B5 is output at the RET_VAL parameter.

The selected data block is not deleted immediately, but rather at the cycle control point after execution of the cycle OB.

Functional description

The "DELETE_DB" instruction works asynchronously. Processing takes place across several calls. You start the interrupt transfer by calling the instruction with REQ = 1.

Output parameter BUSY and bytes 2 and 3 of output parameter RET_VAL show the status of the job.

When the output parameter BUSY has the value FALSE, the deletion of the data block is completed.

Parameters

The following table shows the parameters of the "DELETE_DB" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ =1: Request to delete the DB with the number in the DB_NUMBER parameter
DB_NUMBER	Input	UINT	I, Q, M, D, L or constant	Number of the DB to be deleted
RET_VAL	Output	INT	I, Q, M, D, L	Error information (see "RET_VAL parameter")
BUSY	Output	BOOL	I, Q, M, D, L	BUSY =1: The process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".
80A1	Error in input parameter DB_NUMBER: • The value at the parameter is "0". • The value at the parameter is greater than the maximum permitted DB number for the CPU used.
80B1	The DB with the specified number does not exist on the CPU.
80B4	The DB cannot be deleted because the memory card of the CPU is write-protected.
80B5	The DB was not created using "CREATE_DB".
80BB	Not enough load memory.
80C3	The "Delete a DB" function cannot be executed at this time due to a temporary resource bottleneck.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for CREATE functions (Page 4065).

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568).

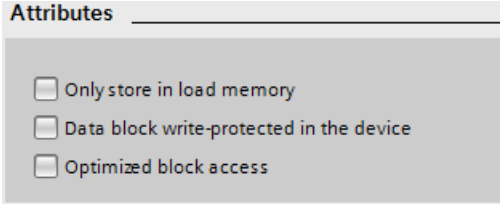
See also

Difference between synchronous and asynchronous instructions (Page 2571)

Program example for CREATE functions (S7-1200, S7-1500)

Introduction

In the following example, you create a DB in the load memory, read its contents, and then delete the DB.



Requirement

Create a global DB ("SLI_srcDB_CREATE_DB") to serve as a template for the new DB.

SLI_srcDB_CREATE_DB

	Name	Data type	Offset	Start value
1	Static			
2	myData	Array[0..3] of Int	0.0	
3	myData[0]	Int	0.0	1
4	myData[1]	Int	2.0	2
5	myData[2]	Int	4.0	3
6	myData[3]	Int	6.0	4
7	readData	Array[0..3] of Int	8.0	
8	readData[0]	Int	0.0	0
9	readData[1]	Int	2.0	0
10	readData[2]	Int	4.0	0
11	readData[3]	Int	6.0	0

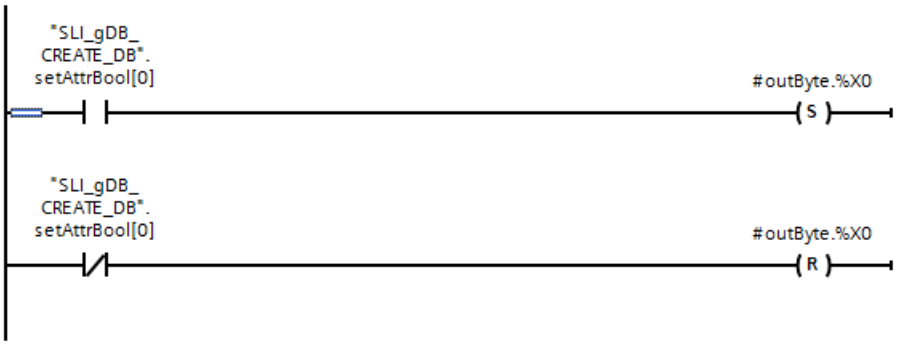
The properties of the DB are as follows.

To store the data for the interconnection, create 14 tags in a global data block ("SLI_gDB_CREATE_DB").

SLI_gDB_CREATE_DB			
	Name	Data type	Start value
1	Static		
2	startCreate	Bool	false
3	lowLim	UInt	60003
4	hiLim	UInt	60003
5	setLenByte	UDInt	8
6	setAttrBool	Array[0..7] of Bool	
7	setAttrBool[0]	Bool	1
8	setAttrBool[1]	Bool	0
9	setAttrBool[2]	Bool	1
10	setAttrBool[3]	Bool	0
11	setAttrBool[4]	Bool	1
12	setAttrBool[5]	Bool	false
13	setAttrBool[6]	Bool	false
14	setAttrBool[7]	Bool	false
15	createRetVal	Int	0
16	createBusy	Bool	false
17	memNbrNewDB	UInt	0
18	startRead	Bool	false
19	rdblRetVal	Int	0
20	rdblBusy	Bool	false
21	startDelete	Bool	false
22	delRetVal	Int	0
23	delBusy	Bool	false

To store the data, also create the following local tags in the FB "SLI_FB_CREATE_DB".

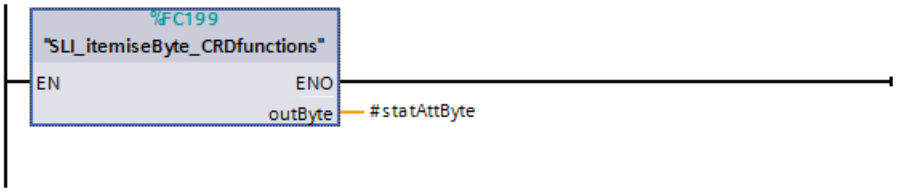
7	Static			
8	statAttByte	Byte	16#0	Non-ret...
9	nbrNewDB	UInt	0	Non-retain
10	Temp			
11	tempCreate	Bool		
12	tempRead	Bool		
13	tempDelete	Bool		



Interconnect parameters: "SLI_itemiseByte_CRDfunctions" FC

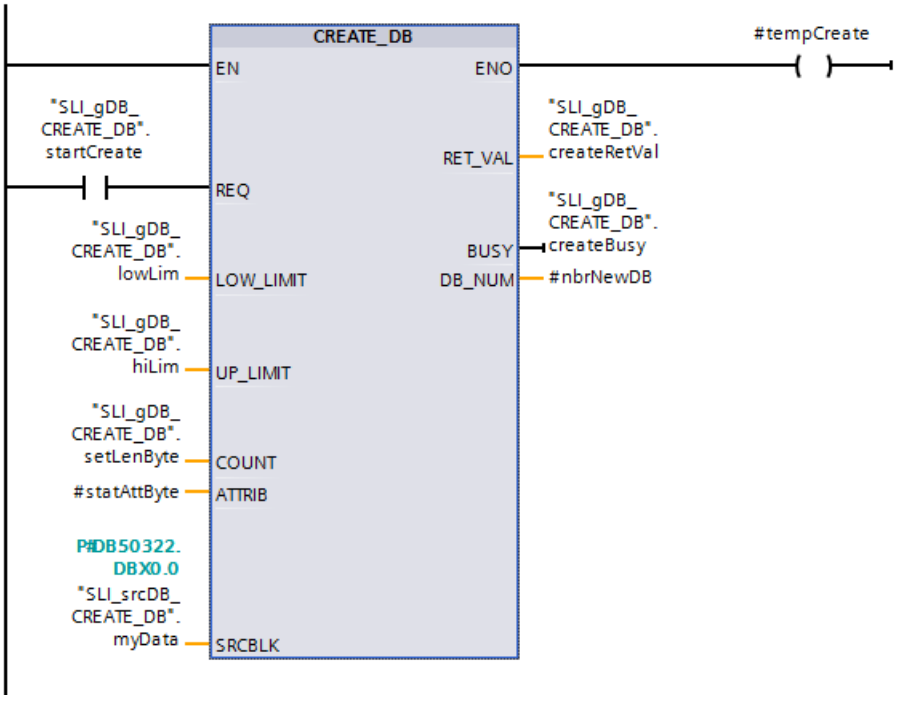
To convert the values of the "setAttrBool" tag into the "#statAttByte" tag, create the FC "SLI_itemiseByte_CRDfunctions".

Create the following local tag in it.

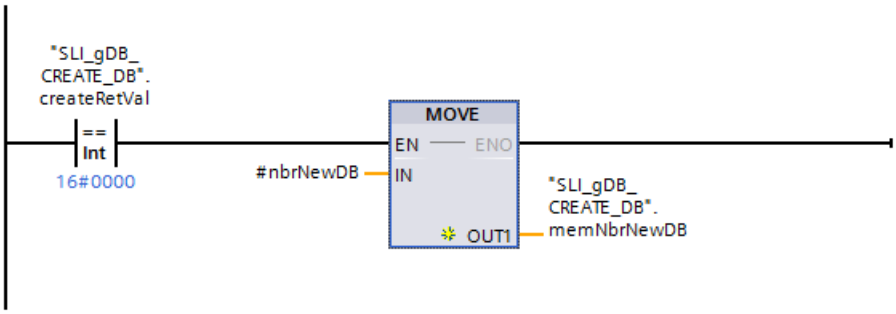


3	Output	
4	outByte	Byte

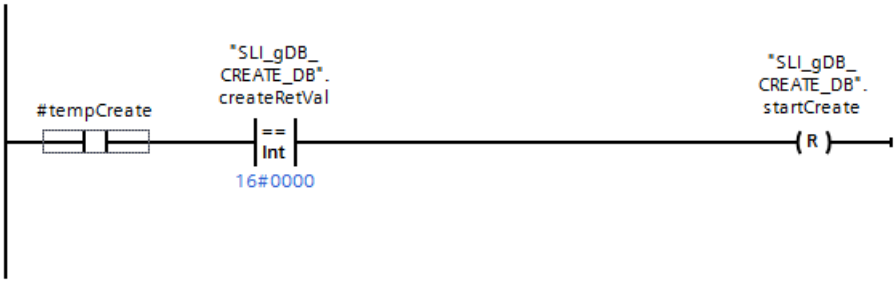
Network 1: Create interconnections for all bits (0..7) of the local tag according to the example of network 1.



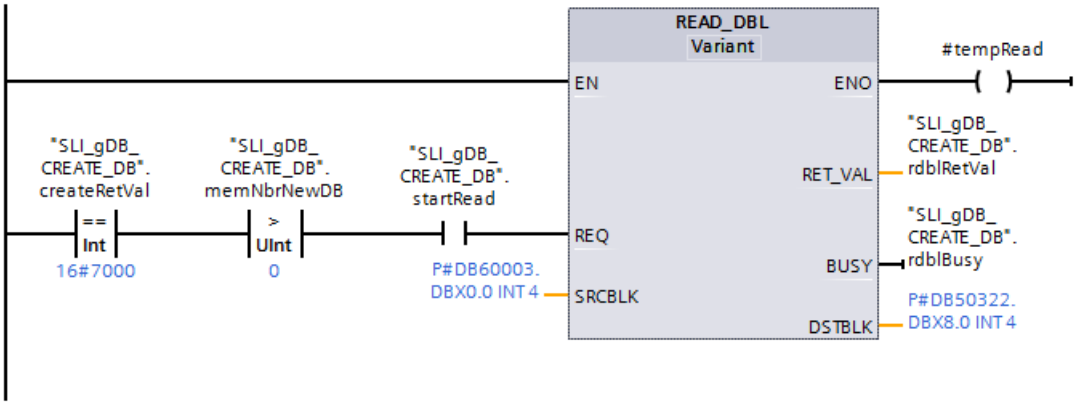
Interconnect parameters: "SLI_FB_CREATE_DB" FB



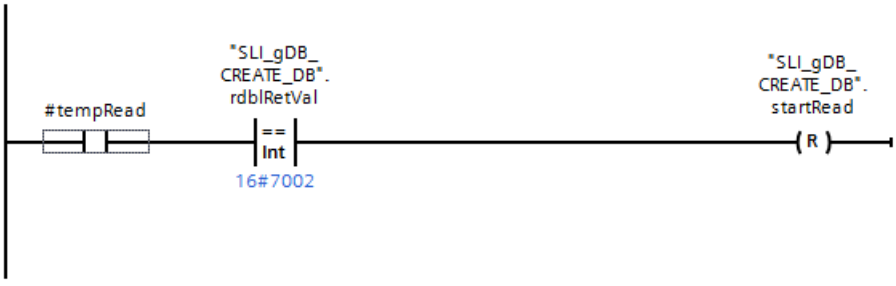
Network 1: Interconnect the parameters of the "SLI_itemiseByte_CRDfunctions" FC as follows.



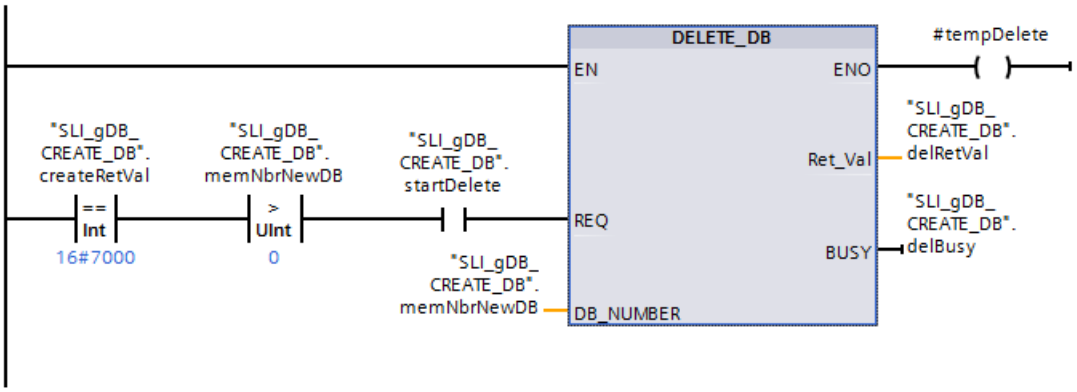
Network 2: Interconnect the parameters of the "CREATE_DB" instruction as follows.



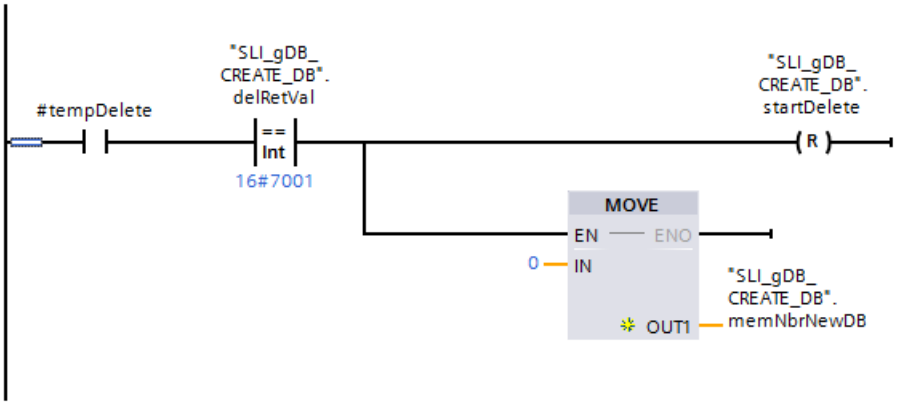
Network 3: To store the number of the newly created DB, create the following interconnections.



Network 4: To end the execution of CREATE_DB once again, create the following interconnections.



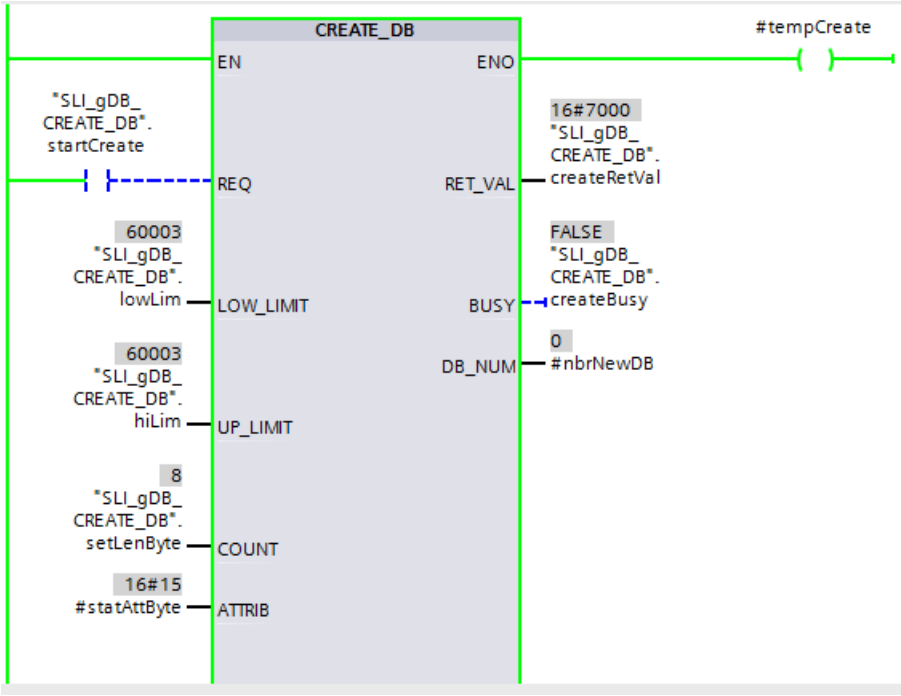
Network 5: Interconnect the parameters of the "READ_DBL" instruction as follows.



Network 6: To end the execution of READ_DBL once again, create the following interconnections.

Network 7: Interconnect the parameters of the "DELETE_DB" instruction as follows.

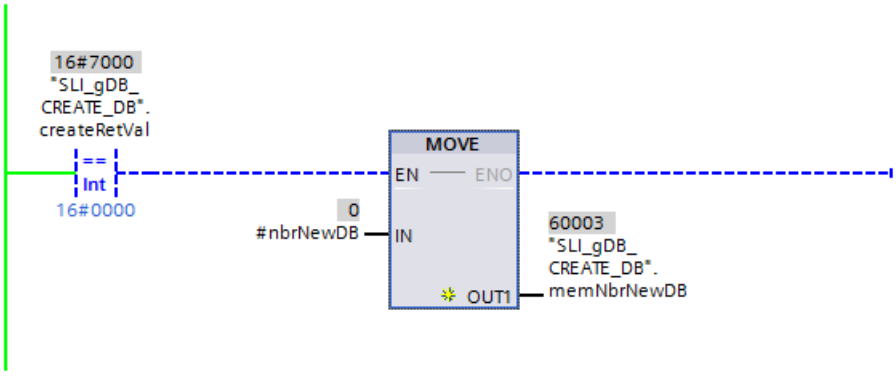
Network 8: To end the execution of DELETE_DB once again, create the following interconnections.



Result of network 1

With an AT construct, the properties ("setAttrBool") stored in the Array of BOOL data type(#statAttBool) are converted into BYTE (#statAttByte) and stored.

Result of network 2 - "CREATE_DB" instruction



If the normally open contact ("startCreate") supplies the signal state "TRUE", the "CREATE_DB" instruction is executed. According to the input parameter COUNT ("setLenByte"), a new DB with a length of 8 bytes is created in the process. The number of the DB that is to be created is specified with the input parameter LOW_LIMIT ("lowLim") or UP_LIMIT ("hiLim"). The properties (in BYTE) with which the DB is to be created are stored at the input parameter ATTR ("#statAttByte"). The DB is to be created only in the load memory and filled with defined contents. A DB is stored at the input parameter SRCBLK ("SLI_srcDB_CREATE_DB.myData") to serve as template for the contents of the new DB.

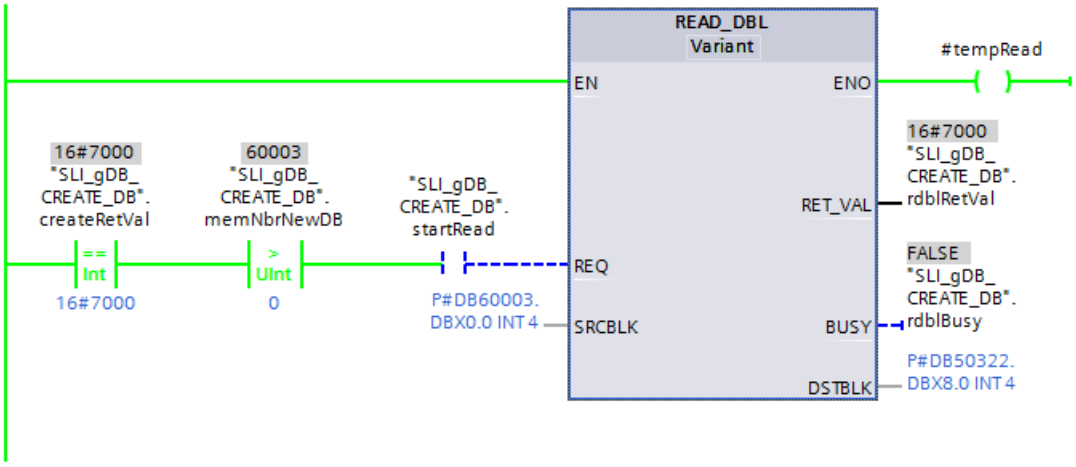
The output parameter RET_VAL ("CreateRetVal") indicates that processing took place without errors. The instruction "CREATE_DB" remains inactive after its execution ("createRetVal" has the value 16#7000"). The number of the new DB is briefly output at the end of the execution at the output parameter DB_NUM ("#nbrNewDB").

Result of network 3

When processing of CREATE_DB took place without errors, "createRetVal" has the value "16#0000". As a result, the number ("#nbrNewDB") of the DB is stored in the "memNbrNewDB" tag.

Result of network 4

When CREATE_DB at the ENO parameter ("#tempCreate") supplies the signal state "TRUE", the interconnection of network 4 is active. In addition, when processing of CREATE_DB took place without errors, the reset ("startCreate") is set to "TRUE" and the execution of CREATE_DB is ended.



SLI_gDB_CREATE_DB

	Name	Data type	Start value	Monitor value
1	Static			
2	startCreate	Bool	false	FALSE
3	lowLim	UInt	60003	60003
4	hiLim	UInt	60003	60003
5	setLenByte	UDInt	8	8
6	setAttrBool	Array[0..7] of Bool		
7	createRetVal	Int	0	28672
8	createBusy	Bool	false	FALSE
9	memNbrNewDB	UInt	0	60003
10	startRead	Bool	false	FALSE
11	rdblRetVal	Int	0	28672
12	rdblBusy	Bool	false	FALSE
13	startDelete	Bool	false	FALSE
14	delRetVal	Int	0	28672
15	delBusy	Bool	false	FALSE

Result of network 5 - "READ_DBL" instruction

The following preconditions exist for executing READ_DBL:

- CREATE_DB is inactive ("createRetVal" has the value "16#7000").
- CREATE_DB has created a new DB whose number was stored ("memNbrNewDB" has a value > 0).

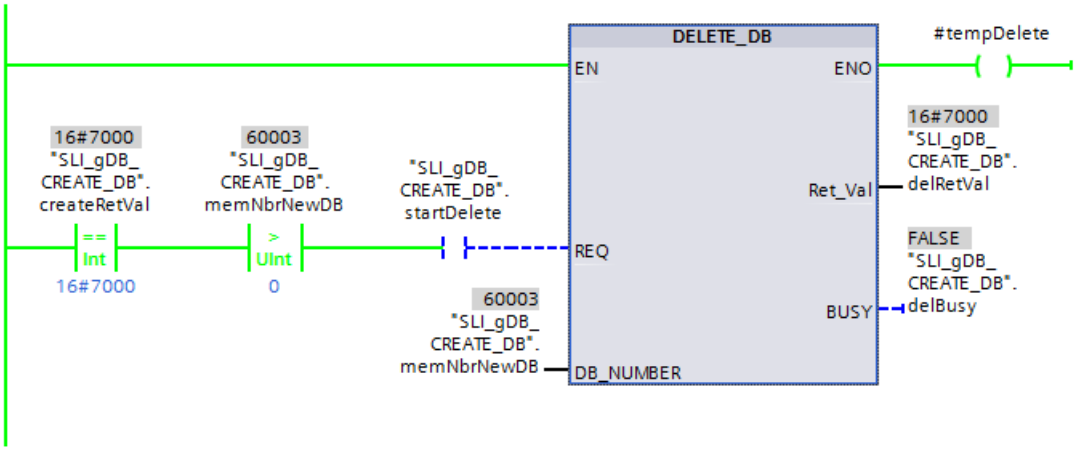
If the normally open contact ("startRead") supplies the signal state "TRUE", the "READ_DBL" instruction is executed. The newly created DB is referenced in the load memory with the input parameter SCRBLK. The DB is referenced in the work memory ("SLI_srcDB_CREATE_DB.readData") with the output parameter DSTBLK. The "READ_DBL"

instruction calls the data to be transferred in the load memory (SCRBLK) and reads the data at the required location in the work memory (DSTBLK).

The output parameter RET_VAL ("rdblRetVal") indicates that processing took place without errors. The transferred data is displayed for the DB in the work memory ("SLI_srcDB_CREATE_DB.readData").

SLI_srcDB_CREATE_DB

	Name	Data type	Offset	Start value	Monitor value
1	Static				
2	myData	Array[0..3] of Int	0.0		
3	myData[0]	Int	0.0	1	1
4	myData[1]	Int	2.0	2	2
5	myData[2]	Int	4.0	3	3
6	myData[3]	Int	6.0	4	4
7	readData	Array[0..3] of Int	8.0		
8	readData[0]	Int	0.0	0	1
9	readData[1]	Int	2.0	0	2
10	readData[2]	Int	4.0	0	3
11	readData[3]	Int	6.0	0	4



Result of network 6

When READ_DBL at the ENO parameter ("#tempRead") supplies the signal state "TRUE", the interconnection of network 6 is active. In addition, when processing of READ_DBL is complete, the reset ("startRead") is set to "TRUE" and the execution of READ_DBL is ended.

Result of network 7 - "DELETE_DB" instruction

The following preconditions exist for executing DELETE_DB:

- CREATE_DB is inactive ("createRetVal" has the value "16#7000").
- CREATE_DB has created a new DB whose number was stored ("memNbrNewDB" has a value > 0).

If the normally open contact ("startDelete") supplies the signal state "TRUE", the "DELETE_DB" instruction is executed. The newly created DB is referenced based on its

number with the input parameter DB_NUMBER ("memNbrNewDB"). The "DELETE_DB" instruction deletes the newly created DB.

The output parameter RET_VAL ("deleteRetVal") indicates that processing took place without errors.

Result of network 8

When DELETE_DB at the ENO parameter ("#tempRead") supplies the signal state "TRUE", the interconnection of network 8 is active. In addition, when processing of DELETE_DB is complete, the reset ("startDelete") is set to "TRUE" and the execution of DELETE_DB is ended.

The previously created block is deleted after the execution of DELETE_DB The "memNbrNewDB" tag is set to "0" in order to prevent a command being issued to delete an already deleted block.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

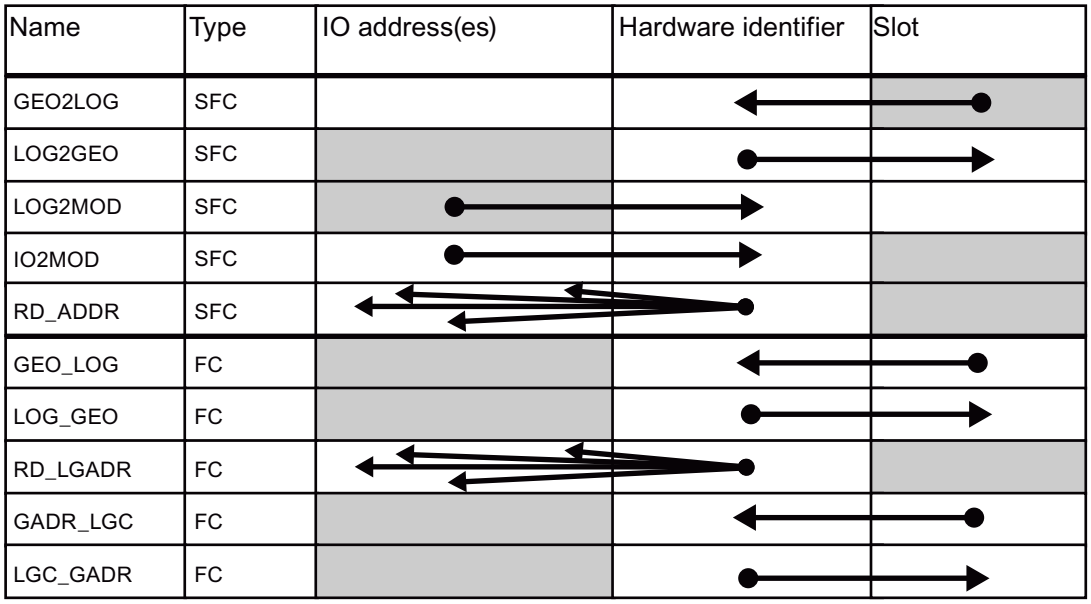
11.4.4.13 Addressing (S7-1200, S7-1500)

Instructions for address conversion (S7-1200, S7-1500)

Description

There are different options for addressing a module (IO address, hardware identifier, slot).

You can convert the address data with the following instructions:



- GEO2LOG: Determine hardware identifier from slot (Page 4074)
- LOG2GEO: Determine slot from hardware identifier (Page 4077)
- LOG2MOD: Determine the hardware identifier from addressing of STEP 7 V5.5 SPx (Page 4079)
- IO2MOD: Determine hardware identifier from an IO address (Page 4080)
- RD_ADDR: Determine IO addresses from the hardware identifier (Page 4083)

The following instructions are supported in addition for migrated projects:

- GEO_LOG: Determine hardware identifier from slot (Page 4086)
- LOG_GEO: Determine slot from hardware identifier (Page 4088)
- RD_LGADR: Determine IO addresses from the hardware identifier (Page 4089)
- GADR_LGC: Determine hardware identifier from slot and offset in the user data address area (Page 4091)
- LGC_GADR: Determine slot from hardware identifier (Page 4092)

Type of address conversion

The figure below shows which instruction runs which address conversion.

GEO2LOG: Determine hardware identifier from slot (S7-1200, S7-1500)

Description

You use the "GEO2LOG" instruction to determine hardware identifier based on slot information that you define using the system data type GEOADDR.

Depending on the type of hardware you define at the parameter HWTYPE the following information is evaluated from the other parameters GEOADDR:

- When HWTYPE = 1 (IO system):
  - Only IOSYSTEM is evaluated. The other parameters of GEOADDR are not taken into consideration.
  - The hardware identifier of the IO system is output.
- When HWTYPE = 2 (IO device):
  - IOSYSTEM and STATION are evaluated. The other parameters of GEOADDR are not taken into consideration.
  - The hardware identifier of the IO device is output.

- With HWTYPE = 4 (module):
  - IOSYSTEM, STATION and SLOT are evaluated. The SUBSLOT parameter of GEOADDR is not taken into consideration.
  - The hardware identifier of the module is output.
- With HWTYPE = 5 (submodule):
  - All parameters of GEOADDR are evaluated.
  - The hardware identifier of the submodule is output.

The AREA parameter of the GEOADDR system data type is not evaluated.

Parameters

The following table shows the parameters of the "GEO2LOG" instruction:

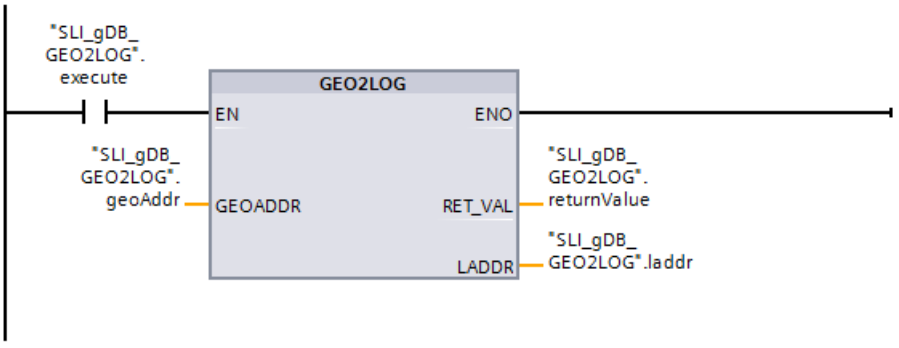
Parameter	Declaration	Data type	Memory area	Description
GEOADDR	Input	VARIANT	D, L	Pointer to the structure of the GEOADDR system data type. The system data type contains the slot information from which the hardware ID is determined. See also: System data type GEOADDR (Page 4085)
RET_VAL	Return	INT	I, Q, M, D, L	Output of error information.
LADDR	Output	HW_ANY	I, Q, M, D, L	Hardware identifier of the assembly or the module. The number is automatically assigned and is stored in the properties in the hardware configuration.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8091	Invalid value for in GEOADDR for HWTYPE.
8094	Invalid value for in GEOADDR for IOSYSTEM.
8095	Invalid value for in GEOADDR for STATION.
8096	Invalid value for in GEOADDR for SLOT.
8097	Invalid value for in GEOADDR for SUBSLOT.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you determine the hardware ID of the CPU based on the slot information.

Create four tags in a global data block for storing the data.

SLI_gDB_GEO2LOG

		Name	Data type	Start value
1		Static		
2		execute	Bool	false
3		geoAddr	GEOADDR	
4		HWTYPE	UInt	4
5		AREA	UInt	0
6		IOSYSTEM	UInt	0
7		STATION	UInt	0
8		SLOT	UInt	1
9		SUBSLOT	UInt	0
10		returnValue	Int	0
11		laddr	HW_ANY	16#0

Interconnect the parameters of the instruction as follows.

If the normally open contact ("execute") supplies the signal state "TRUE", the "GEO2LOG" instruction is executed. The slot information is stored in the input parameter GEOADDR ("geoAddr"). The instruction "GEO2LOG" calls the hardware ID for a module (HWTYPE with the value "4") of the central controller (IOSYSTEM with the value "0") in the rack "0" (value of STATION), in slot "1" (value of SLOT).

The determined hardware ID of the local component of the CPU is displayed at the output parameter LADDR ("laddr"). The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Instructions for address conversion (Page 4073)

LOG2GEO: Determine slot from hardware identifier (S7-1200, S7-1500)

Description

You use the "LOG2GEO" instruction to determine the module slot belonging to a hardware identifier.

Parameters

The following table shows the parameters of the "LOG2GEO" instruction:

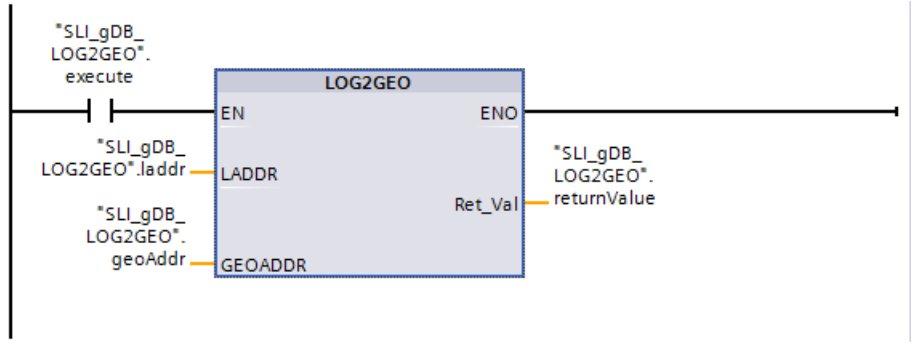
Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Hardware identifier of the module whose slot you want to find. The hardware ID is assigned automatically and is stored in the properties of the module in the hardware configuration and the system constants.
RET_VAL	Output	INT	I, Q, M, D, L	Output of error information.
GEOADDR	InOut	VARIANT	D, L	Pointer to the GEOADDR system data type. The slot information is written in the system data type GEOADDR. See also: System data type GEOADDR (Page 4085)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	The address specified at the LADDR parameter is invalid.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you determine the slot information of an input module based on the hardware ID.

Create four tags in a global data block for storing the data.

SLI_gDB_LOG2GEO

		Name	Data type	Start value
1		Static		
2		execute	Bool	false
3		laddr	HW_ANY	257
4		geoAddr	GEOADDR	
5		HWTYPE	UInt	0
6		AREA	UInt	0
7		IOSYSTEM	UInt	0
8		STATION	UInt	0
9		SLOT	UInt	0
10		SUBSLOT	UInt	0
11		returnValue	Int	0

Interconnect the parameters of the instruction as follows.

If the normally open contact ("execute") supplies the signal state "TRUE", the "LOG2GEO" instruction is executed. The hardware ID of the input module is stored with the input parameter LADDR ("laddr"). The instruction "LOG2GEO" calls the slot information of the input module using the hardware ID.

The determined slot information of the input module is displayed at the output parameter GEOADDR ("geoAddr"). A module (HWTYPE with the value "4") of the central controller (IOSYSTEM with the value "0") in the rack "0" (value of STATION), in slot "2" (value of SLOT) is determined.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

SLI_gDB_LOG2GEO

	Name	Data type	Start value	Monitor value
1	Static			
2	execute	Bool	false	TRUE
3	laddr	HW_ANY	257	16#0101
4	geoAddr	GEOADDR		
5	HWTYPE	UInt	0	4
6	AREA	UInt	0	0
7	IOSYSTEM	UInt	0	0
8	STATION	UInt	0	0
9	SLOT	UInt	0	2
10	SUBSLOT	UInt	0	0
11	returnValue	Int	0	0

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

LOG2MOD: Determine the hardware identifier from addressing of STEP 7 V5.5 SPx (S7-1500)

Description

You use the "LOG2MOD" instruction to determine the hardware identifier for an IO (sub)module from the addressing of STEP 7 5.5 SPx (IO data address or diagnostic address).

The hardware identifier is used at the LADDR input parameter for addressing of various instructions. Convert the addressing parameters from STEP 7 5.5 SPx by calling "LOG2MOD" beforehand.

Parameter

The following table shows the parameters of the "LOG2MOD" instruction:

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Identifier of the address area as in STEP 7 5.5 SPx: • B#16#00: Bit15 of ADDR specifies whether an input (Bit15=0) or output address (Bit15=1) exists. • B#16#54= Peripheral input (PI) • B#16#55= Peripheral output (PQ)
ADDR	Input	WORD	I, Q, M, D, L or constant	Logical address of the IO data of the module as offset (corresponding addressing in STEP 7 5.5 SPx) or diagnostic address.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
HWID	Output	HW_IO	I, Q, M, D, L	Determined hardware identifier of the IO (sub)module.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8093	• Specified address is not used by any hardware components. • Specified value at IOID parameter is invalid.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

IO2MOD: Determine hardware identifier from an IO address (S7-1200, S7-1500)

Description

The "IO2MOD" instruction determines the hardware identifier of the module from an IO address (I, Q, PI, PQ) of a module.

Enter the IO address at the ADDR parameter.

- If a series of IO addresses is used at this parameter, only the first address is evaluated to determine the hardware identifier.

- If the first address is correctly specified, the length for the address specification at the ADDR parameter is of no significance.

- If an address area is used that encompasses several modules or unused addresses, the hardware identifier of the first module can also be determined.

- If no IO address of a module is specified at parameter ADDR, the error code 8090 is output at parameter RET_VAL.

Note

Input of IO address in SCL

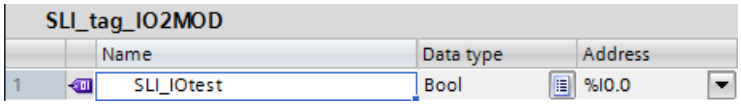
In SCL, you do not program using the I/O access ID "%QWx:P". In this case, use the symbolic tag name or the absolute address in the process image.

Parameters

The following table shows the parameters of the "IO2MOD" instruction:

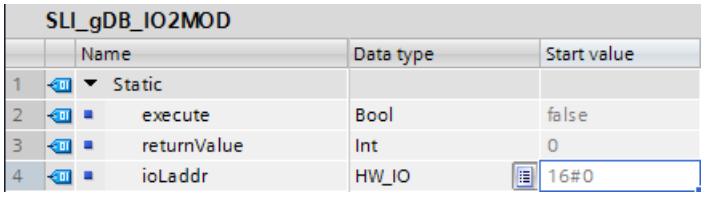
Parameter	Declaration	Data type	Memory area	Description
ADDR	Input	VARIANT	I, Q	IO address (I, Q, PI, PQ) within a module. Make sure that slice access is not used for the parameter ADDR. If this is the case, incorrect values are output at the LADDR parameter.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
LADDR	Output	HW_IO	I, Q, M, D, L	Determined hardware identifier (logical address) of the IO module.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



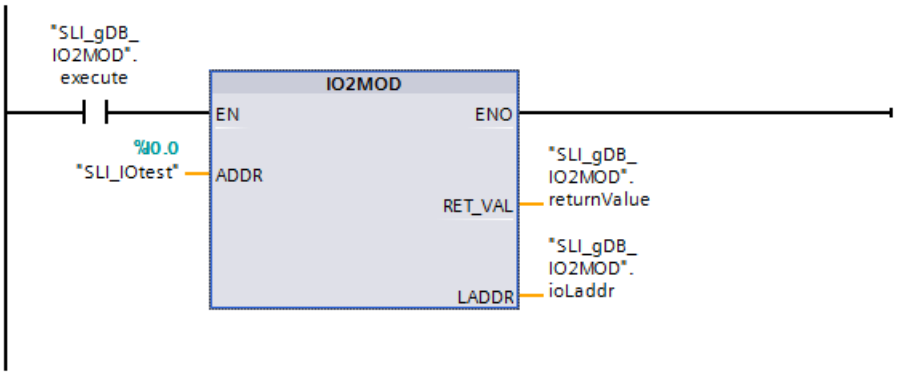
Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	IO address specified at ADDR parameter is not used by any hardware component.
8092	Invalid data type used at parameter ADDR (for example, WCHAR or WSTRING).
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	



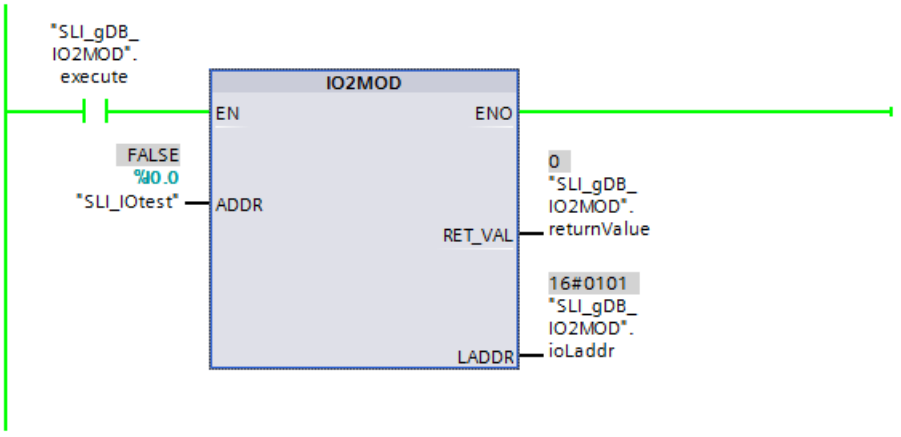
Example

In the following example, you determine the hardware ID of an input module based on an IO address.



Create a PLC tag in a tag table to read the hardware ID.

Create three tags in a global data block for storing the data.



Interconnect the parameters of the instruction as follows.

If the normally open contact ("execute") supplies the signal state "TRUE", the "IO2MOD" instruction is executed. The IO address to be localized is transmitted with the input parameter ADDR ("SLI_IOtest"). The "IO2MOD" instruction calls the IO address and reads the input module.

The determined hardware ID of the input module is displayed at the output parameter LADDR ("ioLaddr"). The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

RD_ADDR: Determine IO addresses from the hardware identifier (S7-1200, S7-1500)

Description

The "RD_ADDR" instruction determines the length and the start address of the inputs or outputs based on the hardware identifier of a sub(module).

- Use the LADDR parameter to select the input or output module based on the hardware identifier.
- The following output parameters are used depending on whether it is an input module or output module:
  - In the case of an input module the determined values are output at the PIADDR and PICOUNT parameters.
  - In the case of an output module the determined values are output at the PQADDR and PQCOUNT parameters.
- The PIADDR and PQADDR parameters each contain the start address of the I/O addresses of the module.
- The PICOUNT and PQCOUNT parameters each contain the number of bytes of the inputs our outputs (1 byte for 8 inputs/outputs, 2 bytes for 16 inputs/outputs).

Note

Determining the IO addresses with packed addresses of an ET200

With packed addresses of an ET200. the first module of the pack group returns all addresses.

For the other modules, the following is output with the PIADDR and PQADDR parameters:

- with PROFINET as address "0"
- with PROFIBUS as address "0" In addition, the error code W#16#8090 is output.

For the number of bytes of the inputs and outputs (parameters PICOUNT and PQCOUNT), "0" is output in each case.

Parameter

The following table shows the parameters of the "RD_ADDR" instruction:

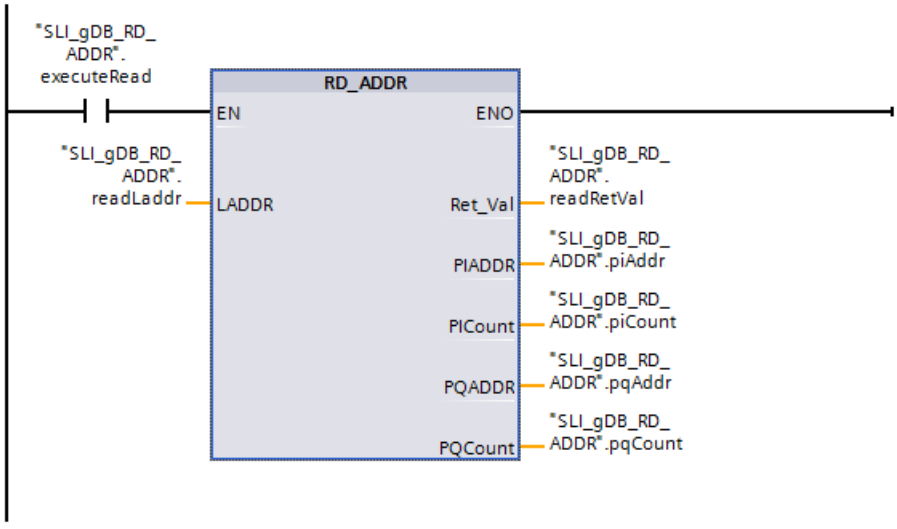
Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the (sub)module.
RET_VAL	Return	INT	I, Q, M, D, L	Error code of the instruction.
PIADDR	Output	UDINT	I, Q, M, D, L	Start address of the input module.
PICOUNT	Output	UINT	I, Q, M, D, L	Number of bytes of the inputs.
PQADDR	Output	UDINT	I, Q, M, D, L	Start address of the output module.
PQCOUNT	Output	UINT	I, Q, M, D, L	Number of bytes of the outputs.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0	No error occurred.
8090	Hardware identifier of the module at the LADDR parameter is invalid.
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Example



In the following example, you determine the length and start address of the inputs in an input module based on the hardware ID.

Create seven tags in a global data block for storing the data.

SLI_gDB_RD_ADDR

		Name	Data type	Start value
1		Static		
2		executeRead	Bool	false
3		readLaddr	HW_IO	257
4		readRetVal	Int	0
5		piAddr	UDInt	0
6		piCount	UInt	0
7		pqAddr	UDInt	0
8		pqCount	UInt	0

Interconnect the parameters of the instruction as follows.

If the normally open contact ("executeRead") supplies the signal state "TRUE", the "RD_ADDR" instruction is executed. The hardware ID of the input module is stored with the input parameter LADDR ("readLaddr"). The instruction "RD_ADDR" determines the input module using the hardware ID and reads the length of the inputs and start address.

The determined start address is displayed at the output parameter PIADDR ("piAddr"). The number of bytes of the inputs is displayed at the output parameter PICOUNT ("piCount").

The output parameter RET_VAL ("readRetVal") indicates that processing took place without errors.

SLI_gDB_RD_ADDR

	Name	Data type	Start value	Monitor value
1	Static			
2	executeRead	Bool	false	TRUE
3	readLaddr	HW_IO	257	16#0101
4	readRetVal	Int	0	0
5	piAddr	UDInt	0	0
6	piCount	UInt	0	2
7	pqAddr	UDInt	0	0
8	pqCount	UInt	0	0

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

System data type GEOADDR (S7-1200, S7-1500)

Geographical address

The system data type GEOADDR contains the geographical address of a module, i.e. the slot information.

- Geographical address for PROFINET IO
  For PROFINET IO the geographical address was composed of the ID of the PROFINET IO system, the device number, the slot number and the submodule (if a sub-module is used).
- Geographical address for PROFIBUS DP
  For PROFIBUS DP, the geographical address consists of the ID of the DP master system, the station number and the slot number.

The slot information of the modules can be found in the hardware configuration of each module.

System data type GEOADDR

If you enter "GEOADDR" as the data type in a data block, the structure GEOADDR is automatically created.

The system data type GEOADDR has the following structure:

Parameter name	Data type	Description
GEOADDR	STRUCT	
HWTYPE	UINT	Hardware type: • 1: IO system (PROFINET/PROFIBUS) • 2: IO device/DP slave • 3: Rack • 4: Module • 5: Submodule If a hardware type is not supported by the instruction, a HWTYPE "0" is output.
AREA	UINT	Area ID: • 0 = CPU • 1 = PROFINET IO • 2 = PROFIBUS DP • 3 = AS-i
IOSYSTEM	UINT	PROFINET IO system (0=central unit in the rack)
STATION	UINT	• Number of the rack if area identifier AREA = 0 (central module). • Station number if area identifier AREA > 0.
SLOT	UINT	Slot number
SUBSLOT	UINT	Number of the submodule. This parameter has the value "0" if no submodule is available or can be plugged.

Legacy (S7-1200, S7-1500)

GEO_LOG: Determine hardware identifier from slot (S7-1500)

Description

The corresponding module slot of a signal module is known. Use the "GEO_LOG" instruction to determine the corresponding hardware identifier of the module from this.

Parameter

The following table shows the parameters of the "GEO_LOG" instruction:

Parameter	Declaration	Data type	Memory area	Description
MASTER	Input	INT	I, Q, M, D, L or constant	Area ID: • 0, if the slot is located in a centralized configuration. • 1 to 32: DP master system ID of the associated field device if the slot is located in a field device on PROFIBUS • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
STATION	Input	INT	I, Q, M, D, L or constant	• If MASTER = 0: Number of the rack • If MASTER > 0: Station number of the field device
SLOT	Input	INT	I, Q, M, D, L or constant	Slot number
SUBSLOT	Input	INT	I, Q, M, D, L or constant	Number of the submodule. If no submodule exists or can be inserted SUBSLOT must have the value "0".
RET_VAL	Return	INT	I, Q, M, D, L	Error information
LADDR	Output	HW_IO	I, Q, M, D, L	Hardware identifier of the module

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8094	No subnet was configured with the specified SUBNETID .
8095	Illegal value for STATION parameter
8096	Illegal value for SLOT parameter
8097	Illegal value for SUBSLOT parameter.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

See also

Instructions for address conversion (Page 4073)

LOG_GEO: Determine slot from hardware identifier (S7-1500)

Description

You use the "LOG_GEO" instruction to determine the module slot belonging to a hardware identifier.

Parameters

The following table shows the parameters of the "LOG_GEO" instruction:

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module for which the slot is to be determined.
RET_VAL	Return	INT	I, Q, M, D, L	Error information
AREA	Output	INT	I, Q, M, D, L	The area ID indicates how the remaining output parameters are to be interpreted: • 0: central device • 2: PROFIBUS DP / PROFINET IO
MASTER	Output	INT	I, Q, M, D, L	With AREA = 0: • 0: If the slot is located in one of the racks (central device). With AREA = 2: • 1 to 32: DP master system ID of the associated field device if the slot is located in a field device on PROFIBUS • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
STATION	Output	INT	I, Q, M, D, L	• With MASTER = 0: Number of the rack • With MASTER > 0: Station number of the field device
SLOT	Output	INT	I, Q, M, D, L	Slot number
SUBSLOT	Output	INT	I, Q, M, D, L	Number of the submodule
OFFSET	Output	INT	I, Q, M, D, L	The OFFSET parameter is not output by the instruction (always "0").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Specified logical address invalid
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Instructions for address conversion (Page 4073)

RD_LGADR: Determine IO addresses from the hardware identifier (S7-1200, S7-1500)

Description

Based on the hardware identifier, you can determine the IO addresses of a module, a central submodule or a submodule for PNIO and DP slaves with the "RD_LGADR" instruction.

- You can specify the hardware ID of the submodule at the LADDR parameter.
- The addresses are written to the PEADDR and PAADDR parameters is ascending order.
  - For an input module, only the PEADDR parameter is written. For an output module, the PAADDR parameter is written.
  - An Array of WORD is used to store the addresses in each case.
- The number of addresses is output at the PECOUNT parameter (for an input module) and PACOUNT parameter (for an output module).

Note

Description of the boxes PEADDR and PAADDR

In PEADDR or PAADDR only as many addresses are entered as are returned (This number is entered in PECOUNT or PACOUNT). Addresses of earlier RD_LGADR-calls located behind the currently returned addresses are retained; they must not be evaluated in the current call.

Note

Determining the IO addresses with packed addresses of an ET200

With packed addresses of an ET200. the first module of the pack group returns all addresses.

For the other modules, the following is output with the PEADDR and PAADDR parameters:

- with PROFINET as address "0"
- with PROFIBUS as address "0" In addition, the error code W#16#8090 is output.

For the number of bytes of the inputs and outputs (parameters PECOUNT and PACOUNT), "0" is output in each case.

Parameters

The following table shows the parameters of the "RD_LGADR" instruction:

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Is not evaluated
LADDR	Input	HW_ANY	I, Q, M, D, L or constant	Hardware identifier of the module or the sub-module.
RET_VAL	Return	INT	I, Q, M, D, L	Error information
PEADDR	Output	ANY	I, Q, M, D, L	Field for the PI addresses with the Array of WORD data type
PECOUNT	Output	INT	I, Q, M, D, L	Number of returned PI addresses
PAADDR	Output	ANY	I, Q, M, D, L	Field for the PQ addresses with the Array of WORD data type
PACOUNT	Output	INT	I, Q, M, D, L	Number of returned PQ addresses

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code (W#16#...)	Explanation
0000	No error occurred.
8090	Specified hardware identifier is invalid
80A0	Error in the output parameter PEADDR: The data type of the array elements is not WORD.
80A1	Error in the output parameter PAADDR: The data type of the array elements is not WORD.
80A2	Error in the output parameter PEADDR: The specified array does not accommodate all the logical addresses.
80A3	Error in the output parameter PAADDR: The specified array does not accommodate all the logical addresses.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)

Instructions for address conversion (Page 4073)

GADR_LGC: Determine hardware identifier from slot and offset in the user data address area (S7-1500)

Description

You use the "GADR_LGC" instruction to determine the hardware identifier of a signal module. The hardware identifier is determined from the module slot and the offset in the user data address area of the module.

Note

Restriction on use

The "GADR_LGC" instruction cannot be used for modules behind gateways (e.g., IE/PB link). Use the "GEO2LOG" instruction instead.

Parameters

The following table shows the parameters of the "GADR_LGC" instruction:

Parameter	Declaration	Data type	Memory area	Description
SUBNETID	Input	BYTE	I, Q, M, D, L or constant	Area ID: • 0: If the slot is located in the central module • 1 to 32: DP master system ID of the corresponding distributed I/O system if the slot is in a distributed I/O device. • 100 to 115: PROFINET IO system ID of the associated field device if the slot is located in a field device on PROFINET
RACK	Input	WORD	I, Q, M, D, L or constant	• Number of the rack, if area identifier is 0 • Device number of the distributed I/O device if the area identifier > 0
SLOT	Input	WORD	I, Q, M, D, L or constant	Slot no.
SUBSLOT	Input	BYTE	I, Q, M, D, L or constant	Irrelevant
SUBADDR	Input	WORD	I, Q, M, D, L or constant	Offset in the user data address area of the module
RET_VAL	Return	INT	I, Q, M, D, L	Error information
IOID	Output	BYTE	I, Q, M, D, L	The IOID output parameter is not written (always "0").
LADDR	Output	HW_MODULE	I, Q, M, D, L	Hardware identifier of the module

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8094	No subnet was configured with the specified SUBNETID .
8095	Illegal value for RACK parameter.
8096	Illegal value for SLOT parameter.
8098	Illegal value for SUBADDR parameter.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Instructions for address conversion (Page 4073)

LGC_GADR: Determine slot from hardware identifier (S7-1500)

Description

You use the "LGC_GADR" instruction to determine the module slot belonging to a hardware identifier.

Note

Restriction on use

The "LGC_GADR" instruction cannot be used for modules behind gateways (e.g., IE/PB link). Use the "LOG2GEO" instruction instead.

Parameters

The following table shows the parameters of the "LGC_GADR" instruction:

Parameter	Declaration	Data type	Memory area	Description
IOID	Input	BYTE	I, Q, M, D, L or constant	Is not evaluated.
LADDR	Input	HW_MODULE	I, Q, M, D, L or constant	Hardware identifier of the module
RET_VAL	Return	INT	I, Q, M, D, L	Error information
AREA	Output	BYTE	I, Q, M, D, L	The area ID indicates how the remaining output parameters are to be interpreted: • 0: Central module • 2: PROFIBUS DP

Parameter	Declaration	Data type	Memory area	Description
RACK	Output	WORD	I, Q, M, D, L	Rack number: • With central module (AREA= 0): – Rack number • For PROFIBUS DP (AREA=2): – Low byte: Station number – High byte: DP master system ID
SLOT	Output	WORD	I, Q, M, D, L	Slot number: • With central module (AREA= 0): – Slot number • For PROFIBUS DP (AREA=2): – Slot no. in the station
SUBADDR	Output	WORD	I, Q, M, D, L	Is not output (always "0").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Specified logical address invalid
8093	This instruction is not permitted for the module selected by the parameters IOID and LADDR .
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)

11.4.5.1 S7-1200 Motion Control (S7-1200)

S7-1200 Motion Control as of V6 (S7-1200)

MC_Power (S7-1200)

MC_Power: Enable, disable axis as of V6 (S7-1200)

Description

The Motion Control instruction "MC_Power" enables or disables an axis.

Requirements

- The positioning axis technology object has been configured correctly.
- There is no pending enable-inhibiting error.

Override response

Execution of "MC_Power" cannot be aborted by a Motion Control command.

Disabling the axis (input parameter "Enable" = FALSE) aborts all Motion Control commands for the associated technology object in accordance with the selected "StopMode".

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The axis is enabled.
				FALSE	All current jobs are interrupted in accordance with the "StopMode" configured. The axis is stopped and disabled.
StartMode	INPUT	INT	1	0	Enable positioning axis not position-controlled *)
				1	Enable positioning axis position-controlled *)
				*) This parameter is ignored when a positioning axis with PTO (Pulse Train Output) drive is used. The parameter initially takes effect when the positioning axis is enabled (Enable changes from FALSE to TRUE) and when the axis is enabled after successful acknowledgment of an interrupt that caused the axis to be disabled.	

Parameter	Declaration	Data type	Default value	Description	
StopMode	INPUT	INT	0	0	Emergency stop If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. The axis is disabled after reaching standstill.
				1	Immediate stop If a request to disable the axis is pending, this set-point zero is output and the axis is disabled. The axis is braked depending on the configuration in the drive, and is brought to a standstill. With drive connection via PTO (Pulse Train Output): When you disable the axis, the pulse output is stopped with a frequency-dependent deceleration: • Output frequency ≥ 100 Hz Deceleration: max. 30 ms • Output frequency < 100 Hz Deceleration: 30 ms up to max. 1.5 s at 2 Hz
				2	Emergency stop with jerk control If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. If the jerk control is activated, the configured jerk is taken into account. The axis is disabled after reaching standstill.
Status	OUTPUT	BOOL	FALSE	Status of axis enable	
				FALSE	The axis is disabled. The axis does not execute Motion Control commands and does not accept any new commands (exception: MC_Reset command) For drive connection via PTO (Pulse Train Output): The axis is not homed. Upon disabling, the status does not change to FALSE until the axis reaches a standstill.
				TRUE	The axis is enabled. The axis is ready to execute Motion Control commands. Upon axis enabling, the status does not change to TRUE until the signal "Drive ready" is pending. If the "Drive ready" drive interface was not configured in the axis configuration, the status changes to TRUE immediately.
Busy	OUTPUT	BOOL	FALSE	TRUE	MC_Power" is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power" or in the associated technology object. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"	

Note

If the axis is switched off due to an error, it will be enabled again automatically after the error has been eliminated and acknowledged. This requires that the input parameter "Enable" has retained the value TRUE during this process.

Enabling an axis with configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameters "StartMode" and "StopMode" with the desired value. Set the input parameter "Enable" to TRUE.
   The enable output for "Drive enabled" changes to TRUE to enable the power to the drive.
   The CPU waits for the "Drive ready" signal of the drive.
   When the "Drive ready" signal is available at the configured ready input of the CPU, the axis is enabled. The output parameter "Status" and the variable of the technology object <axis name>.StatusBits.Enable indicate the value TRUE.

Enabling an axis without configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameters "StartMode" and "StopMode" with the desired value. Set the input parameter "Enable" to TRUE. The axis is enabled. The output parameter "Status" and the variable of the technology object <axis name>.StatusBits.Enable indicate the value TRUE.

Disabling an axis

To disable an axis, you can follow the steps described below:

1. Bring the axis to a standstill.
   You can identify when the axis is at a standstill in the variable of the technology object <axis name>.StatusBits.StandStill.
2. Set input parameter "Enable" to FALSE after standstill is reached.
3. If output parameters "Busy" and "Status" and variable of technology object <axis name>.StatusBits.Enable indicate the value FALSE, disabling of the axis is complete.

Move the axis without position control for servicing (Page 6303)

MC_Power: Function chart as of V6 (S7-1200)

Function chart

①	An axis is enabled and then disabled again. When the drive has signaled "Drive ready" back to the CPU, the successful enable can be read out via "Status_1".
②	Following an axis enable, an error has occurred that caused the axis to be disabled. The error is eliminated and acknowledged with "MC_Reset". The axis is then enabled again.
③	The exact end of the signals depends on the selected drive and the StopMode.

MC_Reset (S7-1200)

MC_Reset: Acknowledge fault, restart technology object as of V6 (S7-1200)

Description

Motion Control instruction "MC_Reset" can be used to acknowledge "Operating error with axis stop" and "Configuration error". The errors that require acknowledgment can be found in the "List of ErrorIDs and ErrorInfos" under "Remedy".

The axis configuration can be downloaded to the work memory after a download in RUN mode.

Requirements

- The positioning axis technology object has been configured correctly.
- The cause of a pending configuration error requiring acknowledgment has been eliminated (for example, acceleration in positioning axis technology object has been changed to a valid value).

Override response

The MC_Reset command cannot be aborted by any other Motion Control command.

The new MC_Reset command does not abort any other active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Restart	INPUT	BOOL	FALSE	TRUE	Download the axis configuration from the load memory to the work memory. The command can only be executed when the axis is disabled. Refer to the notes on Download to the CPU.
				FALSE	Acknowledges pending errors
Done	OUTPUT	BOOL	FALSE	TRUE	Error has been acknowledged.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"	

Acknowledging an error requiring acknowledgment with MC_Reset

To acknowledge an error, follow these steps:

1. Check the requirements indicated above.
2. Start the acknowledgment of the error with a rising edge at input parameter "Execute".
3. If output parameter "Done" indicates the value TRUE and tag of technology object <Axis name>.StatusBits.Error the value FALSE, the error has been acknowledged.

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

MC_Home (S7-1200)

MC_Home: Home axes, set reference point as of V6 (S7-1200)

Description

Motion Control instruction "MC_Home" is used to match the axis coordinates to the real, physical drive position. Homing is required for absolute positioning of the axis. The following types of homing can be executed:

- Active homing (Mode = 3)
  The homing procedure is executed automatically.
- Passive homing (Mode = 2)
  During passive homing, the "MC_Home" Motion Control instruction does not carry out any homing motion. The traversing motion required for this must be implemented by the user via other Motion Control instructions. When the homing switch is detected, the axis is homed.
- Direct homing absolute (Mode = 0)
  The current axis position is set to the value of parameter "Position".

- Direct homing relative (Mode = 1)
  The current axis position is offset by the value of parameter "Position".
- Absolute encoder adjustment relative (Mode = 6)
  The current axis position is offset by the value of parameter "Position".
- Absolute encoder adjustment absolute (Mode = 7)
  The current axis position is set to the value of parameter "Position".

Mode 6 and 7 can only be used with drives with an analog interface and PROFIdrive drive.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- No MC_CommandTable command may be active upon start with Mode = 0, 1, or 2.

Override response

The override response depends on the selected mode:

Mode = 0, 1, 6, 7

The MC_Home command cannot be aborted by any other Motion Control command.

The MC_Home command does not abort any active Motion Control commands. Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 2

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 2, 3

The new MC_Home command aborts the following active Motion Control command:

- MC_Home command Mode = 2

Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 3

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Home command aborts the following active Motion Control commands:

- MC_Home command Mode = 2, 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description
Axis	INPUT	TO_Axis	-	Axis technology object
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge
Position	INPUT	REAL	0.0	• Mode = 0, 2, and 3 Absolute position of axis after completion of the homing operation • Mode = 1 Correction value for the current axis position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$

Parameter	Declaration	Data type	Default value	Description	
Mode	INPUT	INT	0	Homing mode	
				0	Direct homing (absolute) New axis position is the position value of parameter "Position".
				1	Direct homing (relative) New axis position is the current axis position + position value of parameter "Position".
				2	Passive homing Homing according to the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				3	Active homing Homing procedure in accordance with the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				6	Absolute encoder adjustment (relative) The current axis position is offset by the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<AxisName>.StatusSensor.AbsEncoderOffset)
				7	Absolute encoder adjustment (absolute) The current axis position is set to the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<AxisName>.StatusSensor.AbsEncoderOffset)
Done	OUTPUT	BOOL	FALSE	TRUE	Command completed
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"	
ReferenceMarkPosition	OUTPUT	REAL	0.0	Display of the position at which the technology object was homed (valid when "Done" = TRUE)	

Resetting the "Homed" status

The "Homed" status of a technology object (<Axis name>.StatusBits.HomingDone) is reset under the following conditions:

- **Drive connection via PTO (Pulse Train Output):**
  - Start an "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is set again.)
  - Disabling of axis by the "MC_Power" Motion Control instruction
  - Changeover between automatic mode and manual control
  - After POWER OFF -> POWER ON of the CPU
  - After CPU restart (RUN-STOP -> STOP-RUN)
- **Technology objects with incremental actual values:**
  - Start an "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is set again.)
  - Error in the encoder system, or encoder failure
  - Restart of the technology object
  - After POWER OFF → POWER ON of the CPU
  - Memory reset
  - Modification of the encoder configuration
- **Technology objects with absolute actual values:**
  - Errors in the sensor system/encoder failure
  - Replacement of the CPU
  - Modification of the encoder configuration
  - Restoration of the CPU factory settings
  - Transfer of a different project to the controller

Homing an axis

To home the axis, follow these stops:

1. Check the requirements indicated above.
2. Provide the necessary input parameters with values and start the homing operation with a rising edge at input parameter "Execute".
3. If output parameter "Done" and technology object variable <axis name>.StatusBits.HomingDone indicate the value TRUE, homing is complete. The reference position can be taken from the <axis name>.ReferenceMarkPosition variable.

MC_Halt (S7-1200)

MC_Halt: Stop axis as of V6 (S7-1200)

Description

The "MC_Halt" Motion Control instruction stops all movements and brings the axis to a standstill with the configured deceleration. The standstill position is not defined.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_Halt command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Halt command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command

- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Zero velocity reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

Move the axis without position control for servicing (Page 6303)

MC_Halt: Function chart as of V6 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is braked by an MC_Halt command until it comes to a standstill. The axis standstill is signaled via "Done_2".
②	While an MC_Halt command is braking the axis, this command is aborted by another motion command. The abort is signaled via "Abort_2".

MC_MoveAbsolute (S7-1200)

MC_MoveAbsolute: Absolute positioning of axis as of V6 (S7-1200)

Description

The "MC_MoveAbsolute" Motion Control instruction starts an axis positioning motion to move it to an absolute position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- The axis is homed.

Override response

The MC_MoveAbsolute command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveAbsolute command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description
Axis	INPUT	TO_Positionin-gAxis	-	Axis technology object
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge

Parameter	Declaration	Data type	Default value	Description	
Position	INPUT	REAL	0.0	Absolute target position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the target position to be approached. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Direction	INPUT	INT	1	Motion direction of the axis Is only evaluated with "modulo" enabled. "Technology object > Configuration > Extended parameters > Modulo > Enable Modulo" Parameter is ignored with PTO axes.	
				0	The sign for the speed ("Velocity" parameter) determines the motion direction.
				1	Positive direction (Target position is approached in a positive direction)
				2	Negative direction (Target position is approached in a negative direction)
				3	Shortest distance (Starting from the current position, the technology selects the shortest distance to the target position)
Done	OUTPUT	BOOL	FALSE	TRUE	Absolute target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

Configuration - Modulo (PROFIdrive/analog drive connection only) (Page 6197)

MC_MoveAbsolute: Function chart as of V6 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An axis is moved to absolute position 1000.0 with an MC_MoveAbsolute command. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveAbsolute command, with target position 1500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveAbsolute command is aborted by another MC_MoveAbsolute command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveRelative (S7-1200)

MC_MoveRelative: Relative positioning of axis as of V6 (S7-1200)

Description

The "MC_MoveRelative" Motion Control instruction starts a positioning motion relative to the start position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

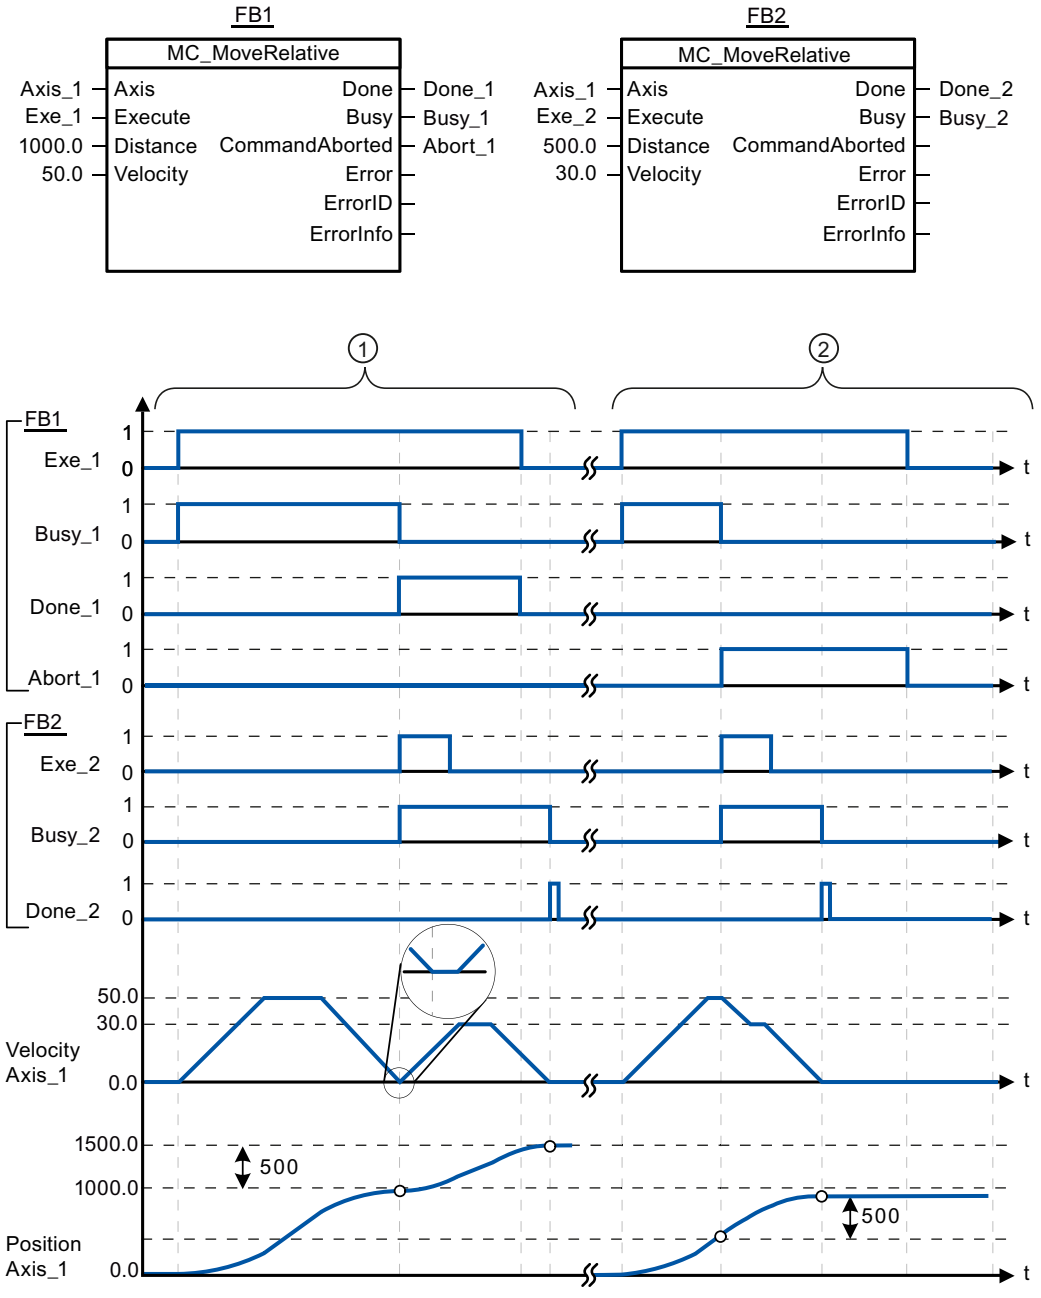
The MC_MoveRelative command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveRelative command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters



Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Positioning-Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Distance	INPUT	REAL	0.0	Travel distance for the positioning operation Limit values: $-1.0e^{12} \leq$ Distance $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the distance to be traveled. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

MC_MoveRelative: Function chart as of V6 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	The axis is moved by an MC_MoveRelative command by the distance ("Distance") 1000.0. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveRelative command, with travel distance 500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveRelative command is aborted by another MC_MoveRelative command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity by the new distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveVelocity (S7-1200)

MC_MoveVelocity: Move axis at set velocity as of V6 (S7-1200)

Description

Motion control instruction "MC_MoveVelocity" moves the axis constantly at the specified velocity.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

MC_MoveVelocity can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveVelocity command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Velocity	INPUT	REAL	10.0	Velocity specification for axis motion Limit values: Start/stop velocity ≤ |Velocity ≤ maximum velocity (Velocity = 0.0 is permitted)	
Direction	INPUT	INT	0	Direction specification	
				0	Direction of rotation corresponds to the sign of the value in parameter "Velocity"
				1	Positive direction of rotation (The sign of the value in parameter "Velocity" is ignored)
				2	Negative direction of rotation (The sign of the value in parameter "Velocity" is ignored)
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	"Maintain current velocity" is deactivated. The values of parameters "Velocity" and "Direction" are used.
				TRUE	"Maintain current velocity" is activated. The values in parameters "Velocity" and "Direction" are not taken into account. When the axis resumes motion at the current velocity, the "InVelocity" parameter returns the value TRUE.
PositionControlled	INPUT	BOOL	TRUE	FALSE	Non position-controlled operation
				TRUE	Position-controlled operation
				The parameter applies as long as the MC_MoveVelocity command is executed. After this, the setting of MC_Power applies again. This parameter is ignored when a PTO axis is used.	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	• "Current" = FALSE: The velocity specified in parameter "Velocity" was reached. • "Current" = TRUE: The axis travels at the current velocity at the start time.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".

Parameter	Declaration	Data type	Default value	Description
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

Note

PLCopen Version 2.0

The Motion Control instruction "MC_MoveVelocity" is compatible to PLCopen Version 2.0 as of V4.

The "InVelocity" and "Busy" parameters show their status regardless of the "Execute" parameter until the command is overridden or stopped by an error. For more information, refer to the section " Tracking active commands.

Behavior with zero setpoint velocity (Velocity = 0.0)

An MC_MoveVelocity command with "Velocity" = 0.0 (such as an MC_Halt command) aborts active motion commands and stops the axis with the configured deceleration.

When the axis comes to a standstill, output parameter "InVelocity" indicates TRUE for at least one program cycle.

"Busy" indicates the value TRUE during the deceleration process and changes to FALSE together with "InVelocity". If parameter "Execute" = TRUE is set, "InVelocity" and "Busy" are latched.

When the "MC_MoveVelocity" command is started, status bit "SpeedCommand" is set in the technology object. Status bit "ConstantVelocity" is set upon axis standstill. Both bits are adapted to the new situation when a new motion command is started.

MC_MoveVelocity: Function chart as of V6 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An active MC_MoveVelocity command signals via "InVel_1" that its target velocity has been reached. It is then aborted by another MC_MoveVelocity command. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.
②	An active MC_MoveVelocity command is aborted by another MC_MoveVelocity command prior to reaching its target velocity. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.

MC_MoveJog (S7-1200)

MC_MoveJog: Move axis in jog mode as of V6 (S7-1200)

Description

Motion control instruction "MC_MoveJog" moves the axis constantly at the specified velocity in jog mode. You use this Motion Control instruction, for example, for testing and commissioning purposes.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveJog command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveJog command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
JogForward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the positive direction at the velocity specified in parameter "Velocity".	
JogBackward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the negative direction at the velocity specified in parameter "Velocity".	
If both parameters are simultaneously TRUE, the axis stops with the configured deceleration. An error is indicated in parameters "Error", "ErrorID", and "ErrorInfo".					
Velocity	INPUT	REAL	10.0	Preset velocity for jog mode Limit values: Start/stop velocity ≤ velocity ≤ maximum velocity	
PositionControlled	INPUT	BOOL	TRUE	FALSE	Non position-controlled operation
				TRUE	Position-controlled operation
				The parameter applies as long as the MC_MoveJog command is executed. After this, the setting of MC_Power applies again. This parameter is ignored when a PTO axis is used.	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity specified in parameter "Velocity" was reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

MC_MoveJog: Function chart as of V6 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is moved in the positive direction in jog mode via "Jog_F". When the target velocity 50.0 is reached, this is signaled via "InVel_1". After "Jog_F" is reset, the axis is braked to a standstill.
②	The axis is moved in the negative direction in jog mode via "Jog_B". When the target velocity -50.0 is reached, this is signaled via "InVel_1". When "Jog_B" is set, the value at parameter "Velocity" changes to 25.0. "InVel_1" is reset and the axis is braked. When the new target velocity -25.0 is reached, this is signaled via "InVel_1". After "Jog_B" is reset, the axis is braked to a standstill.

MC_CommandTable (S7-1200)

MC_CommandTable: Run axis commands as motion sequence as of V6 (S7-1200)

Description

The Motion Control instruction "MC_CommandTable" combines multiple individual axis control commands in one movement sequence. "MC_CommandTable" is available for axes with drive connection via PTO (Pulse Train Output).

Requirements

- The positioning axis technology object has been inserted and correctly configured.
- The drive is connected via PTO (Pulse Train Output).
- The command table technology object has been inserted and correctly configured.
- The axis is enabled.

Override response

The MC_CommandTable command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_CommandTable command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The active Motion Control command is canceled by the start of the first "Positioning Relative", "Positioning Absolute", "Velocity set point" or "Halt" command.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
CommandTable	INPUT	TO_CommandTable	-	Command table technology object	
Execute	INPUT	BOOL	FALSE	Command table start with positive edge	
StartStep	INPUT	INT	1	Defines the step at which the execution of the command table should begin Limit values: 1 ≤ StartStep ≤ EndStep	
EndStep	INPUT	INT	32	Defines the step up to which the execution of command table should take place Limit values: StartStep ≤ EndStep ≤ 32	
Done	OUTPUT	BOOL	FALSE	TRUE	Command table has been successfully executed
Busy	OUTPU	BOOL	FALSE	TRUE	The command table is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The command table was canceled by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command table. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"	
CurrentStep	OUTPUT	INT	0	Step in command table currently being executed	
StepCode	OUTPUT	WORD	16#0000	User-defined numerical value / bit pattern of the step currently being executed

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

MC_ChangeDynamic (S7-1200)

MC_ChangeDynamic: Change dynamic settings of axis as of V6 (S7-1200)

Description

Motion Control instruction "MC_ChangeDynamic" allows you to change the following settings of the axis:

- Change the ramp-up time (acceleration) value
- Change the ramp-down time (deceleration) value
- Change the emergency stop ramp-down time (emergency stop deceleration) value
- Change the smoothing time (jerk) value

For the effectiveness of the change, refer to the description of the tag.

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ChangeDynamic command cannot be aborted by any other Motion Control command.

A new MC_ChangeDynamic command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
ChangeRampUp	INPUT	BOOL	FALSE	TRUE	Change ramp-up time in line with input parameter "RampUpTime"
RampUpTime	INPUT	REAL	5.00	Time (in seconds) to accelerate axis from standstill to configured maximum velocity without jerk limit. The change will influence the tag <Axis name>. Config.DynamicDefaults.Acceleration. For the effectiveness of the change, refer to the description of this tag.	
ChangeRampDown	INPUT	BOOL	FALSE	TRUE	Change ramp-down time to correspond to input parameter "RampDownTime"
RampDownTime	INPUT	REAL	5.00	Time (in seconds) to decelerate axis from the configured maximum velocity to standstill without jerk limiter. The change will influence the tag <Axis name>. Config.DynamicDefaults.Deceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeEmergency	INPUT	BOOL	FALSE	TRUE	Change emergency stop ramp-down time in line with input parameter "EmergencyRampTime"

Parameter	Declaration	Data type	Default value	Description	
EmergencyRampTime	INPUT	REAL	2.00	Time (in seconds) to decelerate the axis from configured maximum velocity to standstill without jerk limiter in emergency stop mode. The change will influence the tag <Axis name>. Config.DynamicDefaults.EmergencyDeceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeJerkTime	INPUT	BOOL	FALSE	TRUE	Change smoothing time according to the input parameter "JerkTime"
JerkTime	INPUT	REAL	0.25	Smoothing time (in seconds) used for the axis acceleration and deceleration ramps The change will influence the tag <Axis name>. Config.DynamicDefaults.Jerk . For the effectiveness of the change, refer to the description of this tag.	
Done	OUTPUT	BOOL	FALSE	TRUE	The changed values have been written to the technology data block. The description of the tags will show when the change becomes effective.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"	

Note

At the input parameters "RampUpTime", "RampDownTime", "EmergencyRampTime" and "JerkTime", values can be entered which exceed the admissible limits of the resulting parameters: "Acceleration", "Deceleration", "Emergency stop deceleration" and "Jerk".

Ensure that your inputs are within the valid range, taking into consideration the equations and limits in section "Dynamic".

MC_ReadParam (S7-1200)

MC_ReadParam: Continuously read motion data of a positioning axis as of V6 (S7-1200)

Description

The Motion Control instruction "MC_ReadParam" enables continuous reading of motion data and status messages of an axis. The current value of the corresponding tags is determined at the start of the command.

The following motion data and status messages can be read:

- As of technology version V4:
  - Setpoint position of the axis
  - Setpoint and actual velocity of the axis
  - Current distance of axis from target position
  - Target position of the axis
- Additional as of technology version V5:
  - Actual position of the axis
  - Actual velocity of the axis
  - Current following error
  - Drive status
  - Encoder status
  - Status bits
  - Error bits

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ReadParam command cannot be aborted by any other Motion Control command.

A new MC_ReadParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Enable	INPUT	BOOL	FALSE	TRUE	Read the tag specified with the "Parameter" and store the value in the destination address specified with "Value".
				FALSE	Do not update assigned motion data
Parameter	INPUT	VARIANT (REAL)	-	VARIANT pointer to the value to be read. The following tags are permitted: • <Axis name>.Position • <Axis name>.Velocity • <Axis name>.ActualPosition • <Axis name>.ActualVelocity • <Axis name>.StatusPositioning.<Tag name> • <Axis name>.StatusDrive.<Tag name> • <Axis name>.StatusSensor.<Tag name> • <Axis name>.StatusBits.<Tag name> • <Axis name>.ErrorBits.<Tag name> The description of the tags named and the tag structures can be found in the Appendix AUTOHOTSPOT.	
Value	INOUT	VARIANT (REAL)	-	VARIANT pointer to the target tag or destination address to which the read value is to be written.	
Valid	OUTPUT	BOOL	FALSE	TRUE	The read value is valid.
				FALSE	The read value is invalid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

MC_WriteParam: Write tag of positioning axis as of V6 (Page 4128)

MC_WriteParam (S7-1200)

MC_WriteParam: Write tag of positioning axis as of V6 (S7-1200)

Description

Motion Control instruction "MC_WriteParam" enables the writing of tags of the positioning axis technology object in the user program. In contrast to the value assignment of the tags in the user program, "MC_WriteParam" can also change values of read-only tags.

You can learn about the tags, the conditions under which they can be written and the time at which they take effect in the description of the technology object tags (Page 6328).

Requirements

- The positioning axis technology object has been configured correctly.
- To write tags that are read-only in the user program, the axis must be disabled.
- Tags whose change requires a restart cannot be written with "MC_WriteParam".

Override response

A MC_WriteParam command cannot be aborted by any other Motion Control command.

A new MC_WriteParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Parameter	INPUT	VARIANT (BOOL, INT, DINT, UDINT, REAL)	-	VARIANT pointer to the technology object tags (Page 6328) positioning axis (destination address) to be written	
Value	INPUT	VARIANT (BOOL, INT, DINT, UDINT, REAL)	-	VARIANT pointer to the value to be written (source address)	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Value was written
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".

Parameter	Declaration	Data type	Default value	Description
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6304) for parameter "Error"
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6304) for parameter "ErrorID"

Tags of the positioning axis technology object as of V6 (Page 6328)

S7-1200 Motion Control V4...5 (S7-1200)

MC_Power (S7-1200)

MC_Power: Enable, disable axis V4...5 (S7-1200)

Description

The Motion Control instruction "MC_Power" enables or disables an axis.

Requirements

- The positioning axis technology object has been configured correctly.
- There is no pending enable-inhibiting error.

Override response

Execution of "MC_Power" cannot be aborted by a Motion Control command.

Disabling the axis (input parameter "Enable" = FALSE) aborts all Motion Control commands for the associated technology object in accordance with the selected "StopMode".

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	The axis is enabled.
				FALSE	All current jobs are interrupted in accordance with the "StopMode" configured. The axis is stopped and disabled.
StopMode	INPUT	INT	0	0	Emergency stop If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. The axis is disabled after reaching standstill.
				1	Immediate stop If a request to disable the axis is pending, this set-point zero is output and the axis is disabled. The axis is braked depending on the configuration in the drive, and is brought to a standstill. With drive connection via PTO (Pulse Train Output): When you disable the axis, the pulse output is stopped with a frequency-dependent deceleration: • Output frequency ≥ 100 Hz Deceleration: max. 30 ms • Output frequency < 100 Hz Deceleration: 30 ms up to max. 1.5 s at 2 Hz
				2	Emergency stop with jerk control If a request to disable the axis is pending, the axis brakes at the configured emergency deceleration. If the jerk control is activated, the configured jerk is taken into account. The axis is disabled after reaching standstill.

Parameter	Declaration	Data type	Default value	Description	
Status	OUTPUT	BOOL	FALSE	Status of axis enable	
				FALSE	The axis is disabled. The axis does not execute Motion Control commands and does not accept any new commands (exception: MC_Reset command). For drive connection via PTO (Pulse Train Output): The axis is not homed. Upon disabling, the status does not change to FALSE until the axis reaches a standstill.
				TRUE	The axis is enabled. The axis is ready to execute Motion Control commands. Upon axis enabling, the status does not change to TRUE until the signal "Drive ready" is pending. If the "Drive ready" drive interface was not configured in the axis configuration, the status changes to TRUE immediately.
Busy	OUTPUT	BOOL	FALSE	TRUE	"MC_Power" is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power" or in the associated technology object. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

If the axis is switched off due to an error, it will be enabled again automatically after the error has been eliminated and acknowledged. This requires that the input parameter "Enable" has retained the value TRUE during this process.

Enabling an axis with configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE.
   The enable output for "Drive enabled" changes to TRUE to enable the power to the drive.
   The CPU waits for the "Drive ready" signal of the drive.
   When the "Drive ready" signal is available at the configured ready input of the CPU, the axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Enabling an axis without configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE. The axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Disabling an axis

To disable an axis, you can follow the steps described below:

1. Bring the axis to a standstill.
   You can identify when the axis is at a standstill in the tag of the technology object <Axis name>.StatusBits.StandStill.
2. Set input parameter "Enable" to FALSE after standstill is reached.
3. If output parameters "Busy" and "Status" and tag of technology object <Axis name>.StatusBits.Enable indicate the value FALSE, disabling of the axis is complete.

MC_Power: Function chart V4...5 (S7-1200)

Function chart

①	An axis is enabled and then disabled again. When the drive has signaled "Drive ready" back to the CPU, the successful enable can be read out via "Status_1".
②	Following an axis enable, an error has occurred that caused the axis to be disabled. The error is eliminated and acknowledged with "MC_Reset". The axis is then enabled again.

See also

MC_Power: Enable, disable axis V4...5 (Page 4129)

MC_Reset (S7-1200)

MC_Reset: Acknowledge fault, restart technology object V4...5 (S7-1200)

Description

Motion Control instruction "MC_Reset" can be used to acknowledge "Operating error with axis stop" and "Configuration error". The errors that require acknowledgment can be found in the "List of ErrorIDs and ErrorInfos" under "Remedy".

The axis configuration can be downloaded to the work memory after a download in RUN mode.

Requirements

- The positioning axis technology object has been configured correctly.
- The cause of a pending configuration error requiring acknowledgment has been eliminated (for example, acceleration in positioning axis technology object has been changed to a valid value).

Override response

The MC_Reset command cannot be aborted by any other Motion Control command.

The new MC_Reset command does not abort any other active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Restart	INPUT	BOOL	FALSE	TRUE	Download the axis configuration from the load memory to the work memory. The command can only be executed when the axis is disabled. Refer to the notes on Download to the CPU (Page 6260).
				FALSE	Acknowledges pending errors
Done	OUTPUT	BOOL	FALSE	TRUE	Error has been acknowledged.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Acknowledging an error requiring acknowledgment with MC_Reset

To acknowledge an error, follow these steps:

1. Check the requirements indicated above.
2. Start the acknowledgment of the error with a rising edge at input parameter "Execute".
3. If output parameter "Done" indicates the value TRUE and tag of technology object <Axis name>.StatusBits.Error the value FALSE, the error has been acknowledged.

S7-1200 Motion Control V1...3 (Page 4165)

MC_Home (S7-1200)

MC_Home: Home axis, set home position V4...5 (S7-1200)

Description

Motion Control instruction "MC_Home" is used to match the axis coordinates to the real, physical drive position. Homing is required for absolute positioning of the axis. The following types of homing can be executed:

- Active homing (Mode = 3)
  The homing procedure is executed automatically.
- Passive homing (Mode = 2)
  During passive homing, the "MC_Home" Motion Control instruction does not carry out any homing motion. The traversing motion required for this must be implemented by the user via other Motion Control instructions. When the homing switch is detected, the axis is homed.
- Direct homing absolute (Mode = 0)
  The current axis position is set to the value of parameter "Position".
- Direct homing relative (Mode = 1)
  The current axis position is offset by the value of parameter "Position".
- Absolute encoder adjustment relative (Mode = 6)
  The current axis position is offset by the value of parameter "Position".
- Absolute encoder adjustment absolute (Mode = 7)
  The current axis position is set to the value of parameter "Position".

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- No MC_CommandTable command may be active upon start with Mode = 0, 1, or 2.

Override response

The override response depends on the selected mode:

Mode = 0, 1, 6, 7

The MC_Home command cannot be aborted by any other Motion Control command.

The MC_Home command does not abort any active Motion Control commands. Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 2

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 2, 3

The new MC_Home command aborts the following active Motion Control command:

- MC_Home command Mode = 2

Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 3

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Home command aborts the following active Motion Control commands:

- MC_Home command Mode = 2, 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description
Axis	INPUT	TO_Axis	-	Axis technology object
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge
Position	INPUT	REAL	0.0	• Mode = 0, 2, and 3 Absolute position of axis after completion of the homing operation • Mode = 1 Correction value for the current axis position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$

Parameter	Declaration	Data type	Default value	Description	
Mode	INPUT	INT	0	Homing mode	
				0	Direct homing (absolute) New axis position is the position value of parameter "Position".
				1	Direct homing (relative) New axis position is the current axis position + position value of parameter "Position".
				2	Passive homing Homing according to the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				3	Active homing Homing procedure in accordance with the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				6	Absolute encoder adjustment (relative) The current axis position is offset by the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<AxisName>.StatusSensor.AbsEncoderOffset)
				7	Absolute encoder adjustment (absolute) The current axis position is set to the value of parameter "Position". The calculated absolute value offset is stored retentively in the CPU. (<AxisName>.StatusSensor.AbsEncoderOffset)
Done	OUTPUT	BOOL	FALSE	TRUE	Command completed
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Resetting the "Homed" status

The "Homed" status of a technology object (<Axis name>.StatusBits.HomingDone) is reset under the following conditions:

- **Drive connection via PTO (Pulse Train Output):**
  - Start an "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is set again.)
  - Disabling of axis by the "MC_Power" Motion Control instruction
  - Changeover between automatic mode and manual control
  - After POWER OFF -> POWER ON of the CPU
  - After CPU restart (RUN-STOP -> STOP-RUN)
- **Technology objects with incremental actual values:**
  - Start an "MC_Home" command for active homing
    (After successful completion of the homing operation, the "Homed" status is set again.)
  - Error in the encoder system, or encoder failure
  - Restart of the technology object
  - After POWER OFF → POWER ON of the CPU
  - Memory reset
  - Modification of the encoder configuration
- **Technology objects with absolute actual values:**
  - Errors in the sensor system/encoder failure
  - Replacement of the CPU
  - Modification of the encoder configuration
  - Restoration of the CPU factory settings
  - Transfer of a different project to the controller

Homing an axis

To home the axis, follow these stops:

1. Check the requirements indicated above.
2. Provide the necessary input parameters with values and start the homing operation with a rising edge at input parameter "Execute".
3. If output parameter "Done" and technology object tag <Axis name>.StatusBits.HomingDone indicate the value TRUE, homing is complete.

MC_Halt (S7-1200)

MC_Halt: Stop axis V4...5 (S7-1200)

Description

The "MC_Halt" Motion Control instruction stops all movements and brings the axis to a standstill with the configured deceleration. The standstill position is not defined.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_Halt command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Halt command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Zero velocity reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_Halt: Function chart V4...5 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is braked by an MC_Halt command until it comes to a standstill. The axis standstill is signaled via "Done_2".
②	While an MC_Halt command is braking the axis, this command is aborted by another motion command. The abort is signaled via "Abort_2".

MC_Halt: Stop axis V4...5 (Page 4140)

MC_MoveAbsolute (S7-1200)

MC_MoveAbsolute: Absolute positioning of axis V4...5 (S7-1200)

Description

The "MC_MoveAbsolute" Motion Control instruction starts an axis positioning motion to move it to an absolute position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.
- The axis is homed.

Override response

The MC_MoveAbsolute command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveAbsolute command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command

- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Positioning-Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	Absolute target position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the target position to be approached. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Absolute target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_MoveAbsolute: Function chart V4...5 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An axis is moved to absolute position 1000.0 with an MC_MoveAbsolute command. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveAbsolute command, with target position 1500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveAbsolute command is aborted by another MC_MoveAbsolute command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveAbsolute: Absolute positioning of axis V4...5 (Page 4143)

MC_MoveRelative (S7-1200)

MC_MoveRelative: Relative positioning of axis V4...5 (S7-1200)

Description

The "MC_MoveRelative" Motion Control instruction starts a positioning motion relative to the start position.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveRelative command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveRelative command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Positioning-Axis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Distance	INPUT	REAL	0.0	Travel distance for the positioning operation Limit values: $-1.0e^{12} \leq$ Distance $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the distance to be traveled. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_MoveRelative: Function chart V4...5 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	The axis is moved by an MC_MoveRelative command by the distance ("Distance") 1000.0. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveRelative command, with travel distance 500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveRelative command is aborted by another MC_MoveRelative command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity by the new distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveRelative: Relative positioning of axis V4...5 (Page 4146)

MC_MoveVelocity (S7-1200)

MC_MoveVelocity: Move axis at set velocity V4...5 (S7-1200)

Description

Motion control instruction "MC_MoveVelocity" moves the axis constantly at the specified velocity.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

MC_MoveVelocity can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveVelocity command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command

- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Velocity	INPUT	REAL	10.0	Velocity specification for axis motion Limit values: Start/stop velocity ≤ |Velocity ≤ maximum velocity (Velocity = 0.0 is permitted)	
Direction	INPUT	INT	0	Direction specification	
				0	Direction of rotation corresponds to the sign of the value in parameter "Velocity"
				1	Positive direction of rotation (The sign of the value in parameter "Velocity" is ignored)
				2	Negative direction of rotation (The sign of the value in parameter "Velocity" is ignored)
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	"Maintain current velocity" is deactivated. The values of parameters "Velocity" and "Direction" are used.
				TRUE	"Maintain current velocity" is activated. The values in parameters "Velocity" and "Direction" are not taken into account. When the axis resumes motion at the current velocity, the "InVelocity" parameter returns the value TRUE.
InVelocity	OUTPUT	BOOL	FALSE	TRUE	• "Current" = FALSE: The velocity specified in parameter "Velocity" was reached. • "Current" = TRUE: The axis travels at the current velocity at the start time.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

PLCopen Version 2.0

The Motion Control instruction "MC_MoveVelocity" is compatible to PLCopen Version 2.0 as of V4.

The "InVelocity" and "Busy" parameters show their status regardless of the "Execute" parameter until the command is overridden or stopped by an error. For more information, refer to the section " Tracking active commands (Page 6276).

Behavior with zero setpoint velocity (Velocity = 0.0)

An MC_MoveVelocity command with "Velocity" = 0.0 (such as an MC_Halt command) aborts active motion commands and stops the axis with the configured deceleration.

When the axis comes to a standstill, output parameter "InVelocity" indicates TRUE for at least one program cycle.

"Busy" indicates the value TRUE during the deceleration process and changes to FALSE together with "InVelocity". If parameter "Execute" = TRUE is set, "InVelocity" and "Busy" are latched.

When the "MC_MoveVelocity" command is started, status bit "SpeedCommand" is set in the technology object. Status bit "ConstantVelocity" is set upon axis standstill. Both bits are adapted to the new situation when a new motion command is started.

MC_MoveVelocity: Function chart V4...5 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An active MC_MoveVelocity command signals via "InVel_1" that its target velocity has been reached. It is then aborted by another MC_MoveVelocity command. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.
②	An active MC_MoveVelocity command is aborted by another MC_MoveVelocity command prior to reaching its target velocity. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.

MC_MoveVelocity: Move axis at set velocity V4...5 (Page 4150)

MC_MoveJog (S7-1200)

MC_MoveJog: Move axis in jog mode V4...5 (S7-1200)

Description

Motion control instruction "MC_MoveJog" moves the axis constantly at the specified velocity in jog mode. You use this Motion Control instruction, for example, for testing and commissioning purposes.

Requirements

- The positioning axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveJog command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveJog command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
JogForward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the positive direction at the velocity specified in parameter "Velocity".	
JogBackward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the negative direction at the velocity specified in parameter "Velocity".	
If both parameters are simultaneously TRUE, the axis stops with the configured deceleration. An error is indicated in parameters "Error", "ErrorID", and "ErrorInfo".					
Velocity	INPUT	REAL	10.0	Preset velocity for jog mode Limit values: Start/stop velocity ≤ velocity ≤ maximum velocity	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity specified in parameter "Velocity" was reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_MoveJog: Function chart V4...5 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is moved in the positive direction in jog mode via "Jog_F". When the target velocity 50.0 is reached, this is signaled via "InVel_1". After "Jog_F" is reset, the axis is braked to a standstill.
②	The axis is moved in the negative direction in jog mode via "Jog_B". When the target velocity -50.0 is reached, this is signaled via "InVel_1". When "Jog_B" is set, the value at parameter "Velocity" changes to 25.0. "InVel_1" is reset and the axis is braked. When the new target velocity -25.0 is reached, this is signaled via "InVel_1". After "Jog_B" is reset, the axis is braked to a standstill.

MC_CommandTable (S7-1200)

MC_CommandTable: Run axis commands as motion sequence V4...5 (S7-1200)

Description

The Motion Control instruction "MC_CommandTable" combines multiple individual axis control commands in one movement sequence. "MC_CommandTable" is available for axes with drive connection via PTO (Pulse Train Output).

Requirements

- The positioning axis technology object has been inserted and correctly configured.
- The drive is connected via PTO (Pulse Train Output).
- The command table technology object has been inserted and correctly configured.
- The axis is enabled.

Override response

The MC_CommandTable command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_CommandTable command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The active Motion Control command is canceled by the start of the first "Positioning Relative", "Positioning Absolute", "Velocity set point" or "Halt" command.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
CommandTable	INPUT	TO_CommandTable	-	Command table technology object	
Execute	INPUT	BOOL	FALSE	Command table start with positive edge	
StartStep	INPUT	INT	1	Defines the step at which the execution of the command table should begin Limit values: 1 ≤ StartStep ≤ EndStep	
EndStep	INPUT	INT	32	Defines the step up to which the execution of command table should take place Limit values: StartStep ≤ EndStep ≤ 32	
Done	OUTPUT	BOOL	FALSE	TRUE	Command table has been successfully executed
Busy	OUTPU	BOOL	FALSE	TRUE	The command table is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The command table was canceled by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command table. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	
CurrentStep	OUTPUT	INT	0	Step in command table currently being executed	
StepCode	OUTPUT	WORD	16#0000	User-defined numerical value / bit pattern of the step currently being executed

S7-1200 Motion Control V1...3 (Page 4165)

MC_ChangeDynamic (S7-1200)

MC_ChangeDynamic: Change dynamic settings of axis V4...5 (S7-1200)

Description

Motion Control instruction "MC_ChangeDynamic" allows you to change the following settings of the axis:

- Change the ramp-up time (acceleration) value
- Change the ramp-down time (deceleration) value
- Change the emergency stop ramp-down time (emergency stop deceleration) value
- Change the smoothing time (jerk) value

For the effectiveness of the change, refer to the description of the tag (Page 6436).

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ChangeDynamic command cannot be aborted by any other Motion Control command.

A new MC_ChangeDynamic command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_SpeedAxis	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
ChangeRampUp	INPUT	BOOL	FALSE	TRUE	Change ramp-up time in line with input parameter "RampUpTime"
RampUpTime	INPUT	REAL	5.00	Time (in seconds) to accelerate axis from standstill to configured maximum velocity without jerk limit. The change will influence the tag <Axis name>. Config.DynamicDefaults.Acceleration. For the effectiveness of the change, refer to the description of this tag.	
ChangeRampDown	INPUT	BOOL	FALSE	TRUE	Change ramp-down time to correspond to input parameter "RampDownTime"

Parameter	Declaration	Data type	Default value	Description	
Ramp-DownTime	INPUT	REAL	5.00	Time (in seconds) to decelerate axis from the configured maximum velocity to standstill without jerk limiter. The change will influence the tag <Axis name>. Config.DynamicDefaults.Deceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeEmergency	INPUT	BOOL	FALSE	TRUE	Change emergency stop ramp-down time in line with input parameter "EmergencyRampTime"
EmergencyRampTime	INPUT	REAL	2.00	Time (in seconds) to decelerate the axis from configured maximum velocity to standstill without jerk limiter in emergency stop mode. The change will influence the tag <Axis name>. Config.DynamicDefaults.EmergencyDeceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeJerkTime	INPUT	BOOL	FALSE	TRUE	Change smoothing time according to the input parameter "JerkTime"
JerkTime	INPUT	REAL	0.25	Smoothing time (in seconds) used for the axis acceleration and deceleration ramps The change will influence the tag <Axis name>. Config.DynamicDefaults.Jerk . For the effectiveness of the change, refer to the description of this tag.	
Done	OUTPUT	BOOL	FALSE	TRUE	The changed values have been written to the technology data block. The description of the tags will show when the change becomes effective.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

At the input parameters "RampUpTime", "RampDownTime", "EmergencyRampTime" and "JerkTime", values can be entered which exceed the admissible limits of the resulting parameters: "Acceleration", "Deceleration", "Emergency stop deceleration" and "Jerk".

Ensure that your inputs are within the valid range, taking into consideration the equations and limits in section "Dynamic (Page 6203)".

MC_ReadParam (S7-1200)

MC_ReadParam: Continuously read motion data of a positioning axis V4...5 (S7-1200)

Description

The Motion Control instruction "MC_ReadParam" enables continuous reading of motion data and status messages of an axis. The current value of the corresponding tags is determined at the start of the command.

The following motion data and status messages can be read:

- As of technology version V4:
  - Setpoint position of the axis
  - Setpoint and actual velocity of the axis
  - Current distance of axis from target position
  - Target position of the axis
- Additional as of technology version V5:
  - Actual position of the axis
  - Actual velocity of the axis
  - Current following error
  - Drive status
  - Encoder status
  - Status bits
  - Error bits

Requirements

The positioning axis technology object has been configured correctly.

Override response

A MC_ReadParam command cannot be aborted by any other Motion Control command.

A new MC_ReadParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Enable	INPUT	BOOL	FALSE	TRUE	Read the tag specified with the "Parameter" and store the value in the destination address specified with "Value".
				FALSE	Do not update assigned motion data
Parameter	INPUT	VARIANT (REAL)	-	VARIANT pointer to the value to be read. The following tags are permitted: • <Axis name>.Position • <Axis name>.Velocity • <Axis name>.ActualPosition • <Axis name>.ActualVelocity • <Axis name>.StatusPositioning.<Tag name> • <Axis name>.StatusDrive.<Tag name> • <Axis name>.StatusSensor.<Tag name> • <Axis name>.StatusBits.<Tag name> • <Axis name>.ErrorBits.<Tag name> The description of the tags named and the tag structures can be found in the Appendix Tags of the positioning axis technology object V4...5 (Page 6436).	
Value	INOUT	VARIANT (REAL)	-	VARIANT pointer to the target tag or destination address to which the read value is to be written.	
Valid	OUTPUT	BOOL	FALSE	TRUE	The read value is valid.
				FALSE	The read value is invalid.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

S7-1200 Motion Control V1...3 (Page 4165)

MC_WriteParam (S7-1200)

MC_WriteParam: Write tag of positioning axis V4...5 (S7-1200)

Description

Motion Control instruction "MC_WriteParam" enables the writing of tags of the positioning axis technology object in the user program. In contrast to the value assignment of the tags in the user program, "MC_WriteParam" can also change values of read-only tags.

You can learn about the tags, the conditions under which they can be written and the time at which they take effect in the description of the technology object tags (Page 6436).

Requirements

- The positioning axis technology object has been configured correctly.
- To write tags that are read-only in the user program, the axis must be disabled.

Override response

A MC_WriteParam command cannot be aborted by any other Motion Control command.

A new MC_WriteParam command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Parameter	INPUT	VARIANT (BOOL, INT, DINT, UDINT*, REAL) *) as of V5	-	VARIANT pointer to the technology object tag (Page 6436) positioning axis (destination address) to be written	
Value	INPUT	VARIANT (BOOL, INT, DINT, UDINT*, REAL) *) as of V5	-	VARIANT pointer to the value to be written (source address)	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Value was written
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

S7-1200 Motion Control V1...3 (S7-1200)

MC_Power (S7-1200)

MC_Power: Enable, disable axis V1...3 (S7-1200)

Description

The Motion Control instruction "MC_Power" enables or disables an axis.

Requirements

- The axis technology object has been configured correctly.
- There is no pending enable-inhibiting error.

Override response

Execution of "MC_Power" cannot be aborted by a Motion Control command.

Disabling the axis (input parameter "Enable" = FALSE) aborts all Motion Control commands for the associated technology object in accordance with the selected "StopMode".

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Enable	INPUT	BOOL	FALSE	TRUE	Motion Control attempts to enable the axis.
				FALSE	All current jobs are interrupted in accordance with the "StopMode" configured. The axis is stopped and disabled.
StopMode	INPUT	INT	0	0	Emergency stop If a request to disable the axis is pending, the axis brakes at the configured emergency stop deceleration. The axis is disabled after reaching standstill.
				1	Immediate stop If a request to disable the axis is pending, this axis is disabled without deceleration. The pulse output is stopped immediately.
				2	Emergency stop with jerk control If a request to disable the axis is pending, the axis brakes at the configured emergency stop deceleration. If the jerk control is activated, the configured jerk is taken into account. The axis is disabled after reaching standstill.

Parameter	Declaration	Data type	Default value	Description	
Status	OUTPUT	BOOL	FALSE	Status of axis enable	
				FALSE	The axis is disabled. The axis does not execute Motion Control commands and does not accept any new commands (exception: MC_Reset command). The axis is not homed. Upon disabling, the status does not change to FALSE until the axis reaches a standstill.
				TRUE	The axis is enabled. The axis is ready to execute Motion Control commands. Upon axis enabling, the status does not change to TRUE until the signal "Drive ready" is pending. If the "Drive ready" drive interface was not configured in the axis configuration, the status changes to TRUE immediately.
Busy	OUTPUT	BOOL	FALSE	TRUE	"MC_Power" is active.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred in Motion Control instruction "MC_Power" or in the associated technology object. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

If the axis is switched off due to an error, it will be enabled again automatically after the error has been eliminated and acknowledged. This requires that the input parameter "Enable" has retained the value TRUE during this process.

Enabling an axis with configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE.
   The enable output for "Drive enabled" changes to TRUE to enable the power to the drive.
   The CPU waits for the "Drive ready" signal of the drive.
   When the "Drive ready" signal is available at the configured Ready input of the CPU, the axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Enabling an axis without configured drive interface

To enable the axis, follow these steps:

1. Check the requirements indicated above.
2. Initialize input parameter "StopMode" with the desired value. Set the input parameter "Enable" to TRUE. The axis is enabled. The output parameter "Status" and the tag of the technology object <Axis name>.StatusBits.Enable indicate the value TRUE.

Disabling an axis

To disable an axis, you can follow the steps described below:

1. Bring the axis to a standstill.
   You can identify when the axis is at a standstill in the tag of the technology object <Axis name>.StatusBits.StandStill.
2. Set input parameter "Enable" to FALSE after standstill is reached.
3. If output parameters "Busy" and "Status" and the tag of technology object <Axis name>.StatusBits.Enable indicate the value FALSE, disabling of the axis is complete.

Function chart

①	An axis is enabled and then disabled again. When the drive has signaled "Drive ready" back to the CPU, the successful enable can be read out via "Status_1".
②	Following an axis enable, an error has occurred that caused the axis to be disabled. The error is eliminated and acknowledged with "MC_Reset". The axis is then enabled again.

See also

MC_Power: Enable, disable axis V1...3 (Page 4165)

MC_Reset (S7-1200)

MC_Reset: Acknowledge fault, restart technology object V1...3 (S7-1200)

Description

Motion Control instruction "MC_Reset" can be used to acknowledge "Operating error with axis stop" and "Configuration error". The errors that require acknowledgement can be found in the "List of ErrorIDs and ErrorInfos" under "Remedy".

From version V3.0, the axis configuration can be downloaded to the work memory in RUN operating mode.

Requirements

- The axis technology object has been configured correctly.
- The cause of a pending configuration error requiring acknowledgement has been eliminated (for example, acceleration in positioning axis technology object has been changed to a valid value).

Override response

The MC_Reset command cannot be aborted by any other Motion Control command.

The new MC_Reset command does not abort any other active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Restart	INPUT	BOOL	FALSE	(From version V3.0)	
				TRUE	Download the axis configuration from the load memory to the work memory. The command can only be executed when the axis is disabled. Refer to the notes on Download to the CPU (Page 6260).
				FALSE	Acknowledges pending errors
Done	OUTPUT	BOOL	FALSE	TRUE	Error has been acknowledged.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Acknowledging an error requiring acknowledgement with MC_Reset

To acknowledge an error, follow these steps:

1. Check the requirements indicated above.
2. Start the acknowledgement of the error with a rising edge at input parameter "Execute".
3. If output parameter "Done" indicates the value TRUE and tag of technology object <Axis name>.StatusBits.Error the value FALSE, the error has been acknowledged.

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 4192)

MC_Home (S7-1200)

MC_Home: Home axis, set home position V1...3 (S7-1200)

Description

Motion Control instruction "MC_Home" is used to match the axis coordinates to the real, physical drive position. Homing is required for absolute positioning of the axis. The following types of homing can be executed:

- Active homing (Mode = 3)
  The homing procedure is executed automatically.
- Passive homing (Mode = 2)
  During passive homing, the "MC_Home" Motion Control instruction does not carry out any homing motion. The traversing motion required for this must be implemented by the user via other Motion Control instructions. When the homing switch is detected, the axis is homed.

- Direct homing absolute (Mode = 0)
  The current axis position is set to the value of parameter "Position".
- Direct homing relative (Mode = 1)
  The current axis position is offset by the value of parameter "Position".

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.
- No MC_CommandTable command may be active upon start with Mode = 0, 1, or 2.

Override response

The override response depends on the selected mode:

Mode = 0, 1

The MC_Home command cannot be aborted by any other Motion Control command.

The MC_Home command does not abort any active Motion Control commands. Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 2

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 2, 3

The new MC_Home command aborts the following active Motion Control command:

- MC_Home command Mode = 2

Position-related motion commands are resumed after homing according to the new homing position (value at input parameter: "Position").

Mode = 3

The MC_Home command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Home command aborts the following active Motion Control commands:

- MC_Home command Mode = 2, 3
- MC_Halt command
- MC_MoveAbsolute command

- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	• Mode = 0, 2, and 3 Absolute position of axis after completion of the homing operation • Mode = 1 Correction value for the current axis position Limit values: -1.0E+12 ≤ Position ≤ 1.0E+12	
Mode	INPUT	INT	0	Homing mode	
				0	Direct homing absolute New axis position is the position value of parameter "Position".
				1	Direct homing relative New axis position is the current axis position + position value of parameter "Position".
				2	Passive homing Homing according to the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
				3	Active homing Homing procedure in accordance with the axis configuration. Following homing, the value of parameter "Position" is set as the new axis position.
Done	OUTPUT	BOOL	FALSE	TRUE	Command completed
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

Axis homing is lost under the following conditions:

- Disabling of axis by the "MC_Power" Motion Control instruction
- Changeover between automatic mode and manual control
- Upon start of active homing. After successful completion of the homing operation, axis homing is again available.
- After POWER OFF -> POWER ON of the CPU
- After CPU restart (RUN-STOP -> STOP-RUN)

Homing an axis

To home the axis, follow these stops:

1. Check the requirements indicated above.
2. Initialize the necessary input parameters with values, and start the homing operation with a rising edge at input parameter "Execute"
3. If output parameter "Done" and technology object tag <Axis name>.StatusBits.HomingDone indicate the value TRUE, homing is complete.

MC_Halt (S7-1200)

MC_Halt: Stop axis V1...3 (S7-1200)

Description

The "MC_Halt" Motion Control instruction stops all movements and brings the axis to a standstill with the configured deceleration. The standstill position is not defined.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_Halt command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_Halt command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Done	OUTPUT	BOOL	FALSE	TRUE	Zero velocity reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_Halt: Function chart V1...3 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is braked by an MC_Halt command until it comes to a standstill. The axis standstill is signaled via "Done_2".
②	While an MC_Halt command is braking the axis, this command is aborted by another motion command. The abort is signaled via "Abort_2".

MC_Halt: Stop axis V1...3 (Page 4174)

MC_MoveAbsolute (S7-1200)

MC_MoveAbsolute: Absolute positioning of axis V1...3 (S7-1200)

Description

The "MC_MoveAbsolute" Motion Control instruction starts an axis positioning motion to move it to an absolute position.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.
- The axis is homed.

Override response

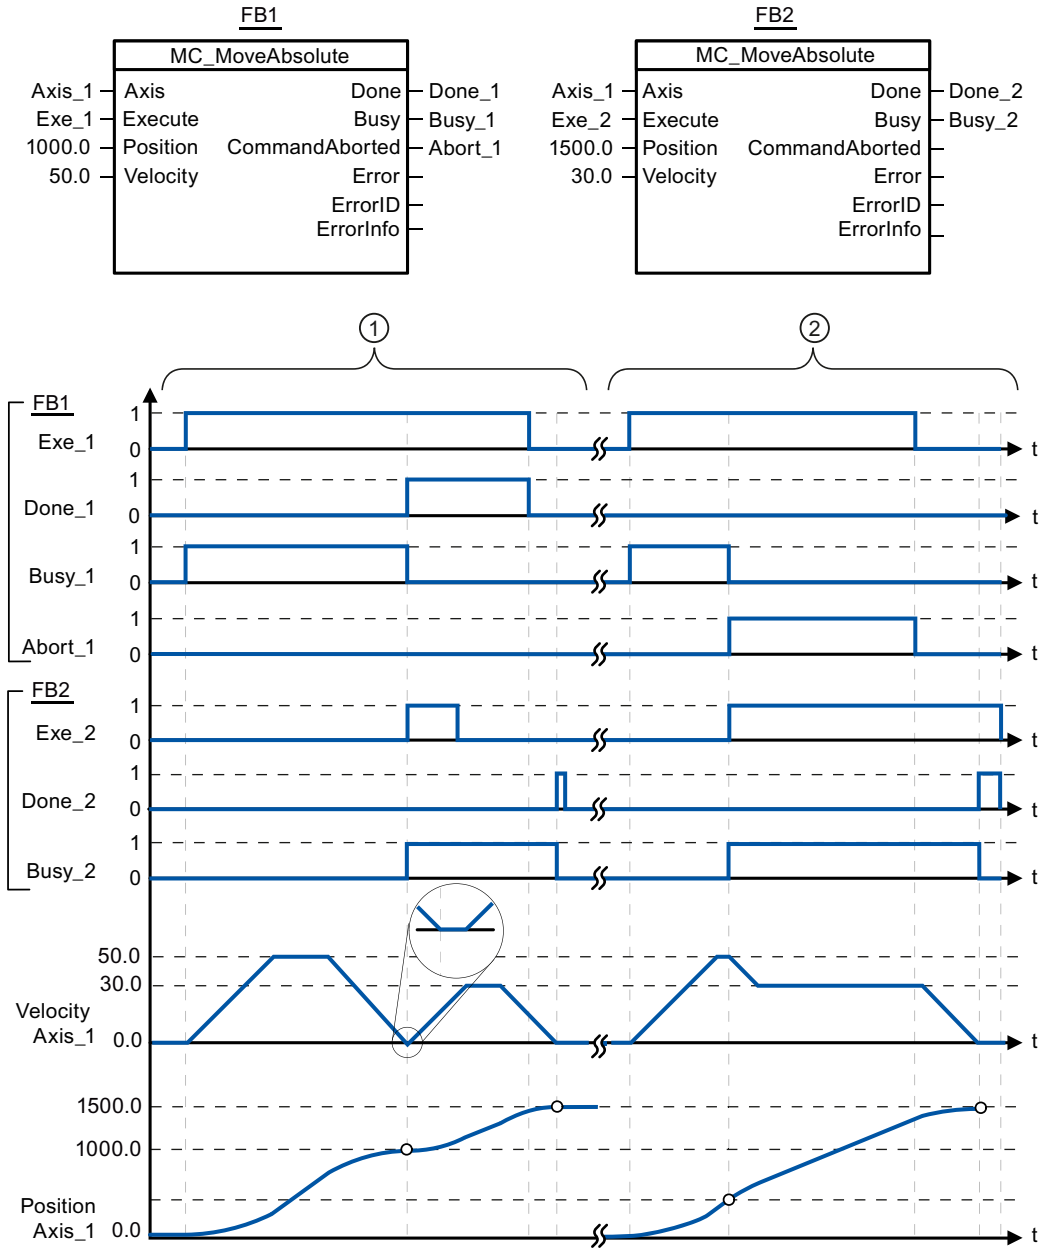
The MC_MoveAbsolute command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveAbsolute command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters



Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Position	INPUT	REAL	0.0	Absolute target position Limit values: $-1.0e^{12} \leq$ Position $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the target position to be approached. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Absolute target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 4192)

MC_MoveAbsolute: Function chart V1...3 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An axis is moved to absolute position 1000.0 with an MC_MoveAbsolute command. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveAbsolute command, with target position 1500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveAbsolute command is aborted by another MC_MoveAbsolute command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity to the new target position 1500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveAbsolute: Absolute positioning of axis V1...3 (Page 4177)

MC_MoveRelative (S7-1200)

MC_MoveRelative: Relative positioning of axis V1...3 (S7-1200)

Description

The "MC_MoveRelative" Motion Control instruction starts a positioning motion relative to the start position.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveRelative command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveRelative command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command

- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Distance	INPUT	REAL	0.0	Travel distance for the positioning operation Limit values: $-1.0e^{12} \leq$ Distance $\leq 1.0e^{12}$	
Velocity	INPUT	REAL	10.0	Velocity of axis This velocity is not always reached on account of the configured acceleration and deceleration and the distance to be traveled. Limit values: Start/stop velocity ≤ Velocity ≤ maximum velocity	
Done	OUTPUT	BOOL	FALSE	TRUE	Target position reached
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 4192)

MC_MoveRelative: Function chart V1...3 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	The axis is moved by an MC_MoveRelative command by the distance ("Distance") 1000.0. When the axis reaches the target position, this is signaled via "Done_1". When "Done_1" = TRUE, another MC_MoveRelative command, with travel distance 500.0, is started. Because of the response times (e.g., cycle time of user program, etc.), the axis comes to a standstill briefly (see zoomed-in detail). When the axis reaches the new target position, this is signaled via "Done_2".
②	An active MC_MoveRelative command is aborted by another MC_MoveRelative command. The abort is signaled via "Abort_1". The axis is then moved at the new velocity by the new distance ("Distance") 500.0. When the new target position is reached, this is signaled via "Done_2".

MC_MoveRelative: Relative positioning of axis V1...3 (Page 4180)

MC_MoveVelocity (S7-1200)

MC_MoveVelocity: Move axis at set velocity V1...3 (S7-1200)

Description

Motion control instruction "MC_MoveVelocity" moves the axis constantly at the specified velocity.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

MC_MoveVelocity can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveVelocity command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
Velocity	INPUT	REAL	10.0	Velocity specification for axis motion Limit values: Start/stop velocity ≤ |Velocity ≤ maximum velocity (Velocity = 0.0 is permitted)	
Direction	INPUT	INT	0	Direction specification	
				0	Direction of rotation corresponds to the sign of the value in parameter "Velocity"
				1	Positive direction of rotation (The sign of the value in parameter "Velocity" is ignored)
				2	Negative direction of rotation (The sign of the value in parameter "Velocity" is ignored)
Current	INPUT	BOOL	FALSE	Maintain current velocity	
				FALSE	"Maintain current velocity" is deactivated. The values of parameters "Velocity" and "Direction" are used.
				TRUE	"Maintain current velocity" is activated. The values in parameters "Velocity" and "Direction" are not taken into account. When the axis resumes motion at the current velocity, the "InVelocity" parameter returns the value TRUE.
InVelocity	OUTPUT	BOOL	FALSE	TRUE	• "Current" = FALSE: The velocity specified in parameter "Velocity" was reached. • "Current" = TRUE: The axis travels at the current velocity at the start time.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed

Parameter	Declaration	Data type	Default value	Description	
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Behavior with zero setpoint velocity (Velocity = 0.0)

An MC_MoveVelocity command with "Velocity" = 0.0 (such as an MC_Halt command) aborts active motion commands and stops the axis with the configured deceleration.

When the axis comes to a standstill, output parameter "InVelocity" indicates TRUE for at least one program cycle.

"Busy" indicates the value TRUE during the deceleration process and changes to FALSE together with "InVelocity". If parameter "Execute" = TRUE is set, "InVelocity" and "Busy" are latched.

When the "MC_MoveVelocity" command is started, status bit "SpeedCommand" is set in the technology object. Status bit "ConstantVelocity" is set upon axis standstill. Both bits are adapted to the new situation when a new motion command is started.

MC_MoveVelocity: Function chart V1...3 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 10.0

①	An active MC_MoveVelocity command signals via "InVel_1" that its target velocity has been reached. It is then aborted by another MC_MoveVelocity command. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.
②	An active MC_MoveVelocity command is aborted by another MC_MoveVelocity command prior to reaching its target velocity. The abort is signaled via "Abort_1". When the new target velocity 15.0 is reached, this is signaled via "InVel_2". The axis then continues moving at the new constant velocity.

MC_MoveVelocity: Move axis at set velocity V1...3 (Page 4183)

MC_MoveJog (S7-1200)

MC_MoveJog: Move axis in jog mode V1...3 (S7-1200)

Description

Motion control instruction "MC_MoveJog" moves the axis constantly at the specified velocity in jog mode. You use this Motion Control instruction, for example, for testing and commissioning purposes.

Requirements

- The axis technology object has been configured correctly.
- The axis is enabled.

Override response

The MC_MoveJog command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_MoveJog command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
JogForward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the positive direction at the velocity specified in parameter "Velocity".	
JogBackward	INPUT	BOOL	FALSE	As long as the parameter is TRUE, the axis moves in the negative direction at the velocity specified in parameter "Velocity".	
If both parameters are simultaneously TRUE, the axis stops with the configured deceleration. An error is indicated in parameters "Error", "ErrorID", and "ErrorInfo".					
Velocity	INPUT	REAL	10.0	Preset velocity for jog mode	
				Limit values, instruction version V1.0: Start/stop velocity ≤ |Velocity ≤ maximum velocity	
				Limits, instruction version V2.0: Start/stop velocity ≤ velocity ≤ maximum velocity	
InVelocity	OUTPUT	BOOL	FALSE	TRUE	The velocity specified in parameter "Velocity" was reached.
Busy	OUTPUT	BOOL	FALSE	TRUE	The command is being executed
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	During execution, the command was aborted by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"

MC_MoveJog: Function chart V1...3 (S7-1200)

Function chart

The following values were configured in the configuration window **Dynamics > General**:

- Acceleration: 10.0
- Deceleration: 5.0

①	The axis is moved in the positive direction in jog mode via "Jog_F". When the target velocity 50.0 is reached, this is signaled via "InVelo_1". After " Jog_F" is reset, the axis brakes again until it comes to a standstill.
②	The axis is moved in the negative direction in jog mode via "Jog_B". When the target velocity 50.0 is reached, this is signaled via "InVelo_1". After " Jog_B" is reset, the axis brakes again until it comes to a standstill.

MC_MoveJog: Move axis in jog mode V1...3 (Page 4187)

MC_CommandTable (S7-1200)

MC_CommandTable: Run axis commands as motion sequence V2...3 (S7-1200)

Description

The Motion Control instruction "MC_CommandTable" combines multiple individual axis control commands in one movement sequence.

Requirements

- The axis technology object has been inserted in V2 and correctly configured.
- The command table technology object has been inserted and correctly configured.
- The axis is enabled.

Override response

The MC_CommandTable command can be aborted by the following Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The new MC_CommandTable command aborts the following active Motion Control commands:

- MC_Home command Mode = 3
- MC_Halt command
- MC_MoveAbsolute command
- MC_MoveRelative command
- MC_MoveVelocity command
- MC_MoveJog command
- MC_CommandTable command

The active Motion Control command is cancelled by the start of the first "Positioning Relative", "Positioning Absolute", "Velocity set point" or "Halt" command.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
CommandTable	INPUT	TO_CommandTable_1	-	Command table technology object	
Execute	INPUT	BOOL	FALSE	Command table start with positive edge	
StartStep	INPUT	INT	1	Defines the step at which the execution of the command table should begin Limit values: 1 ≤ StartStep ≤ EndStep	
EndStep	INPUT	INT	32	Defines the step up to which the execution of command table should take place Limit values: StartStep ≤ EndStep ≤ 32	
Done	OUTPUT	BOOL	FALSE	TRUE	Command table has been successfully executed
Busy	OUTPU	BOOL	FALSE	TRUE	The command table is being executed.
CommandAborted	OUTPUT	BOOL	FALSE	TRUE	The command table was cancelled by another command.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command table. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	
CurrentStep	OUTPUT	INT	0	Step in command table currently being executed	
StepCode	OUTPUT	WORD	16#0000	User-defined numerical value / bit pattern of the step currently being executed

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (Page 4192)

MC_ChangeDynamic (S7-1200)

MC_ChangeDynamic: Change dynamic settings of axis V2...3 (S7-1200)

Description

Motion Control instruction "MC_ChangeDynamic" allows you to change the following settings of the axis:

- Change the ramp-up time (acceleration) value
- Change the ramp-down time (deceleration) value
- Change the emergency stop ramp-down time (emergency stop deceleration) value
- Change the smoothing time (jerk) value

For the effectiveness of the change, refer to the description of the tag (Page 6420).

Requirements

- The axis technology object has been inserted in Version V2.
- The axis technology object has been configured correctly.

Override response

A MC_ChangeDynamic command cannot be aborted by any other Motion Control command.

A new MC_ChangeDynamic command does not abort any active Motion Control commands.

Parameters

Parameter	Declaration	Data type	Default value	Description	
Axis	INPUT	TO_Axis_1	-	Axis technology object	
Execute	INPUT	BOOL	FALSE	Start of the command with a positive edge	
ChangeRampUp	INPUT	BOOL	FALSE	TRUE	Change ramp-up time in line with input parameter "RampUpTime"
RampUpTime	INPUT	REAL	5.00	Time (in seconds) to accelerate axis from standstill to configured maximum velocity without jerk limit. The change will influence the tag <Axis name>. Config.DynamicDefaults.Acceleration. For the effectiveness of the change, refer to the description of this tag.	
ChangeRampDown	INPUT	BOOL	FALSE	TRUE	Change ramp-down time in line with input parameter "RampDownTime"
RampDownTime	INPUT	REAL	5.00	Time (in seconds) to decelerate axis from the configured maximum velocity to standstill without jerk limiter. The change will influence the tag <Axis name>. Config.DynamicDefaults.Deceleration . For the effectiveness of the change, refer to the description of this tag.	

Parameter	Declaration	Data type	Default value	Description	
ChangeEmergency	INPUT	BOOL	FALSE	TRUE	Change emergency stop ramp-down time in line with input parameter "EmergencyRampTime"
EmergencyRampTime	INPUT	REAL	2.00	Time (in seconds) to decelerate the axis from configured maximum velocity to standstill without jerk limiter in emergency stop mode. The change will influence the tag <Axis name>. Config.DynamicDefaults.EmergencyDeceleration . For the effectiveness of the change, refer to the description of this tag.	
ChangeJerkTime	INPUT	BOOL	FALSE	TRUE	Change smoothing time according to the input parameter "JerkTime"
JerkTime	INPUT	REAL	0.25	Smoothing time (in seconds) used for the axis acceleration and deceleration ramps The change will influence the tag <Axis name>. Config.DynamicDefaults.Jerk . For the effectiveness of the change, refer to the description of this tag.	
Done	OUTPUT	BOOL	FALSE	TRUE	The changed values have been written to the technology data block. The description of the tags will show when the change becomes effective.
Error	OUTPUT	BOOL	FALSE	TRUE	An error occurred during execution of the command. The cause of the error can be found in parameters "ErrorID" and "ErrorInfo".
ErrorID	OUTPUT	WORD	16#0000	Error ID (Page 6386) for parameter "Error"	
ErrorInfo	OUTPUT	WORD	16#0000	Error info ID (Page 6386) for parameter "ErrorID"	

Note

At the input parameters "RampUpTime", "RampDownTime", "EmergencyRampTime" and "JerkTime", values can be entered which exceed the admissible limits of the resulting parameters: "Acceleration", "Deceleration", "Emergency stop deceleration" and "Jerk".

Please note the equations and limits in "Axis technology object" -> "Configuring the technology object" -> "Dynamics" and ensure that the values you input are within the valid range.

11.4.5.2 High-speed counters (S7-1200)

CTRL_HSC: Control high-speed counters (S7-1200)

Parameters

Parameter	Declaration	Data type	Memory area	Description
EN	INPUT	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	OUTPUT	BOOL	I, Q, M, D, L	Enable output
HSC	INPUT	HW_HSC	I, Q, M or constant	Hardware address of the high-speed counter (HW-ID)
DIR	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new count direction (see NEW_DIR)
CV	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new count value (see NEW_CV)
RV	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new reference value (see NEW_RV)
PERIOD	INPUT	BOOL	I, Q, M, D, L or constant	Enables the new period of a frequency measurement (see NEW_PERIOD)
NEW_DIR	INPUT	INT	I, Q, M, D, L or constant	Count direction loaded when DIR = TRUE.
NEW_CV	INPUT	DINT	I, Q, M, D, L or constant	Count value loaded when CV = TRUE.
NEW_RV	INPUT	DINT	I, Q, M, D, L or constant	Reference value loaded when RV = TRUE.
NEW_PERIOD	INPUT	INT	I, Q, M, D, L or constant	Period of the frequency measurement loaded when PERIOD = TRUE.
BUSY	OUTPUT	BOOL	I, Q, M, D, L	Processing status *
STATUS	OUTPUT	WORD	I, Q, M, D, L	Status of the operation

* With a high-speed counter in the CPU or in the signal board, the BUSY parameter always has the value 0.

Description

With the "Control high-speed counter" instruction, you can make parameter settings and control the high-speed counters supported by the CPU by loading new values into the counter. Execution of the instruction requires that a high-speed counter to be controlled is enabled. You cannot execute multiple "Control high-speed counter" instructions simultaneously in the program for a given high-speed counter.

You can load the following parameter values into a high-speed counter using the "Control high-speed counter" instruction:

- Count direction (NEW_DIR): The count direction defines whether a high-speed counter counts up or down. The count direction is defined by the following values at the NEW_DIR input: 1 = up, -1 = down.
  A change to the count direction with the "Control high-speed counter" instruction is only possible when direction control is set in the parameters by the program. The count direction specified at the NEW_DIR input is loaded into a high-speed counter when the bit at the DIR input is set.
- Count value (NEW_CV): The count value is the initial value at which a high-speed counter starts counting. The count value can be in the range -2147483648 to 2147483647.
  The count value specified at the NEW_CV input is loaded into a high-speed counter when the bit at the CV input is set.
- Reference value (NEW_RV): You can compare the reference value with the current counter value to trigger an alarm. Similar to the counter value, the reference value can be in the range -2147483648 to 2147483647.
  The reference value specified at the NEW_RV input is loaded into a high-speed counter when the bit at the RV input is set.
- Period of the frequency measurement (NEW_PERIOD): The period of the frequency measurement is specified by the following values at the NEW_PERIOD input: 10 = 0.01s, 100 = 0.1s, 1000 = 1s.
  The time period can be updated if the "Measure frequency" function for the specified high-speed counter is configured. The time period specified at the NEW_PERIOD input is loaded into a high-speed counter when the bit at the PERIOD input is set.

The "Control high-speed counter" instruction is only executed if the signal state at the EN input is "1".

The ENO enable output is set only when the EN enable input has signal state "1" and no errors occur during execution of the operation.

When inserting the "Control high-speed counter" instruction, an instance data block is created in which the operation data is saved.

STATUS parameter

At the STATUS output, you can query whether errors occurred during execution of the "Control high-speed counter" instruction. The following table shows the meaning of the values output at the STATUS output:

Error code (hexadecimal)	Description
0	No error
80A1	Hardware identifier of the high-speed counter invalid

Error code (hexadecimal)	Description
80B1	Count direction (NEW_DIR) invalid
80B2	Count value (NEW_CV) invalid
80B3	Reference value (NEW_RV) invalid
80B4	Period of the frequency measurement (NEW_PERIOD) invalid
80C0	Multiple access to the high-speed counter
80D0	The high-speed counter (HSC) is not enabled in the CPU hardware configuration.

CTRL_HSC_EXT: Control high-speed counter (extended) (S7-1200)

Parameters

Parameters	Declaration	Data type	Memory area	Description
EN	INPUT	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	OUTPUT	BOOL	I, Q, M, D, L	Enable output
HSC	INPUT	HW_HSC	I, Q, M or constant	Hardware address of the high-speed counter (HW-ID)
CTRL	INOUT	VARIANT	M, D	Use of a system data type (SDT)
DONE	OUTPUT	BOOL	I, Q, M, D, L	Feedback after successful processing instruction
BUSY	OUTPUT	BOOL	I, Q, M, D, L	Processing status
ERROR	OUTPUT	BOOL	I, Q, M, D, L	Feedback for faulty processing of the instruction
STATUS	OUTPUT	WORD	I, Q, M, D, L	Status of the operation

Description

With the "Control high-speed counter (extended)" instruction, you can control and assign parameters to the high-speed counters supported by the CPU via the software by loading new values into the counters. Execution of the instruction requires that a high-speed counter to be controlled is enabled. You cannot execute multiple "Control high-speed counter (extended)" instructions simultaneously in the program for a given high-speed counter.

The "Control high-speed counter (extended)" instruction is only executed if the signal state at the EN input is "1". As long as the operation is executing, the bit at the BUSY output is set. Once the operation has executed completely, the bit at the BUSY output is reset.

The ENO enable output is set only when the EN enable input has signal state "1" and no errors occur during execution of the operation.

When the "Control high-speed counter (extended)" instruction is inserted, an instance data block is created in which the operation data is saved.

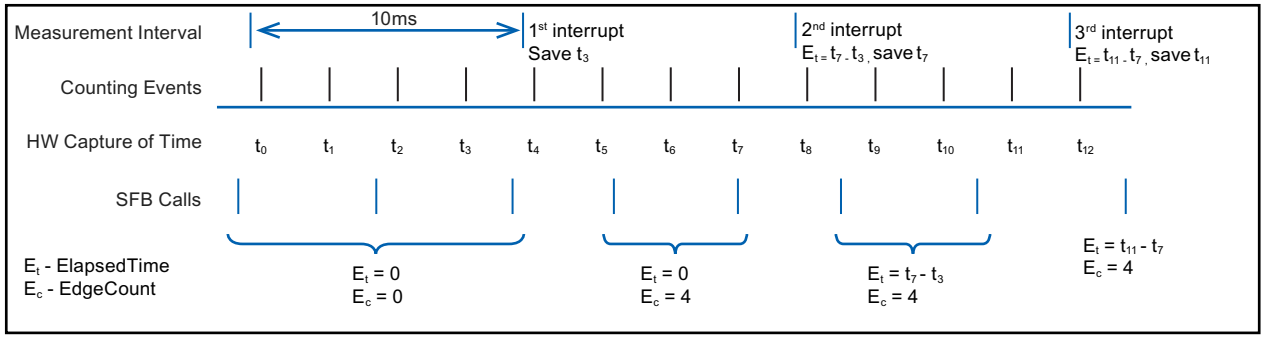
Using the system data type HSC_Period

The "Control high-speed counter (extended)" instruction supports the system data type SDT 381 "HSC_Period" for the period measurement.

The "HSC_Period" data type corresponds to an HSC that is configured for the "Period" operating mode. The CTRL_HSC_EXT instruction offers program access to the number of input pulses across a specified measuring interval. This instruction allows the calculation of the period between the input pulses with a resolution in the nanosecond range.

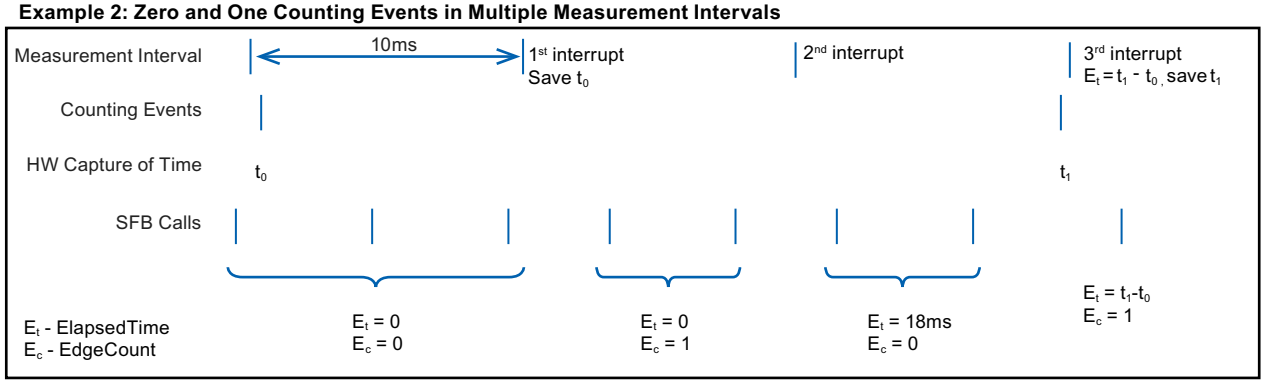
Byte	Parameters	Declaration	Data type	Description
0 … 3	Elapsed-Time	OUT	UDINT	Time between the rising edges of Edge_Count
4 … 7	EdgeCount	OUT	UDINT	Number of the rising edges within the Elapsed_Time. If Edge_Count = 0, the Elapsed_Time is the time since the last rising edge.
8.0	EnHSC	IN	BOOL	Use as an enable input via gate control: • FALSE: Measurement stopped • TRUE: Measurement enabled
8.6	EnPeriod	IN	BOOL	Update of the period • FALSE: No update • TRUE: Update period
10 .. . 11	NewPeriod	IN	INT	Interval of the period measurement in milliseconds. Permissible values are 10, 100 and 1000.

ElapsedTime specifies the time in nanoseconds between the last counter events of consecutive measuring intervals. If no counter events occurred during a measuring interval, ElapsedTime outputs the accumulated time since the last counter event. ElapsedTime has a range of 0 to 4,294,967,280 nanoseconds (0x0000 0000 to 0xFFFF FFF0). The return value 4,294,967,295 (0xFFFF FFFF) signals that a period overflow has occurred. An overflow indicates that the period between two pulse edges exceeds 4.295 seconds and that the period cannot be calculated with this instruction. The values from 0xFFFF FFF1 to 0xFFFF FFFE are reserved.



EdgeCount outputs the number of counter events received during the measuring interval. The period can only be calculated if the value of EdgeCount is greater than zero. If ElapsedTime is either 0 (no input pulses received) or OR 0xFFFF FFFF (period overflow), EdgeCount is not valid.

If EdgeCount is valid, calculate the period in nanoseconds by using the following formula: Period = ElapsedTime/EdgeCount



The calculated period value is a mean value from time periods of all the pulses that occur during the measuring interval. If the period of an incoming pulse is greater than the measuring interval (10, 100 or 1000 ms), the period calculation requires several measuring intervals.

The following figures show examples of the period measurement with the instruction:

Example 1: Multiple Counting Events in a Measurement Interval

Example 2: Zero and One Counting Events in Multiple Measurement Intervals

Rules:
1. If $E1_t = 0$, the period is invalid
2. Else, Period = E_t / E_c

STATUS parameter

At the STATUS output, you can query whether errors occurred during execution of the "Control high-speed counter (extended)" instruction. The following table shows the meaning of the values output at the STATUS output:

Error code (hexadecimal)	Description
0	No error
80A1	Hardware identifier of the high-speed counter invalid
80C0	Multiple access to the high-speed counter
80D0	The high-speed counter (HSC) is not enabled in the CPU hardware configuration.

11.4.5.3 PID Control (S7-1200, S7-1500)

PID_Compact (S7-1200, S7-1500)

New features of PID_Compact (S7-1200, S7-1500)

PID_Compact V2.3

- **Response of the output value when switching from "Inactive" operating mode to "Automatic mode"**
  The new option IntegralResetMode = 4 was added and defined as default. With IntegralResetMode = 4, the integral action is automatically pre-assigned when switching from "Inactive" operating mode to "Automatic mode" so that a control deviation results in a jump of the output value with identical sign.
- **Initialization of the integral action in automatic mode**
  The integral action can be initialized in automatic mode with the tags OverwriteInitialOutputValue and PIDCtrl.PIDInit. This simplifies the use of PID_Compact for override controls.

PID_Compact V2.2

- **Use with S7-1200**
  As of PID_Compact V2.2, the instruction with V2 functionality can also be used on S7-1200 with firmware version 4.0 or higher.

PID_Compact V2.0

- **Reaction to error**
  The reaction to error has been completely overhauled. PID_Compact now reacts in a more fault-tolerant manner in the default setting. This reaction is set when copying PID_Compact V1.X from an S7-1200 CPU to an S7-1500 CPU.

NOTICE
Your system may be damaged. If you use the default setting, PID_Compact remains in automatic mode when the process value limits are exceeded. This may damage your system. It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

  The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. Use ErrorAck to acknowledge the errors and warnings without restarting the controller or clearing the integral action. Switching operating modes no longer clears errors that are no longer pending.
  You can configure the reaction to error with SetSubstituteOutput and ActivateRecoverMode.
- **Substitute output value**
  You can configure a substitute output value that is to be output if an error occurs.

- **Switching the operating mode**
  You specify the operating mode at the Mode in/out parameter and use a rising edge at ModeActivate to start the operating mode. The sRet.i_Mode tag has been omitted.
- **Multi-instance capability**
  You can call up PID_Compact as multi-instance DB. No technology object is created in this case and no parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Compact directly in the multi-instance DB and commission it via a watch table.
- **Startup characteristics**
  The operating mode specified at the Mode parameter is also started on a falling edge at Reset and during a CPU cold restart, if RunModeByStartup = TRUE.
- **ENO characteristics**
  ENO is set depending on the operating mode.
  If State = 0, then ENO = FALSE.
  If State ≠ 0, then ENO = TRUE.
- **Setpoint value specification during tuning**
  You configure the permitted fluctuation of the setpoint during tuning at the CancelTuningLevel tag.
- **Value range for output value limits**
  The value 0.0 no longer has to fall within the output value limits.
- **Pre-assigning the integral action**
  Using the tags IntegralResetMode and OverwriteInitialOutputValue, you can determine the pre-assignment of the integral action when switching from "Inactive" operating mode to "Automatic mode".
- **Switching a disturbance variable on**
  You can switch a disturbance variable on at the Disturbance parameter.
- **Default value of PID parameters**
  The following default settings have been changed:
  - Proportional action weighting (PWeighting) from 0.0 to 1.0
  - Derivative action weighting (DWeighting) from 0.0 to 1.0
  - Coefficient for derivative delay (TdFiltRatio) from 0.0 to 0.2
- **Renaming tags**
  The static tags have been given new names that are compatible with PID_3Step.

PID_Compact V1.2

- **Manual mode on CPU startup**
  If ManualEnable = TRUE when the CPU starts, PID_Compact starts in manual mode. A rising edge at ManualEnable is not necessary.
- **Pretuning**
  If the CPU is switched off during pretuning, pretuning starts again when the CPU is switched back on.

PID_Compact V1.1

- **Manual mode on CPU startup**
  When the CPU starts up, PID_Compact only switches to manual mode with a rising edge at ManualEnable. Without rising edge, PID_Compact starts in the last operating mode in which ManualEnable was FALSE.
- **Reaction to reset**
  A rising edge at Reset resets the errors and warnings and clears the integral action. A falling edge at Reset triggers a switchover to the most recently active operating mode.
- **Default of process value high limit**
  The default value of r_Pv_Hlm has been changed to 120.0.
- **Monitoring the sampling time**
  - An error is no longer output when the current sampling time is ≥ 1.5 x current mean value or when the current sampling time is ≤ 0.5 x current mean value. The sampling time may deviate much more in automatic mode.
  - PID_Compact is compatible with FW, V2.0 or higher.
- **Access to tags**
  The following tags can now be used in the user program.
  - i_Event_SUT
  - i_Event_TIR
  - r_Ctrl_Ioutv
- **Troubleshooting**
  PID_Compact now outputs the correct pulses when the shortest ON time is not equal to the shortest OFF time.

Compatibility with CPU and FW (S7-1200, S7-1500)

The following table shows which version of PID_Compact can be used on which CPU.

CPU	FW	PID_Compact
S7-1200	V4.2 or higher	V2.3 V2.2 V1.2
	V4.0 to V4.1	V2.2 V1.2
	V3.x	V1.2 V1.1
	V2.x	V1.2 V1.1
	V1.x	V1.0

CPU	FW	PID_Compact
S7-1500	V2.0 or higher	V2.3 V2.2 V2.1 V2.0
	V1.5 to V1.8	V2.2 V2.1 V2.0
	V1.1	V2.1 V2.0
	V1.0	V2.0

CPU processing time and memory requirement PID_Compact V2.x (S7-1200, S7-1500)

CPU processing time

Typical CPU processing times of the PID_Compact technology object as of Version V2.0, depending on CPU type.

CPU	Typ. CPU processing time PID_Compact V2.x
CPU 1211C ≥ V4.0	300 µs
CPU 1215C ≥ V4.0	300 µs
CPU 1217C ≥ V4.0	300 µs
CPU 1505S ≥ V1.0	45 µs
CPU 1510SP-1 PN ≥ V1.6	85 µs
CPU 1511-1 PN ≥ V1.5	85 µs
CPU 1512SP-1 PN ≥ V1.6	85 µs
CPU 1516-3 PN/DP ≥ V1.5	50 µs
CPU 1518-4 PN/DP ≥ V1.5	4 µs

Memory requirement

Memory requirement of an instance DB of the PID_Compact technology object as of Version V2.0.

	Memory requirement of the instance DB of PID_Compact V2.x
Load memory requirement	Approx. 12000 bytes
Total work memory requirement	788 bytes
Retentive work memory requirement	44 bytes

PID_Compact V2 (S7-1200, S7-1500)

Description of PID_Compact V2 (S7-1200, S7-1500)

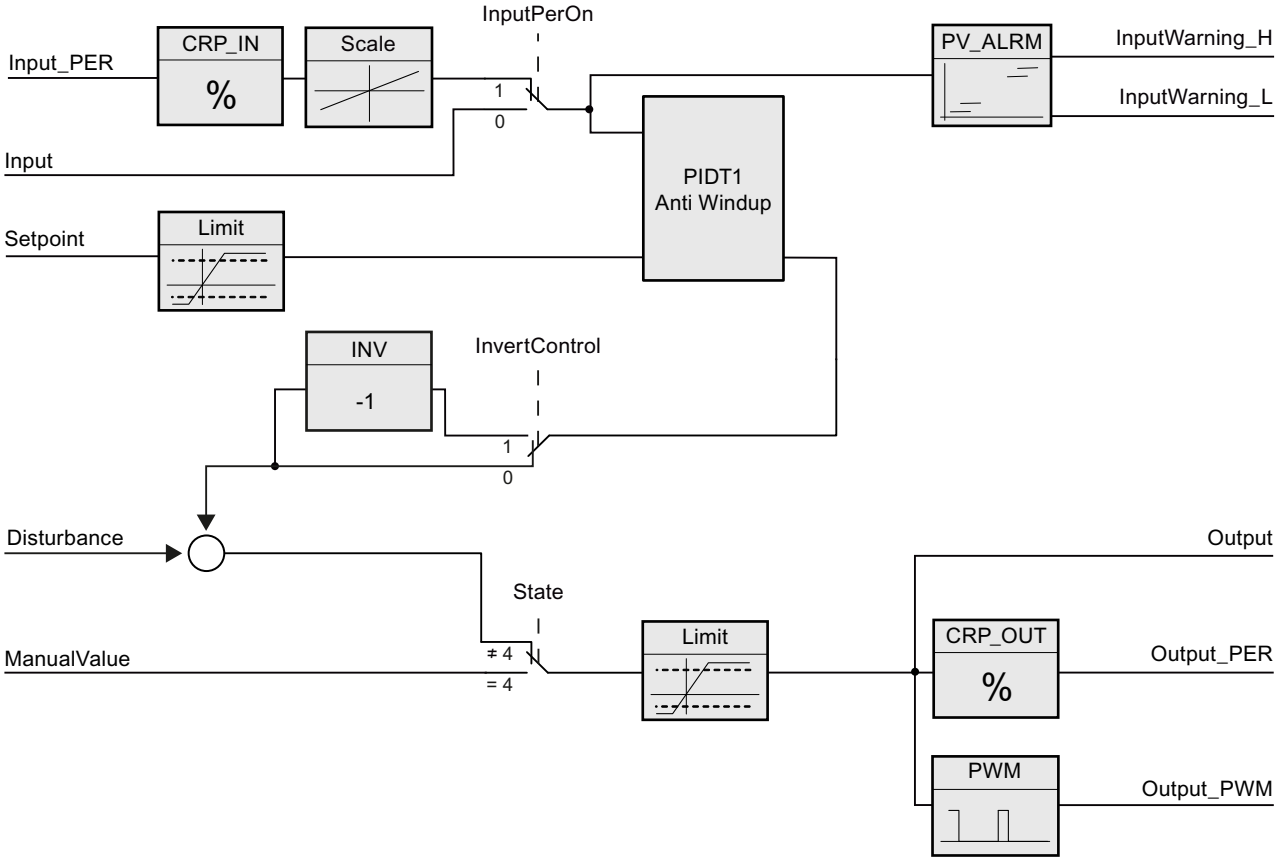
Description

The PID_Compact instruction provides a PID controller with integrated tuning for actuators with proportional action.

The following operating modes are possible:

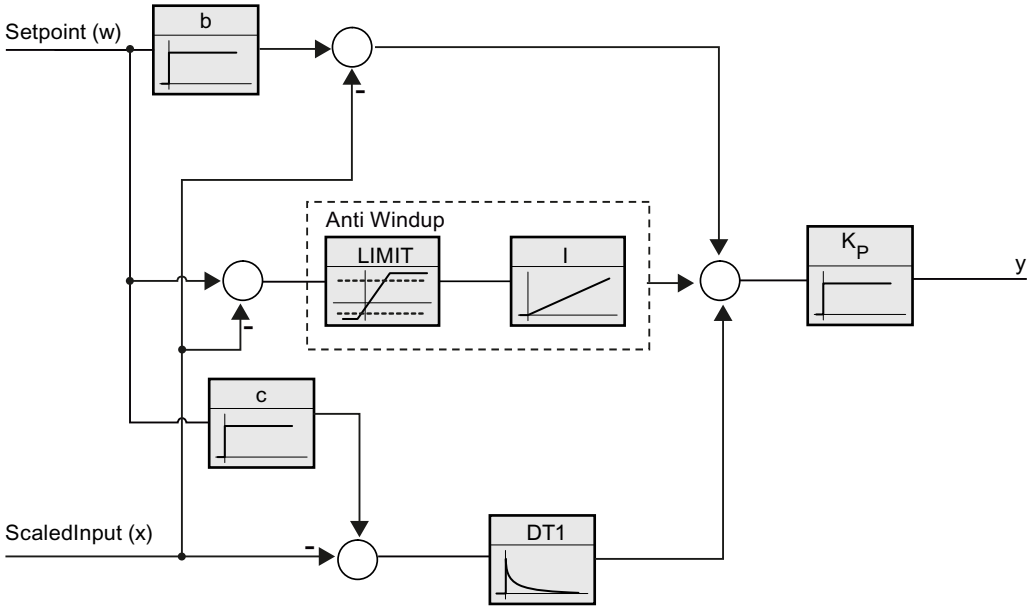
- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Substitute output value with error monitoring

For a more detailed description of the operating modes, see the State parameter.



PID algorithm

PID_Compact is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation:



$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value of the PID algorithm
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
T_D	Derivative action time
a	Derivative delay coefficient (derivative delay T1 = a × T_D)
c	Derivative action weighting

Block diagram of PID_Compact

Block diagram of PIDT1 with anti-windup

Call

PID_Compact is called in the constant time scale of a cycle interrupt OB.

If you call PID_Compact as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Compact directly in the multi-instance DB and commission it via a watch table.

Download to device

The actual values of retentive variables are only updated when you download PID_Compact completely.

Downloading technology objects to device (Page 6000)

Startup

When the CPU starts up, PID_Compact starts in the operating mode that is saved in the Mode in/out parameter. To switch to "Inactive" operating mode during startup, set RunModeByStartup = FALSE.

Reaction to error

In automatic mode and during commissioning, the reaction to error depends on the SetSubstituteOutput and ActivateRecoverMode variables. In manual mode, the reaction is independent of SetSubstituteOutput and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the reaction additionally depends on the error that occurred.

SetSubstituteOutput	ActivateRecoverMode	Configuration editor > output value > Set Output to	Reaction
Not relevant	FALSE	Zero (inactive)	Switch to "Inactive" mode (State = 0) The value 0.0 0 is transferred to the actuator.
FALSE	TRUE	Current output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The current output value is transferred to the actuator while the error is pending.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The value at SubstituteOutput is transferred to the actuator while the error is pending.

In manual mode, PID_Compact uses ManualValue as output value, unless ManualValue is invalid. If ManualValue is invalid, SubstituteOutput is used. If ManualValue and SubstituteOutput are invalid, Config.OutputLowerLimit is used.

The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

Mode of operation of PID_Compact V2 (S7-1200, S7-1500)

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warning = 0040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_Compact automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_Compact checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit tags. Output, ManualValue and SubstituteOutput are limited to these values. The output value limits must match the control logic.

The valid output value limit values depend on the Output used.

Output	-100.0 to 100.0%
Output_PER	-100.0 to 100.0%
Output_PWM	0.0 to 100.0%

Rule:

OutputUpperLimit > OutputLowerLimit

Note

Use with two or more actuators

PID_Compact is not suitable for use with two or more actuators (for example, in heating/cooling applications), because different actuators need different PID parameters to achieve a good control response. Use PID_Temp for applications with two actuators acting in opposite directions.

Substitute output value

In the event of an error, PID_Compact can output a substitute output value that you define at the SubstituteOutput tag. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- Input
- Input_PER
- Disturbance
- ManualValue
- SubstituteOutput
- Output
- Output_PER
- Output_PWM

Monitoring of the sampling time PID_Compact

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_Compact instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (Error = 0800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_Compact in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_Compact are executed at every call.

If you use Output_PWM, the accuracy of the output signal is determined by the ratio of the PID algorithm sampling time to the cycle time of the OB. The cycle time should be at least 10 times the PID algorithm sampling time.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_Compact does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Input parameters of PID_Compact V2 (S7-1200, S7-1500)

Table 11-67

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A tag of the user program is used as source for the process value. If you are using parameter Input, then Config.InputPerOn = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using parameter Input_PER, then Config.InputPerOn = TRUE must be set.
Disturbance	REAL	0.0	Disturbance variable or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "manual mode", while State = 4, Mode remains unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using ModeActivate only.
ManualValue	REAL	0.0	Manual value This value is used as the output value in manual mode. Values from Config.OutputLowerLimit to Config.OutputUpperLimit are permitted.
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.

Parameter	Data type	Default	Description
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warnings are reset. • As long as Reset = TRUE, – PID_Compact remains in "Inactive" mode (State = 0). – You cannot change the operating mode with Mode and ModeActivate or ManualEnable. – You cannot use the commissioning dialog. • TRUE -> FALSE edge – If ManualEnable = FALSE, PID_Compact switches to the operating mode that is saved in Mode. – If Mode = 3, the integral action is treated as configured with the tag IntegralResetMode.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_Compact switches to the operating mode that is saved in the Mode parameter.

Output parameters of PID_Compact V2 (S7-1200, S7-1500)

Table 11-68

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
The "Output", "Output_PER", and "Output_PWM" outputs can be used concurrently.			
Output	REAL	0.0	Output value in REAL format
Output_PER	INT	0	Analog output value
Output_PWM	BOOL	FALSE	Pulse-width-modulated output value The output value is formed by by variable On and Off times.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit). The setpoint is limited to Config.SetpointUpperLimit .
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached (Setpoint ≤ Config.SetpointLowerLimit). The setpoint is limited to Config.SetpointLowerLimit .
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.

Parameter	Data type	Default	Description
State	INT	0	The State parameter (Page 4219) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Substitute output value with error monitoring
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 4223) shows which error messages are pending. ErrorBits is retentive and is reset upon a rising edge at Reset or ErrorAck.

In/out parameters of PID_Compact V2 (S7-1200, S7-1500)

Table 11-69

Parameter	Data type	Default	Description
Mode	INT	4	At Mode, specify the operating mode to which PID_Compact is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE Mode is retentive. A detailed description of the operating modes can be found in Parameters State and Mode V2 (Page 4219).

Parameters State and Mode V2 (Page 4219)

Static tags of PID_Compact V2 (S7-1200, S7-1500)

You must not change tags that are not listed. These are used for internal purposes only.

Tag	Data type	Default	Description
IntegralResetMode	INT	Up to V2.2: 1, V2.3 or higher: 4	The IntegralResetMode V2 tag (Page 4227) determines how the integral actionPIDCtrl.IntegralSum is pre-assigned when switching from "Inactive" operating mode to "Automatic mode". This setting only works for one cycle. Options are: • IntegralResetMode = 0: Smooth • IntegralResetMode = 1: Delete • IntegralResetMode = 2: Hold • IntegralResetMode = 3: Pre-assign • IntegralResetMode = 4: Like setpoint change (only for PID_Compact with version ≥ 2.3)
OverwriteInitialOutputValue	REAL	0.0	If one of the following conditions is met, the integral action PIDCtrl.IntegralSum is pre-assigned automatically as if Output = OverwriteInitialOutputValue in the previous cycle: • IntegralResetMode = 3 when switching from "Inactive" operating mode to "Automatic mode". • TRUE -> FALSE edge at parameter Reset and parameter Mode = 3 • PIDCtrl.PIDInit = TRUE in "Automatic mode" (available as of PID_Compact version 2.3)
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart If RunModeByStartup = TRUE, PID_Compact starts in the operating mode saved in the Mode parameter after CPU startup. If RunModeByStartup = FALSE, PID_Compact remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., °C, or °F.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.
ActivateRecoverMode	BOOL	TRUE	The Tag ActivateRecoverMode V2 (Page 4225) determines the reaction to error.
Warning	DWORD	0	Tag Warning V2 (Page 4227) shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive.
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)
CurrentSetpoint	REAL	0.0	CurrentSetpoint always displays the current setpoint. This value is frozen during tuning.

Tag	Data type	Default	Description
CancelTuningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel
SubstituteOutput	REAL	0.0	Substitute output value When the following conditions are met, the substitute output value is used: • An error has occurred in automatic mode. • SetSubstituteOutput = TRUE • ActivateRecoverMode = TRUE
SetSubstituteOutput	BOOL	TRUE	If SetSubstituteOutput = TRUE and ActivateRecoverMode = TRUE, the substitute output value configured is output as long as an error is pending. If SetSubstituteOutput = FALSE and ActivateRecoverMode = TRUE, the actuator remains at the current output value as long as an error is pending. If ActivateRecoverMode = FALSE, SetSubstituteOutput is not effective. If SubstituteOutput is invalid (ErrorBits = 20000h), the substitute output value cannot be output.
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). This pre-assignment ensures that an error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_Compact reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. InputLowerLimit < InputUpperLimit

Tag	Data type	Default	Description
Config.InputUpperWarning	REAL	3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit OutputUpperLimit > OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value For Output and Output_PER, the range of values from -100.0 to +100.0, including zero, is valid. At -100.0, Output_PER = -27648; at +100.0, Output_PER = 27648. For Output_PWM, the value range 0.0 to +100.0 applies. The output value limits must match the control logic. OutputLowerLimit < OutputUpperLimit
Config.SetpointUpperLimit	REAL	3.402822e+38	High limit of setpoint If you configure SetpointUpperLimit outside the process value limits, the configured process value absolute high limit is used as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.
Config.MinimumOnTime	REAL	0.0	The minimum ON time of the pulse width modulation in seconds is rounded to MinimumOnTime = n×CycleTime.Value
Config.MinimumOffTime	REAL	0.0	The minimum OFF time of the pulse width modulation in seconds is rounded to MinimumOffTime = n×CycleTime.Value

Tag	Data type	Default	Description
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to percent based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn.
CycleTime.StartEstimation	BOOL	TRUE	If CycleTime.StartEstimation = TRUE, the automatic determination of the cycle time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, the PID_Compact sampling time is calculated. If CycleTime.EnEstimation = FALSE, the PID_Compact sampling time is not calculated and you need to correct the configuration of CycleTime.Value manually.
CycleTime.EnMonitoring	BOOL	TRUE	If CycleTime.EnMonitoring = FALSE, the PID_Compact sampling time is not monitored. If it is not possible to execute PID_Compact within the sampling time, no error (ErrorBits=0800h) is output and PID_Compact does not switch to "Inactive" mode.
CycleTime.Value	REAL	0.1	PID_Compact sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.
CtrlParamsBackUp.Ti	REAL	20.0	Saved integral action time [s]
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time [s]
CtrlParamsBackUp.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	1.0	Saved proportional action weighting factor
CtrlParamsBackUp.DWeighting	REAL	1.0	Saved derivative action weighting factor
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm

Tag	Data type	Default	Description
PIDSelfTune.SUT.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If SUT.CalculateParams = TRUE, the parameters for pretuning are recalculated according to these properties. This enables you to change the parameter calculation method without having to repeat controller tuning. SUT.CalculateParams is set to FALSE after the calculation.
PIDSelfTune.SUT.TuneRule	INT	0	Methods used to calculate parameters during pretuning: • SUT.TuneRule = 0: PID according to Chien, Hrones and Reswick • SUT.TuneRule = 1: PI according to Chien, Hrones and Reswick
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 100: Calculate the standard deviation • State = 200: Find the point of inflection • State = 9900: Pretuning successful • State = 1: Pretuning not successful
PIDSelfTune.TIR.RunIn	BOOL	FALSE	With the RunIn tag, you can specify that fine tuning can also be performed without pretuning. • RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If the requirements for pretuning are not met, PID_Compact reacts as if RunIn = TRUE. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_Compact switches to the mode from which tuning was started. • RunIn = TRUE The pretuning is skipped. PID_Compact tries to reach the setpoint with minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If TIR.CalculateParams = TRUE, the parameters for fine tuning are recalculated according to these properties. This enables you to change the parameter calculation method without having to repeat controller tuning. TIR.CalculateParams is set to FALSE after the calculation.

Tag	Data type	Default	Description
PIDSelfTune.TIR.TuneRule	INT	0	Methods used to calculate parameters during fine tuning: • TIR.TuneRule = 0: PID automatic • TIR.TuneRule = 1: PID fast • TIR.TuneRule = 2: PID slow • TIR.TuneRule = 3: Ziegler-Nichols PID • TIR.TuneRule = 4: Ziegler-Nichols PI • TIR.TuneRule = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of fine tuning: • State = -100 Fine tuning is not possible. Pretuning will be performed first. • State = 0: Initialize fine tuning • State = 200: Calculate the standard deviation • State = 300: Attempt to reach setpoint • State = 400: Attempt to reach setpoint with existing PID parameters (if pretuning was successful) • State = 500: Determine oscillation and calculate parameters • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
PIDCtrl.IntegralSum	REAL	0.0	Current integral action
PIDCtrl.PIDInit	BOOL	FALSE	PIDCtrl.PIDInit is available as of PID_Compact version 2.3. If PIDCtrl.PIDInit = TRUE in "Automatic mode", the integral action PIDCtrl.IntegralSum is pre-assigned automatically as if Output = OverwriteInitialOutputValue in the previous cycle. This can be used for a Override control with PID_Compact V2 (Page 6040).
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain To invert the control logic, use the Config.InvertControl tag. Negative values at Gain also invert the control logic. We recommend you use only InvertControl to set the control logic. The control logic is also inverted if InvertControl = TRUE and Gain < 0.0. Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• CtrlParams.Ti > 0.0: Active integral action time • CtrlParams.Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• CtrlParams.Td > 0.0: Active derivative action time • CtrlParams.Td = 0.0: Derivative action is deactivated Td is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.TdFiltRatio	REAL	0.2	Active derivative delay coefficient The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with **one** dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	1.0	Active proportional action weighting The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. PWeighting is retentive.
Retain.CtrlParams.DWeighting	REAL	1.0	Active derivative action weighting The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of the PID algorithm CtrlParams.Cycle is calculated during tuning and rounded to an integer multiple of CycleTime.Value. CtrlParams.Cycle is used as time period of the pulse width modulation. Cycle is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

Parameters State and Mode V2 (S7-1200, S7-1500)

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_Compact switches to the operating mode saved in the Mode in-out parameter.

When the CPU is switched on or switches from Stop to RUN mode, PID_Compact starts in the operating mode that is saved in the Mode parameter. To leave PID_Compact in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State / Mode	Description of operating mode
0	Inactive In "Inactive" operating mode, the output value 0.0 is always output, regardless of Config.OutputUpperLimit and Config.OutputLowerLimit. Pulse width modulation is off.
1	Pretuning The pretuning determines the process response to a jump change of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. Pretuning requirements: • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * | Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. The controller switches to automatic mode following successful pretuning. If pretuning is unsuccessful, the switchover of the operating mode is dependent on ActivateRecoverMode. The phase of pretuning is indicated with PIDSelfTune.SUT.State.

State / Mode	Description of operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are recalculated based on the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Compact automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. Requirements for fine tuning: • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_Compact controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) If the requirements for pretuning are met, pretuning is started. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If the process value for pretuning is already too near the setpoint or PIDSelfTune.TIR.RunIn = TRUE, an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. The controller switches to automatic mode following successful fine tuning. If fine tuning is unsuccessful, the switchover of the operating mode is dependent on ActivateRecoverMode. The "Fine tuning" phase is indicated with PIDSelfTune.TIR.State.
3	Automatic mode In automatic mode, PID_Compact corrects the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State / Mode	Description of operating mode
4	Manual mode In manual mode, you specify a manual output value in the ManualValue parameter. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. Manual mode is also possible when an error is pending.
5	Substitute output value with error monitoring The control algorithm is deactivated. The SetSubstituteOutput tag determines which output value is output in this operating mode. • SetSubstituteOutput = FALSE: Last valid output value • SetSubstituteOutput = TRUE: Substitute output value You cannot activate this operating mode using Mode = 5. In the event of an error, it is activated instead of "Inactive" operating mode if all the following conditions are met: • Automatic mode (Mode = 3) • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode is effective. As soon as the errors are no longer pending, PID_Compact switches back to automatic mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_Compact automatically switches the operating mode in the event of an error. The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started

Cycle no.	Mode	State	Action
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. At the start of pretuning or fine tuning, PID_Compact has saved the value of State in the Mode in/out parameter. PID_Compact therefore switches to the operating mode from which tuning was started.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode.

See also

Output parameters of PID_Compact V2 (Page 4209)

Parameter ErrorBits V2 (S7-1200, S7-1500)

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0003h, for example, indicates that the errors 0001h and 0002h are pending simultaneously.

In manual mode, PID_Compact uses ManualValue as output value. The exception is Errorbits = 10000h.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0004	Error during fine tuning. Oscillation of the process value could not be maintained. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0008	Error at start of pretuning. The process value is too close to the setpoint. Start fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact remains in fine tuning mode.
0080	Error during pretuning. The output value limits are not configured correctly or the actual value does not react as expected. Check whether the limits of the output value are configured correctly and match the control logic. Also make sure that the actual value does not oscillate strongly before starting pretuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_Compact cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
0800	Sampling time error: PID_Compact is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter. If this error occurred during simulation with PLCSIM, see the notes under Simulating PID_Compact V2 with PLCSIM (Page 6044).
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact outputs the configured substitute output value. As soon as the error is no longer pending, PID_Compact switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Compact switches to the operating mode that is saved in the Mode parameter.
10000	Invalid value at ManualValue parameter. Value has an invalid number format. If ActivateRecoverMode = TRUE before an error occurred, PID_Compact uses SubstituteOutput as the output value. As soon as you specify a valid value in ManualValue, PID_Compact uses it as the output value.

ErrorBits (DW#16#...)	Description
20000	Invalid value at SubstituteOutput tag. Value has an invalid number format. PID_Compact uses the output value low limit as the output value. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_Compact switches back to automatic mode.
40000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_Compact remains in automatic mode. If pretuning or fine tuning mode was active and ActivateRecoverMode = TRUE before the error occurred, PID_Compact switches to the operating mode saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled.

Tag ActivateRecoverMode V2 (S7-1200, S7-1500)

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

Automatic mode

NOTICE
Your system may be damaged. If ActivateRecoverMode = TRUE, PID_Compact remains in automatic mode even if there is an error and the process limit values are exceeded. This may damage your system. It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

ActivateRecoverMode	Description
FALSE	PID_Compact automatically switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_Compact switches between the calculated output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more of the following errors occur, PID_Compact stays in automatic mode: • 0001h: The "Input" parameter is outside the process value limits. • 0800h: Sampling time error • 40000h: Invalid value at parameter Disturbance. If one or more of the following errors occur, PID_Compact switches to "Substitute output value with error monitoring" mode: • 0002h: Invalid value at Input_PER parameter. • 0200h: Invalid value at Input parameter. • 0400h: Calculation of output value failed. • 1000h: Invalid value at Setpoint parameter. If the following error occurs, PID_Compact switches to "Substitute output value with error monitoring" mode and moves the actuator to Config.OutputLowerLimit: • 20000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This characteristics are independent of SetSubstituteOutput. As soon as the errors are no longer pending, PID_Compact switches back to automatic mode.

Pretuning and fine tuning

ActivateRecoverMode	Description
FALSE	PID_Compact automatically switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If the following error occurs, PID_Compact remains in the active mode: • 0020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 10000h: Invalid value at ManualValue parameter. • 20000h: Invalid value at SubstituteOutput tag. When any other error occurs, PID_Compact cancels the tuning and switches to the mode from which tuning was started.

Manual mode

ActivateRecoverMode is not effective in manual mode.

Tag Warning V2 (S7-1200, S7-1500)

If several warnings are pending simultaneously, the values of the Warning tag are displayed with binary addition. The display of warning 0003h, for example, indicates that the warnings 0001h and 0002h are pending simultaneously.

Warning (DW#16#....)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the TIR.TuneRule = 3 method.
0010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The specified rule for tuning is not supported. No PID parameters are calculated.
1000	The substitute output value cannot be reached because it is outside the output value limits.

The following warnings are deleted as soon as the cause is eliminated:

- 0001h
- 0004h
- 0008h
- 0040h
- 0100h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

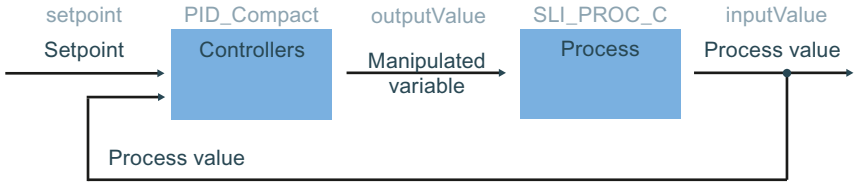
IntegralResetMode V2 tag (S7-1200, S7-1500)

The IntegralResetMode tag determines how the integral action PIDCtrl.IntegralSum is pre-assigned:

- When switching from "Inactive" operating mode to "Automatic mode"
- With edge TRUE -> FALSE at parameter Reset and parameter Mode = 3

This setting only works for one cycle and is only effective if the integral action is activated (Retain.CtrlParams.Ti > 0.0 tag).

IntegralReset-Mode	Description
0	Smooth The value of PIDCtrl.IntegralSum is pre-assigned so that the switchover is bumpless, which means "Automatic mode" starts with the output value = 0.0 (parameter Output) and there is no jump of the output value regardless of the control deviation (setpoint – actual value).
1	Delete We recommend setting the weighting of the proportional action (Retain.CtrlParams.PWeighting) to 1.0 if this option is used. The value of PIDCtrl.IntegralSum is deleted. Any control deviation will cause a jump change of the output value. The direction of the output value jump depends on the configured weighting of the proportional action (Retain.CtrlParams.PWeighting tag) and the control deviation: • Proportional action weighting = 1.0: Output value jump and control deviation have identical signs. Example: If the actual value value is smaller than the setpoint (positive control deviation), the output value jumps to a positive value. • Proportional action weighting < 1.0: For large control deviations, the output value jump and control deviation have identical signs. Example: If the actual value is much smaller than the setpoint (positive control deviation), the output value jumps to a positive value. For small control deviations, the output value jump and control deviation have different signs. Example: If the actual value value is just below the setpoint (positive control deviation), the output value jumps to a negative value. This is usually not desirable, because it results in a temporary increase in the control deviation. The smaller the configured weighting of the proportional action, the greater the control deviation must be to receive an output value jump with identical sign. We recommend setting the weighting of the proportional action (Retain.CtrlParams.PWeighting) to 1.0 when this option is used. Otherwise, you may experience the undesirable behavior described for small control deviations. Alternatively, you can also use IntegralResetMode = 4. This option guarantees identical signs of the output value jump and control deviation independent of the configured weighting of the proportional action and the control deviation.
2	Hold The value of PIDCtrl.IntegralSum is not changed. You can define a new value using the user program.
3	Pre-assign The value of PIDCtrl.IntegralSum is automatically pre-assigned as if Output = OverwriteInitialOutputValue in the last cycle.
4	Like setpoint change (only for PID_Compact with version ≥ 2.3) The value of PIDCtrl.IntegralSum is automatically pre-assigned so that a similar output value jump results as for a PI controller in automatic mode in case of a setpoint change from the current actual value to the current setpoint. Any control deviation will cause a jump of the output value. Output value jump and control deviation have identical signs. Example: If the actual value value is smaller than the setpoint (positive control deviation), the output value jumps to a positive value. This is independent of the configured weighting of the proportional action and the control deviation.



If IntegralResetMode is assigned a value outside the valid value range, PID_Compact behaves as with the pre-assignment of IntegralResetMode:

- PID_Compact up to V2.2: IntegralResetMode = 1
- PID_Compact V2.3 and higher: IntegralResetMode = 4

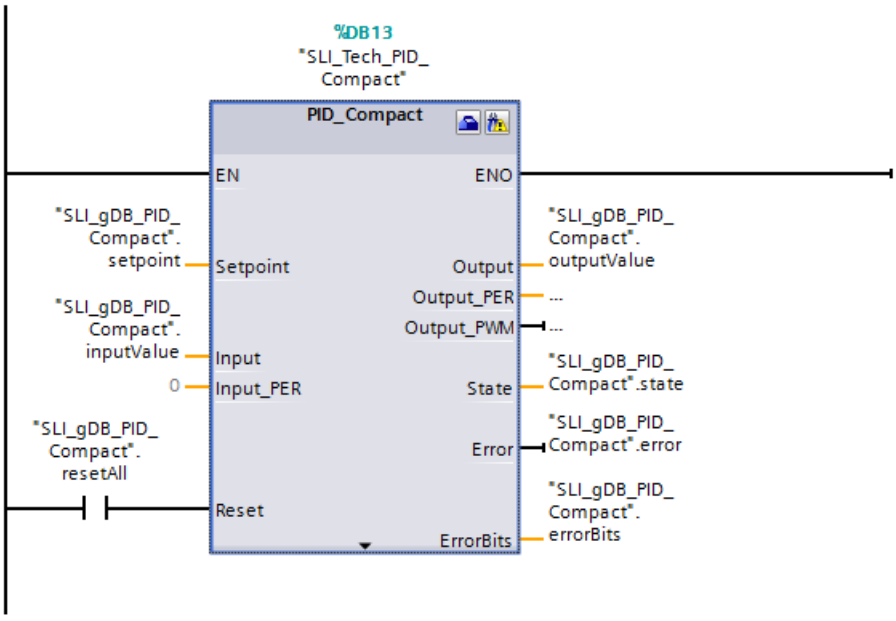
All statements made above regarding the sign of the output value jump are based on a normal control logic (Config.InvertControl = FALSE tag). With an inverted control logic (Config.InvertControl = TRUE), the output value jump will have a reverse sign.

Sample program for PID_Compact (S7-1200, S7-1500)

In the following example, you are controlling temperature values with the technology object of the instruction "PID_Compact". The temperature values are simulated based on a block which simulates a delay element of the third order (PT3 element). The PID parameters of the technology object can be set automatically via the pretuning.

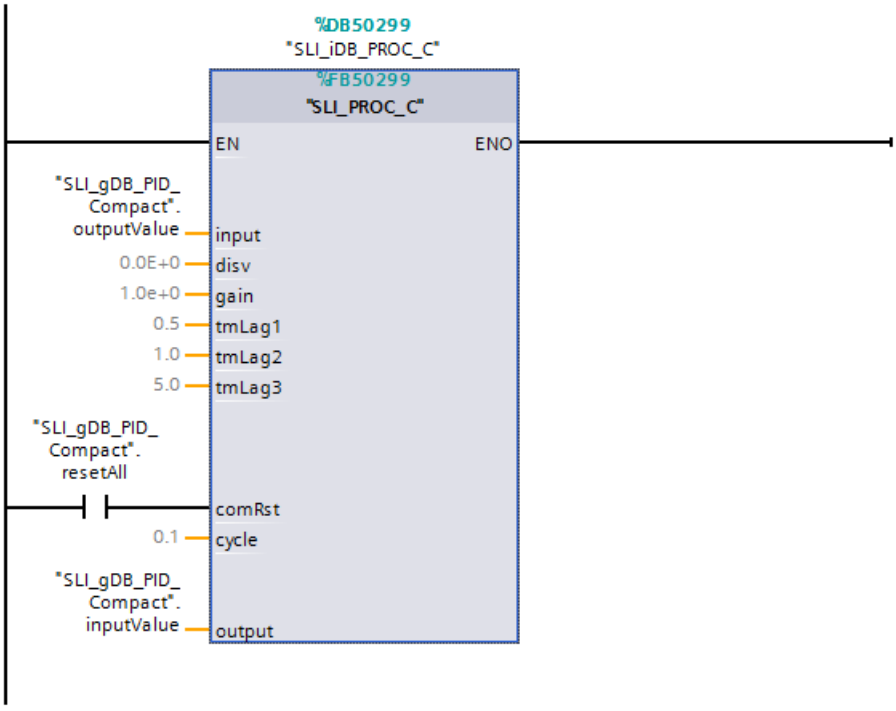
Data storage

Create seven tags in a global data block for storage of the interconnection data.



SLI_gDB_PID_Compact

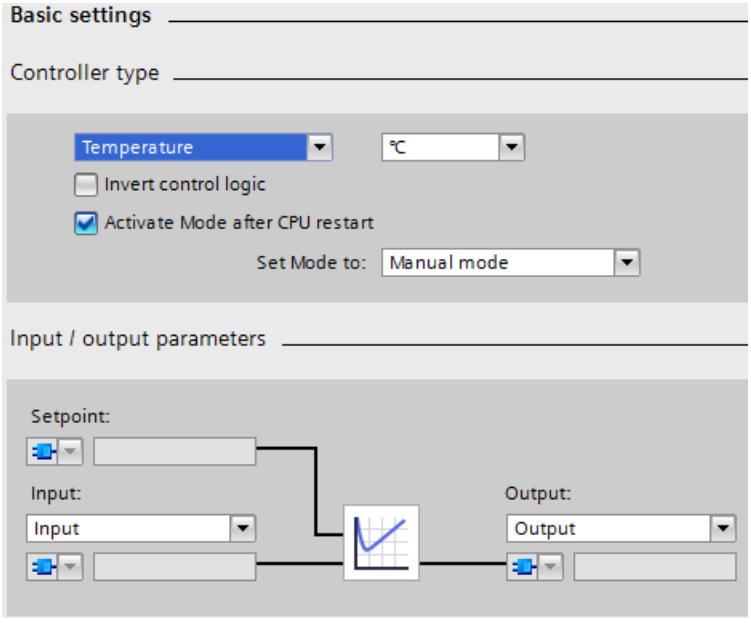
		Name	Data type	Start value
1		Static		
2		setpoint	Real	75.0
3		inputValue	Real	0.0
4		outputValue	Real	0.0
5		state	Int	0
6		error	Bool	false
7		errorBits	DWord	16#0
8		resetAll	Bool	false



Interconnection of the parameters

You call the following interconnections in a cyclic interrupt OB.

Network 1: You interconnect the parameters of the instruction "PID_Compact" as follows.



Network 2: You interconnect the parameters of the block simulating the temperature values "SLI_PROC_C" as follows.

Technology object

You configure the technology object with the properties of the instruction "PID_Compact" or by using the path Technology object > Configuration. The controller type and the input/output parameters are important for the example. With the controller type, you make a preselection for the unit of the value to the controlled. In this example, "Temperature" with the unit "°C" is used as controller type. The parameters of the "PID_Compact" are already interconnected with global tags. Therefore, the information on use of the parameters Input and Output is sufficient.

Procedure for starting the control

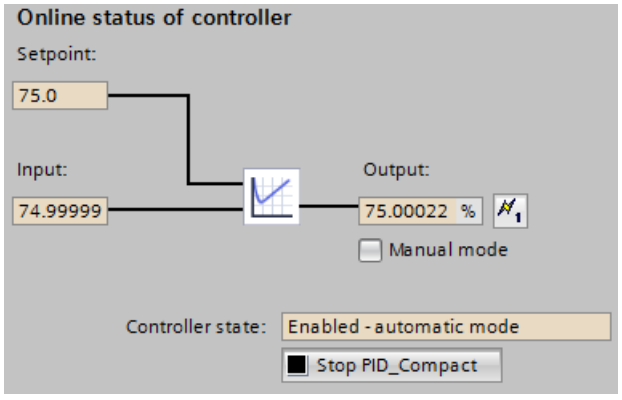
After the download to the CPU the PID_Compact is in manual mode with manual value 0.0. To start the control, follow these steps:

1. Open the Commissioning of the technology object "SLI_Tech_PID_Compact".
2. Click the "Start" button in the "Measurement" area.

Measurement starts and PID_Compact can be activated.

3. Pretuning is selected.
   Click the "Start" button in the "Tuning mode" area.
   A pretuning is performed. The PID parameters are automatically adjusted to the process. After the completion of the pretuning PID_Compact switches to automatic mode.

Note



Alternative to start PID_Compact

Alternatively, you can switch PID_Compact to automatic mode in the "Online status of controller" area with the "Stop PID_Compact" / "Start PID_Compact" without pretuning. In this case the controller uses default values for the PID parameters and shows a worse controller behavior for the application case.

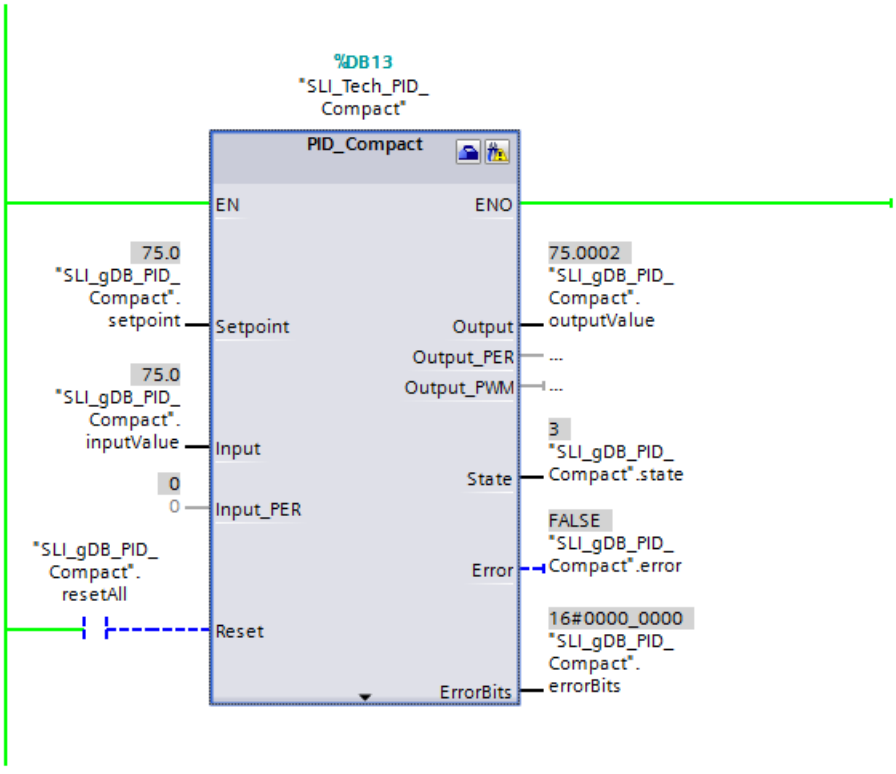
Procedure for stopping control

To stop and exit PID_Compact and the program, follow these steps:

1. Click the "Stop PID_Compact" button in the technology object "SLI_Tech_PID_Compact" in the "Online status of controller" area.

The instruction "PID_Compact" exits the control and outputs the value "0.0" as manipulated variable.

2. Click the "Stop" button in the "Measurement" area.
3. To set the process value immediately to the value "0.0", follow these steps:
   In the block "SLI_OB_PID_Compact", set the "resetAll" tag to the value "TRUE", and then to the value "FALSE".



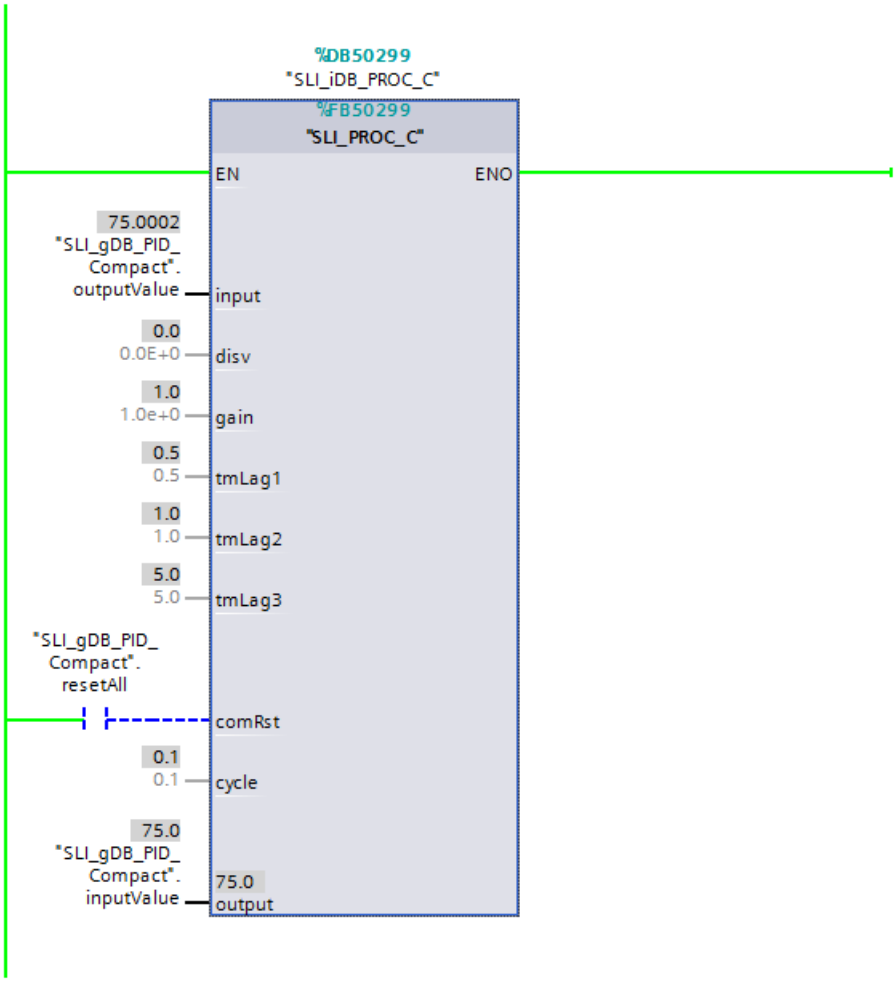
"PID_Compact" instruction

The setpoint for the temperature that is to be controlled is specified at the parameter Setpoint ("setpoint"). The control is started when the instruction "PID_Compact" was started with the technology object. The instruction "PID_Compact" outputs a manipulated variable at the output parameter Output ("outputValue"). The process value of the temperature is transferred to the instruction "PID_Compact" with the input parameter Input ("inputValue").

The instruction "PID_Compact" adjusts the manipulated variable ("outputValue") depending on the history of the difference between setpoint ("setpoint") and process value ("inputValue") . The process is repeated so that the process value ("inputValue") approaches the setpoint ("setpoint") through the manipulated variable ("outputValue").

The current operating mode of the instruction "PID_Compact" is displayed at the output parameter State ("state"). After pretuning (the value of "state" is "1"), the PID_Compact switches to automatic mode (the value is "3").

The output parameter Error ("error") currently shows that no error is pending. The output parameter ErrorBits ("errorBits") provides information on the error type in case of error. If an error occurs, this can be acknowledged in the technology object, in the optimization status area with the "ErrorAck" button.



"SLI_PROC_C" block

The "SLI_PROC_C" block simulates the process value ("inputValue") of the rising temperature of a plant. The block "SLI_PROC_C" contains the manipulated variable of the controller ("outputValue) and simulates the temperature behavior of the process. This temperature is fed as process value ("inputValue") into the controller.

A change in the values of the "resetAll" tag (of the comRst parameter) has the following effects:

Parameter comRst ("resetAll")	The instruction "PID_Compact" is running	The instruction "PID_Compact" was stopped
comRst ("resetAll") remains set to the value "FALSE"	The "SLI_PROC_C" block outputs a new process value ("inputValue") based on a manipulated variable ("outputValue").	The "SLI_PROC_C" block does not receive a manipulated variable > "0.0", but it still outputs a new process value > "0.0".
comRst ("resetAll"): Change from "FALSE" to the value "TRUE"	Both manipulated variable ("outputValue") and output process value ("inputValue") are reset to "0.0".	The output process value ("inputValue") / the temperature of the "SLI_PROC_C" block is reset to "0.0".
comRst ("resetAll"): Change from "TRUE" to the value "FALSE"	Temperature control starts again.	The output process value / the temperature ("inputValue") remains "0.0".

Program code

You can find additional information about the program code for the above-named example under the keyword "Sample Library for Instructions".

PID_Compact V1 (S7-1200)

Description of PID_Compact V1 (S7-1200)

Description

The PID_Compact instruction provides a PID controller with integrated tuning for automatic and manual mode.

Call

PID_Compact is called in the constant interval of the cycle time of the calling OB (preferably in a cyclic interrupt OB).

Download to device

The actual values of retentive tags are only updated when you download PID_Compact completely.

Downloading technology objects to device (Page 6000)

Startup

At the startup of the CPU, PID_Compact starts in the operating mode that was last active. To retain PID_ Compact in "Inactive" mode, set sb_RunModeByStartup = FALSE.

Monitoring of the sampling time PID_Compact

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_Compact instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. If the current sampling time deviates too much from this mean value, Error = 0800 hex occurs and PID_Compact switches to "Inactive" mode.

PID_Compact, Version 1.1 or higher is set to "Inactive" mode during controller tuning under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

In automatic mode, PID_Compact, Version 1.1 or higher, is set to "Inactive" mode under the following conditions:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

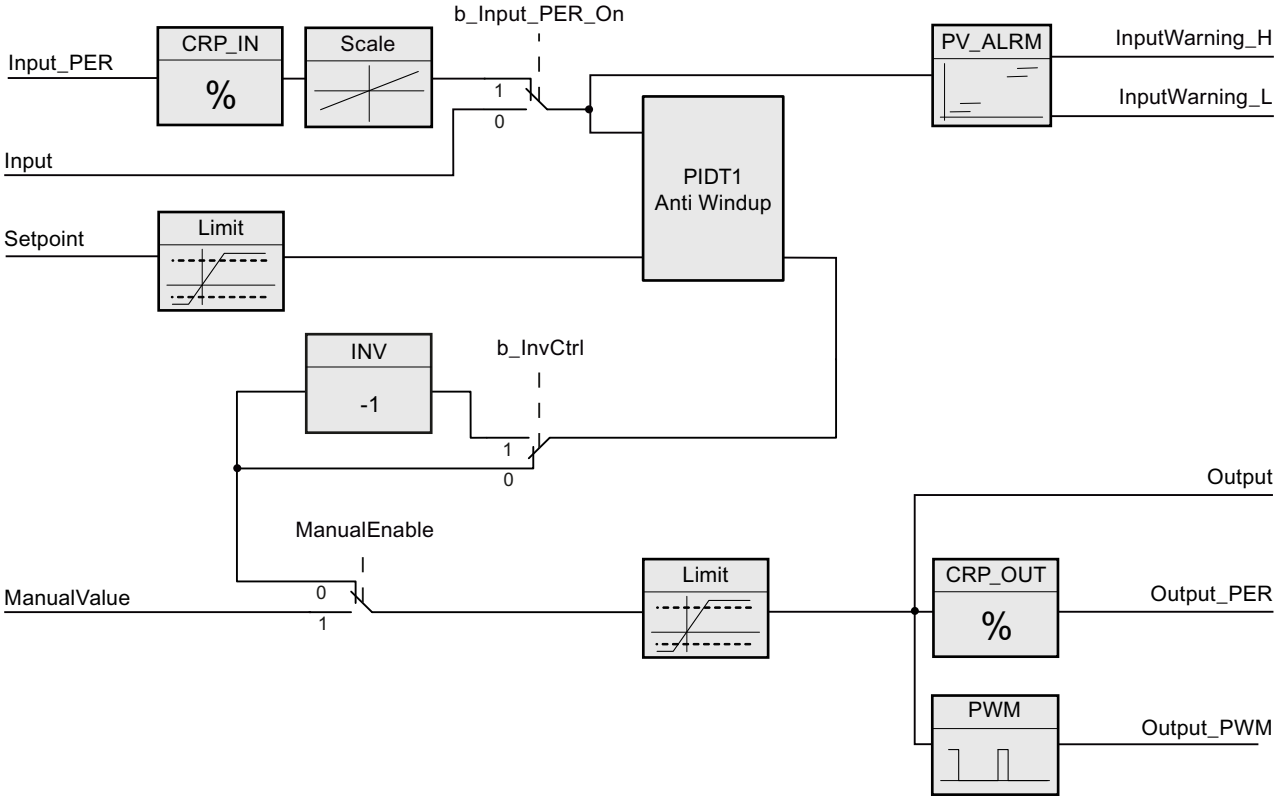
During controller tuning and in automatic mode, PID_Compact 1.0 is set to "Inactive" operating mode under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

- Current sampling time >= 1.5 x current mean value
- Current sampling time <= 0.5 x current mean value

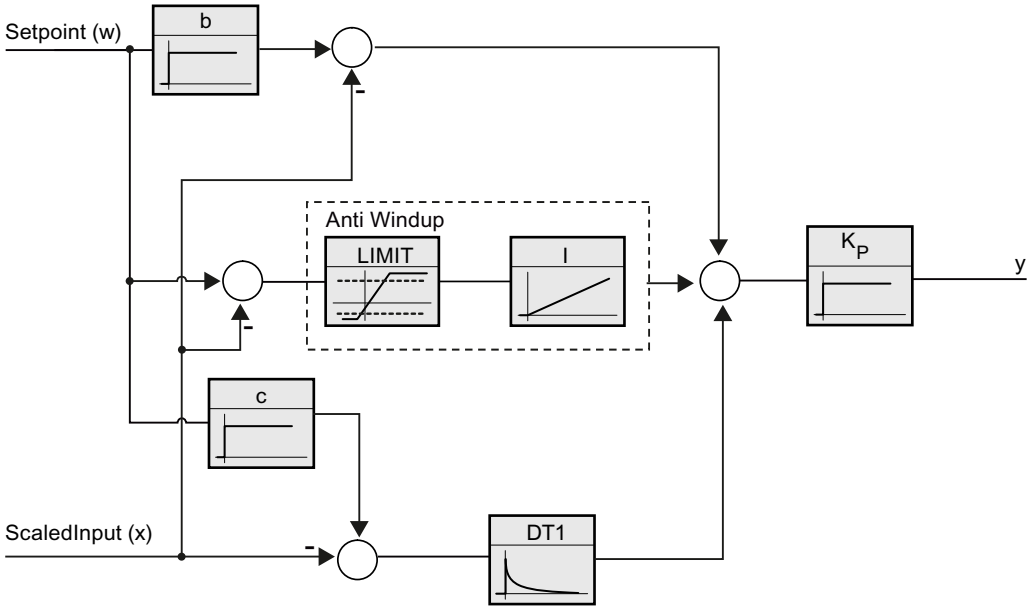
Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_Compact are executed at every call.



PID algorithm

PID_Compact is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The following equation is used to calculate the output value.



$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
a	Derivative delay coefficient (T1 = a × T_D)
	Derivative action time
c	Derivative action weighting

Block diagram of PID_Compact

Block diagram of PIDT1 with anti-windup

Reaction to error

If errors occur, they are output in parameter Error, and PID_Compact changes to "Inactive" mode. Reset the errors using the Reset parameter.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_Compact does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Control mode V1 (Page 6045)

Input parameters of PID_Compact V1 (S7-1200)

Table 11-70

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A variable of the user program is used as source for the process value. If you are using parameter Input, then sPid_Cmpt.b_Input_PER_On = FALSE must be set.
Input_PER	WORD	W#16#0	Analog input as the source of the process value If you are using parameter Input_PER, then sPid_Cmpt.b_Input_PER_On = TRUE must be set.
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge selects "Manual mode", while State = 4, sRet.i_Mode remains unchanged. • A TRUE -> FALSE edge selects the most recently active operating mode, State =sRet.i_Mode A change of sRet.i_Mode will not take effect during ManualEnable = TRUE. The change of sRet.i_Mode will only be considered upon a TRUE -> FALSE edge at ManualEnable . **PID_Compact V1.2 und PID_Compact V1.0** If at start of the CPU ManualEnable = TRUE, PID_Compact starts in manual mode. A rising edge (FALSE > TRUE) at ManualEnable is not necessary. **PID_Compact V1.1** At the start of the CPU, PID_Compact only switches to manual mode with a rising edge (FALSE->TRUE) at ManualEnable . Without rising edge, PID_Compact starts in the last operating mode in which ManualEnable was FALSE.
ManualValue	REAL	0.0	Manual value This value is used as the output value in manual mode.
Reset	BOOL	FALSE	The Reset parameter (Page 4248) restarts the controller.

Output parameters of PID_Compact V1 (S7-1200)

Table 11-71

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Output of the scaled process value
Outputs "Output", "Output_PER", and "Output_PWM" can be used concurrently.			
Output	REAL	0.0	Output value in REAL format
Output_PER	WORD	W#16#0	Analog output value
Output_PWM	BOOL	FALSE	Pulse-width-modulated output value The output value is formed by minimum On and Off times.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the setpoint absolute high limit is reached. The setpoint in the CPU is limited to the configured setpoint absolute high limit. The configured process value absolute high limit is the default for the setpoint high limit. If you set sPid_Cmpt.r_Sp_Hlm to a value within the process value limits, this value is used as the setpoint high limit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the setpoint absolute low limit has been reached. In the CPU, the setpoint is limited to the configured setpoint absolute low limit. The configured process value absolute low limit is the default setting for the setpoint low limit. If you set sPid_Cmpt.r_Sp_Llm to a value within the process value limits, this value is used as the setpoint low limit.
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.
State	INT	0	The State parameter (Page 4244) shows the current operating mode of the PID controller. To change the operating mode, use variable sRet.i_Mode. • State = 0: Inactive • State = 1: pretuning • State = 2: fine tuning • State = 3: Automatic mode • State = 4: Manual mode
Error	DWORD	W#16#0	The Error parameter (Page 4247) indicates the error messages. Error = 0000: No error pending.

Static tags of PID_Compact V1 (S7-1200)

You must not change tags that are not listed. These are used for internal purposes only.

Table 11-72

Tag	Data type	Default	Description
sb_GetCycleTime	BOOL	TRUE	If sb_GetCycleTime = TRUE, the automatic determination of the cycle time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
sb_EnCyclEstimation	BOOL	TRUE	If sb_EnCyclEstimation = TRUE, the PID_Compact sampling time is not monitored.
sb_EnCyclMonitoring	BOOL	TRUE	If sb_EnCyclMonitoring = FALSE, the PID_Compact sampling time is not monitored. If it is not possible to execute PID_Compact within the sampling time, an 0800 error is not output and PID_Compact does not change to "Inactive" mode.
sb_RunModeByStartup	BOOL	TRUE	Activate Mode after CPU restart If sb_RunModeByStartup = FALSE, the controller will remain inactive after a CPU startup. After a CPU startup and if sb_RunModeByStartup = TRUE, the controller will return to the most recently active operating mode.
si_Unit	INT	0	Unit of measurement of the process value and setpoint, e.g., ºC, or ºF.
si_Type	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.
sd_Warning	DWORD	DW#16#0	Variable sd_warning (Page 4250) displays the warnings generated since the reset, or since the last change of the operating mode.
sBackUp.r_Gain	REAL	1.0	Saved proportional gain You can reload values from the sBackUp structure with sPid_Cmpt.b_LoadBackUp = TRUE.
sBackUp.r_Ti	REAL	20.0	Saved integral action time [s]
sBackUp.r_Td	REAL	0.0	Saved derivative action time [s]
sBackUp.r_A	REAL	0.0	Saved derivative delay coefficient
sBackUp.r_B	REAL	0.0	Saved proportional action weighting factor
sBackUp.r_C	REAL	0.0	Saved derivative action weighting factor
sBackUp.r_Cycle	REAL	1.0	Saved sampling time of PID algorithm
sPid_Calc.r_Cycle	REAL	0.1	Sampling time of the PID_Compact instruction r_Cycle is determined automatically and is usually equivalent to the cycle time of the calling OB.

Tag	Data type	Default	Description
sPid_Calc.b_RunIn	BOOL	FALSE	• b_RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If the requirements for pretuning are not met, PID_Compact reacts as if b_RunIn = TRUE. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_Compact switches to "Inactive" mode. • b_RunIn = TRUE The pretuning is skipped. PID_3Compact tries to reach the setpoint with minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. b_RunIn is set to FALSE after fine tuning.
sPid_Calc.b_CalcParamSUT	BOOL	FALSE	The parameters for pretuning will be recalculated if b_CalcParamSUT = TRUE. This enables you to change the parameter calculation method without having to repeat controller tuning. b_CalcParamSUT is set to FALSE after the calculation.
sPid_Calc.b_CalcParamTIR	BOOL	FALSE	The parameters for fine tuning will be recalculated if b_CalcParamTIR = TRUE. This enables you to change the parameter calculation method without having to repeat controller tuning. b_CalcParamTIR will be set to FALSE after calculation.
sPid_Calc.i_CtrlTypeSUT	INT	0	Methods used to calculate parameters during pretuning: • i_CtrlTypeSUT = 0: PID according to Chien, Hrones and Reswick • i_CtrlTypeSUT = 1: PI according to Chien, Hrones and Reswick
sPid_Calc.i_CtrlTypeTIR	INT	0	Methods used to calculate parameters during fine tuning: • i_CtrlTypeTIR = 0: PID automatic • i_CtrlTypeTIR = 1: PID fast • i_CtrlTypeTIR = 2: PID slow • i_CtrlTypeTIR = 3: Ziegler-Nichols PID • i_CtrlTypeTIR = 4: Ziegler-Nichols PI • i_CtrlTypeTIR = 5: Ziegler-Nichols P
sPid_Calc.r_Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)

Tag	Data type	Default	Description
sPid_Cmpt.r_Sp_Hlm	REAL	+3.402822e +38	High limit of setpoint If you configure sPid_Cmpt.r_Sp_Hlm outside the process value limits, the configured process value absolute high limit is used as the setpoint high limit. If you set sPid_Cmpt.r_Sp_Hlm within the process value limits, this value is used as the setpoint high limit.
sPid_Cmpt.r_Sp_Llm	REAL	-3.402822e +38	Low limit of the setpoint If you set sPid_Cmpt.r_Sp_Llm outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. If you set sPid_Cmpt.r_Sp_Llm within the process value limits, this value is used as the setpoint low limit.
sPid_Cmpt.r_Pv_Norm_IN_1	REAL	0.0	Scaling Input_PER low Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_IN_2	REAL	27648.0	Scaling Input_PER high Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_OUT_1	REAL	0.0	Scaled low process value Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Pv_Norm_OUT_2	REAL	100.0	Scaled high process value Input_PER is converted to percent based on the two value pairs r_Pv_Norm_OUT_1, r_Pv_Norm_IN_1 and r_Pv_Norm_OUT_2, r_Pv_Norm_IN_2 from the sPid_Cmpt structure.
sPid_Cmpt.r_Lmn_Hlm	REAL	100.0	Output value high limit for output parameter "Output"
sPid_Cmpt.r_Lmn_Llm	REAL	0.0	Low output value limit for output parameter "Output"
sPid_Cmpt.b_Input_PER_On	BOOL	TRUE	If b_Input_PER_On = TRUE, then parameter Input_PER is used. If b_Input_PER_On = FALSE, then parameter Input is used.
sPid_Cmpt.b_LoadBackUp	BOOL	FALSE	Activate the back-up parameter set. If an optimization has failed, you can reactivate the previous PID parameters by setting this bit.
sPid_Cmpt.b_InvCtrl	BOOL	FALSE	Invert control logic With b_InvCtrl = TRUE, an increasing control deviation causes a reduction in the output value.
sPid_Cmpt.r_Lmn_Pwm_PPTm	REAL	0.0	The minimum ON time of the pulse width modulation in seconds is rounded to r_Lmn_Pwm_PPTm = r_Cycle or r_Lmn_Pwm_PPTm = n*r_Cycle

Tag	Data type	Default	Description
sPid_Cmpt.r_Lmn_Pwm_PBTm	REAL	0.0	The minimum OFF time of the pulse width modulation in seconds is rounded to r_Lmn_Pwm_PBTm = r_Cycle or r_Lmn_Pwm_PBTm = n*r_Cycle
sPid_Cmpt.r_Pv_Hlm	REAL	120.0	High limit of the process value At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer reported for a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and the PID_Compact switches to "Inactive" mode. r_Pv_Hlm > r_Pv_Llm
sPid_Cmpt.r_Pv_Llm	REAL	0.0	Low limit of the process value r_Pv_Llm < r_Pv_Hlm
sPid_Cmpt.r_Pv_HWrn	REAL	+3.402822e +38	Warning high limit of the process value If you set r_Pv_HWrn outside the process value limits, the configured process value absolute high limit is used as the warning high limit. If you configure r_Pv_HWrn within the process value limits, this value is used as the warning high limit. r_Pv_HWrn > r_Pv_LWrn r_Pv_HWrn ≤ r_Pv_Hlm
sPid_Cmpt.r_Pv_LWrn	REAL	-3.402822e +38	Warning low limit of the process value If you set r_Pv_LWrn outside the process value limits, the configured process value absolute low limit is used as the warning low limit. If you configure r_Pv_LWrn within the process value limits, this value is used as the warning low limit. r_Pv_LWrn < r_Pv_HWrn r_Pv_LWrn ≥ r_Pv_LWrn
sPidCalc.i_Ctrl_IOutv	REAL	0.0	Current integral action
sParamCalc.i_Event_SUT	INT	0	Variable i_Event_SUT (Page 4251) indicates the current phase of "pretuning":
sParamCalc.i_Event_TIR	INT	0	Variable i_Event_TIR (Page 4251) indicates the current phase of "fine tuning":
sRet.i_Mode	INT	0	The operating mode is changed edge-triggered. The following operating mode is enabled on a change to • i_Mode = 0: "Inactive" mode (controller stop) • i_Mode = 1: "Pretuning" mode • i_Mode = 2: "Fine tuning" mode • i_Mode = 3: "Automatic" mode • i_Mode = 4: "Manual" mode i_Mode is retentive.
sRet.r_Ctrl_Gain	REAL	1.0	Active proportional gain Gain is retentive.

Tag	Data type	Default	Description
sRet.r_Ctrl_Ti	REAL	20.0	• r_Ctrl_Ti > 0.0: Active integral action time • r_Ctrl_Ti = 0.0: Integral action is deactivated r_Ctrl_Ti is retentive.
sRet.r_Ctrl_Td	REAL	0.0	• r_Ctrl_Td > 0.0: Active derivative action time • r_Ctrl_Td = 0.0: Derivative action is deactivated r_Ctrl_Td is retentive.
sRet.r_Ctrl_A	REAL	0.0	Active derivative delay coefficient r_Ctrl_A is retentive.
sRet.r_Ctrl_B	REAL	0.0	Active proportional action weighting r_Ctrl_B is retentive.
sRet.r_Ctrl_C	REAL	0.0	Active derivative action weighting r_Ctrl_C is retentive.
sRet.r_Ctrl_Cycle	REAL	1.0	Active sampling time of the PID algorithm r_Ctrl_Cycle is calculated during tuning and rounded to an integer multiple of r_Cycle. r_Ctrl_Cycle is used as time period of the pulse width modulation. r_Ctrl_Cycle is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller. "Inactive" mode is forced by setting the "sRet.i_Mode" tag to "0".

Parameters State and sRet.i_Mode V1 (S7-1200)

Correlation of the parameters

The State parameter indicates the current operating mode of the PID controller. You cannot modify the State parameter.

You need to modify the sRet.i_Mode tag to change the operating mode. This also applies when the value for the new operating mode is already in sRet.i_Mode. First set sRet.i_Mode = 0 and then sRet.i_Mode = 3. Provided the current operating mode of the controller supports this change, State is set to the value of sRet.i_Mode.

When PID_Compact automatically switches the operating mode, the following applies: State ! = sRet.i_Mode.

Examples:

- Successful pretuning
  State = 3 and sRet.i_Mode = 1
- Error
  State = 0 and sRet.i_Mode remains at the same value, e.g sRet.i_Mode = 3
- ManualEnalbe = TRUE
  State = 4 and sRet.i_Mode remain at the previous value, for example, sRet.i_Mode = 3

Note

You wish to repeat successful fine tuning without exiting automatic mode with i_Mode = 0.

Setting sRet.i_Mode to an invalid value such as 9999 for one cycle has no effect on State. Set Mode = 2 in the next cycle. You can generate a change to sRet.i_Mode without first switching to "inactive" mode.

Meaning of values

State / sRet.i_Mode	Description of the operating mode
0	Inactive The controller is switched off. The controller was in "inactive" mode before pretuning was performed. The PID controller will change to "inactive" mode when running if an error occurs or if the "Deactivate controller" icon is clicked in the commissioning window.
1	Pretuning The pretuning determines the process response to a jump of the output value and searches for the point of inflection. The optimized PID parameters are calculated as a function of the maximum rate of rise and dead time of the controlled system. Pretuning requirements: • The controller is in inactive mode or manual mode • ManualEnable = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |sPid_Cmpt.r_Pv_Hlm - sPid_Cmpt.r_Pv_Llm| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint may not be changed during pretuning. The higher the stability of the process value, the easier it is to calculate the PID parameters and increase precision of the result. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. PID parameters are backed up before they are recalculated and can be reactivated with sPid_Cmpt.b_LoadBackUp. There is a change to automatic mode following successful pretuning and to "inactive" mode following unsuccessful pretuning. The phase of pretuning is indicated with Tag i_Event_SUT V1 (Page 4251).

State / sRet.i_Mode	Description of the operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are optimized based on the amplitude and frequency of this oscillation. The differences between the process response during pretuning and fine tuning are analyzed. All PID parameters are recalculated on the basis of the findings. PID parameters from fine tuning usually have better master control and disturbance behavior than PID parameters from pretuning. PID_Compact automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. PID parameters are backed up before they are recalculated and can be reactivated with sPid_Cmpt.b_LoadBackUp. Requirements for fine tuning: • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • The setpoint may not be changed during fine tuning. • ManualEnable = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started in: • Automatic mode (State = 3) Start fine tuning in automatic mode if you wish to improve the existing PID parameters using controller tuning. PID_Comact will regulate using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual (State = 4) mode If the requirements for pretuning are met, pretuning is started. The PID parameters established will be used for adjustment until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. If pretuning is not possible, PID_Compact will change to "Inactive" mode. An attempt is made to reach the setpoint with a minimum or maximum output value if the process value for pretuning is already too near the setpoint or sPid_Calc.b_RunIn = TRUE. This can produce increased overshoot. The controller will change to "automatic mode" after successfully completed "fine tuning" and to "inactive" mode if "fine tuning" has not been successfully completed. The "Fine tuning" phase is indicated with Tag i_Event_TIR V1 (Page 4251).

State / sRet.i_Mode	Description of the operating mode
3	Automatic mode In automatic mode, PID_Compact corrects the controlled system in accordance with the parameters specified. The controller changes to automatic mode if one the following conditions is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Change of variable sRet.i_Mode to the value 3. After CPU startup or change from Stop to RUN mode, PID_Compact will start in the most recently active operating mode. To retain PID_Compact in "Inactive" mode, set sb_RunModeByStartup = FALSE.
4	Manual mode In manual mode, you specify a manual output value in the ManualValue parameter. This operating mode is enabled if sRet.i_Mode = 4, or at the rising edge on ManualEnable. If ManualEnable changes to TRUE, only State will change. sRet.i_Mode will retain its current value. PID_Compact will return to the previous operating mode upon a falling edge at ManualEnable. The change to automatic mode is bumpless.

Parameter Error V1 (S7-1200)

If several errors are pending simultaneously, the values of the error codes are displayed with binary addition. The display of error code 0003, for example, indicates that the errors 0001 and 0002 are pending simultaneously.

Error (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > sPid_Cmpt.r_Pv_Hlm or • Input < sPid_Cmpt.r_Pv_Llm You cannot move the actuator again until you eliminate the error.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input.
0004	Error during fine tuning. Oscillation of the process value could not be maintained.
0008	Error at start of pretuning. The process value is too close to the setpoint. Start fine tuning.
0010	The setpoint was changed during tuning.
0020	Pretuning is not permitted in automatic mode or during fine tuning.

Error (DW#16#...)	Description
0080	Error during pretuning. The output value limits are not configured correctly or the actual value does not react as expected. Check whether the limits of the output value are configured correctly and match the control logic. Also make sure that the actual value does not oscillate strongly before starting pretuning.
0100	Error during tuning resulted in invalid parameters.
0200	Invalid value at "Input" parameter: Value has an invalid number format.
0400	Calculation of output value failed. Check the PID parameters.
0800	Sampling time error: PID_Compact is not called within the sampling time of the cyclic interrupt OB. If this error occurred during simulation with PLCSIM, see the notes under Simulating PID_Compact V1 with PLCSIM (Page 6060).
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format.

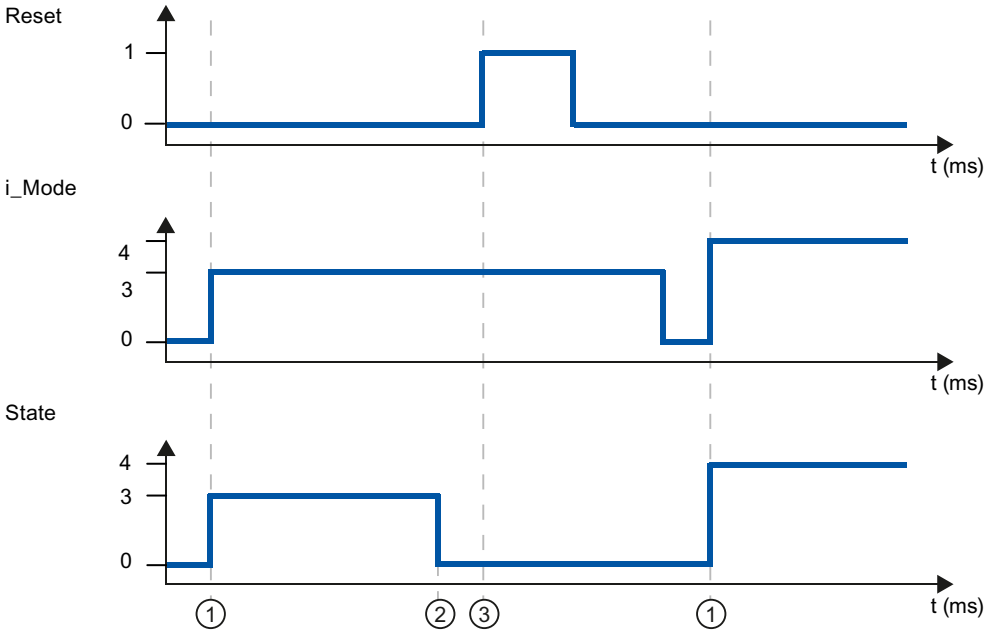
Parameter Reset V1 (S7-1200)

The response to Reset = TRUE depends on the version of the PID_Compact instruction.

Reset response PID_Compact V.1.1 or higher



A rising edge at Reset triggers a change to "Inactive" mode; errors and warnings are reset and the integral action is deleted. A falling edge at Reset triggers a change to the most recently active operating mode. If automatic mode was active before, the integral action is pre-assigned in such a way that the switchover is bumpless.

① Activation
② Error
③ Reset

Reset response PID_Compact V.1.0

A rising edge at Reset triggers a change to "Inactive" mode; errors and warnings are reset and the integral action is deleted. The controller is not reactivated until the next edge at i_Mode.

① Activation
② Error
③ Reset

Tag sd_warning V1 (S7-1200)

If several warnings are pending, the values of variable sd_warning are displayed by means of binary addition. The display of warning 0003, for example, indicates that the warnings 0001 and 0002 are also pending.

sd_warning (DW#16#....)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0002	Oscillation increased during fine tuning.
0004	The setpoint was outside the set limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. The PID parameters were instead calculated using the "i_CtrlTypeTIR = 3" method.
0010	The operating mode could not be changed because ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.

The following warnings are deleted as soon as the cause is dealt with:

- 0004
- 0020
- 0040

All other warnings are cleared with a rising edge at Reset.

Tag i_Event_SUT V1 (S7-1200)

i_Event_SUT	Name	Description
0	SUT_INIT	Initialize pretuning

PID_3Step (S7-1200, S7-1500)

New features of PID_3Step (S7-1200, S7-1500)

PID_3Step V2.3

- As of PID_3Step Version 2.3 the monitoring and limiting of the travel time can be deactivated with Config.VirtualActuatorLimit = 0.0.

PID_3Step V2.2

- **Use with S7-1200**
  As of PID_3Step V2.2, the instruction with V2 functionality can also be used on S7-1200 with firmware version 4.0 or higher.

PID_3Step V2.0

- **Reaction to error**
  The reaction to ActivateRecoverMode = TRUE has been completely overhauled. PID_3Step reacts in a more fault tolerant manner in the default setting.

NOTICE
Your system may be damaged. If you use the default setting, PID_3Step remains in automatic mode even if the process value limits are exceeded. This may damage your system. It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

  You use the ErrorAck input parameter to acknowledge the errors and warnings without restarting the controller or clearing the integral action.
  Switching operating modes does not acknowledge errors that are no longer pending.
- **Switching the operating mode**
  You specify the operating mode at the Mode in/out parameter and use a positive edge at ModeActivate to start the operating mode. The Retain.Mode tag has been omitted.
  The transition time measurement can no longer be started with GetTransitTime.Start, but only with Mode = 6 and a positive edge at ModeActivate.
- **Multi-instance capability**
  You can call up PID_3Step as multi-instance DB. No technology object is created in this case and no parameter assignment interface or commissioning interface is available. You must assign parameters for PID_3Step directly in the multi-instance DB and commission it via a watch table.
- **Startup characteristics**
  The operating mode specified at the Mode parameter is also started on a negative edge at Reset and during a CPU cold restart, if RunModeByStartup = TRUE.

- **ENO characteristics**
  ENO is set depending on the operating mode.
  If State = 0, then ENO = FALSE.
  If State ≠ 0, then ENO = TRUE.
- **Manual mode**
  The Manual_UP and Manual_DN input parameters no longer function as edge-triggered parameters. Edge-triggered manual mode continues to be possible using the ManualUpInternal and ManualDnInternal tags.
  In "Manual mode without endstop signals" (Mode = 10), the endstop signals Actuator_H and Actuator_L are ignored even though they are activated.
- **Default value of PID parameters**
  The following default settings have been changed:
  - Proportional action weighting (PWeighting) from 0.0 to 1.0
  - Derivative action weighting (DWeighting) from 0.0 to 1.0
  - Coefficient for derivative delay (TdFiltRatio) from 0.0 to 0.2
- **Limiting of motor transition time**
  You configure the maximum percentage of the motor transition time that the actuator will travel in one direction in the Config.VirtualActuatorLimit tag.
- **Setpoint value specification during tuning**
  You configure the permitted fluctuation of the setpoint during tuning at the CancelTuningLevel tag.
- **Switching a disturbance variable on**
  You can switch a disturbance variable on at the Disturbance parameter.
- **Troubleshooting**
  If the endstop signals are not activated (ActuatorEndStopOn = FALSE), ScaledFeedback is determined without Actuator_H or Actuator_L.

PID_3Step V1.1

- **Manual mode on CPU startup**
  If ManualEnable = TRUE when the CPU starts, PID_3Step starts in manual mode. A positive edge at ManualEnable is not necessary.
- **Reaction to error**
  The ActivateRecoverMode tag is no longer effective in manual mode.
- **Troubleshooting**
  The Progress tag is reset following successful tuning or transition time measurement.

Compatibility with CPU and FW (S7-1200, S7-1500)

The following table shows which version of PID_3Step can be used on which CPU.

CPU	FW	PID_3Step
S7-1200	V4.2 or higher	V2.3 V2.2 V1.1
	V4.0 to V4.1	V2.2 V1.1
	V3.x	V1.1 V1.0
	V2.x	V1.1 V1.0
	V1.x	-
S7-1500	V2.0 or higher	V2.3 V2.2 V2.1 V2.0
	V1.5 to V1.8	V2.2 V2.1 V2.0
	V1.1	V2.1 V2.0
	V1.0	V2.0

CPU processing time and memory requirement PID_3Step V2.x (S7-1200, S7-1500)

CPU processing time

Typical CPU processing times of the PID_3Step technology object as of Version V2.0, depending on CPU type.

CPU	Typ. CPU processing time PID_3Step V2.x
CPU 1211C ≥ V4.0	410 µs
CPU 1215C ≥ V4.0	410 µs
CPU 1217C ≥ V4.0	410 µs
CPU 1505S ≥ V1.0	50 µs
CPU 1510SP-1 PN ≥ V1.6	120 µs
CPU 1511-1 PN ≥ V1.5	120 µs
CPU 1512SP-1 PN ≥ V1.6	120 µs
CPU 1516-3 PN/DP ≥ V1.5	65 µs
CPU 1518-4 PN/DP ≥ V1.5	5 µs

Memory requirement

Memory requirement of an instance DB of the PID_3Step technology object as of Version V2.0.

	Memory requirement of the instance DB of PID_3Step V2.x
Load memory requirement	Approx. 15000 bytes
Total work memory requirement	1040 bytes
Retentive work memory requirement	60 bytes

PID_3Step V2 (S7-1200, S7-1500)

Description of PID_3Step V2 (S7-1200, S7-1500)

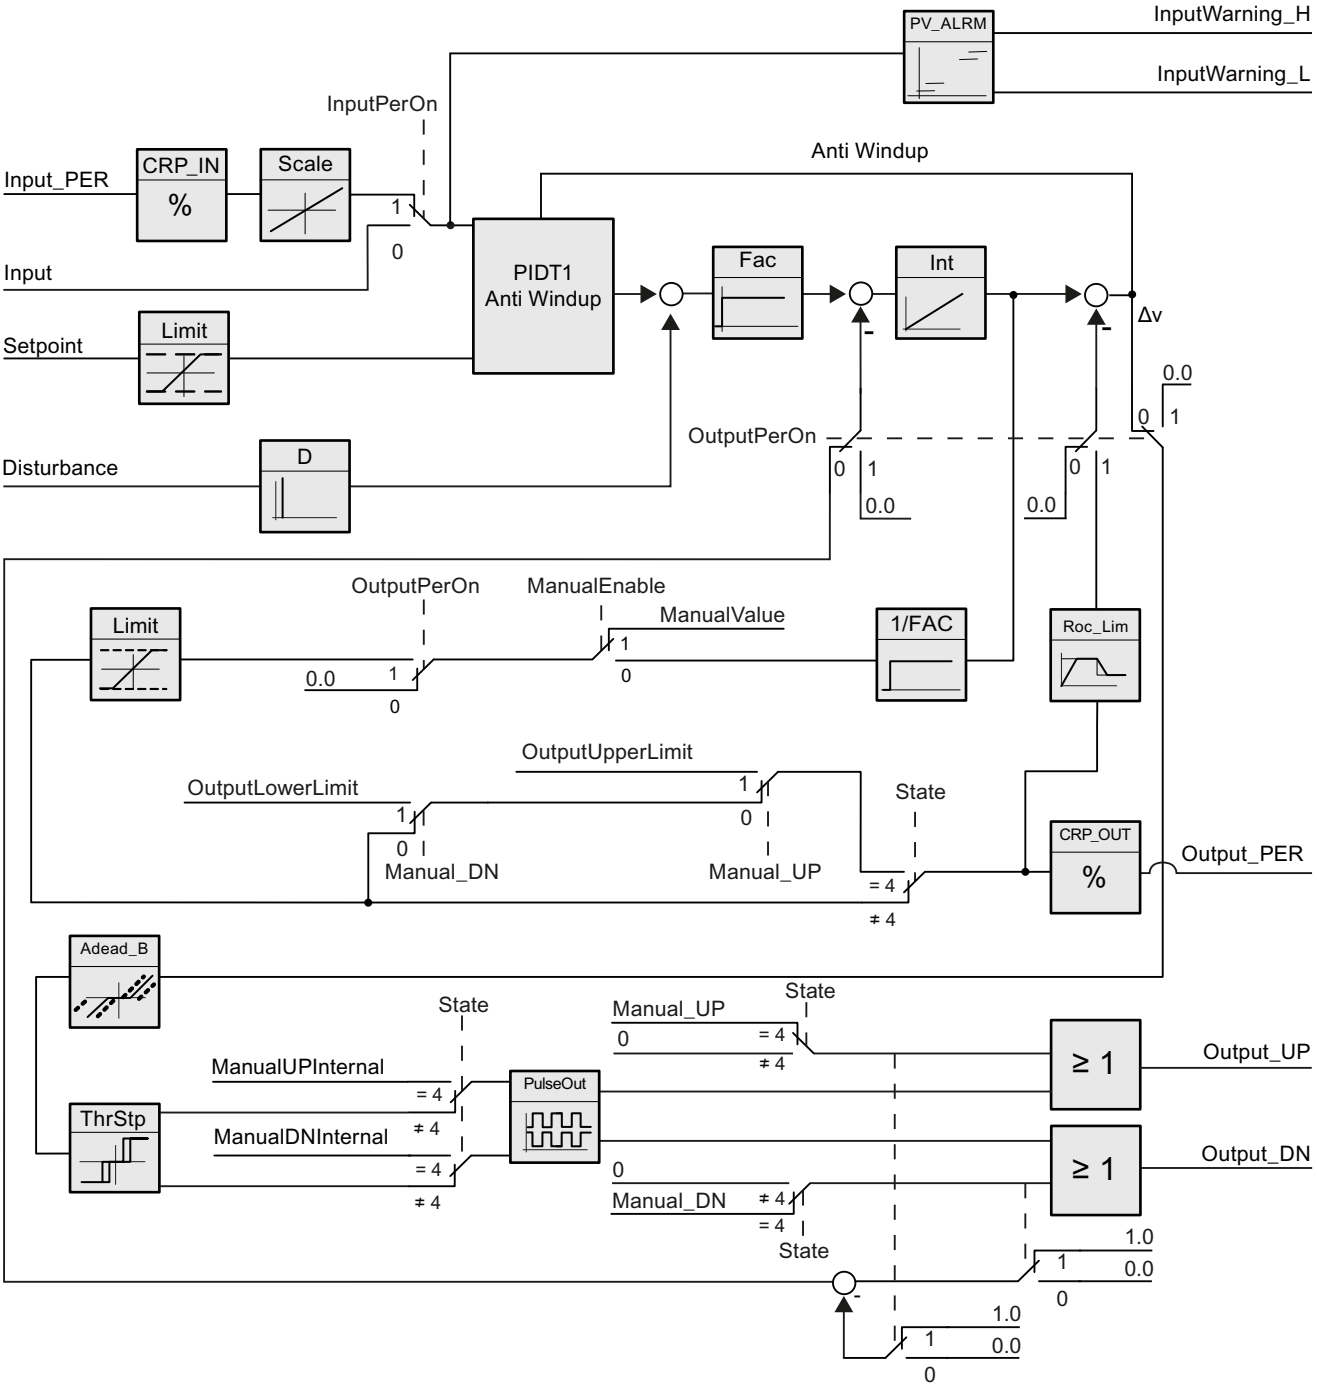
Description

You use the PID_3Step instruction to configure a PID controller with self tuning for valves or actuators with integrating behavior.

The following operating modes are possible:

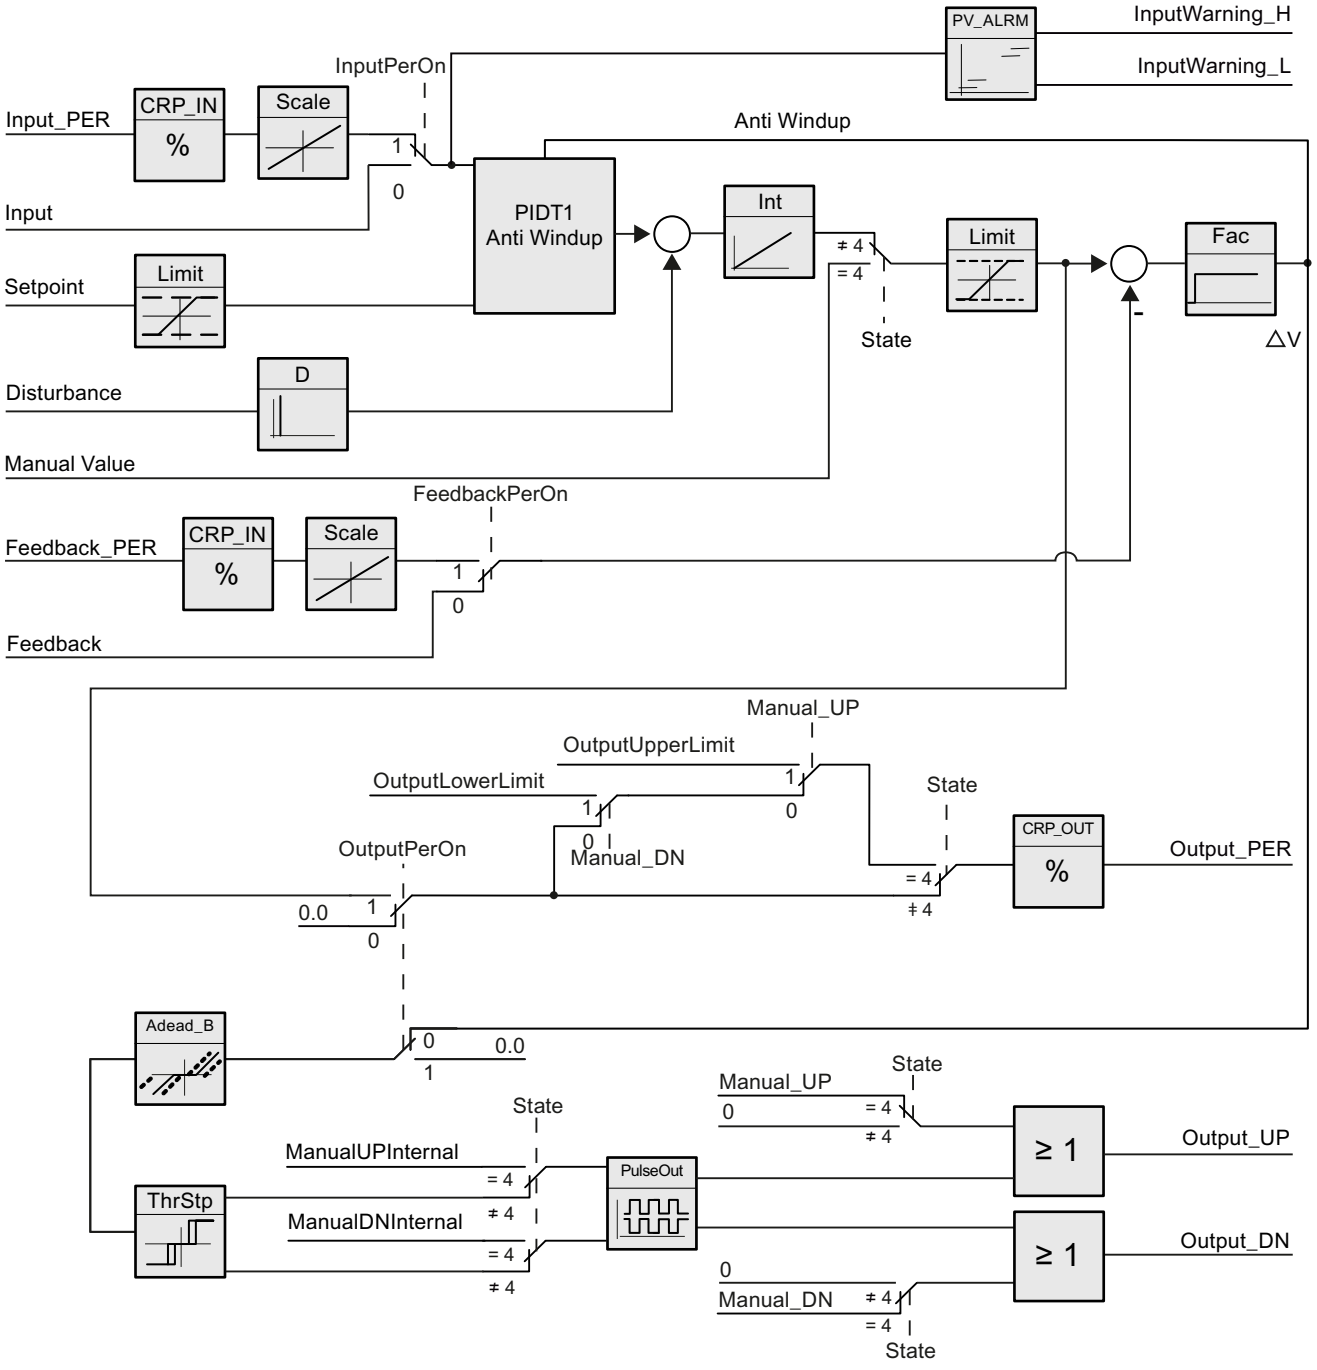
- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Approach substitute output value
- Transition time measurement
- Error monitoring
- Approach substitute output value with error monitoring
- Manual mode without endstop signals

For a more detailed description of the operating modes, see the State parameter.



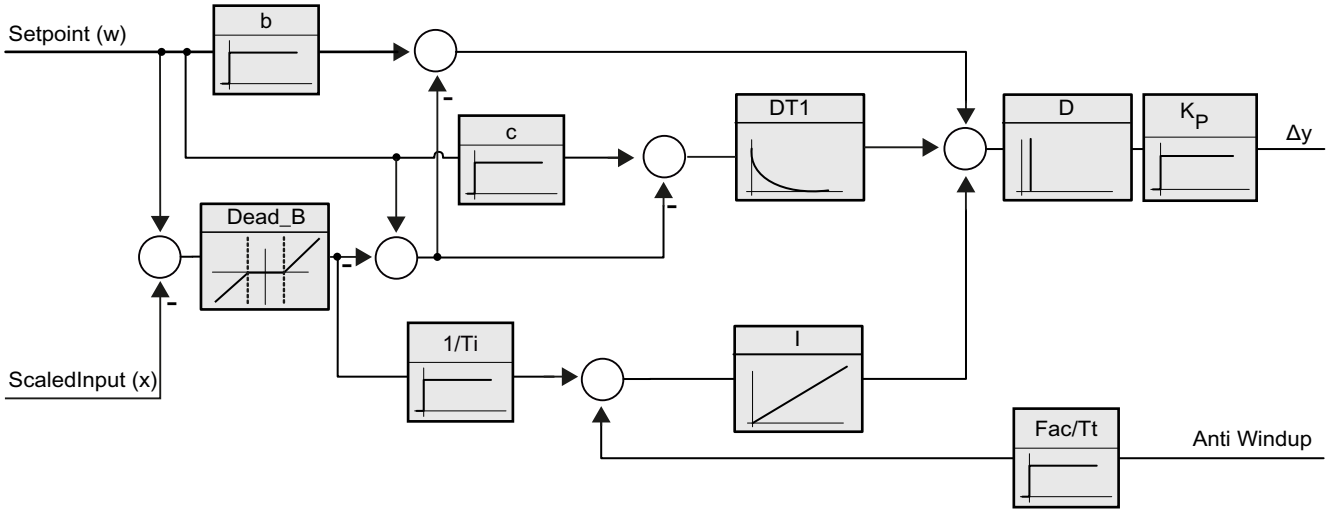
PID algorithm

PID_3Step is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation:



$$\Delta y = K_p \cdot s \cdot \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
Δy	Output value of the PID algorithm
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
T_D	Derivative action time
a	Derivative delay coefficient (derivative delay T1 = a × T_D)
c	Derivative action weighting



Block diagram without position feedback

Block diagram with position feedback

Block diagram of PIDT1 with anti-windup

Call

PID_3Step is called in the constant time scale of a cycle interrupt OB.

If you call PID_3Step as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_3Step directly in the multi-instance DB and commission it via a watch table.

Download to device

The actual values of retentive tags are only updated when you download PID_3Step completely.

Downloading technology objects to device (Page 6000)

Startup

When the CPU starts up, PID_3Step starts in the operating mode that is saved in the Mode in/out parameter. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Reaction to error

In automatic mode and during commissioning, the reaction to error depends on the ErrorBehaviour and ActivateRecoverMode tags. In manual mode, the reaction is independent of ErrorBehaviour and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the reaction additionally depends on the error that occurred.

ErrorBehaviour	ActivateRecoverMode	Configuration editor > actuator setting > Set Output to	Reaction
FALSE	FALSE	Current output value	Switch to "Inactive" mode (State = 0) The actuator remains in the current position.
FALSE	TRUE	Current output value while error is pending	Switch to "Error monitoring" mode (State = 7) The actuator remains in the current position while the error is pending.
TRUE	FALSE	Substitute output value	Switch to "Approach substitute output value" mode (State = 5) The actuator moves to the configured substitute output value. Switch to "Inactive" mode (State = 0) The actuator remains in the current position.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Approach substitute output value with error monitoring" mode (State = 8) The actuator moves to the configured substitute output value. Switch to "Error monitoring" mode (State = 7)

In manual mode, PID_3Step uses ManualValue as output value, unless the following errors occur:

- 2000h: Invalid value at Feedback_PER parameter.
- 4000h: Invalid value at Feedback parameter.
- 8000h: Error during digital position feedback.

You can only change the position of the actuator with Manual_UP and Manual_DN, not with ManualValue.

The Error parameter indicates whether an error has occurred in this cycle. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

Parameter ErrorBits V2 (Page 4281)

Configuring PID_3Step V2 (Page 6061)

Mode of operation of PID_3Step V2 (S7-1200, S7-1500)

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warning = 0040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_3Step automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_3Step checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit tags. The output value limits must be within "Low endstop" and "High endstop".

- High endstop: Config.FeedbackScaling.UpperPointOut
- Low endstop: Config.FeedbackScaling.LowerPointOut

Rule:

UpperPointOut ≥ OutputUpperLimit > OutputLowerLimit ≥ LowerPointOut

The valid values for "High endstop" and "Low endstop" depend upon:

- FeedbackOn
- FeedbackPerOn
- OutputPerOn

OutputPerOn	FeedbackOn	FeedbackPerOn	LowerPointOut	UpperPointOut
FALSE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
FALSE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
FALSE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
TRUE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%

If OutputPerOn = FALSE and FeedbackOn = FALSE, you cannot limit the output value. Output_UP and Output_DN are then reset upon Actuator_H = TRUE or Actuator_L = TRUE. If endstop signals are also not present, Output_UP and Output_DN are reset after a travel time of Config.VirtualActuatorLimit × Retain.TransitTime/100. As of PID_3Step Version 2.3 the monitoring and limiting of the travel time can be deactivated with Config.VirtualActuatorLimit = 0.0.

The output value is 27648 at 100% and -27648 at -100%. PID_3Step must be able to completely close the valve.

Note

Use with two or more actuators

PID_3 Step is not suitable for use with two or more actuators (for example, in heating/cooling applications), because different actuators need different PID parameters to achieve a good control response.

Substitute output value

If an error has occurred, PID_3Step can output a substitute output value and move the actuator to a safe position that is specified in the SavePosition tag. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- Input
- Input_PER
- Input_PER
- Feedback
- Feedback_PER
- Disturbance
- ManualValue
- SavePosition
- Output_PER

Monitoring the PID_3Step sampling time

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_3Step instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (ErrorBits = 0800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_3Step in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_3Step are executed at every call.

Measuring the motor transition time

The motor transition time is the time in seconds the motor requires to move the actuator from the closed to the opened state. The actuator is moved in one direction for a maximum time of Config.VirtualActuatorLimit × Retain.TransitTime/100. PID_3Step requires the motor transition time to be as accurate as possible for good controller results. The data in the actuator documentation contains average values for this type of actuator. The value for the specific actuator used may differ. You can measure the motor transition time during commissioning. The output value limits are not taken into consideration during the motor transition time measurement. The actuator can travel to the high or the low endstop.

The motor transition time is taken into consideration in the calculation of the analog output value as well as in the calculation of the digital output values. It is mainly required for correct operation during auto-tuning and the anti-windup behavior. You should therefore configure the motor transition time with the value that the motor requires to move the actuator from the closed to the opened state.

If no relevant motor transition time is in effect in your process (e.g. with solenoid valves), so that the output value has a direct and full effect on the process, use PID_Compact instead.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_3Step does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Input parameters of PID_3Step V2 (S7-1200, S7-1500)

Table 11-73

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A tag of the user program is used as source for the process value. If you are using parameter Input, then Config.InputPer-On = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using parameter Input_PER, then Config.InputPer-On = TRUE must be set.

Parameter	Data type	Default	Description
Actuator_H	BOOL	FALSE	Digital position feedback of the valve for the high endstop If Actuator_H = TRUE, the valve is at the high endstop and is no longer moved towards this direction.
Actuator_L	BOOL	FALSE	Digital position feedback of the valve for the low endstop If Actuator_L = TRUE, the valve is at the low endstop and is no longer moved towards this direction.
Feedback	REAL	0.0	Position feedback of the valve If you are using parameter Feedback, then Config.Feedback-PerOn = FALSE must be set.
Feedback_PER	INT	0	Analog position feedback of a valve If you are using parameter Feedback_PER, then Config.Feed-backPerOn = TRUE must be set. Feedback_PER is scaled based on the tags: • Config.FeedbackScaling.LowerPointIn • Config.FeedbackScaling.UpperPointIn • Config.FeedbackScaling.LowerPointOut • Config.FeedbackScaling.UpperPointOut
Disturbance	REAL	0.0	Disturbance variable or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "manual mode", while State = 4, Mode remains unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using ModeActivate only.
ManualValue	REAL	0.0	In manual mode, the absolute position of the valve is specified. ManualValue is only evaluated if you are using Output_PER, **or** if position feedback is available.
Manual_UP	BOOL	FALSE	• Manual_UP = TRUE The valve is opened even if you are using Output_PER or a position feedback. The valve is no longer moved if the high endstop has been reached. See also Config.VirtualActuatorLimit • Manual_UP = FALSE If you are using Output_PER or a position feedback, the valve is moved to ManualValue. Otherwise, the valve is no longer moved. If Manual_UP and Manual_DN are set to TRUE simultaneously, the valve is not moved.

Parameter	Data type	Default	Description
Manual_DN	BOOL	FALSE	• Manual_DN = TRUE The valve is closed even if you are using Output_PER or a position feedback. The valve is no longer moved if the low endstop has been reached. See also Config.VirtualActuatorLimit • Manual_DN = FALSE If you are using Output_PER or a position feedback, the valve is moved to ManualValue. Otherwise, the valve is no longer moved.
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warnings are reset. • As long as Reset = TRUE, – PID_3Step remains in "Inactive" mode (State = 0). – You cannot change the operating mode with Mode and ModeActivate or ManualEnable. – You cannot use the commissioning dialog. • TRUE -> FALSE edge – If ManualEnable = FALSE, PID_3Step switches to the operating mode that is saved in Mode. – If Mode = 3, the integral action is treated as configured with the tag IntegralResetMode.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_3Step switches to the operating mode that is saved in the Mode parameter.

Output parameters of PID_3Step V2 (S7-1200, S7-1500)

Table 11-74

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
ScaledFeedback	REAL	0.0	Scaled position feedback For an actuator without position feedback, the position of the actuator indicated by ScaledFeedback is very imprecise. ScaledFeedback may only be used for rough estimation of the current position in this case.
Output_UP	BOOL	FALSE	Digital output value for opening the valve If Config.OutputPerOn = FALSE, the Output_UP parameter is used.

Parameter	Data type	Default	Description
Output_DN	BOOL	FALSE	Digital output value for closing the valve If Config.OutputPerOn = FALSE, the Output_DN parameter is used.
Output_PER	INT	0	Analog output value If Config.OutputPerOn = TRUE, Output_PER is used. Use Output_PER if you are using a valve as actuator which is triggered via an analog output and controlled with a continuous signal, e.g. 0...10 V or 4...20 mA. The value at Output_PER corresponds to the target position of the valve, e.g. Output_PER = 13824, when the valve is to be opened by 50%.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit). The setpoint is limited to Config.SetpointUpperLimit .
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached (Setpoint ≤ Config.SetpointLowerLimit). The setpoint is limited to Config.SetpointLowerLimit .
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.
State	INT	0	The State parameter (Page 4276) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Approach substitute output value • State = 6: Transition time measurement • State = 7: Error monitoring • State = 8: Approach substitute output value with error monitoring • State = 10: Manual mode without endstop signals
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 4281) shows which error messages are pending. ErrorBits is retentive and is reset upon a rising edge at Reset or ErrorAck.

Parameter ErrorBits V2 (Page 4281)

In/out parameters of PID-3Step V2 (S7-1200, S7-1500)

Table 11-75

Parameter	Data type	Default	Description
Mode	INT	4	At the Mode parameter, you specify the operating mode to which PID_3Step is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode • Mode = 6: Transition time measurement • Mode = 10: Manual mode without endstop signals The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE Mode is retentive. A detailed description of the operating modes can be found in Parameters State and Mode V2 (Page 4276).

Static tags of PID_3Step V2 (S7-1200, S7-1500)

You must not change tags that are not listed. These are used for internal purposes only.

Tag	Data type	Default	Description
ManualUpInternal	BOOL	FALSE	In manual mode, each rising edge opens the valve by 5% of the total control range or for the duration of the minimum motor transition time. ManualUpInternal is only evaluated if you are not using Output_PER or a position feedback. This tag is used in the commissioning dialog.
ManualDnInternal	BOOL	FALSE	In manual mode, every rising edge closes the valve by 5% of the total control range or for the duration of the minimum motor transition time. ManualDnInternal is only evaluated if you are not using Output_PER or position feedback. This tag is used in the commissioning dialog.
ActivateRecoverMode	BOOL	TRUE	The ActivateRecoverMode V2 (Page 4284) tag determines the reaction to error.
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart If RunModeByStartup = TRUE, PID_3Step starts in the operating mode saved in the Mode parameter after CPU startup. If RunModeByStartup = FALSE, PID_3Step remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE.

Tag	Data type	Default	Description
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., ºC, or ºF.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature
ErrorBehaviour	BOOL	FALSE	If ErrorBehaviour = FALSE and an error has occurred, the valve stays at its current position and the controller switches directly to "Inactive" or "Error monitoring" mode. If ErrorBehaviour = TRUE and an error occurs, the actuator moves to the substitute output value and only then switches to "Inactive" or "Error monitoring" mode. If the following errors occur, you can no longer move the valve to a configured substitute output value. • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback. • 20000h: Invalid value at SavePosition tag.
Warning	DWORD	DW#16#0	The Warning tag (Page 4276) shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive. Cyclic warnings (for example, process value warning) are shown until the cause of the warning is removed. They are automatically deleted once their cause has gone. Non-cyclic warnings (for example, point of inflection not found) remain and are deleted like errors.
SavePosition	REAL	0.0	Substitute output value If ErrorBehaviour = TRUE, the actuator is moved to a position that is safe for the plant when an error occurs. As soon as the substitute output value has been reached, PID_3Step switches the operating mode according to ActivateRecoverMode.
CurrentSetpoint	REAL	0.0	Currently active setpoint. This value is frozen at the start of tuning.
CancelTuningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.OutputPerOn	BOOL	FALSE	If OutputPerOn = TRUE, the Output_PER parameter is used. If OutputPerOn = FALSE, the Ouput_UP and Output_DN parameters are used.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.FeedbackOn	BOOL	FALSE	If FeedbackOn = FALSE, a position feedback is simulated. Position feedback is generally activated when Feedback-On = TRUE.

Tag	Data type	Default	Description
Config.FeedbackPerOn	BOOL	FALSE	FeedbackPerOn is only effective when FeedbackOn = TRUE. If FeedbackPerOn = TRUE, the analog input is used for the position feedback (Feedback_PER parameter). If FeedbackPerOn = FALSE, the Feedback parameter is used for the position feedback.
Config.ActuatorEndStopOn	BOOL	FALSE	If ActuatorEndStopOn = TRUE, the digital position feedback Actuator_L and Actuator_H are taken into consideration.
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_3Step reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	+3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value If OutputPerOn = TRUE or FeedbackOn = TRUE, the range of values from -100% to +100%, including zero, is valid. At -100%, Output = -27648; at +100% Output = 27648 If OutputPerOn = FALSE, the range of values from 0% to 100% is valid. The valve is completely closed at 0% and completely opened at 100%.
Config.SetpointUpperLimit	REAL	+3.402822e+38	High limit of setpoint If you set SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is preassigned as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.

Tag	Data type	Default	Description
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured absolute process value low limit is preassigned as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.
Config.MinimumOnTime	REAL	0.0	Minimum ON time Minimum time in seconds for which the servo drive must be switched on. Config.MinimumOnTime is only effective if Output_UP and Output_DN are used (Config.OutputPerOn = FALSE).
Config.MinimumOffTime	REAL	0.0	Minimum OFF time Minimum time in seconds for which the servo drive must be switched off. Config.MinimumOffTime is only effective if Output_UP and Output_DN are used (Config.OutputPerOn = FALSE).
Config.VirtualActuatorLimit	REAL	150.0	If all the following conditions have been satisfied, the actuator is moved in one direction for the maximum period of VirtualActuatorLimit × Retain.TransitTime/100 and the warning 2000h is output: • Config.OutputPerOn = FALSE • Config.ActuatorEndStopOn = FALSE • Config.FeedbackOn = FALSE If Config.OutputPerOn = FALSE and Config.ActuatorEndStopOn = TRUE or Config.FeedbackOn = TRUE, only the warning 2000h is output. If Config.OutputPerOn = TRUE, VirtualActuatorLimit is not taken into consideration. As of PID_3Step Version 2.3 the monitoring and limiting of the travel time can be deactivated with Config.VirtualActuatorLimit = 0.0.
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.

Tag	Data type	Default	Description
Config.FeedbackScaling.UpperPointIn	REAL	27648.0	Scaling Feedback_PER high Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointIn	REAL	0.0	Scaling Feedback_PER low Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.UpperPointOut	REAL	100.0	High endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointOut	REAL	0.0	Low endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
GetTransitTime.InvertDirection	BOOL	FALSE	If InvertDirection = FALSE, the valve is fully opened, closed, and then reopened in order to determine the valve transition time. If InvertDirection = TRUE, the valve is fully closed, opened, and then closed again.
GetTransitTime.SelectFeedback	BOOL	FALSE	If SelectFeedback = TRUE, then Feedback_PER, or Feedback is taken into consideration in the transition time measurement. If SelectFeedback = FALSE, then Actuator_H and Actuator_L are taken into consideration in the transition time measurement.
GetTransitTime.State	INT	0	Current phase of the transition time measurement • State = 0: Inactive • State = 1: Open valve completely • State = 2: Close valve completely • State = 3: Move valve to target position (NewOutput) • State = 4: Transition time measurement successfully completed • State = 5: Transition time measurement canceled
GetTransitTime.NewOutput	REAL	0.0	Target position for transition time measurement with position feedback The target position must be between "High endstop" and "Low endstop". The difference between NewOutput and ScaledFeedback must be at least 50% of the permissible control range.
CycleTime.StartEstimation	BOOL	TRUE	If StartEstimation = TRUE, the measurement of the PID_3Step sampling time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If EnEstimation = TRUE, the PID_3Step sampling time is calculated. If CycleTime.EnEstimation = FALSE, the PID_3Step sampling time is not calculated and you need to correct the configuration of CycleTime.Value manually.

Tag	Data type	Default	Description
CycleTime.EnMonitoring	BOOL	TRUE	If EnMonitoring = TRUE, the PID_3Step sampling time is monitored. If it is not possible to execute PID_3Step within the sampling time, the error 0800h is output and the operating mode is switched. ActivateRecoverMode and ErrorBehaviour determine which operating mode is switched to. If EnMonitoring = FALSE, the PID_3Step sampling time is not monitored, the error 0800h is not output, and the operating mode is not switched.
CycleTime.Value	REAL	0.1	PID_3Step sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain
CtrlParamsBackUp.Ti	REAL	20.0	Saved integration time in seconds
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time in seconds
CtrlParamsBackUp.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	1.0	Saved proportional action weighting
CtrlParamsBackUp.DWeighting	REAL	1.0	Saved derivative action weighting
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm in seconds
CtrlParamsBackUp.InputDeadBand	REAL	0.0	Saved dead band width of the control deviation
PIDSelfTune.SUT.CalculateParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRule. CalculateParams is set to FALSE following calculation.
PIDSelfTune.SUT.TuneRule	INT	1	Methods used to calculate parameters during pretuning: • SUT.TuneRule = 0: PID fast I • SUT.TuneRule = 1: PID slow I • SUT.TuneRule = 2: Chien, Hrones and Reswick PID • SUT.TuneRule = 3: Chien, Hrones, Reswick PI • SUT.TuneRule = 4: PID fast II • SUT.TuneRule = 5: PID slow II
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 50: Determine start position without position feedback • State = 100: Calculate the standard deviation • State = 200: Find the point of inflection • State = 300: Determine the rise time • State = 9900: Pretuning successful • State = 1: Pretuning not successful

Tag	Data type	Default	Description
PIDSelfTune.TIR.RunIn	BOOL	FALSE	With the RunIn tag, you can specify that fine tuning can also be performed without pretuning. • RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_3Step switches to the mode from which tuning was started. • RunIn = TRUE The pretuning is skipped. PID_3Step attempts to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.Calculate-Params	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRule. CalculateParams is set to FALSE following calculation.
PIDSelfTune.TIR.TuneRule	INT	0	Methods used to calculate parameters during fine tuning: • TIR.TuneRule = 0: PID automatic • TIR.TuneRule = 1: PID fast • TIR.TuneRule = 2: PID slow • TIR.TuneRule = 3: Ziegler-Nichols PID • TIR.TuneRule = 4: Ziegler-Nichols PI • TIR.TuneRule = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of fine tuning: • State = -100 Fine tuning is not possible. Pretuning will be performed first. • State = 0: Initialize fine tuning • State = 200: Calculate the standard deviation • State = 300: Attempt to reach the setpoint with the maximum or minimum output value • State = 400: Attempt to reach the setpoint with existing PID parameters (if pretuning was successful) • State = 500: Determine oscillation and calculate parameters • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
Retain.TransitTime	REAL	30.0	Motor transition time in seconds Time in seconds the actuating drive requires to move the valve from the closed to the opened state. TransitTime is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.SetByUser	BOOL	FALSE	If SetByUser = FALSE, the PID parameters are determined automatically and PID_3Step operates with a dead zone at the output value. The dead band width is calculated during tuning on the basis of the standard deviation of the output value and saved in Retain.CtrlParams.OutputDeadBand. If SetByUser = TRUE, the PID parameters are entered manually and PID_3 Step operates without a dead zone at the output value. Retain.CtrlParams.OutputDeadBand = 0.0 SetByUser is retentive.
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain To invert the control logic, use the Config.InvertControl tag. Negative values at Gain also invert the control logic. We recommend you use only InvertControl to set the control logic. The control logic is also inverted if InvertControl = TRUE and Gain < 0.0. Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• Ti > 0.0: Active integration time in seconds • Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• Td > 0.0: Active derivative action time in seconds • Td = 0.0: Derivative action is deactivated Td is retentive.
Retain.CtrlParams.TdFiltRatio	REAL	0.2	Active derivative delay coefficient The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with **one** dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	1.0	Active proportional action weighting The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. PWeighting is retentive.

Tag	Data type	Default	Description
Retain.CtrlParams.DWeight-ing	REAL	1.0	Active derivative action weighting The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of PID algorithm in seconds, rounded to an integer multiple of the cycle time of the calling OB. Cycle is retentive.
Retain.CtrlParams.InputDead-Band	REAL	0.0	Dead band width of the control deviation InputDeadBand is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

Parameters State and Mode V2 (S7-1200, S7-1500)

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_3Step switches to the operating mode saved in the Mode in-out parameter.

When the CPU is switched on or switches from Stop to RUN mode, PID_3Step starts in the operating mode that is saved in the Mode parameter. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State	Description of operating mode
0	Inactive The controller is switched off and no longer changes the valve position.
1	Pretuning The pretuning determines the process response to a pulse of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. Pretuning requirements: • The motor transition time has been configured or measured. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher as compared to the noise. This is most likely the case in operating modes "Inactive" and "manual mode". The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel Before the PID parameters are recalculated, they are backed up and can be reactivated with LoadBackUp. The controller switches to automatic mode following successful pretuning. If pretuning is unsuccessful, the switchover of operating mode is dependent on ActivateRecoverMode and ErrorBehaviour. The pretuning phase is indicated with the SUT.State tag.

State	Description of operating mode
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are recalculated based on the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_3Step automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The PID parameters are backed up before fine tuning. They can be reactivated with LoadBackUp. Requirements for fine tuning: • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_3Step controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) If the requirements for pretuning are met, pretuning is started. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If PIDSelfTune.TIR.RunIn = TRUE, pretuning is skipped and an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. The controller switches to automatic mode following successful fine tuning. If fine tuning is unsuccessful, the switchover of operating mode is dependent on ActivateRecoverMode and ErrorBehaviour. The fine tuning phase is indicated with the TIR.State tag.
3	Automatic mode In automatic mode, PID_3Step controls the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State	Description of operating mode
4	Manual mode In manual mode, you specify manual output values in the Manual_UP and Manual_DN parameters or ManualValue parameter. Whether or not the actuator can be moved to the output value in the event of an error is described in the ErrorBits parameter. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. Manual mode is also possible when an error is pending.
5	Approach substitute output value This operating mode is activated in the event of an error, if Errorbehaviour = TRUE and ActivateRecoverMode = FALSE.. PID_3Step moves the actuator to the substitute output value and then switches to "Inactive" mode.
6	Transition time measurement The time that the motor needs to completely open the valve from the closed condition is determined. This operating mode is activated when Mode = 6 and ModeActivate = TRUE is set. If endstop signals are used to measure the transition time, the valve will be opened completely from its current position, closed completely, and opened completely again. If GetTransitTime.InvertDirection = TRUE, this behavior is inverted. If position feedback is used to measure the transition time, the actuator will be moved from its current position to a target position. The output value limits are not taken into consideration during the transition time measurement. The actuator can travel to the high or the low endstop.
7	Error monitoring The control algorithm is switched off and no longer changes the valve position. This operating mode is activated instead of "Inactive" mode in the event of an error. All the following conditions must be met: • Automatic mode (Mode = 3) • Errorbehaviour = FALSE • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 4284) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
8	Approach substitute output value with error monitoring This operating mode is activated instead of "approach substitute output value" mode when an error occurs. PID_3Step moves the actuator to the substitute output value and then switches to "error monitoring" mode. All the following conditions must be met: • Automatic mode (Mode = 3) • Errorbehaviour = TRUE • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 4284) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
10	Manual mode without endstop signals The endstop signals are **not** taken into consideration, even though Config.ActuatorEndStopOn = TRUE. The output value limits are not taken into consideration. Otherwise, PID_3Step behaves the same as in manual mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

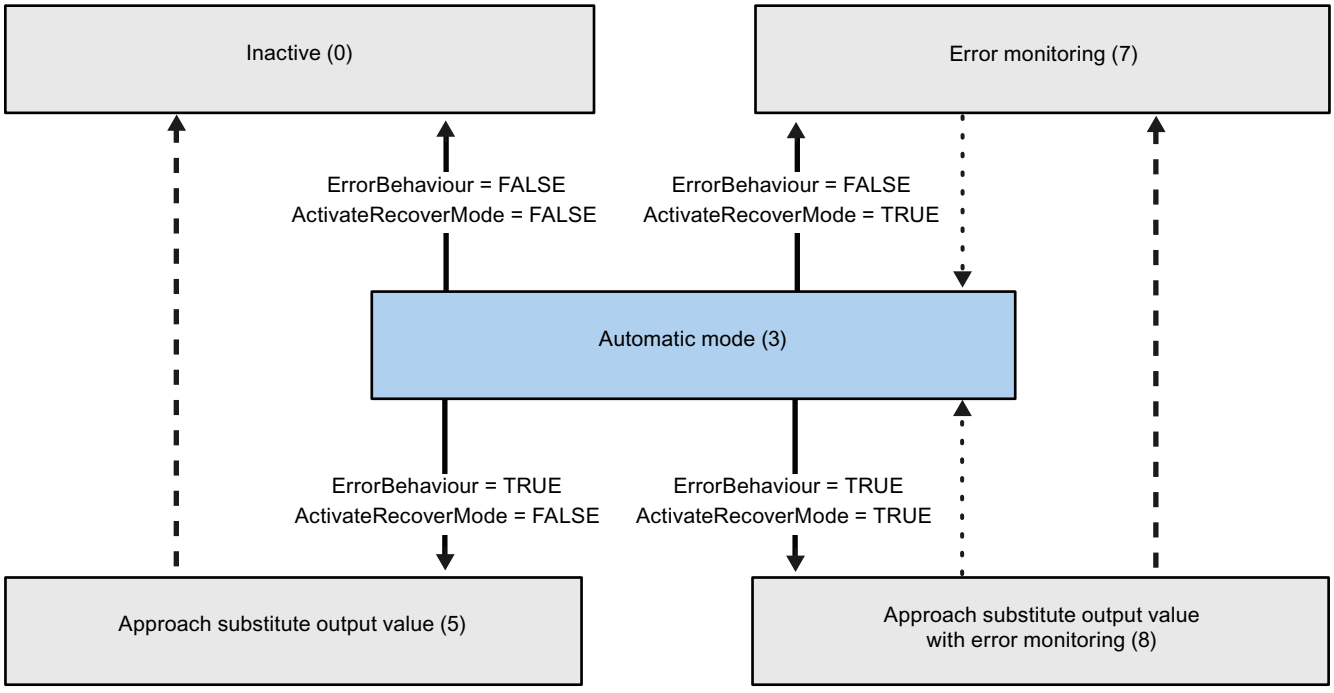
Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_3Step automatically switches the operating mode in the event of an error. The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. At the start of transition time measurement, pretuning, or fine tuning, PID_3Step saved the value of State in the Mode in/out parameter. PID_3Step therefore switches to the operating mode from which transition time measurement or tuning was started.

If ActivateRecoverMode = FALSE, "Inactive" or "Approach substitute output value" mode is activated.



Automatic switchover of operating mode after transition time measurement

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated after successful transition time measurement.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode after successful transition time measurement.

Automatic switchover of operating mode in automatic mode

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.

Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode when error is no longer pending.

Tag ActivateRecoverMode V2 (Page 4284)

Parameter ErrorBits V2 (Page 4281)

Parameter ErrorBits V2 (S7-1200, S7-1500)

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0003h, for example, indicates that the errors 0001h and 0002h are pending simultaneously.

If there is a position feedback, PID_3Step uses ManualValue as output value in manual mode. The exception is Errorbits = 10000h.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0004	Error during fine tuning. Oscillation of the process value could not be maintained. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step remains in fine tuning mode.
0080	Error during pretuning. The output value limits are not configured correctly or the actual value does not react as expected. Check whether the limits of the output value are configured correctly and match the control logic. Also make sure that the actual value does not oscillate strongly before starting pretuning. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_3Step cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
0800	Sampling time error: PID_3Step is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter. If this error occurred during simulation with PLCSIM, see the notes under Simulating PID_3Step V2 with PLCSIM (Page 6079).
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode. As soon as the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
2000	Invalid value at Feedback_PER parameter. Check whether an error is pending at the analog input. The actuator cannot be moved to the substitute output value and remains in its current position. In manual mode, you can change the position of the actuator only with Manual_UP and Manual_DN, and not with ManualValue. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
4000	Invalid value at Feedback parameter. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position. In manual mode, you can change the position of the actuator only with Manual_UP and Manual_DN, and not with ManualValue. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
8000	Error during digital position feedback. Actuator_H = TRUE and Actuator_L = TRUE. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. In order to move the actuator from this state, you must deactivate the "Actuator endstop" (Config.ActuatorEndStopOn = FALSE) or switch to manual mode without endstop signals (Mode = 10). If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If pretuning, fine tuning, or transition time measurement mode and ActivateRecoverMode = TRUE were active before the error occurred, PID_3Step switches to the operating mode that is saved in the Mode parameter.
10000	Invalid value at ManualValue parameter. Value has an invalid number format. The actuator cannot be moved to the manual value and remains in its current position. Specify a valid value in ManualValue or move the actuator in manual mode with Manual_UP and Manual_DN.
20000	Invalid value at SavePosition tag. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position.
40000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_3Step remains in automatic mode. If pretuning or fine tuning mode was active and ActivateRecoverMode = TRUE before the error occurred, PID_3Step switches to the operating mode saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled. The error has no effect during transition time measurement.

Tag ActivateRecoverMode V2 (S7-1200, S7-1500)

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

NOTICE
Your system may be damaged. If ActivateRecoverMode = TRUE, PID_3Step remains in automatic mode even if the process limit values are exceeded. This may damage your system. It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

Automatic mode

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" mode. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_3Step switches between the calculated output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more of the following errors occur, PID_3Step stays in automatic mode: • 0001h: The "Input" parameter is outside the process value limits. • 0800h: Sampling time error • 40000h: Invalid value at Disturbance parameter. If one or more of the following errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at Input_PER parameter. • 0200h: Invalid value at Input parameter. • 0400h: Calculation of output value failed. • 1000h: Invalid value at Setpoint parameter. If one or more of the following errors occur, PID_3Step can no longer move the actuator: • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback. • 20000h: Invalid value at SavePosition tag. Value has an invalid number format. The characteristics are independent of ErrorBehaviour. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Pretuning, fine tuning, and transition time measurement

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" mode. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate. The controller changes to "Inactive" mode after successful transition time measurement.
TRUE	If the following error occurs, PID_3Step remains in the active mode: • 0020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 10000h: Invalid value at ManualValue parameter. • 20000h: Invalid value at SavePosition tag. When any other error occurs, PID_3Step cancels the tuning and switches to the mode from which tuning was started.

Manual mode

ActivateRecoverMode is not effective in manual mode.

Static tags of PID_3Step V2 (Page 4268)

Parameters State and Mode V2 (Page 4276)

Tag Warning V2 (S7-1200, S7-1500)

If several warnings are pending simultaneously, their values are displayed with binary addition. The display of warning 0005h, for example, indicates that the warnings 0001h and 0004h are pending simultaneously.

Warning (DW#16#...)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the TIR.TuneRule = 3 method.
0010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The specified rule for tuning is not supported. No PID parameters are calculated.
0400	The transition time cannot be measured because the actuator settings do not match the selected measuring method.
0800	The difference between the current position and the new output value is too small for transition time measurement. This can produce incorrect results. The difference between the current output value and new output value must be at least 50% of the entire control range.
1000	The substitute output value cannot be reached because it is outside the output value limits.
2000	The actuator was moved in one direction for longer than Config.VirtualActuatorLimit × Retain.TransitTime. Check whether the actuator has reached an endstop signal.

The following warnings are deleted as soon as the cause is eliminated:

- 0001h
- 0004h
- 0008h
- 0040h
- 0100h
- 2000h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

PID_3Step V1 (S7-1200)

Description PID_3Step V1 (S7-1200)

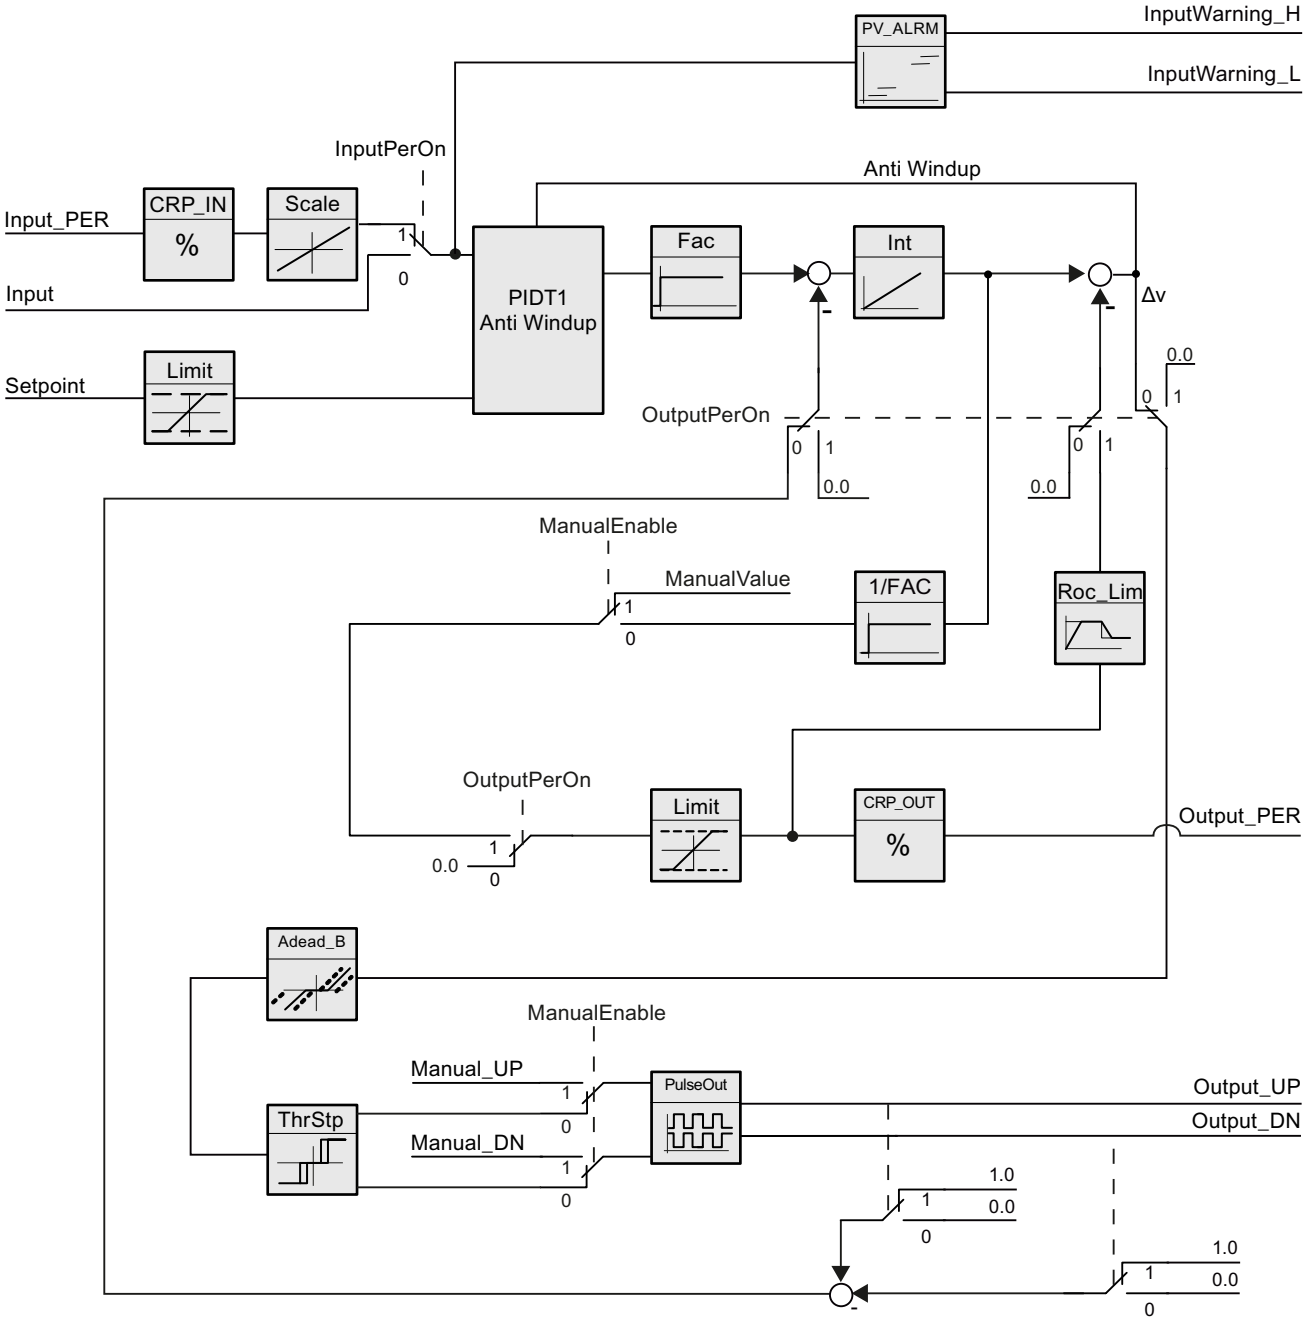
Description

You use the PID_3Step instruction to configure a PID controller with self tuning for valves or actuators with integrating behavior.

The following operating modes are possible:

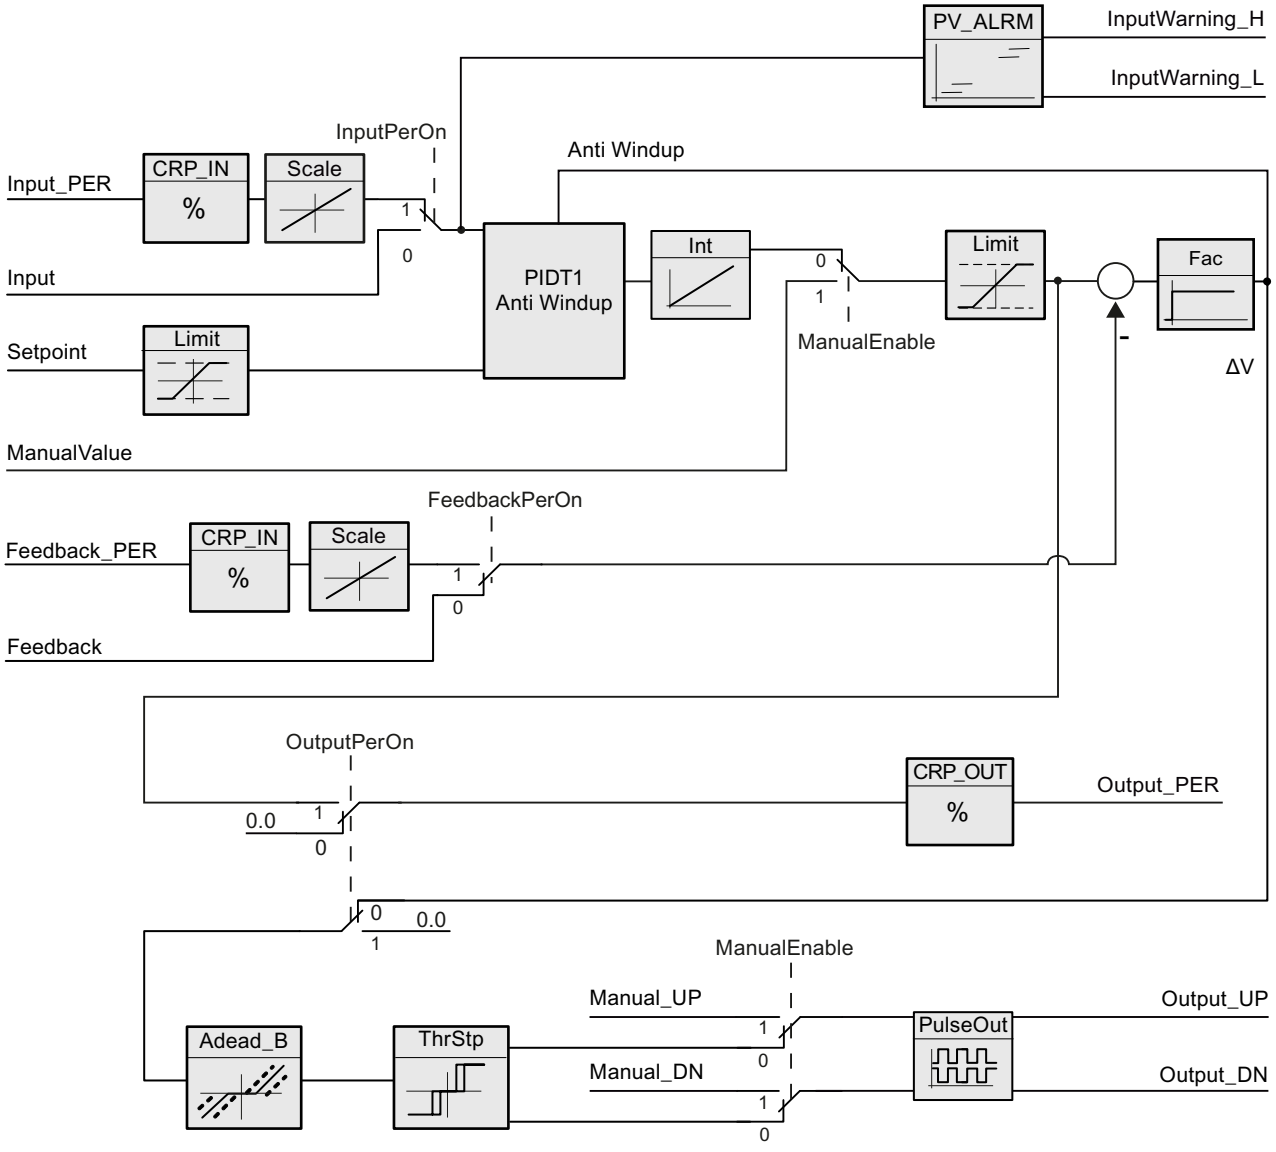
- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Approach substitute output value
- Transition time measurement
- Approach substitute output value with error monitoring
- Error monitoring

For a more detailed description of the operating modes, see the State parameter.



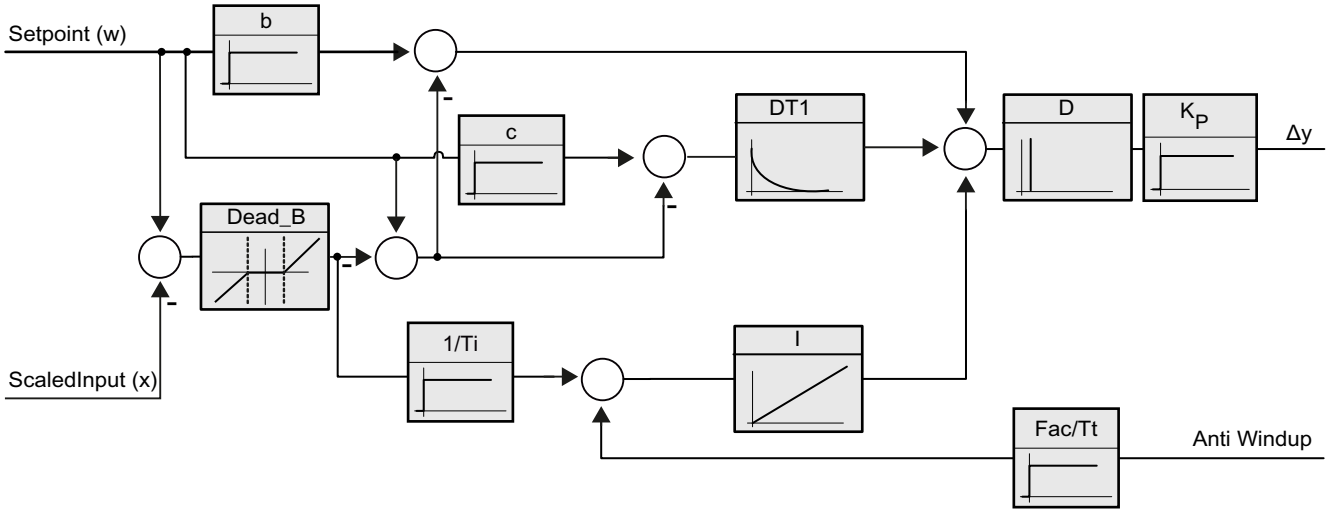
PID algorithm

PID_3Step is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The following equation is used to calculate the output value.



$$\Delta y = K_p \cdot s \cdot \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$

Symbol	Description
y	Output value
K_p	Proportional gain
s	Laplace operator
b	Proportional action weighting
w	Setpoint
x	Process value
T_I	Integral action time
a	Derivative delay coefficient (T1 = a × T_D)
T_D	Derivative action time
c	Derivative action weighting



Block diagram without position feedback

Block diagram with position feedback

Block diagram of PIDT1 with anti-windup

Call

PID_3Step is called in a constant time interval of the cycle time of the calling OB (preferably in a cyclic interrupt OB).

Download to device

The actual values of retentive tags are only updated when you download PID_3Step completely.

Downloading technology objects to device (Page 6000)

Startup

At the startup of the CPU, PID_3Step starts in the operating mode that was last active. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE.

Reaction to error

If errors occur, these are output in the Error parameter. You configure the reaction of PID_3Step using the ErrorBehaviour and ActivateRecoverMode tags.

ErrorBehaviour	ActivateRecoverMode	Actuator setting configuration Set Output to	Reaction
0	FALSE	Current output value	Switch to "Inactive" mode (Mode = 0)
0	TRUE	Current output value while error is pending	Switch to "Error monitoring" mode (Mode = 7)

ErrorBehaviour	ActivateRecoverMode	Actuator setting configuration Set Output to	Reaction
1	FALSE	Substitute output value	Switch to "Approach substitute output value" mode (Mode = 5) Switch to "Inactive" mode (Mode = 0)
1	TRUE	Substitute output value while error is pending	Switch to "Approach substitute output value with error monitoring" mode (Mode = 8) Switch to "Error monitoring" mode (Mode = 7)

The ErrorBits parameter shows which errors have occurred.

Parameter ErrorBits V1 (Page 4312)

Configuring PID_3Step V1 (Page 6079)

Operating principle PID_3Step V1 (S7-1200)

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0001hex).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warnings = 0040hex), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_3Step automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller range. PID_3Step checks whether this range falls within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Limiting the output value

You specify a high limit and low limit of the output value in the Config.OutputUpperLimit and Config.OutputLowerLimit tags. The output value limits must be within "Low endstop" and "High endstop".

- High endstop: Config.FeedbackScaling.UpperPointOut
- Low endstop: Config.FeedbackScaling.LowerPointOut

Rule:

UpperPointOut ≥ OutputUpperLimit > OutputLowerLimit ≥ LowerPointOut

The valid values for "High endstop" and "Low endstop" depend upon:

- FeedbackOn
- FeedbackPerOn
- OutputPerOn

OutputPerOn	FeedbackOn	FeedbackPerOn	LowerPointOut	UpperPointOut
FALSE	FALSE	FALSE	Cannot be set (0.0%)	Cannot be set (100.0%)
FALSE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
FALSE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	FALSE	FALSE	Cannot be set (100.0%)	Cannot be set (100.0%)
TRUE	TRUE	FALSE	-100.0% or 0.0%	0.0% or +100.0%
TRUE	TRUE	TRUE	-100.0% or 0.0%	0.0% or +100.0%

If OutputPerOn = FALSE and FeedbackOn = FALSE, you cannot limit the output value. The digital outputs are reset with Actuator_H = TRUE or Actuator_L = TRUE, or after a travel time amounting to 110% of the motor transition time.

The output value is 27648 at 100% and -27648 at -100%. PID_3Step must be able to completely close the valve. Therefore, zero must be included in the output value limits.

Note

Use with two or more actuators

PID_3 Step is not suitable for use with two or more actuators (for example, in heating/cooling applications), because different actuators need different PID parameters to achieve a good control response.

Substitute output value

If an error has occurred, PID_3Step can output a substitute output value and move the actuator to a safe position that is specified in the SavePosition tag. The substitute output value must be within the output value limits.

Monitoring signal validity

The values of the following parameters are monitored for validity:

- Setpoint
- Input
- Input_PER
- Feedback
- Feedback_PER
- Output

Monitoring the PID_3Step sampling time

Ideally, the sampling time is equivalent to the cycle time of the calling OB. The PID_3Step instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (ErrorBits = 0800 hex).

PID_3Step is set to "Inactive" mode during tuning under the following conditions:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

In automatic mode, PID_3Step is set to "Inactive" mode under the following conditions:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time. All other functions of PID_3Step are executed at every call.

Measuring the motor transition time

The motor transition time is the time in seconds the motor requires to move the actuator from the closed to the opened state. The maximum time that the actuator is moved in one direction is 110% of the motor transition time. PID_3Step requires the motor transition time to be as accurate as possible for good controller results. The data in the actuator documentation contains average values for this type of actuator. The value for the specific actuator used may differ. You can measure the motor transition time during commissioning. The output value limits are not taken into consideration during the motor transition time measurement. The actuator can travel to the high or the low endstop.

The motor transition time is taken into consideration in the calculation of the analog output value as well as in the calculation of the digital output values. It is mainly required for correct operation during auto-tuning and the anti-windup behavior. You should therefore configure the

motor transition time with the value that the motor requires to move the actuator from the closed to the opened state.

If no relevant motor transition time is in effect in your process (e.g. with solenoid valves), so that the output value has a direct and full effect on the process, use PID_Compact instead.

Control logic

An increase of the output value is generally intended to cause an increase in the process value. This is referred to as a normal control logic. For cooling and discharge control systems, it may be necessary to invert the control logic. PID_3Step does not work with negative proportional gain. If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value. The control logic is also taken into account during pretuning and fine tuning.

Configuring PID_3Step V1 (Page 6079)

PID_3Step V1 input parameters (S7-1200)

Table 11-76

Parameters	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode
Input	REAL	0.0	A tag of the user program is used as source for the process value. If you are using parameter Input, then Config.InputPer-On = FALSE must be set.
Input_PER	WORD	W#16#0	An analog input is used as the source of the process value. If you are using parameter Input_PER, then Config.InputPer-On = TRUE must be set.
Actuator_H	BOOL	FALSE	Digital position feedback of the valve for the high endstop If Actuator_H = TRUE, the valve is at the high endstop and is no longer moved towards this direction.
Actuator_L	BOOL	FALSE	Digital position feedback of the valve for the low endstop If Actuator_L = TRUE, the valve is at the low endstop and is no longer moved towards this direction.
Feedback	REAL	0.0	Position feedback of the valve If you are using parameter Feedback, then Config.Feedback-PerOn = FALSE must be set.
Feedback_PER	WORD	W#16#0	Analog position feedback of a valve If you are using parameter Feedback_PER, then Config.Feed-backPerOn = TRUE must be set. Feedback_PER is scaled based on the tags: • Config.FeedbackScaling.LowerPointIn • Config.FeedbackScaling.UpperPointIn • Config.FeedbackScaling.LowerPointOut • Config.FeedbackScaling.UpperPointOut

Parameters	Data type	Default	Description
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge selects "Manual mode", while State = 4, Retain.Mode remains unchanged. • A TRUE -> FALSE edge selects the most recently active operating mode A change of Retain.Mode will not take effect during ManualEnable = TRUE. The change of Retain.Mode will only be considered upon a TRUE -> FALSE edge at ManualEnable . **PID_3Step V1.1**If ManualEnable = TRUE when the CPU starts, PID_3Step starts in manual mode. A rising edge (FALSE > TRUE) at ManualEnable is not necessary. **PID_3Step V1.0** At the start of the CPU, PID_3Step only switches to manual mode with a rising edge (FALSE->TRUE) at ManualEnable . Without rising edge, PID_3Step starts in the last operating mode in which ManualEnable was FALSE.
ManualValue	REAL	0.0	In manual mode, you specify the absolute position of the valve. ManualValue will only be evaluated if you are using OutputPer, **or** if position feedback is available.
Manual_UP	BOOL	FALSE	In manual mode, every rising edge opens the valve by 5% of the total control range, or for the duration of the minimum motor transition time. Manual_UP is evaluated only if you are not using Output_PER and there is no position feedback available.
Manual_DN	BOOL	FALSE	In manual mode, every rising edge closes the valve by 5% of the total control range, or for the duration of the minimum motor transition time. Manual_DN is evaluated only if you are not using Output_PER and there is no position feedback available.
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warning are reset – Intermediate controller values are reset (PID parameters are retained) • TRUE -> FALSE edge – Change in most recent active mode – If automatic mode was active before, switchover to automatic mode is bumpless.

PID_3Step V1 output parameters (S7-1200)

Table 11-77

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
ScaledFeedback	REAL	0.0	Scaled position feedback For an actuator without position feedback, the position of the actuator indicated by ScaledFeedback is very imprecise. ScaledFeedback may only be used for rough estimation of the current position in this case.
Output_UP	BOOL	FALSE	Digital output value for opening the valve If Config.OutputPerOn = FALSE, the Output_UP parameter is used.
Output_DN	BOOL	FALSE	Digital output value for closing the valve If Config.OutputPerOn = FALSE, the Output_DN parameter is used.
Output_PER	WORD	W#16#0	Analog output value If Config.OutputPerOn = TRUE, Output_PER is used. Use Output_PER if you are using a valve as actuator which is triggered via an analog output and controlled with a continuous signal, e.g. 0...10 V or 4...20 mA. The value at Output_PER corresponds to the target position of the valve, e.g. Output_PER = 13824, when the valve is to be opened by 50%.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached. In the CPU, the setpoint is limited to the configured absolute setpoint high limit. The configured absolute process value high limit is the default for the setpoint high limit. If you configure Config.SetpointUpperLimit to a value within the process value limits, this value is used as the setpoint high limit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit has been reached. In the CPU, the setpoint is limited to the configured absolute setpoint low limit. The configured absolute process value low limit is the default setting for the setpoint low limit. If you configure Config.SetpointLowerLimit to a value within the process value limits, this value is used as the setpoint low limit.
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit.
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit.

Parameter	Data type	Default	Description
State	INT	0	The State parameter (Page 4305) shows the current operating mode of the PID controller. You change the operating mode with the Retain.Mode tag. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Approach substitute output value • State = 6: Transition time measurement • State = 7: Error monitoring • State = 8: Approach substitute output value with error monitoring
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending.
ErrorBits	DWORD	DW#16#0	The ErrorBits parameter (Page 4312) indicates the error messages.

Parameter ErrorBits V1 (Page 4312)

PID_3Step V1 static tags (S7-1200)

You must not change tags that are not listed. These are used for internal purposes only.

Table 11-78

Tag	Data type	Default	Description
ActivateRecoverMode	BOOL	TRUE	The ActivateRecoverMode tag (Page 4314) determines the reaction to error.
RunModeByStartup	BOOL	TRUE	Activate Mode after CPU restart If RunModeByStartup = TRUE, the controller returns to the last active operating mode after a CPU restart. If RunModeByStartup = FALSE, the controller remains inactive after a CPU restart.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., °C, or °F.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature.

Tag	Data type	Default	Description
ErrorBehaviour	INT	0	If ErrorBehaviour = 0 and an error has occurred, the valve stays at its current position and the controller switches directly to "Inactive" or "Error monitoring" mode. If ErrorBehaviour = 1 and an error occurs, the actuator moves to the substitute output value and only then switches to "Inactive" or "Error monitoring" mode. If the following errors occur, you can no longer move the valve to a configured substitute output value. • 2000h: Invalid value at Feedback_PER parameter. • 4000h: Invalid value at Feedback parameter. • 8000h: Error during digital position feedback.
Warning	DWORD	DW#16#0	The Warning tag (Page 4305) displays the warnings generated since a Reset or since the last operating mode switchover. Cyclic warnings (for example, process value warning) are shown until the cause of the warning is removed. They are automatically deleted once their cause has gone. Non-cyclic warnings (for example, point of inflection not found) remain and are deleted like errors.
SavePosition	REAL	0.0	Substitute output value If ErrorBehaviour = 1 and an error occurs, the actuator moves to a safe position for the plant and only then switches to "Inactive" mode.
CurrentSetpoint	REAL	0.0	Currently active setpoint. This value is frozen at the start of tuning.
Progress	REAL	0.0	Progress of tuning as a percentage (0.0 - 100.0)
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used. If InputPerOn = FALSE, the Input parameter is used.
Config.OutputPerOn	BOOL	FALSE	If OutputPerOn = TRUE, the Output_PER parameter is used. If OutputPerOn = FALSE, the Ouput_UP and Output_DN parameters are used.
Config.LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE.
Config.InvertControl	BOOL	FALSE	Invert control logic If InvertControl = TRUE, an increasing control deviation causes a reduction in the output value.
Config.FeedbackOn	BOOL	FALSE	If FeedbackOn = FALSE, a position feedback is simulated. Position feedback is generally activated when FeedbackOn = TRUE.
Config.FeedbackPerOn	BOOL	FALSE	FeedbackPerOn is only effective when FeedbackOn = TRUE. If FeedbackPerOn = TRUE, the analog input is used for the position feedback (Feedback_PER parameter). If FeedbackPerOn = FALSE, the Feedback parameter is used for the position feedback.
Config.ActuatorEndStopOn	BOOL	FALSE	If ActuatorEndStopOn = TRUE, the digital position feedback Actuator_L and Actuator_H are taken into consideration.

Tag	Data type	Default	Description
Config.InputUpperLimit	REAL	120.0	High limit of the process value At the I/O input, the process value can be a maximum of 18% higher than the standard range (overrange). An error is no longer signaled due to a violation of the "Process value high limit". Only a wire-break and a short-circuit are recognized and PID_3Step reacts according to the configured reaction to error. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	+3.402822e+38	Warning high limit of the process value If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning InputUpperWarning ≤ InputUpperLimit
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning InputLowerWarning ≥ InputLowerLimit
Config.OutputUpperLimit	REAL	100.0	High limit of output value For details, see OutputLowerLimit
Config.OutputLowerLimit	REAL	0.0	Low limit of output value If OutputPerOn = TRUE or FeedbackOn = TRUE, the range of values from -100% to +100%, including zero, is valid. At -100%, Output = -27648; at +100%, Output = 27648 If OutputPerOn = FALSE, the range of values from 0% to 100% is valid. The valve is completely closed at 0% and completely opened at 100%.
Config.SetpointUpperLimit	REAL	+3.402822e+38	High limit of setpoint If you set SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is preassigned as the setpoint high limit. If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit.
Config.SetpointLowerLimit	REAL	-3.402822e+38	Low limit of the setpoint If you set SetpointLowerLimit outside the process value limits, the configured absolute process value low limit is preassigned as the setpoint low limit. If you set SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit.

Tag	Data type	Default	Description
Config.MinimumOnTime	REAL	0.0	Minimum ON time Minimum time in seconds for which the servo drive must be switched on. Config.MinimumOnTime is only effective if Output_UP and Output_DN are used (Config.OutputPerOn = FALSE).
Config.MinimumOffTime	REAL	0.0	Minimum OFF time Minimum time in seconds for which the servo drive must be switched off. Config.MinimumOffTime is only effective if Output_UP and Output_DN are used (Config.OutputPerOn = FALSE).
Config.TransitTime	REAL	30.0	Motor transition time Time in seconds the actuating drive requires to move the valve from the closed to the opened state.
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.UpperPointOut	REAL	100.0	Scaled high process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.InputScaling.LowerPointOut	REAL	0.0	Scaled low process value Input_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the InputScaling structure.
Config.FeedbackScaling.UpperPointIn	REAL	27648.0	Scaling Feedback_PER high Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointIn	REAL	0.0	Scaling Feedback_PER low Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.UpperPointOut	REAL	100.0	High endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.
Config.FeedbackScaling.LowerPointOut	REAL	0.0	Low endstop Feedback_PER is converted to a percentage based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn of the FeedbackScaling structure.

Tag	Data type	Default	Description
GetTransitTime.InvertDirection	BOOL	FALSE	If InvertDirection = FALSE, the valve is fully opened, closed, and then reopened in order to determine the valve transition time. If InvertDirection = TRUE, the valve is fully closed, opened, and then closed again.
GetTransitTime.SelectFeedback	BOOL	FALSE	If SelectFeedback = TRUE, then Feedback_PER, or Feedback is taken into consideration in the transition time measurement. If SelectFeedback = FALSE, then Actuator_H and Actuator_L are taken into consideration in the transition time measurement.
GetTransitTime.Start	BOOL	FALSE	If Start = TRUE, the transition time measurement is started.
GetTransitTime.State	INT	0	Current phase of the transition time measurement • State = 0: Inactive • State = 1: Open valve completely • State = 2: Close valve completely • State = 3: Move valve to target position (NewOutput) • State = 4: Transition time measurement successfully completed • State = 5: Transition time measurement canceled
GetTransitTime.NewOutput	REAL	0.0	Target position for transition time measurement with position feedback The target position must be between "High endstop" and "Low endstop". The difference between NewOutput and ScaledFeedback must be at least 50% of the permissible control range.
CycleTime.StartEstimation	BOOL	TRUE	If StartEstimation = TRUE, the measurement of the PID_3Step sampling time is started. CycleTime.StartEstimation = FALSE once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If EnEstimation = TRUE, the PID_3Step sampling time is calculated.
CycleTime.EnMonitoring	BOOL	TRUE	If EnMonitoring = TRUE, the PID_3Step sampling time is monitored. If it is not possible to execute PID_3Step within the sampling time, the error 0800h is output and the operating mode is switched. ActivateRecoverMode and ErrorBehaviour determine which operating mode is switched to. If EnMonitoring = FALSE, the PID_3Step sampling time is not monitored, the error 0800h is not output, and the operating mode is not switched.
CycleTime.Value	REAL	0.1	PID_3Step sampling time in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser. You can reload values from the CtrlParamsBackUp structure with Config.LoadBackUp = TRUE.
CtrlParamsBackUp.Gain	REAL	1.0	Saved proportional gain
CtrlParamsBackUp.Ti	REAL	20.0	Saved integral action time
CtrlParamsBackUp.Td	REAL	0.0	Saved derivative action time
CtrlParamsBackUp.TdFiltRatio	REAL	0.0	Saved derivative delay coefficient
CtrlParamsBackUp.PWeighting	REAL	0.0	Saved proportional action weighting

Tag	Data type	Default	Description
CtrlParamsBackUp.DWeighting	REAL	0.0	Saved derivative action weighting
CtrlParamsBackUp.Cycle	REAL	1.0	Saved sampling time of PID algorithm
CtrlParamsBackUp.InputDeadBand	REAL	0.0	Saved dead zone width of the control deviation
PIDSelfTune.SUT.CalculateSUTParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateSUTParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRuleSUT. CalculateSUTParams is set to FALSE following calculation.
PIDSelfTune.SUT.TuneRuleSUT	INT	1	Methods used to calculate parameters during pretuning: • TuneRuleSUT = 0: PID fast I • TuneRuleSUT = 1: PID slow I • TuneRuleSUT = 2: Chien, Hrones and Reswick PID • TuneRuleSUT = 3: Chien, Hrones, Reswick PI • TuneRuleSUT = 4: PID fast II • TuneRuleSUT = 5: PID slow II
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning:
PIDSelfTune.TIR.RunIn	BOOL	FALSE	• RunIn = FALSE Pretuning is started when fine tuning is started from inactive or manual mode. If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint. Only then will fine tuning start. If pretuning is not possible, PID_3Step switches to "Inactive" mode. • RunIn = TRUE The pretuning is skipped. PID_3Step attempts to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Only then will fine tuning start. RunIn is set to FALSE after fine tuning.
PIDSelfTune.TIR.CalculateTIRParams	BOOL	FALSE	The properties of the controlled system are saved during tuning. If CalculateTIRParams = TRUE, the PID parameters are recalculated on the basis of these properties. The PID parameters are calculated using the method set in TuneRuleTIR. CalculateTIRParams is set to FALSE following calculation.
PIDSelfTune.TIR.TuneRuleTIR	INT	0	Methods used to calculate parameters during fine tuning: • TuneRuleTIR = 0: PID automatic • TuneRuleTIR = 1: PID fast • TuneRuleTIR = 2: PID slow • TuneRuleTIR = 3: Ziegler-Nichols PID • TuneRuleTIR = 4: Ziegler-Nichols PI • TuneRuleTIR = 5: Ziegler-Nichols P
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of "fine tuning":

Tag	Data type	Default	Description
Retain.Mode	INT	0	A change to the value of Retain.Mode initiates a switch to another operating mode. The following operating mode is enabled upon a change of Mode to: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode • Mode = 5: Approach substitute output value • Mode = 6: Transition time measurement • Mode = 7: Error monitoring • Mode = 8: Approach substitute output value with error monitoring Mode is retentive.
Retain.CtrlParams.SetByUser	BOOL	FALSE	If SetByUser = FALSE, the PID parameters are determined automatically and PID_3Step operates with a dead zone at the output value. The dead zone width is calculated during tuning on the basis of the standard deviation of the output value and saved in Retain.CtrlParams.OutputDeadBand. If SetByUser = TRUE, the PID parameters are entered manually and PID_3 Step operates without a dead zone at the output value. Retain.CtrlParams.OutputDeadBand = 0.0 SetByUser is retentive.
Retain.CtrlParams.Gain	REAL	1.0	Active proportional gain Gain is retentive.
Retain.CtrlParams.Ti	REAL	20.0	• Ti > 0.0: Active integral action time • Ti = 0.0: Integral action is deactivated Ti is retentive.
Retain.CtrlParams.Td	REAL	0.0	• Td > 0.0: Active derivative action time • Td = 0.0: Derivative action is deactivated Td is retentive.
Retain.CtrlParams.TdFiltRatio	REAL	0.0	Active derivative delay coefficient TdFiltRatio is retentive.
Retain.CtrlParams.PWeighting	REAL	0.0	Active proportional action weighting PWeighting is retentive.
Retain.CtrlParams.DWeighting	REAL	0.0	Active derivative action weighting DWeighting is retentive.
Retain.CtrlParams.Cycle	REAL	1.0	Active sampling time of PID algorithm in seconds, rounded to an integer multiple of the cycle time of the calling OB. Cycle is retentive.
Retain.CtrlParams.InputDeadBand	REAL	0.0	Dead zone width of the control deviation InputDeadBand is retentive.

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller. "Inactive" mode is forced by setting the "Retain.Mode" tag to "0".

Downloading technology objects to device (Page 6000)

Parameter State and Retain.Mode V1 (S7-1200)

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

To switch from one operating mode to another, you must change the Retain.Mode tag. This also applies when the value for the new operating mode is already in Retain.Mode. For example, set Retain.Mode = 0 first and then Retain.Mode = 3. Provided the current operating mode of the controller permits this switchover, State will be set to the value of Retain.Mode.

When PID_3Step automatically switches from one operating mode to another, the following applies: State != Retain.Mode.

Examples:

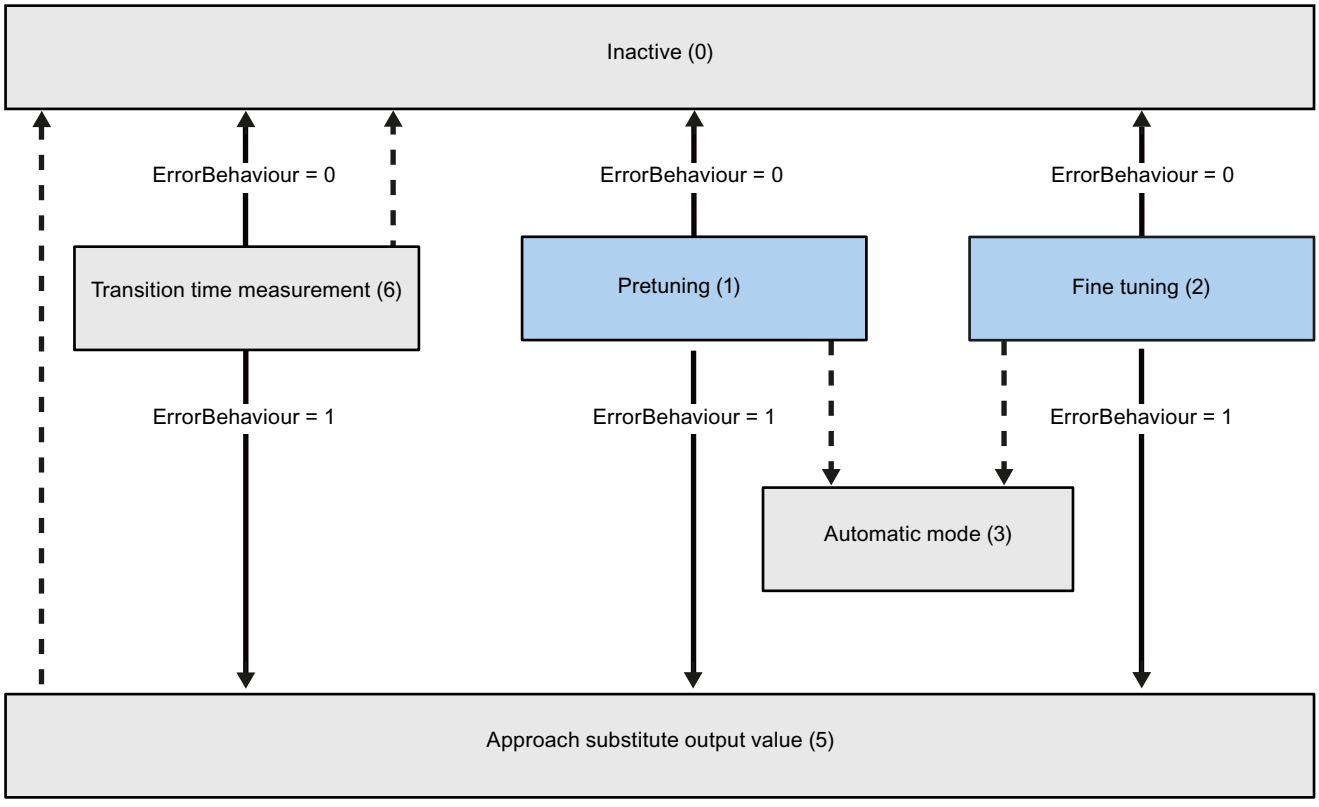
- After successful pretuning
  State = 3 and Retain.Mode = 1
- In the event of an error
  State = 0 and Retain.Mode remain at the previous value, for example, Retain.Mode = 3
- ManualEnalbe = TRUE
  State = 4 and Retain.Mode remain at the previous value, e.g., Retain.Mode = 3

Note

You want, for example, to repeat successful fine tuning without exiting automatic mode with Mode = 0.

Setting Retain.Mode to an invalid value such as 9999 for one cycle has no effect on State. Set Mode = 2 in the next cycle. In this way, you can generate a change to Retain.Mode without first switching to "Inactive" mode.

Meaning of values



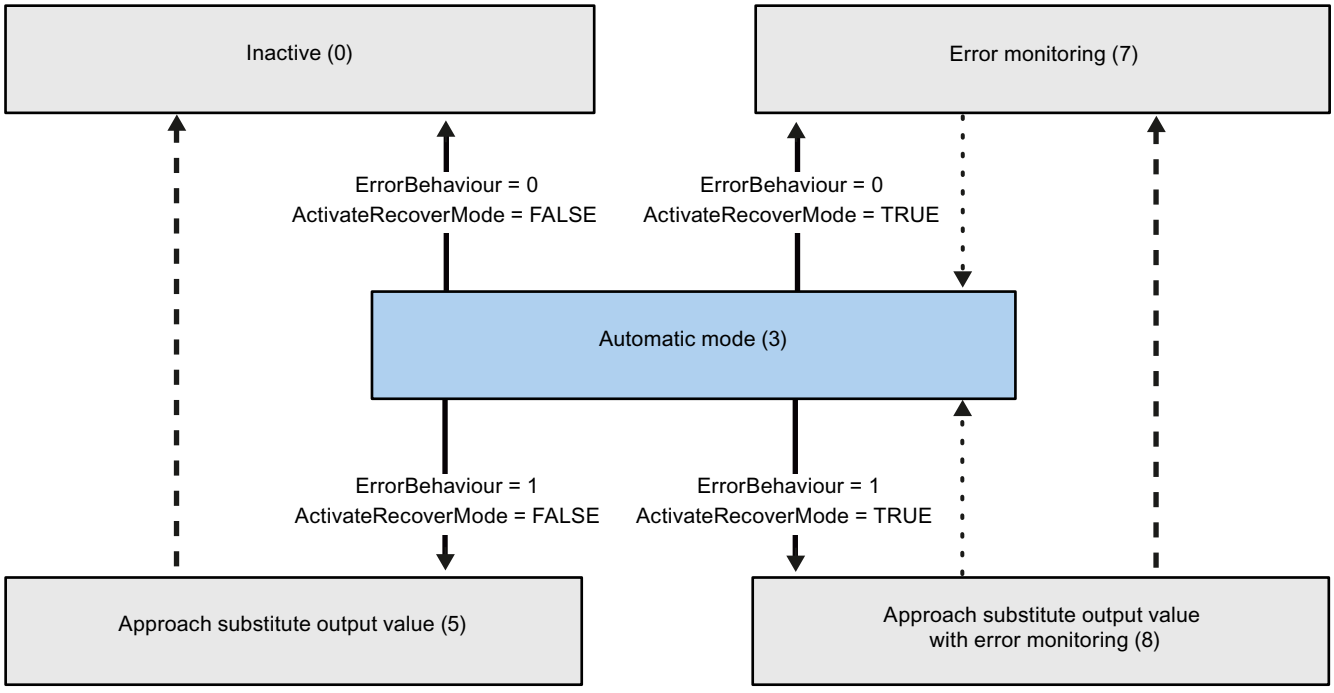
State / Retain.Mode	Description
0	Inactive The controller is switched off and no longer changes the valve position.
1	Pretuning The pretuning determines the process response to a pulse of the output value and searches for the point of inflection. The optimized PID parameters are calculated as a function of the maximum rate of rise and dead time of the controlled system. Pretuning requirements: • State = 0 or State = 4 • ManualEnable = FALSE • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher as compared to the noise. Before the PID parameters are recalculated, they are backed up and can be reactivated with Config.LoadBackUp. The setpoint is frozen in the CurrentSetpoint tag. The controller switches to automatic mode following successful pretuning and to "Inactive" mode following unsuccessful pretuning. The pretuning phase is indicated with the SUT.State tag.

State / Retain.Mode	Description
2	Fine tuning Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are tuned based on the amplitude and frequency of this oscillation. The differences between the process response during pretuning and fine tuning are analyzed. All PID parameters are recalculated from the results. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. PID_3Step automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. The PID parameters are backed up before fine tuning. They can be reactivated with Config.LoadBackUp. The setpoint is frozen in the CurrentSetpoint tag. Requirements for fine tuning: • The motor transition time has been configured or measured. • The setpoint and the process value lie within the configured limits. • ManualEnable = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode Fine tuning proceeds as follows when started from: • Automatic mode (State = 3) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_3Step controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0) or manual mode (State = 4) Pretuning is always started first. The determined PID parameters will be used for control until the control loop has stabilized and the requirements for fine tuning have been met. If PIDSelfTune.TIR.RunIn = TRUE, pretuning is skipped and an attempt is made to reach the setpoint with the minimum or maximum output value. This can produce increased overshoot. Fine tuning then starts automatically. The controller switches to automatic mode following successful fine tuning. If fine tuning was not successful, the controller switches to "Inactive" mode. The fine tuning phase is indicated with the TIR.State tag.
3	Automatic mode In automatic mode, PID_3Step controls the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is fulfilled: • Pretuning successfully completed • Fine tuning successfully completed • Changing the Retain.Mode tag to the value 3. When the CPU is switched on or switches from Stop to RUN mode, PID_3Step starts in the most recently active operating mode. To leave PID_3Step in "Inactive" mode, set RunModeByStartup = FALSE. The ActivateRecoverMode tag is taken into consideration in automatic mode.

State / Retain.Mode	Description
4	Manual mode In manual mode, you specify manual output values in the Manual_UP and Manual_DN parameters or ManualValue parameter. Whether or not the actuator can be moved to the output value in the event of an error is described in the ErrorBits parameter. This operating mode is enabled if Retain.Mode = 4, or on a rising edge at ManualEnable. If ManualEnable changes to TRUE, only State changes. Retain.Mode retains its current value. On a falling edge at ManualEnable, PID_3Step returns to the previous operating mode. The switchover to automatic mode is bumpless. **PID_3Step V1.1** Manual mode is always possible in the event of an error. **PID_3Step V1.0** Manual mode is dependent on the ActivateRecoverMode tag in the event of an error.
5	Approach substitute output value This operating mode is activated in the event of an error or when Reset = TRUE if Errorbehaviour = 1 and ActivateRecoverMode = FALSE.. PID_3Step moves the actuator to the substitute output value and then switches to "Inactive" mode.
6	Transition time measurement The time that the motor needs to completely open the valve from the closed condition is determined. This operating mode is activated when GetTransitTime.Start = TRUE is set. If endstop signals are used to measure the transition time, the valve will be opened completely from its current position, closed completely, and opened completely again. If GetTransitTime.InvertDirection = TRUE, this behavior is inverted. If position feedback is used to measure the transition time, the actuator will be moved from its current position to a target position. The output value limits are not taken into consideration during the transition time measurement. The actuator can travel to the high or the low endstop.
7	Error monitoring The control algorithm is switched off and no longer changes the valve position. This operating mode is activated instead of "Inactive" mode in the event of an error. All the following conditions must be met: • Mode = 3 (automatic mode) • Errorbehaviour = 0 • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 4314) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.
8	Approach substitute output value with error monitoring This operating mode is activated instead of "Approach substitute output value" mode in the event of an error. PID_3Step moves the actuator to the substitute output value and then switches to "Error monitoring" mode. All the following conditions must be met: • Mode = 3 (automatic mode) • Errorbehaviour = 1 • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode (Page 4314) is effective. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Automatic switchover of operating mode during commissioning

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour on the switchover of operating mode from transition time measurement, pretuning, and fine tuning modes.

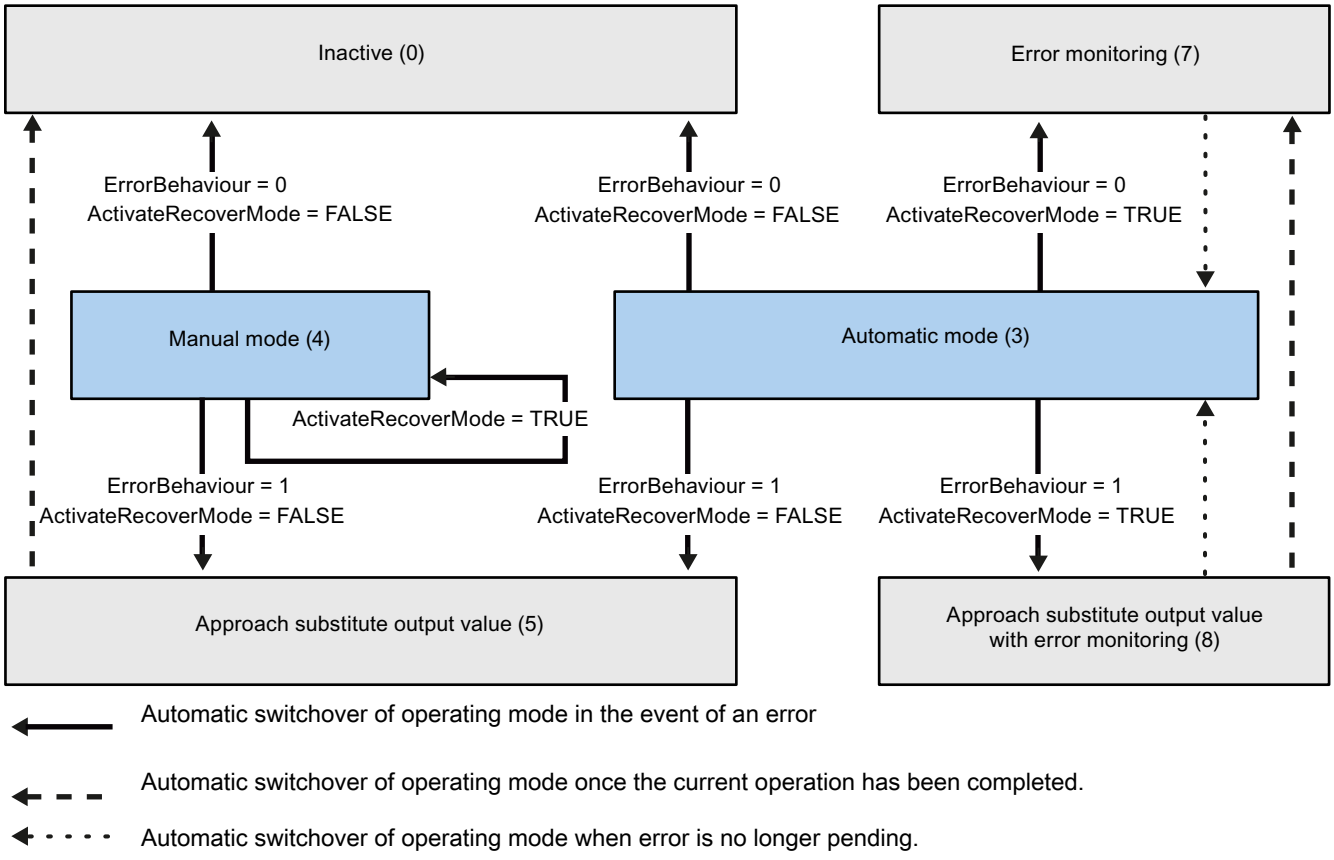


Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode in automatic mode (PID_3Step V1.1)

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.



Automatic switchover of operating mode in the event of an error

Automatic switchover of operating mode once the current operation has been completed.

Automatic switchover of operating mode in automatic and manual modes (PID_3Step V1.0)

PID_3Step automatically switches the operating mode in the event of an error. The following diagram illustrates the influence of ErrorBehaviour and ActivateRecoverMode on this switchover of operating mode.

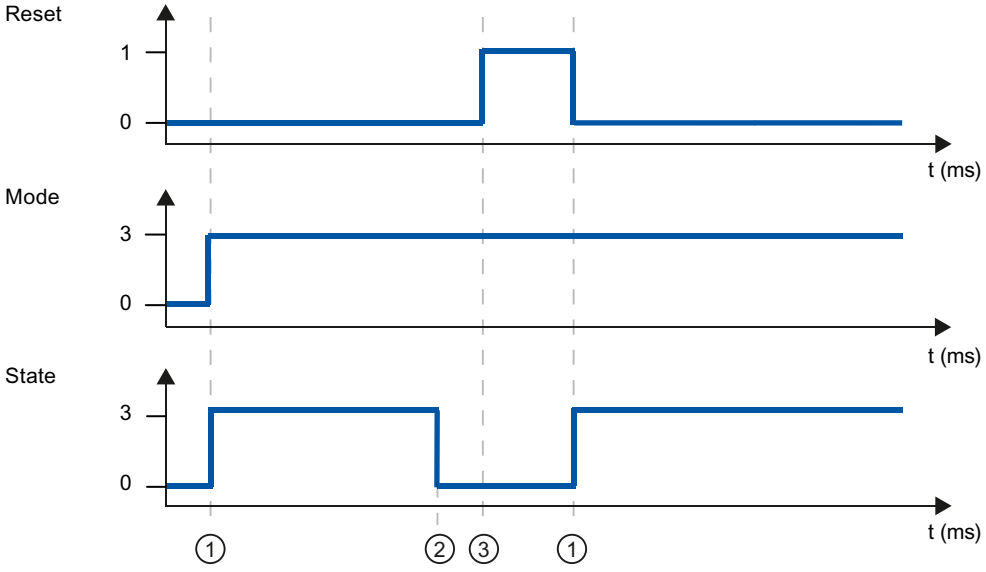
Tag ActivateRecoverMode V1 (Page 4314)

Parameter ErrorBits V1 (Page 4312)

Parameter ErrorBits V1 (S7-1200)



If several errors are pending simultaneously, the values of the error codes are displayed with binary addition. The display of error code 0003, for example, indicates that the errors 0001 and 0002 are pending simultaneously.

ErrorBits (DW#16#...)	Description
0000	There is no error.
0001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If ActivateRecoverMode = TRUE and ErrorBehaviour = 1, the actuator moves to the substitute output value. If ActivateRecoverMode = TRUE and ErrorBehaviour = 0, the actuator stops in its current position. If ActivateRecoverMode = FALSE, the actuator stops in its current position. PID_3Step V1.1 You can move the actuator in manual mode. PID_3Step V1.0 Manual mode is not possible in this state. You cannot move the actuator again until you eliminate the error.
0002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
0004	Error during fine tuning. Oscillation of the process value could not be maintained.
0020	Pretuning is not permitted in automatic mode or during fine tuning.
0080	Error during pretuning. The output value limits are not configured correctly or the actual value does not react as expected. Check whether the limits of the output value are configured correctly and match the control logic. Also make sure that the actual value does not oscillate strongly before starting pretuning.
0100	Error during fine tuning resulted in invalid parameters.
0200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
0400	Calculation of output value failed. Check the PID parameters.
0800	Sampling time error: PID_3Step is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode. If this error occurred during simulation with PLCSIM, see the notes under Simulating PID_3Step V1 with PLCSIM (Page 6096).
1000	Invalid value at "Setpoint" parameter: Value has an invalid number format. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.

ErrorBits (DW#16#...)	Description
2000	Invalid value at Feedback_PER parameter. Check whether an error is pending at the analog input. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. You must deactivate position feedback (Config. FeedbackOn = FALSE) to move the actuator from this state. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
4000	Invalid value at Feedback parameter. Value has an invalid number format. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. You must deactivate position feedback (Config. FeedbackOn = FALSE) to move the actuator from this state. If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.
8000	Error during digital position feedback. Actuator_H = TRUE and Actuator_L = TRUE. The actuator cannot be moved to the substitute output value and remains in its current position. Manual mode is not possible in this state. In order to move the actuator from this state, you must deactivate the "Actuator endstop" (Config.ActuatorEndStopOn = FALSE). If automatic mode was active before the error occurred, ActivateRecoverMode = TRUE, and the error is no longer pending, PID_3Step switches back to automatic mode.

Parameter Reset V1 (S7-1200)

A rising edge at Reset triggers a change to "Inactive" mode, and errors and warnings are reset. A falling edge at Reset triggers a change to the most recently active operating mode. If automatic mode was active before, switchover to automatic mode is bumpless.

① Activation
② Error
③ Reset

Tag ActivateRecoverMode V1 (S7-1200)

The effect of the ActivateRecoverMode variable depends on the version of the PID_3Step.

Behavior in version 1.1

The ActivateRecoverMode variable determines the behavior in the event of an error in automatic mode. ActivateRecoverMode is not effective during pretuning, fine tuning and transition time measurement.

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" operating mode. The controller is activated by a reset or a change in Retain.Mode.
TRUE	If errors occur frequently in automatic mode, this setting has a negative effect on the control response. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, PID_3Step **cannot** approach the configured substitute output value. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode.

Behavior in version 1.0

The ActivateRecoverMode variable determines the behavior in the event of an error in automatic and manual mode. ActivateRecoverMode is not effective during pretuning, fine tuning and transition time measurement.

ActivateRecoverMode	Description
FALSE	In the event of an error, PID_3Step switches to "Inactive" or "Approach substitute output value" operating mode. The controller is activated by a reset or a change in Retain.Mode.
TRUE	**Errors in automatic mode** If errors occur frequently in automatic mode, this setting has a negative effect on the control response. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or more errors occur, PID_3Step switches to "Approach substitute output value with error monitoring" or "Error monitoring" mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, PID_3Step **cannot** approach the configured substitute output value. As soon as the errors are no longer pending, PID_3Step switches back to automatic mode. **Errors in manual mode** If one or more of the following errors occur, PID_3Step stays in manual mode: • 0002h: Invalid value at parameter Input_PER. • 0200h: Invalid value at parameter Input. • 0800h: Sampling time error • 1000h: Invalid value at parameter Setpoint. • 2000h: Invalid value at parameter Feedback_PER. • 4000h: Invalid value at parameter Feedback. • 8000h: Error in digital position feedback. With errors 2000h, 4000h and 8000h, you **cannot** move the valve to a suitable position.

Tag Warning V1 (S7-1200)

If several warnings are pending simultaneously, their values are displayed with binary addition. The display of warning 0003, for example, indicates that the warnings 0001 and 0002 are pending simultaneously.

Warning (DW#16#...)	Description
0000	No warning pending.
0001	The point of inflection was not found during pretuning.
0002	Oscillation increased during fine tuning.
0004	The setpoint was limited to the configured limits.
0008	Not all the necessary controlled system properties were defined for the selected method of calculation. The PID parameters were instead calculated using the TuneRuleTIR = 3 method.
0010	The operating mode could not be changed because ManualEnable = TRUE.
0020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0040	The process value exceeded one of its warning limits.
0080	Invalid value at Retain.Mode. The operating mode is not switched.
0100	The manual value was limited to the limits of the controller output.
0200	The rule used for tuning produces an incorrect result, or is not supported.
0400	Method selected for transition time measurement not suitable for actuator. The transition time cannot be measured because the actuator settings do not match the selected measuring method.
0800	The difference between the current position and the new output value is too small for transition time measurement. This can produce incorrect results. The difference between the current output value and new output value must be at least 50% of the entire control range.
1000	The substitute output value cannot be reached because it is outside the output value limits.

The following warnings are deleted as soon as the cause is eliminated:

- 0004
- 0020
- 0040
- 0100

All other warnings are cleared with a rising edge at Reset.

Tag SUT.State V1 (S7-1200)

SUT.State	Name	Description
0	SUT_INIT	Initialize pretuning
50	SUT_TPDN	Determine start position without position feedback
100	SUT_STDABW	Calculate the standard deviation
200	SUT_GET_POI	Find the point of inflection
300	SUT_GET_RISETM	Determine the rise time

SUT.State	Name	Description
9900	SUT_IO	Pretuning successful
1	SUT_NIO	Pretuning not successful

Tag TIR.State V1 (S7-1200)

TIR.State	Name	Description
-100	TIR_FIRST_SUT	Fine tuning is not possible. Pretuning will be executed first.
0	TIR_INIT	Initialize fine tuning
200	TIR_STDABW	Calculate the standard deviation
300	TIR_RUN_IN	Attempt to reach the setpoint with the maximum or minimum output value
400	TIR_CTRLN	Attempt to reach the setpoint with the existing PID parameters (if pretuning has been successful)
500	TIR_OSZIL	Determine oscillation and calculate parameters
9900	TIR_IO	Fine tuning successful
1	TIR_NIO	Fine tuning not successful

PID_Temp (S7-1200, S7-1500)

New features of PID_Temp (S7-1200, S7-1500)

PID_Temp V1.1

- **Response of the output value on switchover from "Inactive" operating mode to "Automatic mode"**
  The new option IntegralResetMode = 4 was added and defined as default. With IntegralResetMode = 4, the integral action is automatically pre-assigned when switching from "Inactive" operating mode to "Automatic mode" so that a control deviation results in a jump of the PID output value with identical sign.
- **Initialization of the integral action in automatic mode**
  The integral action can be initialized in automatic mode with the tags OverwriteInitialOutputValue and PIDCtrl.PIDInit. This simplifies the use of PID_Temp for override controls.

Compatibility with CPU and FW (S7-1200, S7-1500)

The following table shows which version of PID_Temp can be used on which CPU.

CPU	FW	PID_Temp
S7-1200	V4.2 or higher	V1.1 V1.0
	V4.1	V1.0

CPU	FW	PID_Temp
S7-1500	V2.0 or higher	V1.1 V1.0
	V1.7 to V1.8	V1.0

CPU processing time and memory requirement PID_Temp V1 (S7-1200, S7-1500)

CPU processing time

Typical CPU processing times of the PID_Temp technology object as of Version 1.0, depending on CPU type.

CPU	Typ. CPU processing time PID_Temp V1
CPU 1211C ≥ V4.1	580 µs
CPU 1215C ≥ V4.1	580 µs
CPU 1217C ≥ V4.1	580 µs
CPU 1505S ≥ V1.0	50 µs
CPU 1510SP-1 PN ≥ V1.7	130 µs
CPU 1511-1 PN ≥ V1.7	130 µs
CPU 1512SP-1 PN ≥ V1.7	130 µs
CPU 1516-3 PN/DP ≥ V1.7	75 µs
CPU 1518-4 PN/DP ≥ V1.7	6 µs

Memory requirement

Memory requirement of an instance DB of the PID_Temp technology object as of Version V1.0.

	Memory requirement of the instance DB of PID_Temp V1
Load memory requirement	Approx. 17000 bytes
Total work memory requirement	1280 bytes
Retentive work memory requirement	100 bytes

PID_Temp (S7-1200, S7-1500)

Description of PID_Temp (S7-1200, S7-1500)

Description

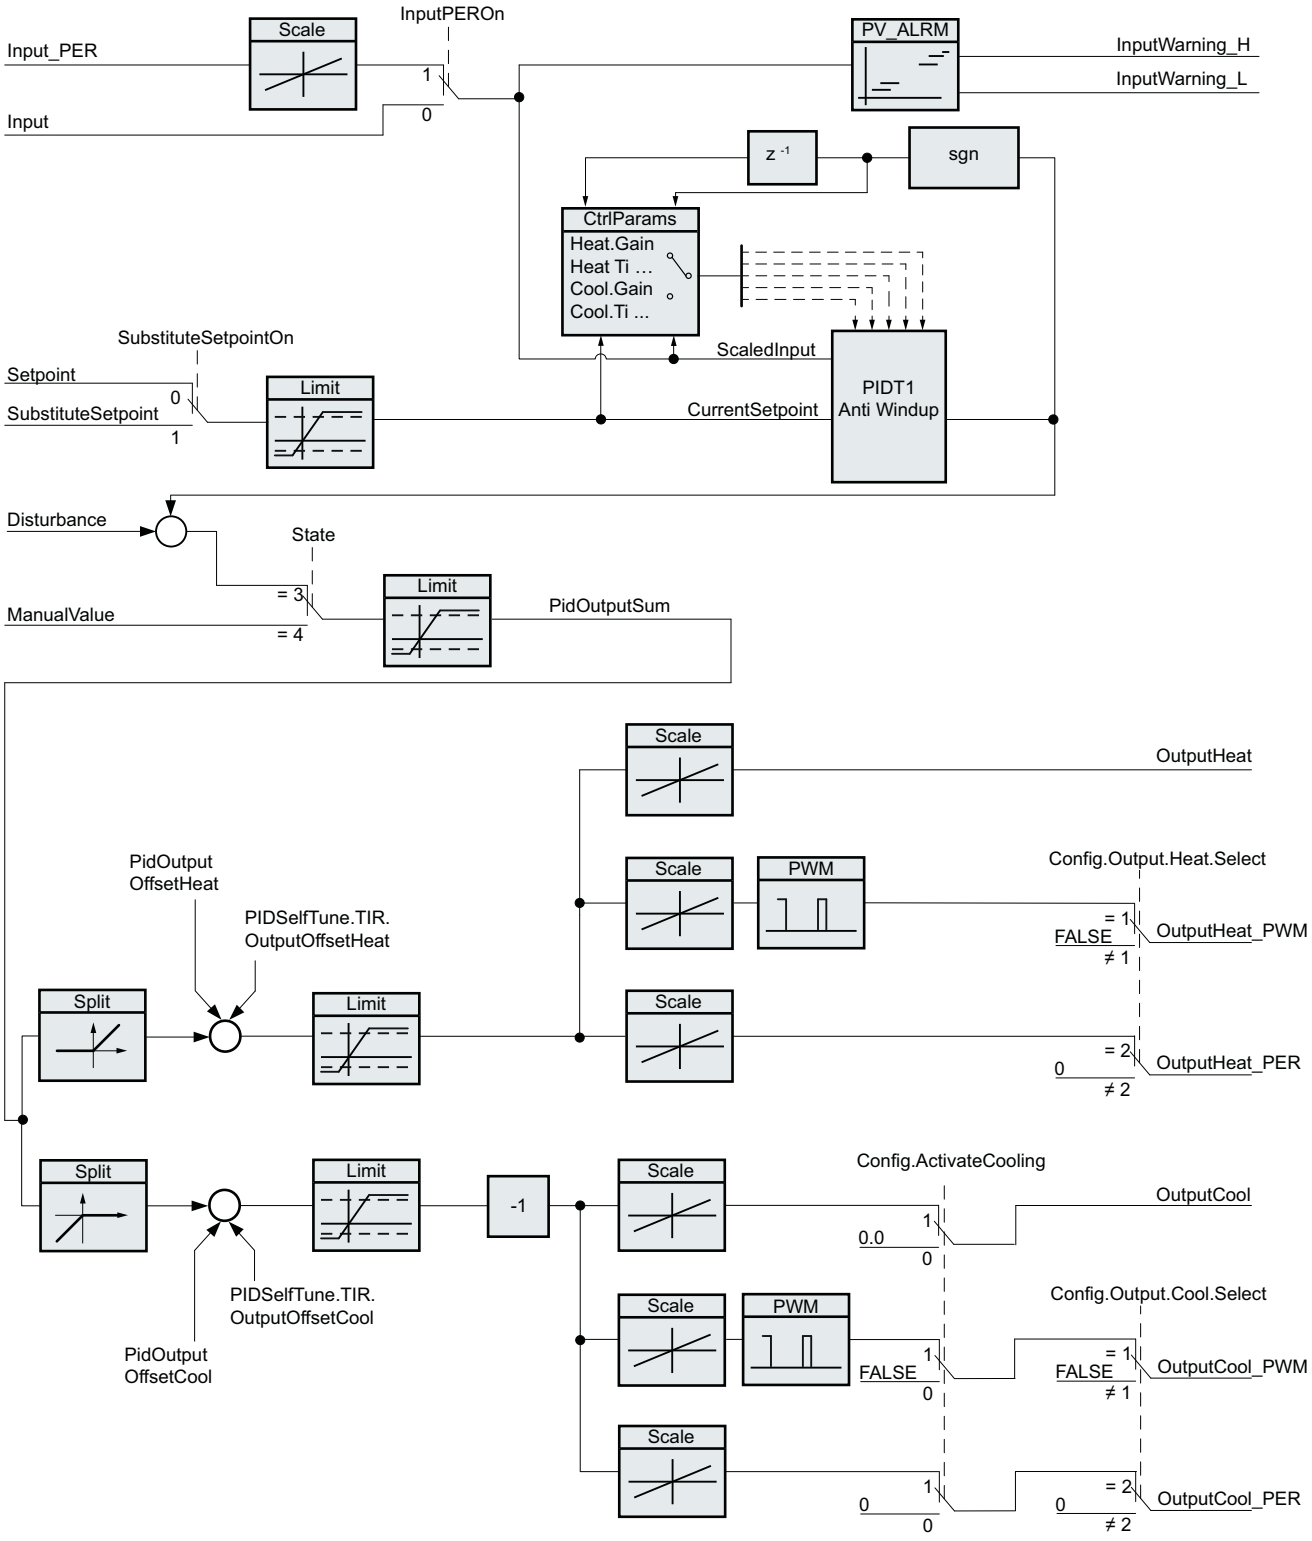
The PID_Temp instruction provides a PID controller with integrated tuning for temperature processes. PID_Temp can be used for pure heating or heating/cooling applications.

The following operating modes are possible:

- Inactive
- Pretuning
- Fine tuning
- Automatic mode
- Manual mode
- Substitute output value with error monitoring

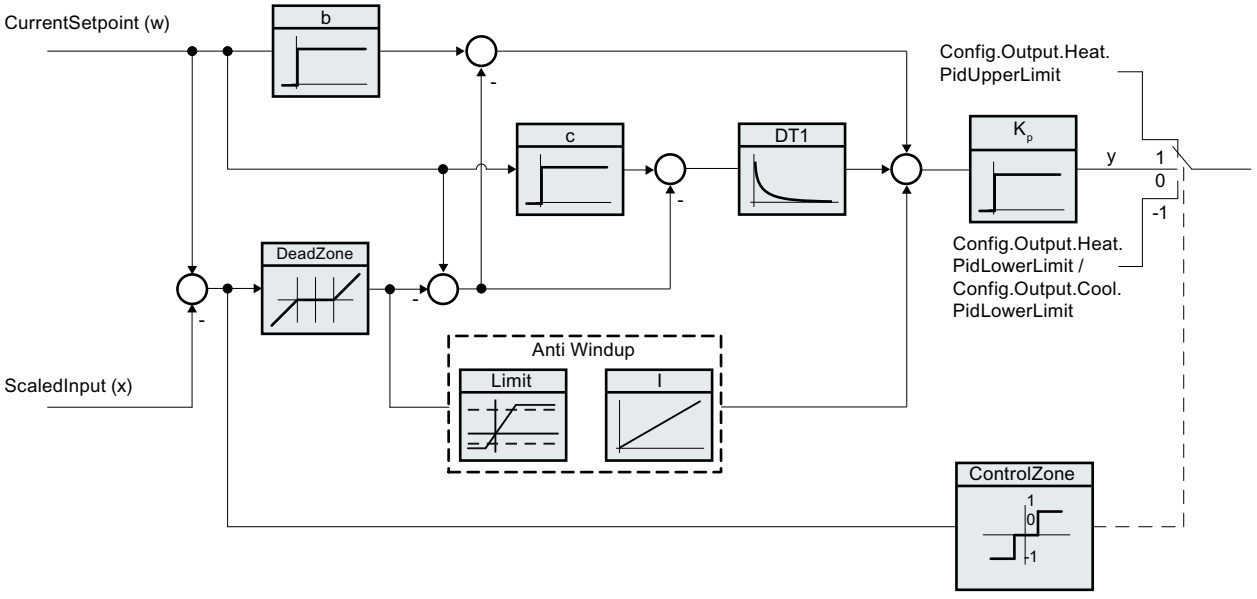
For a more detailed description of the operating modes, see the State parameter.

PID algorithm



PID_Temp is a PIDT1 controller with anti-windup and weighting of the proportional and derivative actions. The PID algorithm operates according to the following equation (control zone and dead zone deactivated):

$$y = K_p \left[(b \cdot w - x) + \frac{1}{T_I \cdot s} (w - x) + \frac{T_D \cdot s}{a \cdot T_D \cdot s + 1} (c \cdot w - x) \right]$$



The table below shows the meaning of the icons used in the equation and in the subsequent figures.

Icon	Description	Associated parameters of the PID_Temp instruction
y	Output value of the PID algorithm	-
K_p	Proportional gain	Retain.CtrlParams.Heat.Gain Retain.CtrlParams.Cool.Gain CoolFactor
s	Laplace operator	-
b	Proportional action weighting	Retain.CtrlParams.Heat.PWeighting Retain.CtrlParams.Cool.PWeighting
w	Setpoint	CurrentSetpoint
x	Process value	ScaledInput
T_I	Integral action time	Retain.CtrlParams.Heat.Ti Retain.CtrlParams.Cool.Ti
T_D	Derivative action time	Retain.CtrlParams.Heat.Td Retain.CtrlParams.Cool.Td
a	Derivative delay coefficient (derivative delay T1 = a × T_D)	Retain.CtrlParams.Heat.TdFiltRatio Retain.CtrlParams.Cool.TdFiltRatio
c	Derivative action weighting	Retain.CtrlParams.Heat.DWeighting Retain.CtrlParams.Cool.DWeighting
DeadZone	Dead zone width	Retain.CtrlParams.Heat.DeadZone Retain.CtrlParams.Cool.DeadZone
ControlZone	Control zone width	Retain.CtrlParams.Heat.ControlZone Retain.CtrlParams.Cool.ControlZone

PID_Temp block diagram

Block diagram of PIDT1 with anti-windup

Call

PID_Temp is called in the constant time scale of a cyclic interrupt OB.

If you call PID_Temp as a multi-instance DB, no technology object is created. No parameter assignment interface or commissioning interface is available. You must assign parameters for PID_Temp directly in the multi-instance DB and commission it via a watch table.

Download to device

The process values of retentive tags are only updated when you download PID_Temp completely.

Download technology object to device (Page 6000)

Startup

When the CPU starts up, PID_Temp starts in the operating mode that is saved in the Mode in/out parameter. To switch to "Inactive" operating mode during startup, set RunModeByStartup = FALSE.

Reaction to error

The behavior in the case of an error is determined by the tags SetSubstituteOutput and ActivateRecoverMode. If ActivateRecoverMode = TRUE, the behavior also depends on the error that occurred.

SetSubstitu-teOutput	ActivateReco-verMode	Configuration editor > Basic settings of output > Set PidOutputSum to	Reaction
Not relevant	FALSE	Zero (inactive)	Switch to "Inactive" (State = 0) mode The output value of the PID algorithm and all outputs for heating and cooling are set to 0. The scaling of the outputs for heating and cooling is not active.
FALSE	TRUE	Current value for error while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The current output value is transferred to the actuator while the error is pending.
TRUE	TRUE	Substitute output value while error is pending	Switch to "Substitute output value with error monitoring" mode (State = 5) The value at SubstituteOutput is transferred to the actuator while the error is pending.

In manual mode, PID_Temp uses ManualValue as output value, unless ManualValue is invalid.

- If ManualValue is invalid, SubstituteOutput is used.
- If ManualValue and SubstituteOutput are invalid, Config.Output.Heat.PidLowerLimit is used.

The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred. ErrorBits is reset by a rising edge at Reset or ErrorAck.

Mode of operation of PID_Temp (S7-1200, S7-1500)

Monitoring process value limits

You specify the high limit and low limit of the process value in the Config.InputUpperLimit and Config.InputLowerLimit tags. If the process value is outside these limits, an error occurs (ErrorBits = 0000001h).

You specify a high and low warning limit of the process value in the Config.InputUpperWarning and Config.InputLowerWarning tags. If the process value is outside these warning limits, a warning occurs (Warning = 0000040h), and the InputWarning_H or InputWarning_L output parameter changes to TRUE.

Limiting the setpoint

You specify a high limit and low limit of the setpoint in the Config.SetpointUpperLimit and Config.SetpointLowerLimit tags. PID_Temp automatically limits the setpoint to the process value limits. You can limit the setpoint to a smaller area. PID_Temp checks whether this area is within the process value limits. If the setpoint is outside these limits, the high or low limit is used as the setpoint, and output parameter SetpointLimit_H or SetpointLimit_L is set to TRUE.

The setpoint is limited in all operating modes.

Substitute setpoint

You can specify a substitute setpoint at the SubstituteSetpoint tag and activate it with SubstituteSetpointOn = TRUE. In this way, you can temporarily specify the setpoint directly, for example for a slave controller in a cascade, without having to change the user program. The limits set for the setpoint also apply to the substitute setpoint.

Heating and cooling

With the default setting, PID_Temp only uses the outputs for heating (OutputHeat, OutputHeat_PWM, OutputHeat_PER). The output value of the PID algorithm (PidOutputSum) is scaled and output at the outputs for heating. You specify with Config.Output.Heat.Select if OutputHeat_PWM or OutputHeat_PER is calculated. OutputHeat is always calculated.

With Config.ActivateCooling = TRUE, you can also activate the outputs for cooling (OutputCool, OutputCool_PWM, OutputCool_PER). Positive output values of the PID algorithm (PidOutputSum) are scaled and output at the outputs for heating. Negative output values of the PID algorithm are scaled and output at the outputs for cooling. You specify with Config.Output.Cool.Select if OutputCool_PWM or OutputCool_PER is calculated. OutputCool is always calculated.

Two methods are available to calculate the PID output value with activated cooling:

- Cooling factor (Config.AdvancedCooling = FALSE):
  The output value calculation for cooling takes place with the PID parameters for heating, taking into consideration the configurable cooling factor Config.CoolFactor. This method is suitable if the heating and cooling actuators have a similar time response but different gains. If this method is selected, pretuning and fine tuning for cooling as well as the PID parameter set for cooling are not available. You can only execute the tuning for heating.
- PID parameter switching (Config.AdvancedCooling = TRUE):
  The output value calculation for cooling takes place by means of a separate PID parameter set. Based on the calculated output value and the control deviation, the PID algorithm decides whether the PID parameter for heating or cooling is used. This method is suitable if the heating and cooling actuator have different time responses and different gains. Pretuning and fine tuning for cooling are only available if this method is selected.

Output value limits and scaling

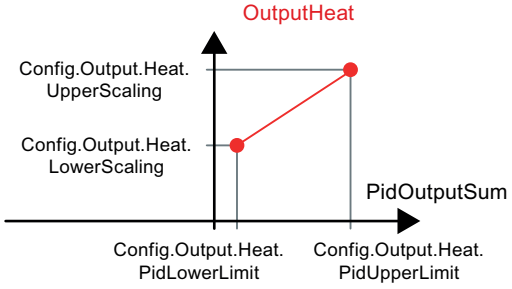
Depending on the operating mode, the PID output value (PidOutputSum) is calculated automatically by the PID algorithm or defined by the manual value (ManualValue) or the configured substitute output value (SubstituteOutput).

The PID output value is limited according to the configuration:

- If cooling is deactivated (Config.ActivateCooling = FALSE), Config.Output.Heat.PidUpperLimit is the high limit and Config.Output.Heat.PidLowerLimit the low limit.
- If cooling is activated (Config.ActivateCooling = TRUE), Config.Output.Heat.PidUpperLimit is the high limit and Config.Output.Cool.PidLowerLimit the low limit.

The PID output value is scaled and output at the outputs for heating and cooling. Scaling can be defined separately for each output and is specified in the structures Config.Output.Heat or Config.Output.Cool with 2 value pairs each:

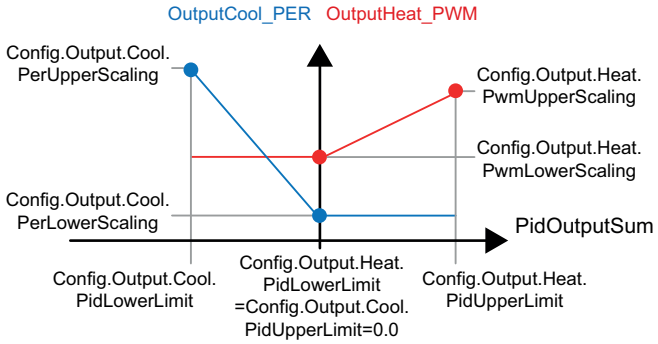
Output	Value pair	Parameter
OutputHeat	Value pair 1	PID output value high limit (heating) Config.Output.Heat.PidUpperLimit, Scaled high output value (heating) Config.Output.Heat.UpperScaling
	Value pair 2	PID output value low limit (heating) Config.Output.Heat.PidLowerLimit, Scaled low output value (heating) Config.Output.Heat.LowerScaling
OutputHeat_PWM	Value pair 1	PID output value high limit (heating) Config.Output.Heat.PidUpperLimit, Scaled high PWM output value (heating) Config.Output.Heat.PwmUpperScaling
	Value pair 2	PID output value low limit (heating) Config.Output.Heat.PidLowerLimit, Scaled low PWM output value (heating) Config.Output.Heat.PwmLowerScaling
OutputHeat_PER	Value pair 1	PID output value high limit (heating) Config.Output.Heat.PidUpperLimit, Scaled high analog output value (heating) Config.Output.Heat.PerUpperScaling
	Value pair 2	PID output value low limit (heating) Config.Output.Heat.PidLowerLimit, Scaled low analog output value (heating) Config.Output.Heat.PerLowerScaling
OutputCool	Value pair 1	PID output value low limit (cooling) Config.Output.Cool.PidLowerLimit, Scaled high output value (cooling) Config.Output.Cool.UpperScaling
	Value pair 2	PID output value high limit (cooling) Config.Output.Cool.PidUpperLimit, Scaled low output value (cooling) Config.Output.Cool.LowerScaling



Output	Value pair	Parameter
OutputCool_PWM	Value pair 1	PID output value low limit (cooling) Config.Output.Cool.PidLowerLimit, Scaled high PWM output value (cooling) Config.Output.Cool.PwmUpperScaling
	Value pair 2	PID output value high limit (cooling) Config.Output.Cool.PidUpperLimit, Scaled low PWM output value (cooling) Config.Output.Cool.PwmLowerScaling
OutputCool_PER	Value pair 1	PID output value low limit (cooling) Config.Output.Cool.PidLowerLimit, Scaled high analog output value (cooling) Config.Output.Cool.PerUpperScaling
	Value pair 2	PID output value high limit (cooling) Config.Output.Cool.PidUpperLimit, Scaled low analog output value (cooling) Config.Output.Cool.PerLowerScaling

If cooling is activated (Config.ActivateCooling = TRUE), Config.Output.Heat.PidLowerLimit must have the value 0.0.

Config.Output.Cool.PidUpperLimit must always have the value 0.0.



Example:

Output scaling when using output OutputHeat (cooling deactivated; Config.Output.Heat.PidLowerLimit may be unequal to 0.0):

Example:

Output scaling when using output OutputHeat_PWM and OutputCool_PER (cooling activated; Config.Output.Heat.PidLowerLimit must be 0.0):

With the exception of the "Inactive" operating mode, the value at an output is always located between its scaled high output value and scaled low output value, for example, for OutputHeat always between Config.Output.Heat.UpperScaling and Config.Output.Heat.LowerScaling.

If you want to limit the value at the associated output, you therefore have to adapt these scaling values as well.

Cascading

PID_Temp supports you when you use cascade control (see: Program creation (Page 6128)).

Substitute output value

In the event of an error, PID_Temp can output a substitute output value that you define at the SubstituteOutput tag. The substitute output value must be within the limits for the PID output value. The values at the outputs for heating and cooling resulting from the substitute output value are the result of the configured output scaling.

Monitoring signal validity

The values of the following parameters are monitored for validity when used:

- Setpoint
- SubstituteSetpoint
- Input
- Input_PER
- Disturbance
- ManualValue
- SubstituteOutput
- PID parameters in the structures Retain.CtrlParams.Heat and Retain.CtrlParams.Cool.

Monitoring the sampling time PID_Temp

Ideally, the sampling time is equivalent to the cycle time of the cyclic interrupt OB. The PID_Temp instruction measures the time interval between two calls. This is the current sampling time. On every switchover of operating mode and during the initial startup, the mean value is formed from the first 10 sampling times. Too great a difference between the current sampling time and this mean value triggers an error (Error = 0000800h).

The error occurs during tuning if:

- New mean value >= 1.1 x old mean value
- New mean value <= 0.9 x old mean value

The error occurs in automatic mode if:

- New mean value >= 1.5 x old mean value
- New mean value <= 0.5 x old mean value

If you deactivate the sampling time monitoring (CycleTime.EnMonitoring = FALSE), you can also call PID_Temp in OB1. You must then accept a lower control quality due to the deviating sampling time.

Sampling time of the PID algorithm

The controlled system needs a certain amount of time to respond to changes in the output value. It is therefore not advisable to calculate the output value in every cycle. The sampling time of the PID algorithm represents the time between two calculations of the output value. It is calculated during tuning and rounded to a multiple of the cycle time of the cyclic interrupt OB (sampling time PID_Temp). All other functions of the PID_Temp are executed at every call.

If cooling and PID parameter switching are activated, PID_Temp uses a separate sampling time of the PID algorithm for heating and cooling. In all other configurations, only the sampling time of the PID algorithm for heating is used.

If you use OutputHeat_PWM or OutputCool_PWM, the sampling time of the PID algorithm is used as time period of the pulse width modulation. The accuracy of the output signal is determined by the ratio of the PID algorithm sampling time to the cycle time of the OB. The cycle time should be no more than a tenth of the PID algorithm sampling time.

If the PID algorithm sampling time and thus the time period of the pulse width modulation is very high when you use OutputHeat_PWM or OutputCool_PWM, you can define a deviating shorter period duration at the Config.Output.Heat.PwmPeriode or Config.Output.Cool.PwmPeriode parameters to improve the smoothness of the process value.

Control logic

PID_Temp can be used for heating or heating/cooling applications and always works with normal control logic.

An increase of the PID output value (PidOutputSum) is intended to increase the process value. The values at the outputs for heating and cooling resulting from the PID output value are the result of the configured output scaling.

An inverted control logic or negative proportional gain are not supported.

If you only need an output value for your application in which an increase is to reduce the process value (for example, discharge control), you can use PID_Compact with inverted control logic.

Input parameters of PID_Temp (S7-1200, S7-1500)

Parameter	Data type	Default	Description
Setpoint	REAL	0.0	Setpoint of the PID controller in automatic mode Valid range of values: Config.SetpointUpperLimit ≥ Setpoint ≥ Config.SetpointLowerLimit Config.InputUpperLimit ≥ Setpoint ≥ Config.InputLowerLimit
Input	REAL	0.0	A tag of the user program is used as source for the process value. If you are using the Input parameter, Config.InputPerOn = FALSE must be set.
Input_PER	INT	0	An analog input is used as the source of the process value. If you are using the Input_PER parameter, Config.InputPerOn = TRUE must be set.
Disturbance	REAL	0.0	Disturbance variable or precontrol value
ManualEnable	BOOL	FALSE	• A FALSE -> TRUE edge activates "Manual mode", whileState = 4, Mode remains unchanged. As long as ManualEnable = TRUE, you cannot change the operating mode via a rising edge at ModeActivate or use the commissioning dialog. • A TRUE -> FALSE edge activates the operating mode that is specified by Mode. We recommend that you change the operating mode using Mode and ModeActivate only.
ManualValue	REAL	0.0	Manual value This value is used in manual mode as PID output value (PidOutputSum). The values at the outputs for heating and cooling resulting from this manual value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). For controllers with activated cooling output (Config.ActivateCooling = TRUE), define: • a positive manual value to output the value at the outputs for heating • a negative manual value to output the value at the outputs for cooling The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ ManualValue ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (Config.ActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ ManualValue ≥ Config.Output.Cool.PidLowerLimit
ErrorAck	BOOL	FALSE	• FALSE -> TRUE edge ErrorBits and Warning are reset.

Parameter	Data type	Default	Description
Reset	BOOL	FALSE	Restarts the controller. • FALSE -> TRUE edge – Switch to "Inactive" mode – ErrorBits and Warning are reset. • As long as Reset = TRUE, – PID_Temp remains in "Inactive" mode (State = 0). – you cannot change the operating mode with Mode and ModeActivate or ManualEnable – You cannot use the commissioning dialog. • TRUE -> FALSE edge – If ManualEnable = FALSE, PID_Temp switches to the operating mode that is saved in Mode. – If Mode = 3 (automatic mode), the integral action is treated as configured with the tag IntegralResetMode.
ModeActivate	BOOL	FALSE	• FALSE -> TRUE edge PID_Temp switches to the operating mode that is saved at the Mode input.

Output parameters of PID_Temp (S7-1200, S7-1500)

Parameter	Data type	Default	Description
ScaledInput	REAL	0.0	Scaled process value
OutputHeat	REAL	0.0	Output value (heating) in REAL format The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.UpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.LowerScaling and output in REAL format at OutputHeat. OutputHeat is always calculated.
OutputCool	REAL	0.0	Output value (cooling) in REAL format The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.LowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.UpperScaling and output in REAL format at OutputCool. OutputCool is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE).
OutputHeat_PER	INT	0	Analog output value (heating) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.PerUpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.PerLowerScaling and output as analog value at OutputHeat_PER. OutputHeat_PER is only calculated if Config.Output.Heat.Select = 2.

Parameter	Data type	Default	Description
Output-Cool_PER	INT	0	Analog output value (cooling) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.PerLowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.PerUpperScaling and output as analog value at OutputCool_PER. OutputCool_PER is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE) and Config.Output.Cool.Select = 2.
OutputHeat_PWM	BOOL	FALSE	Pulse-width modulated output value (heating) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Heat.PidUpperLimit, Config.Output.Heat.PwmUpperScaling and Config.Output.Heat.PidLowerLimit, Config.Output.Heat.PwmLowerScaling and output as pulse-width modulated value (variable switch on and switch off times) at OutputHeat_PWM. OutputHeat_PWM is only calculated if Config.Output.Heat.Select = 1.
Output-Cool_PWM	BOOL	FALSE	Pulse-width modulated output value (cooling) The PID output value (PidOutputSum) is scaled with the two value pairs Config.Output.Cool.PidUpperLimit, Config.Output.Cool.PwmLowerScaling and Config.Output.Cool.PidLowerLimit, Config.Output.Cool.PwmUpperScaling and output as pulse-width modulated value (variable switch on and switch off times) at OutputCool_PWM. OutputCool_PWM is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE) and Config.Output.Cool.Select = 1.
SetpointLimit_H	BOOL	FALSE	If SetpointLimit_H = TRUE, the absolute setpoint high limit is reached (Setpoint ≥ Config.SetpointUpperLimit) or Setpoint ≥ Config.InputUpperLimit. The setpoint high limit is the minimum of Config.SetpointUpperLimit and Config.InputUpperLimit.
SetpointLimit_L	BOOL	FALSE	If SetpointLimit_L = TRUE, the absolute setpoint low limit is reached (Setpoint ≤ Config.SetpointLowerLimit) or Setpoint ≤ Config.InputLowerLimit. The setpoint low limit is the maximum of Config.SetpointLowerLimit and Config.InputLowerLimit.
InputWarning_H	BOOL	FALSE	If InputWarning_H = TRUE, the process value has reached or exceeded the warning high limit (ScaledInput ≥ Config.InputUpperWarning).
InputWarning_L	BOOL	FALSE	If InputWarning_L = TRUE, the process value has reached or fallen below the warning low limit (ScaledInput ≤ Config.InputLowerWarning).
State	INT	0	The PID_Temp state and mode parameters (Page 4364) shows the current operating mode of the PID controller. You can change the operating mode using the input parameter Mode and a rising edge at ModeActivate. For pretuning and fine tuning, you specify with Heat.EnableTuning and Cool.EnableTuning whether tuning takes place for heating or cooling. • State = 0: Inactive • State = 1: Pretuning • State = 2: Fine tuning • State = 3: Automatic mode • State = 4: Manual mode • State = 5: Substitute output value with error monitoring

Parameter	Data type	Default	Description
Error	BOOL	FALSE	If Error = TRUE, at least one error message is pending in this cycle.
ErrorBits	DWORD	DW#16#0	The PID_Temp ErrorBits parameter (Page 4373) shows the pending error messages. ErrorBits is retentive and is reset with a rising edge at Reset or ErrorAck.

In/out parameters of PID_Temp V2 (S7-1200, S7-1500)

Parameter	Data type	Default	Description
Mode	INT	4	At Mode, specify the operating mode to which PID_Temp is to switch. Options are: • Mode = 0: Inactive • Mode = 1: Pretuning • Mode = 2: Fine tuning • Mode = 3: Automatic mode • Mode = 4: Manual mode The operating mode is activated by: • Rising edge at ModeActivate • Falling edge at Reset • Falling edge at ManualEnable • Cold restart of CPU if RunModeByStartup = TRUE For pretuning and fine tuning, you specify with Heat.EnableTuning and Cool.EnableTuning whether tuning takes place for heating or cooling. Mode is retentive. A detailed description of the operating modes can be found in State and Mode parameters (Page 4364).
Master	DWORD	DW#16#0	Interface for cascade control If this PID_Temp instance is used as slave controller in a cascade (Config.Cascade.IsSlave = TRUE), assign the Master parameter at the instruction call with the Slave parameter of the master controller. Example: Call of a slave controller "PID_Temp_2" with master controller "PID_Temp_1" in SCL: --- `"PID_Temp_2"(Master := "PID_Temp_1".Slave, Setpoint := "PID_Temp_1".OutputHeat);` --- You use this interface to exchange slave controller information about operating mode, limit and substitute setpoint with your master controller. Keep in mind that the call of the master controller has to take place before the call of the slave controller in the same cyclic interrupt OB. Assignment: • Bits 0 to 15: Unassigned • Bits 16 to 23 – Limit counter: A slave controller whose output value is limited increments this counter. Depending on the configured number of slaves (Config.Cascade.CountSlaves) and of the anti-windup mode (Config.Cascade.AntiWindUpMode), the master controller reacts accordingly. • Bit 24 – Automatic mode of the slave controllers: TRUE, if all slave controllers are in automatic mode • Bit 25 – Substitute setpoint of the slave controllers: TRUE, if a slave controller has activated the substitute setpoint (SubstituteSetpointOn = TRUE)

Parameter	Data type	Default	Description
Slave	DWORD	DW#16#0	Interface for cascade control You use this interface to exchange slave controller information about operating mode, limit and substitute setpoint with your master controller. See description of Master parameter

Cascade control with PID_Temp (Page 6126)

PID_Temp static tags (S7-1200, S7-1500)

You must not change tags that are not listed. These are used for internal purposes only.

Tag	Data type	Default	Description
IntegralResetMode	Int	V1.0: 1, V1.1 or higher: 4	The IntegralResetMode tag (Page 4381) determines how the integral action PIDCtrl.IOutputOld is pre-assigned when switching from "Inactive" operating mode to "Automatic mode". This setting only works for one cycle. • IntegralResetMode = 0: Smooth • IntegralResetMode = 1: Delete • IntegralResetMode = 2: Hold • IntegralResetMode = 3: Pre-assign • IntegralResetMode = 4: Like setpoint change (only for PID_Temp with version ≥ 1.1)
OverwriteInitialOutputValue	REAL	0.0	If one of the following conditions is met, the integral action PIDCtrl.IOutputOld is pre-assigned automatically as if PIDOutputSum = OverwriteInitialOutputValue in the previous cycle: • IntegralResetMode = 3 when switching from "Inactive" operating mode to "Automatic mode" • TRUE -> FALSE edge at parameter Reset and parameter Mode = 3 • PIDCtrl.PIDInit = TRUE in "Automatic mode" (available as of PID_Temp version 1.1)
RunModeByStartup	BOOL	TRUE	Activate operating mode at Mode parameter after CPU restart • If RunModeByStartup = TRUE, PID_Temp starts in the operating mode saved in the Mode parameter after CPU startup. • If RunModeByStartup = FALSE, PID_Temp remains in "Inactive" mode after CPU startup.
LoadBackUp	BOOL	FALSE	If LoadBackUp = TRUE, the last set of PID parameters is reloaded from the CtrlParamsBackUp structure. The set was saved prior to the last tuning. LoadBackUp is automatically set back to FALSE. The acceptance is bumpless.

Tag	Data type	Default	Description
SetSubstituteOutput	BOOL	TRUE	Selection of the output value while an error is pending (State = 5): • If SetSubstituteOutput = TRUE and ActivateRecoverMode = TRUE, the configured substitute output value SubstituteOutput is output as PID output value as long as an error is pending. • If SetSubstituteOutput = FALSE and ActivateRecoverMode = TRUE, the actuator remains at the current PID output value as long as an error is pending. • If ActivateRecoverMode = FALSE, SetSubstituteOutput is not effective. • If SubstituteOutput is invalid (ErrorBits = 0020000h), the substitute output value cannot be output. In this case, the low limit of the PID output value for heating (Config.Output.Heat.PidLowerLimit) is used as PID output value.
PhysicalUnit	INT	0	Unit of measurement of the process value and setpoint, e.g., ºC, or ºF. This parameter is used for display in the editors and does not influence the control algorithm.
PhysicalQuantity	INT	0	Physical quantity of the process value and setpoint, e.g., temperature. This parameter is used for display in the editors and does not influence the control algorithm.
ActivateRecoverMode	BOOL	TRUE	The ActivateRecoverMode tag determines the reaction to error.
Warning	DWORD	0	The Warning tag shows the warnings since Reset = TRUE or ErrorAck =TRUE. Warning is retentive.
Progress	REAL	0.0	Progress of current tuning phase as a percentage (0.0 - 100.0)
CurrentSetpoint	REAL	0.0	CurrentSetpoint always displays the currently effective setpoint. This value is frozen during tuning.
CancelTuningLevel	REAL	10.0	Permissible fluctuation of setpoint during tuning. Tuning is not canceled until: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel

Tag	Data type	Default	Description
SubstituteOutput	REAL	0.0	The substitute output value is used as PID output value as long as the following conditions are met: • One or more errors are pending in automatic mode for which ActivateRecoverMode is in effect • SetSubstituteOutput = TRUE • ActivateRecoverMode = TRUE The values at the outputs for heating and cooling resulting from the substitute output value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). For controllers with activated cooling output (Config.ActivateCooling = TRUE), define: • a positive substitute output value to output the value at the outputs for heating • a negative substitute output value to output the value at the outputs for cooling The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ SubstituteOutput ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (Config.ActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ SubstituteOutput ≥ Config.Output.Cool.PidLowerLimit
PidOutputSum	REAL	0.0	PID output value PidOutputSum displays the output value of the PID algorithm. Depending on the operating mode, it is either calculated automatically or defined by the manual value or the configured substitute output value. The values at the outputs for heating and cooling resulting from the PID output value are the result of the configured output scaling (structures Config.Output.Heat and Config.Output.Cool). The PidOutputSum is limited as defined in the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Config.Output.Heat.PidUpperLimit ≥ PidOutputSum ≥ Config.Output.Heat.PidLowerLimit • Cooling output activated (ConfigActivateCooling = TRUE): Config.Output.Heat.PidUpperLimit ≥ PidOutputSum ≥ Config.Output.Cool.PidLowerLimit

Tag	Data type	Default	Description
PidOutputOffsetHeat	REAL	0.0	Offset of the PID output value heating PidOutputOffsetHeat is added to the value that results from PidOutputSum for the heating branch. Enter a positive value for PidOutputOffsetHeat to receive a positive offset at the outputs for heating. The resulting values at the outputs for heating are the result of the configured output scaling (Config.Output.Heat structure). This offset can be used for actuators which need a fixed minimum value, for example, fans with minimum speed.
PidOutputOffsetCool	REAL	0.0	Offset of the PID output value cooling PidOutputOffsetCool is added to the value that results from PidOutputSum for the cooling branch. Enter a negative value for PidOutputOffsetCool to receive a positive offset at the outputs for cooling. The resulting values at the outputs for cooling are the result of the configured output scaling (Config.Output.Cool structure). This offset can be used for actuators which need a fixed minimum value, for example, fans with minimum speed.
SubstituteSetpointOn	BOOL	FALSE	Activates the substitute setpoint as controller setpoint. • FALSE = the Setpoint parameter is used. • TRUE = the SubstituteSetpoint parameter is used as setpoint SubstituteSetpointOn can be used to specify the setpoint of a slave controller in a cascade directly without having to change the user program.
SubstituteSetpoint	REAL	0.0	Substitute setpoint If SubstituteSetpointOn = TRUE, the SubstituteSetpoint parameter is used as setpoint. Valid range of values: Config.SetpointUpperLimit ≥ SubstituteSetpoint ≥ Config.SetpointLowerLimit, Config.InputUpperLimit ≥ SubstituteSetpoint ≥ Config.InputLowerLimit
DisableCooling	BOOL	FALSE	DisableCooling = TRUE deactivates the cooling branch for heating/cooling controllers (Config.ActivateCooling = TRUE) in Automatic mode by setting PidOutputSum to 0.0 as low limit. PidOutputOffsetCool and the output scaling for the cooling outputs remain active. DisableCooling can be used for tuning of multi-zone applications to temporarily deactivate the cooling branch as long as all controllers have not completed their tuning yet. This parameter is set/reset by the user manually and is not automatically reset by the PID_Temp instruction.

Tag	Data type	Default	Description
AllSlaveAutomaticState	BOOL	FALSE	If this PID_Temp instance is used as master controller in a cascade (Config.Cascade.IsMaster = TRUE), AllSlaveAutomaticState = TRUE indicates that all slave controllers are in automatic mode. Tuning, manual mode or automatic mode of the master controller can only be executed accurately if all slave controllers are in automatic mode. AllSlaveAutomaticState is only determined if you interconnect the master controller and slave controller with the Master and Slave parameters. For details, see the Master parameter.
NoSlaveSubstituteSetpoint	BOOL	FALSE	If this PID_Temp instance is used as master controller in a cascade (Config.Cascade.IsMaster = TRUE), NoSlaveSubstituteSetpoint = TRUE indicates that no slave controller has activated its substitute setpoint. Tuning, manual mode or automatic mode of the master controller can only be executed accurately if no slave controller has activated its substitute setpoint. NoSlaveSubstituteSetpoint is only determined if you interconnect the master controller and slave controller with the Master and Slave parameters. For details, see the Master parameter.
Heat.EnableTuning	BOOL	TRUE	Enabling of tuning for heating Heat.EnableTuning must be set for the following tunings (at the same time or prior to the start with Mode and ModeActivate): • Pretuning heating • Pretuning heating and cooling • Fine tuning heating This parameter is not automatically reset by the PID_Temp instruction.
Cool.EnableTuning	BOOL	FALSE	Enabling of tuning for cooling Cool.EnableTuning must be set for the following tunings (simultaneously with or prior to the start with Mode and ModeActivate): • Pretuning cooling • Pretuning heating and cooling • Fine tuning cooling Only effective if the cooling output and PID parameter switching are activated ("Config.ActivateCooling" = TRUE and "Config.AdvancedCooling" = TRUE). This parameter is not automatically reset by the PID_Temp instruction.
Config.InputPerOn	BOOL	TRUE	If InputPerOn = TRUE, the Input_PER parameter is used for detecting the process value. If InputPerOn = FALSE, the Input parameter is used.

Tag	Data type	Default	Description
Config.InputUpperLimit	REAL	120.0	High limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is exceeded, an error is output and the reaction is determined by ActivateRecoverMode. At the I/O input, the process value can be a maximum of 18% higher than the nominal range (overrange). This means the limit cannot be exceeded when you use an I/O input with the pre-setting for high limit and process value scaling. When pretuning is started, the difference between high and low limit of the process value is checked to determine whether the distance between setpoint and process value meets the necessary requirements. InputUpperLimit > InputLowerLimit
Config.InputLowerLimit	REAL	0.0	Low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is undershot, an error is output and the reaction is determined by ActivateRecoverMode. InputLowerLimit < InputUpperLimit
Config.InputUpperWarning	REAL	3.402822e+38	Warning high limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is exceeded, a warning is output at the Warning parameter. • If you set InputUpperWarning outside the process value limits, the configured absolute process value high limit is used as the warning high limit. • If you configure InputUpperWarning within the process value limits, this value is used as the warning high limit. InputUpperWarning > InputLowerWarning
Config.InputLowerWarning	REAL	-3.402822e+38	Warning low limit of the process value Input and Input_PER are monitored to ensure adherence to this limit. If the limit is undershot, a warning is output at the Warning parameter. • If you set InputLowerWarning outside the process value limits, the configured absolute process value low limit is used as the warning low limit. • If you configure InputLowerWarning within the process value limits, this value is used as the warning low limit. InputLowerWarning < InputUpperWarning

Tag	Data type	Default	Description
Config.SetpointUpperLimit	REAL	3.402822e +38	High limit of setpoint Setpoint and SubstituteSetpoint are monitored to ensure adherence to this limit. If the limit is exceeded, a warning is output at the Warning parameter. • If you configure SetpointUpperLimit outside the process value limits, the configured absolute process value high limit is used as the setpoint high limit. • If you configure SetpointUpperLimit within the process value limits, this value is used as the setpoint high limit. SetpointUpperLimit > SetpointLowerLimit
Config.SetpointLowerLimit	REAL	-3.402822e +38	Low limit of the setpoint Setpoint and SubstituteSetpoint are monitored to ensure adherence to this limit. If the limit is undershot, a warning is output at the Warning parameter. • If you set SetpointLowerLimit outside the process value limits, the configured process value absolute low limit is used as the setpoint low limit. • If you configure SetpointLowerLimit within the process value limits, this value is used as the setpoint low limit. SetpointLowerLimit < SetpointUpperLimit
Config.ActivateCooling	BOOL	FALSE	Activate cooling output • Config.ActivateCooling = FALSE Only the outputs for heating are used. • Config.ActivateCooling = TRUE The outputs for heating and cooling are used. If you are using the cooling output, the controller must not be configured as master controller (Config.Cascade.IsMaster must be FALSE) .

Tag	Data type	Default	Description
Config.AdvancedCooling	BOOL	TRUE	Method for heating/cooling • Cooling factor (Config.AdvancedCooling = FALSE) The output value calculation for cooling takes place with the PID parameters for heating (Retain.CtrlParams.Heat structure) taking into consideration the configurable cooling factor Config.CoolFactor. This method is suitable if the heating and cooling actuators have a similar time response but different gains. Pretuning and fine tuning for cooling are not available when you select this method. You can only execute the tuning for heating. • PID parameter switching (Config.AdvancedCooling = TRUE) The output value calculation for cooling takes place by means of a separate PID parameter set (Retain.CtrlParams.Cool structure). This method is suitable if the heating and cooling actuator have different time responses and different gains. Pretuning and fine tuning for cooling are only available when you select this method (Mode = 1 or 2, Cool.EnableTuning = TRUE). Config.AdvancedCooling is only calculated if the cooling output is activated (Config.ActivateCooling = TRUE).
Config.CoolFactor	REAL	1.0	Cooling factor If Config.AdvancedCooling = FALSE, Config.CoolFactor is considered as factor in the calculation of the output value for cooling. This allows different gains of heating and cooling actuators to be taken into account. Config.CoolFactor is not set automatically or adjusted during tuning. You must correctly configure Config.CoolFactor manually with the ratio "heating actuator gain/cooling actuator gain". Example: Config.CoolFactor = 2.0 means that the gain of the heating actuator is twice as high as the gain of the cooling actuator. Config.CoolFactor is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and cooling factor is selected as method for heating/cooling (Config.AdvancedCooling = FALSE). Config.CoolFactor > 0.0
Config.InputScaling.UpperPointIn	REAL	27648.0	Scaling Input_PER high Input_PER is scaled based on the two value pairs UpperPointOut, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). UpperPointIn > LowerPointIn

Tag	Data type	Default	Description
Config.InputScaling.LowerPointIn	REAL	0.0	Scaling Input_PER low Input_PER is scaled based on the two value pairs UpperPoint-Out, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). LowerPointIn < UpperPointIn
Config.InputScaling.UpperPoint-Out	REAL	100.0	Scaled high process value Input_PER is scaled based on the two value pairs UpperPoint-Out, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). UpperPointOut > LowerPointOut
Config.InputScaling.LowerPoint-Out	REAL	0.0	Scaled low process value Input_PER is scaled based on the two value pairs UpperPoint-Out, UpperPointIn and LowerPointOut, LowerPointIn. Only effective if Input_PER is used for process value detection (Config.InputPerOn = TRUE). LowerPointOut < UpperPointOut
Config.Output.Heat.Select	INT	1	Selecting the output value for heating Config.Output.Heat.Select specifies which outputs are used for heating: • Heat.Select = 0 - OutputHeat is used • Heat.Select = 1 - OutputHeat and OutputHeat_PWM are used • Heat.Select = 2 -OutputHeat and OutputHeat_PER are used Outputs that are not used are not calculated and remain at their default value.

Tag	Data type	Default	Description
Config.Output.Heat.PwmPeriode	REAL	0.0	Period duration of the pulse width modulation (PWM) for heating (OutputHeat_PWM output) in seconds: • Heat.PwmPeriode = 0.0 The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as period duration of the PWM. • Heat.PwmPeriode > 0.0 The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as period duration of the PWM. This setting can be used to improve the smoothing of the process value with a long sampling time of the PID algorithm. The value must meet the following conditions: – Heat.PwmPeriode ≤ Retain.CtrlParams.Heat.Cycle, – Heat.PwmPeriode > Config.Output.Heat.MinimumOnTime – Heat.PwmPeriode > Config.Output.Heat.MinimumOffTime
Config.Output.Heat.PidUpperLimit	REAL	100.0	High limit of the PID output value for heating The PID output value (PidOutputSum) is limited to the high limit. Heat.PidUpperLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for heating: • Heat.UpperScaling for OutputHeat • Heat.PwmUpperScaling for OutputHeat_PWM • Heat.PerUpperScaling for OutputHeat_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Heat.PidUpperLimit > Heat.PidLowerLimit

Tag	Data type	Default	Description
Config.Output.Heat.PidLowerLimit	REAL	0.0	Low limit of the PID output value for heating For controllers with **deactivated** cooling output (Config.ActivateCooling = FALSE), the PID output value (PidOutputSum) is limited to this low limit. For controllers with **activated** cooling output (Config.ActivateCooling = TRUE), the value must be 0.0. Heat.PidLowerLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for heating: • Heat.LowerScaling for OutputHeat • Heat.PwmLowerScaling for OutputHeat_PWM • Heat.PerLowerScaling for OutputHeat_PER If you want to limit the value at the associated output, you must also adjust these scaling values. The permitted value range is determined by the configuration. • Cooling output deactivated (Config.ActivateCooling = FALSE): Heat.PidLowerLimit < Heat.PidUpperLimit • Cooling output activated (Config.ActivateCooling = TRUE): Heat.PidLowerLimit = 0.0
Config.Output.Heat.UpperScaling	REAL	100.0	Scaled high output value for heating Heat.UpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for heating (OutputHeat). The OutputHeat value is always located between Heat.UpperScaling and Heat.LowerScaling. Heat.UpperScaling ≠ Heat.LowerScaling
Config.Output.Heat.LowerScaling	REAL	0.0	Scaled low output value for heating Heat.LowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for heating (OutputHeat). The OutputHeat value is always located between Heat.UpperScaling and Heat.LowerScaling. Heat.UpperScaling ≠ Heat.LowerScaling
Config.Output.Heat.PwmUpperScaling	REAL	100.0	Scaled high PWM output value for heating Heat.PwmUpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for heating (OutputHeat_PWM). The OutputHeat_PWM value is always located between Heat.PwmUpperScaling and Heat.PWMLowerScaling. Heat.PwmUpperScaling is only effective if OutputHeat_PWM is selected as output for heating (Heat.Select = 1) 100.0 ≥ Heat.PwmUpperScaling ≥ 0.0 Heat.PwmUpperScaling ≠ Heat.PwmLowerScaling

Tag	Data type	Default	Description
Config.Output.Heat.PwmLowerScaling	REAL	0.0	Scaled low PWM output value for heating Heat.PwmLowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for heating (OutputHeat_PWM). The OutputHeat_PWM value is always located between Heat.PwmUpperScaling and Heat.PwmLowerScaling. Heat.PwmLowerScaling is only effective if OutputHeat_PWM is selected as output for heating (Heat.Select = 1) 100.0 ≥ Heat.PwmLowerScaling ≥ 0.0 Heat.PwmUpperScaling ≠ Heat.PwmLowerScaling
Config.Output.Heat.PerUpperScaling	REAL	27648.0	Scaled high analog output value for heating Heat.PerUpperScaling and Heat.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for heating (OutputHeat_PER). The OutputHeat_PER value is always located between Heat.PerUpperScaling and Heat.PerLowerScaling. Heat.PerUpperScaling is only effective if OutputHeat_PER is selected as output for heating (Heat.Select = 2) 32511.0 ≥ Heat.PerUpperScaling ≥ -32512.0 Heat.PerUpperScaling ≠ Heat.PerLowerScaling
Config.Output.Heat.PerLowerScaling	REAL	0.0	Scaled low analog output value for heating Heat.PerLowerScaling and Heat.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for heating (OutputHeat_PER). The OutputHeat_PER value is always located between Heat.PerUpperScaling and Heat.PerLowerScaling. Heat.PerLowerScaling is only effective if OutputHeat_PER is selected as output for heating (Heat.Select = 2) 32511.0 ≥ Heat.PerLowerScaling ≥ -32512.0 Heat.PerUpperScaling ≠ Heat.PerLowerScaling
Config.Output.Heat.MinimumOnTime	REAL	0.0	Minimum on time of the pulse width modulation for heating (OutputHeat_PWM output) A PWM pulse is never shorter than this value. The value is rounded off to: Heat.MinimumOnTime = n × CycleTime.Value Heat.MinimumOnTime is only effective if the output for heating OutputHeat_PWM is selected (Heat.Select = 1)". 100000.0 ≥ Heat.MinimumOnTime ≥ 0.0

Tag	Data type	Default	Description
Config.Output.Heat.MinimumOff-Time	REAL	0.0	Minimum off time of the pulse width modulation for heating (OutputHeat_PWM output) A PWM pause is never shorter than this value. The value is rounded off to: Heat.MinimumOffTime = n × CycleTime.Value Heat.MinimumOffTime is only effective if the output for heating OutputHeat_PWM is selected (Heat.Select = 1)". 100000.0 ≥ Heat.MinimumOffTime ≥ 0.0
Config.Output.Cool.Select	INT	1	Selecting the output value for cooling Config.Output.Cool.Select specifies which outputs are used for cooling: • Cool.Select = 0 - OutputCool is used • Cool.Select = 1 -OutputCool and OutputCool_PWM are used • Cool.Select = 2 - OutputCool and OutputCool_PER are used Outputs that are not used are not calculated and remain at their default value. Only effective if the cooling output is activated (Config.Activa-teCooling = TRUE).

Tag	Data type	Default	Description
Config.Output.Cool.PwmPeriode	REAL	0.0	Period duration of the pulse width modulation for cooling (OutputCool_PWM output) in seconds: • Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE: sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as period duration of the PWM. • Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = TRUE: The sampling time of the PID algorithm for cooling (Retain.CtrlParams.Cool.Cycle) is used as period duration of the PWM. • Cool.PwmPeriode > 0.0: The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as period duration of the PWM. This setting can be used to improve the smoothing of the process value with a long sampling time of the PID algorithm. The value must meet the following conditions: – Cool.PwmPeriode ≤ Retain.CtrlParams.Cool.Cycle or Retain.CtrlParams.Heat.Cycle – Cool.PwmPeriode > Config.Output.Cool.MinimumOnTime – Cool.PwmPeriode > Config.Output.Cool.MinimumOffTime Only effective if the cooling output is activated (Config.ActivateCooling = TRUE).
Config.Output.Cool.PidUpperLimit	REAL	0.0	High limit of the PID output value for cooling The value must be 0.0. Cool.PidUpperLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for cooling: • Cool.LowerScaling for OutputCool • Cool.PwmLowerScaling for OutputCool_PWM • Cool.PerLowerScaling for OutputCool_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.PidUpperLimit = 0.0

Tag	Data type	Default	Description
Config.Output.Cool.PidLowerLimit	REAL	-100.0	Low limit of the PID output value for cooling For controllers with activated cooling output (Config.ActivateCooling = TRUE), the PID output value (PidOutputSum) is limited to this low limit. Cool.PidLowerLimit forms a value pair together with the following parameters for scaling of the PID output value (PidOutputSum) to the outputs for cooling: • Cool.UpperScaling for OutputCool • Cool.PwmUpperScaling for OutputCool_PWM • Cool.PerUpperScaling for OutputCool_PER If you want to limit the value at the associated output, you must also adjust these scaling values. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.PidLowerLimit < Cool.PidUpperLimit
Config.Output.Cool.UpperScaling	REAL	100.0	Scaled high output value for cooling Cool.UpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for cooling (OutputCool). The OutputCool value is always located between Cool.UpperScaling and Cool.LowerScaling. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.UpperScaling ≠ Cool.LowerScaling
Config.Output.Cool.LowerScaling	REAL	0.0	Scaled low output value for cooling Cool.LowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the output value for cooling (OutputCool). The OutputCool value is always located between Cool.UpperScaling and Cool.LowerScaling. Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). Cool.UpperScaling ≠ Cool.LowerScaling
Config.Output.Cool.PwmUpperScaling	REAL	100.0	Scaled high PWM output value for cooling Cool.PwmUpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for cooling (OutputCool_PWM). The OutputCool_PWM value is always located between Cool.PwmUpperScaling and Cool.PwmLowerScaling. Cool.PwmUpperScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PWM is selected as output for cooling (Cool.Select = 1). 100.0 ≥ Cool.PwmUpperScaling ≥ 0.0 Cool.PwmUpperScaling ≠ Cool.PwmLowerScaling

Tag	Data type	Default	Description
Config.Output.Cool.PwmLowerScaling	REAL	0.0	Scaled low PWM output value for cooling Cool.PwmLowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the pulse-width modulated output value for cooling (OutputCool_PWM). The OutputCool_PWM value is always located between Cool.PwmUpperScaling and CoolPwm.LowerScaling. Cool.PwmLowerScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PWM is selected as output for cooling (Cool.Select = 1). 100.0 ≥ Cool.PwmLowerScaling ≥ 0.0 Cool.PwmUpperScaling ≠ Cool.PwmLowerScaling
Config.Output.Cool.PerUpperScaling	REAL	27648.0	Scaled high analog output value for cooling Cool.PerUpperScaling and Cool.PidLowerLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for cooling (OutputCool_PER). The OutputCool_PER value is always located between Cool.PerUpperScaling and Cool.PerLowerScaling. Cool.PerUpperScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PER is selected as output for cooling (Cool.Select = 2). 32511.0 ≥ Cool.PerUpperScaling ≥ -32512.0 Cool.PerUpperScaling ≠ Cool.PerLowerScaling
Config.Output.Cool.PerLowerScaling	REAL	0.0	Scaled low analog output value for cooling Cool.PerLowerScaling and Cool.PidUpperLimit form a value pair for scaling of the PID output value (PidOutputSum) to the analog output value for cooling (OutputCool_PER). The OutputCool_PER value is always located between Cool.PerUpperScaling and Cool.PerLowerScaling. Cool.PerLowerScaling is only effective if the cooling output is activated (Config.ActivateCooling = TRUE) and OutputCool_PER is selected as output for cooling (Cool.Select = 2). 32511.0 ≥ Cool.PerLowerScaling ≥ -32512.0 Cool.PerUpperScaling ≠ Cool.PerLowerScaling
Config.Output.Cool.MinimumOnTime	REAL	0.0	Minimum on time of the pulse width modulation for cooling (OutputCool_PWM output) A PWM pulse is never shorter than this value. The value is rounded off to: Cool.MinimumOnTime = n × CycleTime.Value Cool.MinimumOnTime is only effective if the output for cooling OutputCool_PWM is selected (Cool.Select = 1). Only effective if the cooling output is activated (Config.ActivateCooling = TRUE). 100000.0 ≥ Cool.MinimumOnTime ≥ 0.0

Tag	Data type	Default	Description
Config.Output.Cool.MinimumOff-Time	REAL	0.0	Minimum off time of the pulse width modulation for cooling (OutputCool_PWM output) A PWM pause is never shorter than this value. The value is rounded off to: Cool.MinimumOffTime = n × CycleTime.Value Cool.MinimumOffTime is only effective if the output for cooling OutputCool_PWM is selected (Cool.Select = 1). Only effective if the cooling output is activated (Config.Activa-teCooling = TRUE). 100000.0 ≥ Cool.MinimumOffTime ≥ 0.0
If you are using PID_Temp in a cascade, the master controller and slave controller exchange information via the Master and Slave parameters. You need to make the interconnection. For details, see the Master parameter.			
Config.Cascade.IsMaster	BOOL	FALSE	The controller is master in a cascade and provides the slave setpoint. Set IsMaster = TRUE if you are using this PID_Temp instance as master controller in a cascade. A master controller defines the setpoint of a slave controller with its output. A PID_Temp instance can be master controller and slave controller at the same time. If the controller is used as master controller, the cooling output must be deactivated (Config.ActivateCooling = FALSE).
Config.Cascade.IsSlave	BOOL	FALSE	The controller is slave in a cascade and receives its setpoint from the master. Set IsSlave = TRUE if you are using this PID_Temp instance as slave controller in a cascade. A slave controller receives its setpoint (Setpoint parameter) from the output of its master controller (OutputHeat parame-ter). A PID_Temp instance can be master controller and slave controller at the same time.
Config.Cascade.AntiWindUpMode	INT	1	Anti-windup behavior in the cascade Options are: • Anti-windup = 0 The AntiWindUp functionality is deactivated. The master controller does not respond to the limit of its slave controllers. • Anti-windup = 1 The integral action of the master controller is reduced in the ratio "Slaves in limit" to "Number of slaves" ("CountSlaves" parameter). This reduces the effects of the limitation on the control behavior. • Anti-windup = 2 The integral action of the master controller is held as soon as a slave controller is in the limit. Only effective if the controller is configured as master controller (Config.Cascade.IsMaster = TRUE).

Tag	Data type	Default	Description
Config.Cascade.CountSlaves	INT	1	Number of subordinate slaves Here you enter the number of directly subordinate slave controllers which receive their setpoint from this master controller. Only effective if the controller is configured as master controller (Config.Cascade.IsMaster = TRUE). 255 ≥ CountSlaves ≥ 1
CycleTime.StartEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, CycleTime.StartEstimation = TRUE starts automatic determination of the PID_Temp sampling time (cycle time of the calling OB). CycleTime.StartEstimation = FALSE is set once measurement is complete.
CycleTime.EnEstimation	BOOL	TRUE	If CycleTime.EnEstimation = TRUE, the PID_Temp sampling time is determined automatically. If CycleTime.EnEstimation = FALSE, the sampling time PID_Temp is not determined automatically and must be configured correctly manually with CycleTime.Value.
CycleTime.EnMonitoring	BOOL	TRUE	If CycleTime.EnMonitoring = FALSE, the PID_Temp sampling time is not monitored. If PID_Temp cannot be executed within the sampling time, no error (ErrorBits=0000800h) is output and PID_Temp does not respond as configured with ActivateRecoverMode.
CycleTime.Value	REAL	0.1	PID_Temp sampling time (cycle time of the calling OB) in seconds CycleTime.Value is determined automatically and is usually equivalent to the cycle time of the calling OB.
You can reload values from the CtrlParamsBackUp structure with LoadBackUp = TRUE.			
CtrlParamsBackUp.SetByUser	BOOL	FALSE	Saved value of Retain.CtrlParams.SetByUser
CtrlParamsBackUp.Heat.Gain	REAL	1.0	Saved proportional gain for heating
CtrlParamsBackUp.Heat.Ti	REAL	20.0	Saved integral action time for heating in seconds
CtrlParamsBackUp.Heat.Td	REAL	0.0	Saved derivative action time for heating in seconds
CtrlParamsBackUp.Heat.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient for heating
CtrlParamsBackUp.Heat.PWeighting	REAL	1.0	Saved weighting of the proportional action for heating
CtrlParamsBackUp.Heat.DWeighting	REAL	1.0	Saved weighting of the derivative action for heating
CtrlParamsBackUp.Heat.Cycle	REAL	1.0	Saved sampling time of the PID algorithm for heating in seconds
CtrlParamsBackUp.Heat.ControlZone	REAL	3.402822e+38	Saved control zone width for heating
CtrlParamsBackUp.Heat.DeadZone	REAL	0.0	Saved dead zone width for heating
CtrlParamsBackUp.Cool.Gain	REAL	1.0	Saved proportional gain for cooling
CtrlParamsBackUp.Cool.Ti	REAL	20.0	Saved integral action time for cooling in seconds
CtrlParamsBackUp.Cool.Td	REAL	0.0	Saved derivative action time for cooling in seconds
CtrlParamsBackUp.Cool.TdFiltRatio	REAL	0.2	Saved derivative delay coefficient for cooling

Tag	Data type	Default	Description
CtrlParamsBackUp.Cool.PWeighting	REAL	1.0	Saved proportional action weighting factor for cooling
CtrlParamsBackUp.Cool.DWeighting	REAL	1.0	Saved derivative action weighting factor for cooling
CtrlParamsBackUp.Cool.Cycle	REAL	1.0	Saved sampling time of the PID algorithm for cooling in seconds
CtrlParamsBackUp.Cool.ControlZone	REAL	3.402822e+38	Saved control zone width for cooling
CtrlParamsBackUp.Cool.DeadZone	REAL	0.0	Saved dead zone width for cooling
PIDSelfTune.SUT.CalculateParamsHeat	BOOL	FALSE	The properties of the heating branch of the controlled system are saved during pretuning for heating. If SUT.CalculateParamsHeat = TRUE, the PID parameters for heating (Retain.CtrlParams.Heat structure) are recalculated on the basis of these properties. This enables you to change the parameter calculation method (PIDSelfTune.SUT.TuneRuleHeat parameter) without having to repeat the tuning. SUT.CalculateParamsHeat is set to FALSE after the calculation. Only possible if the pretuning was successful (SUT.ProcParHeatOk = TRUE).
PIDSelfTune.SUT.CalculateParamsCool	BOOL	FALSE	The properties of the cooling branch of the controlled system are saved during tuning for cooling. If SUT.CalculateParamsCool = TRUE, the PID parameters for cooling (Retain.CtrlParams.Cool structure) are recalculated on the basis of these properties. This enables you to change the parameter calculation method (PIDSelfTune.SUT.TuneRuleCool parameter) without having to repeat the tuning. SUT.CalculateParamsCool is set to FALSE after the calculation. Only possible if the pretuning was successful (SUT.ProcParCoolOk = TRUE). Only effective if Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE.
PIDSelfTune.SUT.TuneRuleHeat	INT	2	Method for PID parameter calculation with pretuning for heating Options are: • SUT.TuneRuleHeat = 0: PID according to CHR • SUT.TuneRuleHeat = 1: PI according to CHR • SUT.TuneRuleHeat = 2: PID for temperature processes according to CHR (results in a slower and rather asymptomatic control response with lower overshoot than SUT.TuneRuleHeat = 0) (CHR = Chien, Hrones and Reswick) Only with SUT.TuneRuleHeat = 2 is the control zone Retain.CtrlParams.Heat.ControlZone automatically set during pretuning for heating.

Tag	Data type	Default	Description
PIDSelfTune.SUT.TuneRuleCool	INT	2	Method for PID parameter calculation with pretuning for cooling Options are: • SUT.TuneRuleCool = 0: PID according to CHR • SUT.TuneRuleCool = 1: PI according to CHR • SUT.TuneRuleCool = 2: PID for temperature processes according to CHR (results in a slower and rather asymptomatic control response with lower overshoot than SUT.TuneRuleCool = 0) (CHR = Chien, Hrones and Reswick) Only with SUT.TuneRuleCool = 2 is the control zone Retain.CtrlParams.Cool.ControlZone automatically set during pretuning for cooling. SUT.TuneRuleCool is only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE, Config.AdvancedCooling = TRUE).
PIDSelfTune.SUT.State	INT	0	The SUT.State tag indicates the current phase of pretuning: • State = 0: Initialize pretuning • State = 100: Calculate standard deviation for heating • State = 200: Calculate standard deviation for cooling • State = 300: Determine point of inflection for heating • State = 400: Determine point of inflection for cooling • State = 500: Set heating to setpoint after reaching point of inflection • State = 600: Set cooling to setpoint after reaching point of inflection • State = 700: Compare efficiency of the heating actuator and cooling actuator • State = 800: Heating and cooling activated • State = 900: Cooling activated • State = 1000: Determine delay time after switching off heating • State = 9900: Pretuning successful • State = 1: Pretuning not successful
PIDSelfTune.SUT.ProcParHeatOk	BOOL	FALSE	TRUE: The calculation of the process parameters for pretuning heating was successful. This tag is set during tuning. It must be TRUE for calculation of the PID parameters for heating.
PIDSelfTune.SUT.ProcParCoolOk	BOOL	FALSE	TRUE: The calculation of the process parameters for pretuning cooling was successful. This tag is set during tuning. It must be TRUE for calculation of the PID parameters for cooling.

Tag	Data type	Default	Description
PIDSelfTune.SUT.AdaptDelay-Time	INT	0	The AdaptDelayTime tag determines the adaptation of the delay time for heating at the operating point (for "Pretuning heating" and "Pretuning heating and cooling"). Options are: • SUT.AdaptDelayTime = 0: No adaptation of delay time. The SUT.State = 1000 phase is skipped. This option results in a shorter tuning time than with SUT.AdaptDelayTime = 1. • SUT.AdaptDelayTime = 1: Adaptation of the delay time to the setpoint in SUT.State = 1000 phase by switching off heating temporarily. This option results in a longer tuning time than withSUT.AdaptDelayTime = 0. It can improve the control response if the process behavior depends significantly on the operating point (non-linearity). This option should not be used for multi-zone applications with strong thermal connections.
PIDSelfTune.SUT.CoolingMode	INT	0	The CoolingMode tag determines the manipulated variable output to determine the cooling parameters (for pretuning heating and cooling). Options are: • SUT.CoolingMode = 0: Switch off heating and switch on cooling after reaching the setpoint. The SUT.State = 700 phase is skipped. Phase SUT.State = 500 is followed by phase SUT.State = 900. This option can improve the control response if the gain of the cooling actuator is low compared to the gain of the heating actuator. It results in a shorter tuning time than with SUT.CoolingMode = 1 or 2. • SUT.CoolingMode = 1: Switch on cooling in addition to heating after reaching the setpoint. The SUT.State = 700 phase is skipped. Phase SUT.State = 500 is followed by phase SUT.State = 800. This option can improve the control response if the gain of the cooling actuator is high compared to the gain of the heating actuator. • SUT.CoolingMode = 2: After heating up to the setpoint, a decision is automatically made in phase SUT.State = 700 as to whether heating is switched off. Phase SUT.State = 500 is followed by phase SUT.State = 700 and then SUT.State = 800 or SUT.State = 900. This option requires more time than options 0 and 1.

Tag	Data type	Default	Description
PIDSelfTune.TIR.RunIn	BOOL	FALSE	Use the RunIn tag to specify the sequence of fine tuning during start from automatic mode. • RunIn = FALSE If fine tuning is started from automatic mode, the system uses the existing PID parameters to control to the setpoint (TIR.State = 500 or 600). Only then will fine tuning start. • RunIn = TRUE PID_Temp tries to reach the setpoint with minimum or maximum output value (TIR.State = 300 or 400). This can produce increased overshoot. Fine tuning then starts automatically. RunIn is set to FALSE after fine tuning. During start of fine tuning from Inactive or Manual mode, PID_Temp reacts as described under RunIn = TRUE.
PIDSelfTune.TIR.CalculateParamsHeat	BOOL	FALSE	The properties of the heating branch of the controlled system are saved during fine tuning for heating. If TIR.CalculateParamsHeat= TRUE, the PID parameters for heating (Retain.CtrlParams.Heat structure) are recalculated on the basis of these properties. This enables you to change the parameter calculation method (PIDSelfTune.TIR.TuneRuleHeat parameter) without having to repeat the tuning. TIR.CalculateParamsHeat is set to FALSE after the calculation. Only possible if fine tuning heating was successful beforehand (TIR.ProcParHeatOk = TRUE).
PIDSelfTune.TIR.CalculateParamsCool	BOOL	FALSE	The properties of the cooling branch of the controlled system are saved during fine tuning for cooling. If TIR.CalculateParamsCool= TRUE, the PID parameters for cooling (Retain.CtrlParams.Cool structure) are recalculated on the basis of these properties. This enables you to change the parameter calculation method (PIDSelfTune.TIR.TuneRuleCool parameter) without having to repeat the tuning. TIR.CalculateParamsCool is set to FALSE after the calculation. Only possible if fine tuning cooling was successful beforehand (TIR.ProcParCoolOk = TRUE). Only effective if Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE

Tag	Data type	Default	Description
PIDSelfTune.TIR.TuneRuleHeat	INT	0	Method for parameter calculation during fine tuning for heating Options are: • TIR.TuneRuleHeat = 0: PID automatic • TIR.TuneRuleHeat = 1: PID fast (faster control response with higher amplitudes of the output value than with TIR.TuneRuleHeat = 2) • TIR.TuneRuleHeat = 2: PID slow (slower control response with lower amplitudes of the output value than with TIR.TuneRuleHeat = 1) • TIR.TuneRuleHeat = 3: ZN PID • TIR.TuneRuleHeat = 4: ZN PI • TIR.TuneRuleHeat = 5: ZN P (ZN=Ziegler-Nichols) To be able to repeat the calculation of the PID parameters for heating with TIR.CalculateParamsHeat and TIR.TuneRuleHeat = 0, 1 or 2, the previous fine tuning also has to have been executed with TIR.TuneRuleHeat = 0, 1 or 2. If this is not the case, TIR.TuneRuleHeat = 3 is used. The recalculation of the PID parameters for heating with TIR.CalculateParamsHeat and TIR.TuneRuleHeat = 3, 4 or 5 is always possible.
PIDSelfTune.TIR.TuneRuleCool	INT	0	Method for parameter calculation during fine tuning for cooling Options are: • TIR.TuneRuleCool = 0: PID automatic • TIR.TuneRuleCool = 1: PID fast (faster control response with higher amplitudes of the output value than with TIR.TuneRuleCool = 2) • TIR.TuneRuleCool = 2: PID slow (slower control response with lower amplitudes of the output value than with TIR.TuneRuleCool = 1) • TIR.TuneRuleCool = 3: ZN PID • TIR.TuneRuleCool = 4: ZN PI • TIR.TuneRuleCool = 5: ZN P (ZN=Ziegler-Nichols) To be able to repeat the calculation of the PID parameters for cooling with TIR.CalculateParamsCool and TIR.TuneRuleCool = 0, 1 or 2, the previous fine tuning also has to have been executed with TIR.TuneRuleCool = 0, 1 or 2. If this is not the case, TIR.TuneRuleCool = 3 is used. The recalculation of the PID parameters for cooling with TIR.CalculateParamsCool and TIR.TuneRuleCool = 3, 4 or 5 is always possible. Only effective if the cooling output and PID parameter switching are activated (ConfigActivateCooling = TRUE and Config.AdvancedCooling = TRUE).

Tag	Data type	Default	Description
PIDSelfTune.TIR.State	INT	0	The TIR.State tag indicates the current phase of "fine tuning": • State = 0: Initialize fine tuning • State = 100: Calculate standard deviation for heating • State = 200: Calculate standard deviation for cooling • State = 300: Attempting to reach setpoint for heating with two-step control using heating • State = 400: Attempting to reach setpoint for cooling with two-step control using cooling • State = 500: Attempting to reach setpoint for heating with PID control • State = 600: Attempting to reach setpoint for cooling with PID control • State = 700: Calculate standard deviation for heating • State = 800: Calculate standard deviation for cooling • State = 900: Determine oscillation and calculate parameters for heating • State = 1000: Determine oscillation and calculate parameters for cooling • State = 9900: Fine tuning successful • State = 1: Fine tuning not successful
PIDSelfTune.TIR.ProcParHeatOk	BOOL	FALSE	TRUE: The calculation of the process parameters for fine tuning heating was successful. This tag is set during tuning. It must be met for calculation of the PID parameters for heating.
PIDSelfTune.TIR.ProcParCoolOk	BOOL	FALSE	TRUE: The calculation of the process parameters for fine tuning cooling was successful. This tag is set during tuning. It must be met for calculation of the PID parameters for cooling.

Tag	Data type	Default	Description
PIDSelfTune.TIR.OutputOffsetHeat	REAL	0.0	Tuning offset heating of the PID output value TIR.OutputOffsetHeat is added to the value that results from PidOutputSum for the heating branch. To receive a positive offset at the outputs for heating, define a positive value for TIR.OutputOffsetHeat. The resulting values at the outputs for heating are the result of the configured output scaling (Struktur Config.Output.Heat). This tuning offset can be used in controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.AdvancedCooling = TRUE) for fine tuning cooling. If the outputs for cooling are not active at the setpoint that is to be tuned (PidOutputSum > 0.0), fine tuning cooling is not possible. In this case, define a positive tuning offset heating which is greater than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. This step increases the values at the outputs for heating and activates the outputs for cooling (PidOutputSum < 0.0). Fine tuning cooling is now possible. When fine tuning is complete, TIR.OutputOffsetHeat is reset to 0.0. Major changes at TIR.OutputOffsetHeat in one step can result in temporary overshoots. Config.Output.Heat.PidUpperLimit ≥ PIDSelfTune.TIR.OutputOffsetHeat ≥ Config.Output.Heat.PidLowerLimit
PIDSelfTune.TIR.OutputOffsetCool	REAL	0.0	Tuning offset cooling of the PID output value TIR.OutputOffsetCool is added to the value that results from PidOutputSum for the cooling branch. To receive a positive offset at the outputs for cooling, define a negative value for TIR.OutputOffsetCool. The resulting values at the outputs for cooling are the result of the configured output scaling (Struktur Config.Output.Coool). This tuning offset can be used in controllers with activated cooling output (Config.ActivateCooling = TRUE) for fine tuning heating. If the outputs for heating are not active at the setpoint that is to be tuned (PidOutputSum < 0.0), fine tuning heating is not possible. In this case, define a negative tuning offset cooling which is less than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. This step increases the values at the outputs for cooling and activates the outputs for heating (PidOutputSum > 0.0). Fine tuning heating is now possible. When fine tuning is complete, TIR.OutputOffsetCool is reset to 0.0. Major changes at TIR.OutputOffsetCool in one step can result in temporary overshoots. Config.Output.Cool.PidUpperLimit ≥ PIDSelfTune.TIR.OutputOffsetCool ≥ Config.Output.Cool.PidLowerLimit

Tag	Data type	Default	Description
PIDSelfTune.TIR.WaitForControlIn	BOOL	FALSE	Waiting with fine tuning after reaching the setpoint If TIR.WaitForControlIn = TRUE, fine tuning waits in between reaching the setpoint (TIR.State = 500 or 600) and calculation of the standard deviation (TIR.State = 700 or 800) until a FALSE -> TRUE edge is given at TIR.FinishControlIn. TIR.WaitForControlIn can be used for simultaneous fine tuning of several controllers in multi-zone applications to synchronize tuning of the individual zones. It ensures that all zones have reached their setpoints before the actual tuning starts. The influence of thermal connections between the zones on tuning can be reduced in this way. TIR.WaitForControlIn is only effective if fine tuning is started from automatic mode with PIDSelfTune.TIR.RunIn = FALSE.
PIDSelfTune.TIR.ControlInReady	BOOL	FALSE	If TIR.WaitForControlIn = TRUE, PID_Temp sets TIR.ControlInReady = TRUE as soon as the setpoint has been reached and waits with additional tuning steps until a FALSE -> TRUE edge is given at TIR.FinishControlIn.
PIDSelfTune.TIR.FinishControlIn	BOOL	FALSE	If TIR.ControlInReady = TRUE, a FALSE -> TRUE edge at TIR.FinishControlIn stops the wait and fine tuning resumes.
PIDCtrl.IOutputOld	REAL	0.0	Integral action in last cycle
PIDCtrl.PIDInit	BOOL	FALSE	PIDCtrl.PIDInit is available as of PID_Temp version 1.1. If PIDCtrl.PIDInit = TRUE in "Automatic mode", the integral action PIDCtrl.IOutputOld is pre-assigned automatically as if PidOutputSum = OverwriteInitialOutputValue in the previous cycle. This can be used for a Override control with PID_Temp (Page 6135).
Retain.CtrlParams.SetByUser	BOOL	FALSE	If the PID parameters are entered manually in the configuration editor, SetByUser = TRUE. This parameter is used for display in the editors and does not influence the control algorithm. SetByUser is retentive.
Retain.CtrlParams.Heat.Gain	REAL	1.0	Active proportional gain for heating Heat.Gain is retentive. Heat.Gain ≥ 0.0
Retain..CtrlParams.Heat.Ti	REAL	20.0	Active integral action time for heating in seconds The integral action for heating is switched off with Heat.CtrlParams.Ti = 0.0. Heat.Ti is retentive. 100000.0 ≥ Heat.Ti ≥ 0.0
Retain.CtrlParams.Heat.Td	REAL	0.0	Active derivative action time for heating in seconds The derivative action for heating is switched off with Heat.CtrlParams.Td = 0.0. Heat.Td is retentive. 100000.0 ≥ Heat.Td ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Heat.TdFiltRatio	REAL	0.2	Active derivative delay coefficient for heating The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with **one** dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. Heat.TdFiltRatio is retentive. Heat.TdFiltRatio ≥ 0.0
Retain.CtrlParams.Heat.PWeighting	REAL	1.0	Active weighting of the proportional action for heating The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. Heat.PWeighting is retentive. 1.0 ≥ Heat.PWeighting ≥ 0.0
Retain.CtrlParams.Heat.DWeighting	REAL	1.0	Active weighting of the derivative action for heating The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. Heat.DWeighting is retentive. 1.0 ≥ Heat.DWeighting ≥ 0.0
Retain.CtrlParams.Heat.Cycle	REAL	1.0	Active sampling time of the PID algorithm for heating in seconds CtrlParams.Heat.Cycle is calculated during tuning and rounded to an integer multiple of CycleTime.Value. If Config.Output.Heat.PwmPeriode = 0.0, Heat.Cycle is used as period duration of the pulse width modulation for heating. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE, Heat.Cycle is used as period duration of the pulse width modulation for cooling. Heat.Cycle is retentive. 100000.0 ≥ Heat.Cycle > 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Heat.Control-Zone	REAL	3.402822e +38	Active control zone width for heating The control zone for heating is switched off with Heat.Control-Zone = 3.402822e+38. Heat.ControlZone is only set automatically during pretuning heating or pretuning heating and cooling if PIDSelf-Tune.SUT.TuneRuleHeat = 2 is selected as method of the parameter calculation. For controllers with deactivated cooling output (Config.Activa-teCooling = FALSE) or controllers with activated cooling output and cooling factor (Config.AdvancedCooling = FALSE), the control zone is symmetrically located between Setpoint – Heat.ControlZone and Setpoint + Heat.ControlZone. For controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.Advanced-Cooling = TRUE), the control zone is located between Setpoint – Heat.ControlZone and Setpoint + Cool.ControlZone. Heat.ControlZone is retentive. Heat.ControlZone > 0.0
Retain.CtrlParams.Heat.Dead-Zone	REAL	0.0	Active dead zone width for heating (see PID parameters (Page 6112)) The dead zone for heating is switched off with Heat.DeadZone = 0.0. Heat.DeadZone is not set automatically or adjusted during tuning. You must correctly configure Heat.DeadZone manually. When the dead zone is switched on, the result can be a permanent control deviation (deviation between setpoint and process value). This can have a negative effect on fine tuning. For controllers with deactivated cooling output (Config.Activa-teCooling = FALSE) or controllers with activated cooling output and cooling factor (Config.AdvancedCooling = FALSE), the dead zone is symmetrically located between Setpoint – Heat.DeadZone and Setpoint + Heat.DeadZone. For controllers with activated cooling output and PID parameter switching (Config.ActivateCooling = TRUE, Config.Advanced-Cooling = TRUE), the dead zone is located between Setpoint – Heat.DeadZone and Setpoint + Cool.DeadZone. Heat.DeadZone is retentive. Heat.DeadZone ≥ 0.0
Retain.CtrlParams.Cool.Gain	REAL	1.0	Active proportional gain for cooling Cool.Gain is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.Gain ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Cool.Ti	REAL	20.0	Active integral action time for cooling in seconds The integral action for cooling is switched off with Cool.CtrlParams.Ti = 0.0. Cool.Ti is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Ti ≥ 0.0
Retain.CtrlParams.Cool.Td	REAL	0.0	Active derivative action time for cooling in seconds The derivative action for cooling is switched off with Cool.CtrlParams.Td = 0.0. Cool.Td is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Td ≥ 0.0
Retain.CtrlParams.Cool.TdFiltRatio	REAL	0.2	Active derivative delay coefficient for cooling The derivative delay coefficient delays the effect of the derivative action. Derivative delay = derivative action time × derivative delay coefficient • 0.0: Derivative action is effective for one cycle only and therefore almost not effective. • 0.5: This value has proved useful in practice for controlled systems with one dominant time constant. • > 1.0: The greater the coefficient, the longer the effect of the derivative action is delayed. Cool.TdFiltRatio is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.TdFiltRatio ≥ 0.0
Retain.CtrlParams.Cool.PWeighting	REAL	1.0	Active weighting of the proportional action for cooling The proportional action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Proportional action for setpoint change is fully effective • 0.0: Proportional action for setpoint change is not effective The proportional action is always fully effective when the process value is changed. Cool.PWeighting is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 1.0 ≥ Cool.PWeighting ≥ 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Cool.DWeighting	REAL	1.0	Active weighting of the derivative action for cooling The derivative action may weaken with changes to the setpoint. Values from 0.0 to 1.0 are applicable. • 1.0: Derivative action is fully effective upon setpoint change • 0.0: Derivative action is not effective upon setpoint change The derivative action is always fully effective when the process value is changed. Cool.DWeighting is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 1.0 ≥ Cool.DWeighting ≥ 0.0
Retain.CtrlParams.Cool.Cycle	REAL	1.0	Active sampling time of the PID algorithm for cooling in seconds CtrlParams.Cool.Cycle is calculated during tuning and rounded off to an integer multiple of CycleTime.. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = TRUE, Cool.Cycle is used as period duration of the pulse width modulation for cooling. If Config.Output.Cool.PwmPeriode = 0.0 and Config.AdvancedCooling = FALSE, Heat.Cycle is used as period duration of the pulse width modulation for cooling. Cool.Cycle is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). 100000.0 ≥ Cool.Cycle > 0.0

Tag	Data type	Default	Description
Retain.CtrlParams.Cool.Control-Zone	REAL	3.402822e+38	Active control zone width for cooling The control zone for cooling is switched off with Cool.Control-Zone = 3.402822e+38. Cool.ControlZone is only set automatically during pretuning cooling or pretuning heating and cooling if PIDSelf-Tune.SUT.TuneRuleCool = 2 is selected as method of the parameter calculation. Cool.ControlZone is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.ControlZone > 0.0
Retain.CtrlParams.Cool.Dead-Zone	REAL	0.0	Active dead zone width for cooling (see PID parameters (Page 6112)) The dead zone for cooling is switched off with Cool.DeadZone = 0.0. Cool.DeadZone is not set automatically or adjusted during tuning. You must correctly configure Cool.DeadZone manually. When the dead zone is switched on, the result can be a permanent control deviation (deviation between setpoint and process value). This can have a negative effect on fine tuning. Cool.DeadZone is retentive. Only effective if the cooling output and PID parameter switching are activated (Config.ActivateCooling = TRUE and Config.AdvancedCooling = TRUE). Cool.DeadZone ≥ 0.0

Note

Change the tags listed in this table in "Inactive" mode to prevent malfunction of the PID controller.

See also

PID_Temp ActivateRecoverMode tag (Page 4375)

PID_Temp Warning tag (Page 4378)

Multi-zone controlling with PID_Temp (Page 6133)

PID_Temp state and mode parameters (S7-1200, S7-1500)

Correlation of the parameters

The State parameter shows the current operating mode of the PID controller. You cannot change the State parameter.

With a rising edge at ModeActivate, PID_Temp switches to the operating mode saved in the Mode in-out parameter.

Heat.EnableTuning and Cool.EnableTuning specify for pretuning and fine tuning, if tuning takes place for heating or cooling.

If the CPU is switched on or switches from Stop to RUN mode, PID_Temp starts in the operating mode that is saved in the Mode parameter. To leave PID_Temp in "Inactive" mode, set RunModeByStartup = FALSE.

Meaning of values

State / Mode	Description of operating mode
0	**Inactive** The following output values are output in "Inactive" mode: • 0.0 as PID output value (PidOutputSum) • 0.0 as output value for heating (OutputHeat) and output value for cooling (OutputCool) • 0 as analog output value for heating (OutputHeat_PER) and analog output value for cooling (OutputCool_PER) • FALSE as PWM output value for heating (OutputHeat_PWM) and PWM output value for cooling (OutputCool_PWM) This does not depend on the configured output value limits and scaling in the structures Config.Output.Heat and Config.Output.Cool.

State / Mode	Description of operating mode
1	**Pretuning** The pretuning determines the process response to a jump change of the output value and searches for the point of inflection. The PID parameters are calculated from the maximum rate of rise and dead time of the controlled system. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Temp offers different pretuning types depending on the configuration: • Pretuning heating: A jump change is output at the output value heating, the PID parameters for heating are calculated (Retain.CtrlParams.Heat structure), and control to the setpoint then takes place in automatic mode. If the process behavior strongly depends on the operating point, an adaptation of the delay time can be activated at the setpoint with PIDSelfTune.SUT.AdaptDelayTime. • Pretuning heating and cooling: A jump is output at the output value heating. As soon as the process value is close to the setpoint, a jump change is output at the output value cooling. The PID parameters for heating (Retain.CtrlParams.Heat structure) and cooling (Retain.CtrlParams.Cool structure) are calculated. Then, control to the setpoint takes place in automatic mode. If the process behavior strongly depends on the operating point, an adaptation of the delay time can be activated at the setpoint with PIDSelfTune.SUT.AdaptDelayTime. Depending on the effect of the cooling actuator compared to the heating actuator, the quality of tuning can be influenced by whether or not the heating and cooling outputs are operated simultaneously during tuning. You can specify this with PIDSelfTune.SUT.CoolingMode. • Pretuning cooling: A jump change is output at the output value cooling and the PID parameters for cooling are calculated (Struktur Retain.CtrlParams.Cool). Then, control to the setpoint takes place in automatic mode. If you want to tune the PID parameters for heating and cooling, you can expect a better control response with "Pretuning heating" followed by "Pretuning cooling" rather than with "Pretuning heating and cooling". However, carrying out pretuning in two steps takes more time. **General requirements for pretuning:** • The PID_Temp instruction is called in a cyclic interrupt OB. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) • ManualEnable = FALSE • Reset = FALSE • The setpoint and the process value lie within the configured limits. **Requirements for pretuning heating:** • Heat.EnableTuning = TRUE • Cool.EnableTuning = FALSE • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint is greater than the process value.

State / Mode	Description of operating mode
	Setpoint > Input **Requirements for pretuning heating and cooling:** • Heat.EnableTuning = TRUE· • Cool.EnableTuning = TRUE • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE). • The process value must not be too close to the setpoint. |Setpoint - Input| > 0.3 * |Config.InputUpperLimit - Config.InputLowerLimit| and |Setpoint - Input| > 0.5 * |Setpoint| • The setpoint is greater than the process value. Setpoint > Input **Requirements for pretuning cooling:** • Heat.EnableTuning = FALSE· • Cool.EnableTuning = TRUE· • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE). • A "pretuning heating" or "pretuning heating and cooling" has been successful (PIDSelfTune.SUT.ProcParHeatOk = TRUE), if possible at the same setpoint. • The process value must be close to the setpoint. |Setpoint - Input| < 0.05 * |Config.InputUpperLimit - Config.InputLowerLimit| The more stable the process value is, the easier it is to calculate the PID parameters and the more precise the result will be. Noise on the process value can be tolerated as long as the rate of rise of the process value is significantly higher compared to the noise. This is most likely the case in operating modes "Inactive" or "Manual mode". The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The method for calculation of the PID parameters can be specified separately for heating and cooling with PIDSelfTune.SUT.TuneRuleHeat and PIDSelfTune.SUT.TuneRuleCool. Before the PID parameters are recalculated, they are backed up in the CtrlParamsBackUp structure and can be reactivated with LoadBackUp. After successful pretuning, the switch is made to automatic mode. After unsuccessful pretuning, the switch to the mode is determined by ActivateRecoverMode. The phase of pretuning is indicated with PIDSelfTune.SUT.State.

State / Mode	Description of operating mode
2	**Fine tuning** Fine tuning generates a constant, limited oscillation of the process value. The PID parameters are tuned for the operating point from the amplitude and frequency of this oscillation. PID parameters from fine tuning usually have better master control and disturbance characteristics than PID parameters from pretuning. You obtain the best PID parameters when you perform pretuning and fine tuning. PID_Temp automatically attempts to generate an oscillation greater than the noise of the process value. Fine tuning is only minimally influenced by the stability of the process value. PID_Temp offers different fine tuning types depending on the configuration: • Fine tuning heating: PID_Temp generates an oscillation of the process value with periodic changes at the output value heating and calculates the PID parameters for heating (Struktur Retain.CtrlParams.Heat). • Fine tuning cooling: PID_Temp generates an oscillation of the process value with periodic changes at the output value cooling and calculates the PID parameters for cooling (Struktur Retain.CtrlParams.Cool). **Temporary tuning offset for heating/cooling controllers** If PID_Temp is used as heating/cooling controller (Config.ActivateCooling = TRUE), the PID output value (PidOutputSum) at the setpoint must meet the following requirements for a process value oscillation to be generated and fine tuning to be successful: • Positive PID output value for fine tuning heating • Negative PID output value for fine tuning cooling If this requirement is not met, you can define a temporary offset for fine tuning which is output at the output with the opposite effect: • Offset for cooling output (PIDSelfTune.TIR.OutputOffsetCool) with fine tuning heating. Define a negative tuning offset cooling which is less than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. • Offset for heating output (PIDSelfTune.TIR.OutputOffsetHeat) with fine tuning cooling. Define a positive tuning offset heating which is greater than the PID output value (PidOutputSum) at the setpoint in the steady state before you start tuning. The defined offset is balanced by the PID algorithm so that the process value remains at the setpoint. The height of the offset allows the PID output value to be adapted correspondingly so that it fulfills the requirement mentioned above. To avoid larger overshoots of the process value when defining the offset, it can also be increased in several steps. If PID_Temp exits the fine tuning mode, the tuning offset is reset. Example for definition of an offset for fine tuning cooling: • Without offset: – Setpoint = Process value (ScaledInput) = 80°C – PID output value (PidOutputSum) = 30.0 – Output value heating (OutputHeat) = 30.0 – Output value cooling (OutputCool) = 0.0 Oscillation of the process value around the setpoint cannot be generated with the cooling output alone. Fine tuning would fail here. • With definition of an offset for heating output (PIDSelfTune.TIR.OutputOffsetHeat) = 80.0 – Setpoint = process value (ScaledInput) = 80°C – PID output value (PidOutputSum) = -50.0

State / Mode	Description of operating mode
	– Output value heating (OutputHeat) = 80.0 – Output value cooling (OutputCool) = -50.0 By defining an offset for the heating output, the cooling output can now create an oscillation of the process value around the setpoint. Fine tuning can now be carried out successfully. **General requirements for fine tuning:** • The PID_Temp instruction is called in a cyclic interrupt OB. • No disturbances are expected. • The setpoint and the process value lie within the configured limits. • The control loop has stabilized at the operating point. The operating point is reached when the process value corresponds to the setpoint. When the dead zone is switched on, the result can be a permanent control deviation (deviation between setpoint and actual value). This can have a negative effect on fine tuning. • ManualEnable = FALSE • Reset = FALSE • Automatic (State = 3), inactive (State = 0) or manual (State = 4) mode **Requirements for fine tuning heating:** • Heat.EnableTuning = TRUE • Cool.EnableTuning = FALSE • If PID_Temp is configured as heating/cooling controller (Config.ActivateCooling = TRUE), the heating output must be active at the operating point at which tuning is to take place (PidOutputSum > 0.0 (see tuning offset)). **Requirements for fine tuning cooling:** • Heat.EnableTuning = FALSE • Cool.EnableTuning = TRUE • The cooling output is activated (Config.ActivateCooling = TRUE). • The PID parameter switching is activated (Config.AdvancedCooling = TRUE) • The cooling output must be active at the operating point at which tuning is to take place (PidOutputSum < 0.0 (see tuning offset)). **The course of fine tuning is determined by the mode from which it is started:** • Automatic mode (State = 3) with PIDSelfTune.TIR.RunIn = FALSE (default) Start fine tuning from automatic mode if you wish to improve the existing PID parameters through tuning. PID_Temp controls the system using the existing PID parameters until the control loop has stabilized and the requirements for fine tuning have been met. Only then will fine tuning start. • Inactive (State = 0), manual mode (State = 4), or automatic mode (State = 3) with PIDSelfTune.TIR.RunIn = TRUE Attempts are made to reach the setpoint with the minimum or maximum output value: – with minimum or maximum output value heating for fine tuning heating – With minimum or maximum output value cooling for fine tuning cooling. This can produce increased overshoot. Fine tuning starts when the setpoint is reached.

State / Mode	Description of operating mode
	If the setpoint cannot be reached, PID_Temp does not automatically abort tuning. The setpoint is frozen in the CurrentSetpoint tag. Tuning is canceled when: • Setpoint > CurrentSetpoint + CancelTuningLevel or • Setpoint < CurrentSetpoint - CancelTuningLevel The method for calculation of the PID parameters can be specified separately for heating and cooling with PIDSelfTune.TIR.TuneRuleHeat and PIDSelfTune.TIR.TuneRuleCool. Before the PID parameters are recalculated, they are backed up in the CtrlParamsBackUp structure and can be reactivated with LoadBackUp. The controller changes to automatic mode after successful fine tuning. After unsuccessful fine tuning, the switch to the mode is determined by ActivateRecoverMode. The "Fine tuning" phase is indicated with PIDSelfTune.TIR.State.
3	**Automatic mode** In automatic mode, PID_Temp corrects the controlled system in accordance with the parameters specified. The controller switches to automatic mode if one the following requirements is met: • Pretuning successfully completed • Fine tuning successfully completed • Changing of the Mode in-out parameter to the value 3 and a rising edge at ModeActivate. The switchover from automatic mode to manual mode is only bumpless if carried out in the commissioning editor. The ActivateRecoverMode tag is taken into consideration in automatic mode.
4	**Manual mode** In manual mode, you specify a manual PID output value in the ManualValue parameter. The values at the outputs for heating and cooling resulting from this manual value are the result of the configured output scaling. You can also activate this operating mode using ManualEnable = TRUE. We recommend that you change the operating mode using Mode and ModeActivate only. The switchover from manual mode to automatic mode is bumpless. The ActivateRecoverMode tag is taken into consideration in manual mode.
5	**Substitute output value with error monitoring** The control algorithm is deactivated. The SetSubstituteOutput tag determines which PID output value (PidOutputSum) is output in this operating mode. • SetSubstituteOutput = FALSE: Last valid PID output value • SetSubstituteOutput = TRUE: Substitute output value (SubstituteOutput) You cannot activate this operating mode using Mode = 5. In the event of an error, it is activated instead of "Inactive" operating mode if all the following conditions are met: • Automatic mode (State = 3) • ActivateRecoverMode = TRUE • One or more errors have occurred in which ActivateRecoverMode is effective. As soon as the errors are no longer pending, PID_Temp switches back to automatic mode.

ENO characteristics

If State = 0, then ENO = FALSE.

If State ≠ 0, then ENO = TRUE.

Automatic switchover of operating mode during commissioning

Automatic mode is activated following successful pretuning or fine tuning. The following table shows how Mode and State change during successful pretuning.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning successfully completed
n	3	3	Automatic mode is started

PID_Temp automatically switches the operating mode in the event of an error.

The following table shows how Mode and State change during pretuning with errors.

Cycle no.	Mode	State	Action
0	4	4	Set Mode = 1
1	1	4	Set ModeActivate = TRUE
1	4	1	Value of State is saved in Mode parameter Pretuning is started
n	4	1	Pretuning canceled
n	4	4	Manual mode is started

If ActivateRecoverMode = TRUE, the operating mode that is saved in the Mode parameter is activated. When you start pretuning or fine tuning, PID_Temp has saved the value of State in the Mode in-out parameter. This means PID_Temp switches to the mode from which tuning was started.

If ActivateRecoverMode = FALSE, the system switches to "Inactive" operating mode.

PID_Temp ErrorBits parameter (S7-1200, S7-1500)

If several errors are pending simultaneously, the values of the ErrorBits are displayed with binary addition. The display of ErrorBits = 0000003h, for example, indicates that the errors 0000001h and 0000002h are pending simultaneously.

ErrorBits (DW#16#...)	Description
0000000	There is no error.
0000001	The "Input" parameter is outside the process value limits. • Input > Config.InputUpperLimit or • Input < Config.InputLowerLimit If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000002	Invalid value at "Input_PER" parameter. Check whether an error is pending at the analog input. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000004	Error during fine tuning. Oscillation of the process value could not be maintained. If PID_Temp is used as heating-cooling controller (Config.ActivateCooling = TRUE), to be able to generate actual value oscillation, the PID output value (PidOutputSum) at the setpoint must be • positive for fine tuning heating • negative for fine tuning cooling If this requirement is not met, use the tuning offsets (PIDSelfTune.TIR.OutputOffsetCool and PIDSelf-Tune.TIR.OutputOffsetHeat tags), see Fine tuning (Page 6121). If ActivateRecoverMode was = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000008	Error at start of pretuning. The process value is too close to the setpoint or greater than the setpoint. Start fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000010	The setpoint was changed during tuning. You can set the permitted fluctuation of the setpoint at the CancelTuningLevel tag. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000020	Pretuning is not permitted during fine tuning. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp remains in fine tuning mode.
0000040	Error during pretuning. Cooling could not reduce the process value. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.

ErrorBits (DW#16#...)	Description
0000100	Error during fine tuning resulted in invalid parameters. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0000200	Invalid value at "Input" parameter: Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000400	Calculation of output value failed. Check the PID parameters. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0000800	Sampling time error: PID_Temp is not called within the sampling time of the cyclic interrupt OB. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter. If this error occurred during simulation with PLCSIM, see the notes under Simulating PID_Temp with PLCSIM (Page 6139).
0001000	Invalid value at "Setpoint" parameter or "SubstituteSetpoint": Value has an invalid number format. If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp outputs the configured substitute output value. As soon as the error is no longer pending, PID_Temp switches back to automatic mode. If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.
0010000	Invalid value at ManualValue parameter. Value has an invalid number format. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp remains in manual mode and uses SubstituteOutput as PID output value. As soon as you specify a valid value in ManualValue, PID_Temp uses it as the PID output value.
0020000	Invalid value at SubstituteOutput tag. Value has an invalid number format. PID_Temp remains in the "Substitute output value with error monitoring" mode or manual mode and uses the low limit of the PID output value for heating (Config.Output.Heat.PidLowerLimit) as PID output value. As soon as you specify a valid value in SubstituteOutput, PID_Temp uses it as the PID output value.

ErrorBits (DW#16#...)	Description
0040000	Invalid value at Disturbance parameter. Value has an invalid number format. If automatic mode was active and ActivateRecoverMode = TRUE before the error occurred, Disturbance is set to zero. PID_Temp remains in automatic mode. If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter. If Disturbance in the current phase has no effect on the output value, tuning is not be canceled.
0200000	Error in master in the cascade: Slaves are not in automatic mode or have activated substitute setpoint and prevent tuning of the master. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0400000	Pretuning heating is not permitted while cooling is active. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
0800000	The process value must be close to the setpoint to start pretuning cooling. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
1000000	Error at start of tuning: Heat.EnableTuning and Cool.EnableTuning are not set or do not match the configuration. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
2000000	Pretuning cooling requires successful pretuning heating. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
4000000	Error at start of fine tuning: Heat.EnableTuning and Cool.EnableTuning must not be set simultaneously. If ActivateRecoverMode = TRUE before the error occurred, PID_Temp cancels the tuning and switches to the operating mode that is saved in the Mode parameter.
8000000	Error during calculation of the PID parameters resulted in invalid parameters. The invalid parameters are discarded and the original PID parameters are retained unchanged. We can distinguish between the following cases: • If automatic mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode. • If manual mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp remains in manual mode. • If pretuning or fine tuning mode was active before the error occurred and ActivateRecoverMode = TRUE, PID_Temp switches to the operating mode that is saved in the Mode parameter.

PID_Temp ActivateRecoverMode tag (S7-1200, S7-1500)

The ActivateRecoverMode tag determines the reaction to error. The Error parameter indicates if an error is pending. When the error is no longer pending, Error = FALSE. The ErrorBits parameter shows which errors have occurred.

Automatic mode and manual mode

NOTICE
Your system may be damaged. If ActivateRecoverMode = TRUE, PID_Temp remains in automatic mode or in manual mode even if there is an error and the process limit values are exceeded. This may damage your system. It is essential to configure how your controlled system reacts in the event of an error to protect your system from damage.

ActivateRecoverMode	Description
FALSE	PID_Temp switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	**Automatic mode** If errors occur frequently in automatic mode, this setting has a negative effect on the control response, because PID_Temp switches between the calculated PID output value and the substitute output value at each error. In this case, check the ErrorBits parameter and eliminate the cause of the error. If one or several of the following errors occur and automatic mode was active before the error occurred, PID_Temp remains in automatic mode: • 0000001h: The "Input" parameter is outside the process value limits. • 0000800h: Sampling time error • 0040000h: Invalid value at Disturbance parameter. • 8000000h: Error during calculation of the PID parameters If one or several of the following errors occur and automatic mode was active before the error occurred, PID_Temp switches to "Substitute output value with error monitoring" mode: • 0000002h: Invalid value at Input_PER parameter. • 0000200h: Invalid value at Input parameter. • 0000400h: Calculation of output value failed. • 0001000h: Invalid value at Setpoint parameter or SubstituteSetpoint. As soon as the errors are no longer pending, PID_Temp switches back to automatic mode. If the following error occurs in "Substitute output value with error monitoring" mode, PID_Temp sets the PID output value to Config.Output.Heat.PidLowerLimit as long as this error is pending: • 0020000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This behavior is independent of SetSubstituteOutput.
	Manual mode If one or several errors occur and manual mode was active before the error occurred, PID_Temp remains in manual mode. If the following error occurs in manual mode, as long as this error is pending, PID_Temp sets the PID output value to SubstituteOutput: • 0010000h: Invalid value at ManualValue parameter. Value has an invalid number format. If the error 0010000h is pending in manual mode and the following error occurs, PID_Temp sets the PID output value to Config.Output.Heat.PidLowerLimit as long as this error is pending: • 0020000h: Invalid value at SubstituteOutput tag. Value has an invalid number format. This behavior is independent of SetSubstituteOutput.

Pretuning and fine tuning

ActivateRecoverMode	Description
FALSE	PID_Temp switches to "Inactive" mode in the event of an error. The controller is only activated by a falling edge at Reset or a rising edge at ModeActivate.
TRUE	If the following error occurs, PID_Temp remains in the active mode: • 0000020h: Pretuning is not permitted during fine tuning. The following errors are ignored: • 0010000h: Invalid value at ManualValue parameter. • 0020000h: Invalid value at SubstituteOutput tag. When any other error occurs, PID_Temp cancels the tuning and switches to the mode from which tuning was started.

PID_Temp Warning tag (S7-1200, S7-1500)

If several warnings are pending simultaneously, the values of the Warning tag are displayed with binary addition. If the warning 0000003h is displayed, for example, the warnings 0000001h and 0000002h are pending simultaneously.

Warning (DW#16#....)	Description
0000000	No warning pending.
0000001	The point of inflection was not found during pretuning.
0000004	The setpoint was limited to the configured limits.
0000008	Not all the necessary controlled system properties were defined for the selected method of calculation. Instead, the PID parameters were calculated using the method TIR.TuneRuleHeat = 3 or TIR.TuneRuleCool = 3.
0000010	The operating mode could not be changed because Reset = TRUE or ManualEnable = TRUE.
0000020	The cycle time of the calling OB limits the sampling time of the PID algorithm. Improve results by using shorter OB cycle times.
0000040	The process value exceeded one of its warning limits.
0000080	Invalid value at Mode. The operating mode is not switched.
0000100	The manual value was limited to the limits of the PID output value.
0000200	The specified rule for tuning is not supported. No PID parameters are calculated.
0001000	The substitute output value cannot be reached because it is outside the output value limits.
0004000	The specified selection of the output value for heating and/or cooling is not supported. Only the output OutputHeat or OutputCool is used.
0008000	Invalid value at PIDSelfTune.SUT.AdaptDelayTime. The default value 0 is used.
0010000	Invalid value at PIDSelfTune.SUT.CoolingMode. The default value 0 is used.
0020000	The activation of cooling (Config.ActivateCooling tag) is not supported by the controller that is used as master (Config.Cascade.IsMaster tag). PID_Temp works as heating controller. Set the Config.ActivateCooling tag to FALSE.
0040000	Invalid value at Retain.CtrlParams.Heat.Gain, Retain.CtrlParams.Cool.Gain oder Config.CoolFactor. PID_Temp supports only positive values for proportional gain (heating and cooling) and cooling factor. Automatic mode remains active with PID output value 0.0. The integral component is stopped.

The following warnings are deleted as soon as the cause has been remedied or you repeat the action with valid parameters:

- 0000001h
- 0000004h
- 0000008h
- 0000040h
- 0000100h

All other warnings are cleared with a rising edge at Reset or ErrorAck.

PwmPeriode tag (S7-1200, S7-1500)

If the PID algorithm sampling time (Retain.CtrlParams.Heat.Cycle or Retain.CtrlParams.Heat.Cycle) and thus the time period of the pulse width modulation is very high when you use OutputHeat_PWM or OutputCool_PWM, you can define a deviating shorter time period at the Config.Output.Heat.PwmPeriode or Config.Output.Cool.PwmPeriode parameters to improve the smoothness of the process value.

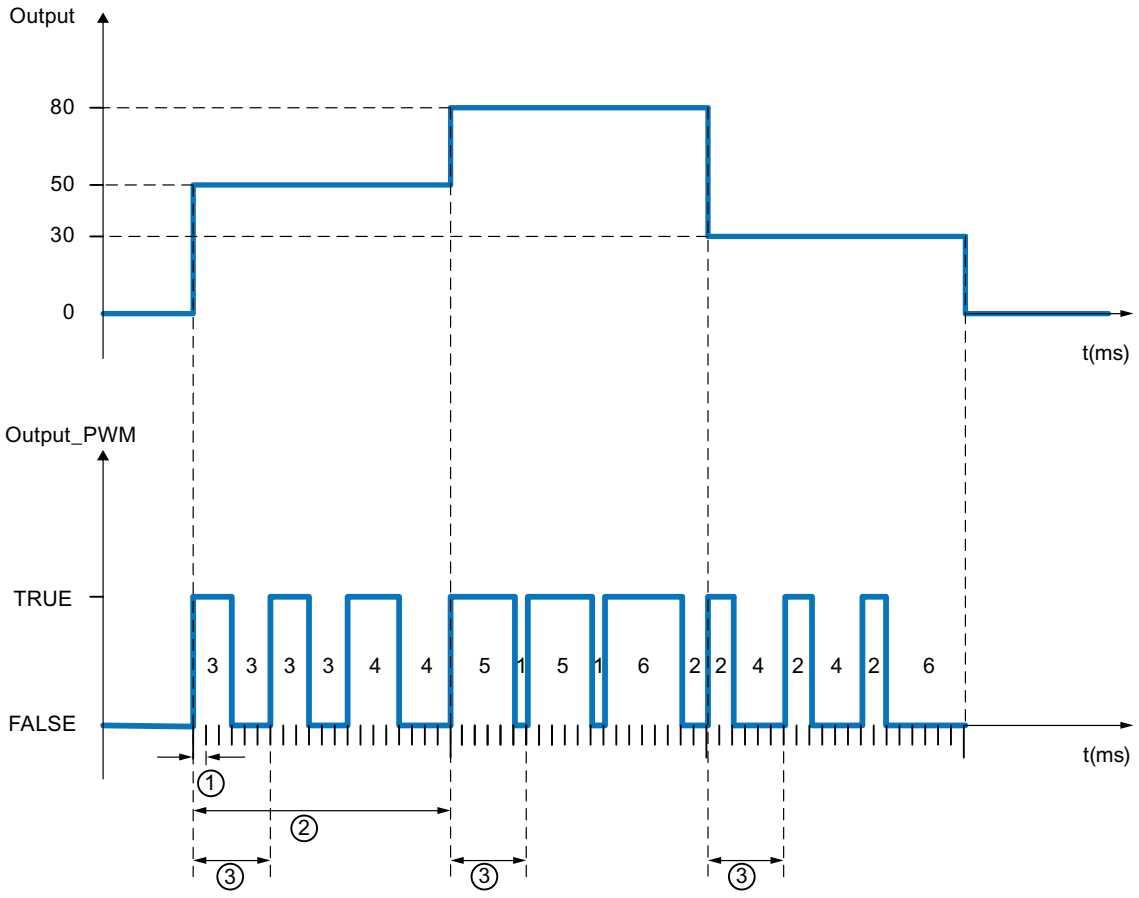
Time period of the pulse width modulation at OutputHeat_PWM

Time period of the PWM at output OutputHeat_PWM depending on Config.Output.Heat.PwmPeriode:

- Heat.PwmPeriode = 0.0 (default)
  The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM.
- Heat.PwmPeriode > 0.0
  The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM.
  The value must meet the following conditions:
  - Heat.PwmPeriode ≤ Retain.CtrlParams.Heat.Cycle
  - Heat.PwmPeriode > Config.Output.Heat.MinimumOnTime
  - Heat.PwmPeriode > Config.Output.Heat.MinimumOffTime

Time period of the pulse width modulation at OutputCool_PWM

Time period of the PWM at output OutputCool_PWM depending on Config.Output.Cool.PwmPeriode and the method for heating/cooling:



- Cool.PwmPeriode = 0.0 and cooling factor (Config.AdvancedCooling = FALSE):
  The sampling time of the PID algorithm for heating (Retain.CtrlParams.Heat.Cycle) is used as time period of the PWM.
- Cool.PwmPeriode = 0.0 and PID parameter switching (Config.AdvancedCooling = TRUE):
  The sampling time of the PID algorithm for cooling (Retain.CtrlParams.Cool.Cycle) is used as time period of the PWM.
- Cool.PwmPeriode > 0.0:
  The value is rounded off to an integer multiple of the PID_Temp sampling time (CycleTime.Value) and used as time period of the PWM.
  The value must meet the following conditions:
  - Cool.PwmPeriode ≤ Retain.CtrlParams.Cool.Cycle or Retain.CtrlParams.Heat.Cycle
  - Cool.PwmPeriode > Config.Output.Cool.MinimumOnTime
  - Cool.PwmPeriode > Config.Output.Cool.MinimumOffTime

Config.Output.Cool.PwmPeriode is only effective if the cooling output is activated (Config.ActivateCooling =TRUE).

When you use PwmPeriode, the accuracy of the PWM output signal is determined by the relationship of PwmPeriode to the PID_Temp sampling time (cycle time of the OB). PwmPeriode should be at least 10 times the PID_Temp sampling time.

If the sampling time of the PID algorithm is not an integer multiple of PwmPeriode, each last period of the PWM within the sampling time of the PID algorithm is extended accordingly.

Example for OutputHeat_PWM

① PID_Temp sampling time = 100.0 ms (cycle time of the calling cyclic interrupt OB, CycleTime.Value tag)

② PID algorithm sampling time = 2000.0 ms (Retain.CtrlParams.Heat.Cycle tag)

③ Time period of the PWM for heating = 600.0 ms (Config.Output.Heat.PwmPeriode tag)

IntegralResetMode tag (S7-1200, S7-1500)

The IntegralResetMode tag determines how the integral action PIDCtrl.IOutputOld is pre-assigned:

- When switching from "Inactive" operating mode to "Automatic mode"
- With edge TRUE -> FALSE at parameter Reset and parameter Mode = 3

This setting only works for one cycle and is only effective if the integral action is activated (Retain.CtrlParams.Heat.Ti and Retain.CtrlParams.Cool.Ti > 0.0 tags).

IntegralReset-Mode	Description
0	Smooth The value of PIDCtrl.IOutputOld is pre-assigned so that the switchover is bumpless, which means "Automatic mode" starts with the output value = 0.0 (parameter PidOutputSum) and there is no jump of the output value regardless of the control deviation (setpoint – process value).
1	Delete We recommend setting the weighting of the proportional action (Retain.CtrlParams.Heat.PWeighting and Retain.CtrlParams.Cool.PWeighting tags) to 1.0 if this option is used. The value of PIDCtrl.IOutputOld is deleted. Any control deviation will cause a jump of the PID output value. The direction of the output value jump depends on the active weighting of the proportional action (Retain.CtrlParams.Heat.PWeighting and Retain.CtrlParams.Cool.PWeighting tags) and the control deviation: • Active proportional action weighting = 1.0: Output value jump and control deviation have identical signs. Example: If the process value value is smaller than the setpoint (positive control deviation), the PID output value jumps to a positive value. • Active proportional action weighting < 1.0: For large control deviations, the PID output value jump and control deviation have identical signs. Example: If the process value is much smaller than the setpoint (positive control deviation), the PID output value jumps to a positive value. For small control deviations, the PID output value jump and control deviation have different signs. Example: If the process value is just below the setpoint (positive control deviation), the PID output value jumps to a negative value. This is usually not desirable, because it results in a temporary increase in the control deviation. The smaller the configured weighting of the proportional action, the greater the control deviation must be to receive a PID output value jump with identical sign. We recommend setting the weighting of the proportional action (Retain.CtrlParams.Heat.PWeighting and Retain.CtrlParams.Cool.PWeighting tags) to 1.0 when this option is used. Otherwise, you may experience the undesirable behavior described for small control deviations. Alternatively, you can also use IntegralResetMode = 4. This option guarantees identical signs of the PID output value jump and control deviation independent of the configured weighting of the proportional action and the control deviation.
2	Hold The value of PIDCtrl.IOutputOld is not changed. You can define a new value using the user program.
3	Pre-assign The value of PIDCtrl.IOutputOld is automatically pre-assigned as if PidOutputSum = OverwriteInitialOutputValue in the last cycle.
4	Like setpoint change (only for PID_Temp with version ≥ 1.1) The value of PIDCtrl.IOutputOld is automatically pre-assigned so that a similar PID output value jump results as for a PI controller in automatic mode in case of a setpoint change from the current process value to the current setpoint. Any control deviation will cause a jump of the PID output value. The PID output value jump and control deviation have identical signs. Example: If the process value value is smaller than the setpoint (positive control deviation), the PID output value jumps to a positive value. This is independent of the configured weighting of the proportional action and the control deviation.

If IntegralResetMode is assigned a value outside the valid value range, PID_Temp behaves as with the pre-assignment of IntegralResetMode:

- PID_Temp up to V1.0: IntegralResetMode = 1
- PID_Temp as of V1.1: IntegralResetMode = 4

11.4.6 Communication (S7-1200, S7-1500)

11.4.6.1 S7 communication (S7-1200, S7-1500)

Data consistency (S7-1200, S7-1500)

Definition

A data block which cannot be modified by concurrent processes is called consistent data area. A data block which is larger than the consistent data area can thus be falsified as a whole during transmission. This means that a data block which belongs together and which is larger than consistent data area can consist in part of new and of old consistent data at the same time.

Example

An inconsistency can occur when an instruction for communication is interrupted, for example, by a hardware interrupt OB with higher priority. If the user program in this OB now changes the data that has already been partly processed by the instruction, the transferred data originates:

- In part from the time before the hardware interrupt was processed
- And in part from the time after the hardware interrupt was processed

This means that these data are inconsistent (not coherent).

Ensuring data consistency

If the communication process can be interrupted by an interrupt OB, you must ensure that the data is transferred consistently. Make sure that only an image of the data and not the data to be transferred is not changed directly by the interrupt OB. Copy the image of the data to the transfer area of the communication instruction prior to the next data transfer.

- If the user program contains a communication instruction that accesses common data, access to this data area can be coordinated, for example, by means of the DONE parameter. The data consistency of the communication areas which are transferred locally with a communication instruction can therefore be ensured in the user program.
- In the case of S7 communication instructions "PUT (Page 4393)"/"GET (Page 4388)", the size of the consistent data areas must already be taken into consideration during programming or configuration, because a communication block is not available in the user program of the target device (server) to synchronize communication data to the user program.
- For the S7-300 and C7-300 (exception: CPU 318-2 DP) the communication data are copied consistently into the user memory in blocks of 32 bytes in the cycle control point of the operating system. Data consistency is not guaranteed for larger data areas. If a defined data consistency is required, the communication data in the user program may not exceed 32 bytes (maximum of 8 bytes, depending on the version).
- In the S7-400 and S7-1500, on the other hand, the communication data in 462-byte blocks is not processed at the cycle control point, but in fixed time slices during the program cycle. The consistency of a tag is ensured by the system. These communication areas can then be accessed consistently using the "PUT (Page 4393)" / "GET (Page 4388)" instructions or when reading/writing tags, for example by an OP or an OS.

Note

Additional information on data consistency is provided in the description of the specific instructions.

In the S7-1500 module series, you can change parameters during ongoing operation with the instructions of S7 communication. Changed parameters are used immediately, even if a job is still active. Both can lead to data inconsistency! To avoid data inconsistencies, you should never change parameters while a job is running.

Effect on interrupt reaction times

The interrupt reaction times of the CPU are slightly extended by copying the data. The greater the quantity of data which must be transferred with absolute consistency, the longer the interrupt reaction time of a system.

Common parameters of instructions for S7 communication (S7-1200, S7-1500)

Classification

The parameters of the instructions for S7 communication can be divided into the following five categories according to their functions:

1. Control parameters are used to activate an instruction.
2. Addressing parameters are used to address the remote communication partner.
3. Send parameters point to the data areas that are to be sent to the remote partner.
4. Receive parameters point to the data areas where the data received from remote partners will be entered.
5. Status parameters are used to monitor whether the instruction has completed its task without error or for the analysis of any errors that have occurred.

Control parameter

Data exchange will only be activated if the appropriate control parameters have a defined value (for example, are set) when the instruction is called or when the value has undergone a specific change since the previous call (for example, a positive edge).

Addressing parameters

Parameter	Description
ID	Reference to the local connection description (specified by the configuration of the connection).
R_ID	With the R_ID parameter, you specify that a send and a receive instruction belong together: The R_ID parameter must match in the instruction at the sending end and the instruction at the receiving end. This allows the communication of several instruction pairs via the same logic connection. • R_ID must be specified in the form DW#16#wxyzWXYZ. • The instruction pairs of a logical connection specified in R_ID must be unique for this connection.

Note

Addressing parameters ID and R_ID

You can reassign the addressing parameters ID and R_ID during runtime. The new parameters are validated with each new job after the previous job has been closed.

You can use the following options to reduce the number of instance DBs and therefore the work memory required:

1. With tag IDs, you can use several connections via one data instance block.
2. With tag R_IDs, you can define several pairs of sending and receiving instructions for one job with a single instance.
3. You can combine cases 1 and 2.

Please note that the new parameters are valid after the last job is executed. When you activate the sending operation, the R_ID parameter in the instruction at the sending end must match its counterpart at the receiving end.

Status parameter

With the status parameters, you monitor whether the instruction has completed its task correctly or whether it is still active. The status parameters also indicate errors.

Note

The status parameters are valid for one cycle only, namely from the first command following the call until the next call. As a result, you must evaluate these parameters after each instruction cycle.

Send and receive parameters

For communication instructions configured at both ends

- The number of the SD_i and RD_i parameters used must match at the send and receive end.
- The data types of the SD_i and RD_i parameters that belong together must match at the send and receive end.
- The amount of data to be sent according to the SD_i parameter must not exceed the range made available by the corresponding RD_i (does not apply to "BSEND (Page 4407)" / "BRCV (Page 4410)"). The RD_i parameters must (with exception of "BSEND"/"BRCV") have the identical data size.

If you do not keep to the rules above, this is indicated by ERROR = 1 and STATUS = 4.

Note

Supplying the send and receive parameters

With the VARIANT data type, send and receive parameters must always be supplied any time a communication instruction is called. It is not possible, for example, to supply the send parameters of the communication instructions at startup and to only trigger the send job in cyclic operation.

User data size

With the "USEND (Page 4399)", "URCV (Page 4401)", "GET (Page 4388)" and "PUT (Page 4393)" instructions, the amount of data to be transferred must not exceed a defined user data size. The maximum user data size depends on:

- The instruction used
- The communication partner.

The guaranteed minimum size of the user data for an instruction with 1-4 tags is listed in the following table:

Instruction	Partner: S7-300	Partner: S7-400	Partner: S7-1200	Partner: S7-1500
PUT / GET	160 bytes	400 bytes	160 bytes	880 bytes
USEND / URCV	160 bytes	440 bytes	-	920 bytes
BSEND / BRCV	32768/65534 bytes	65534 bytes	-	• 65534 bytes with standard access • 65535 bytes with optimized access

Further information on the user data size can be found in the technical data of the respective CPU.

Exact user data size

If the user data size specified above is insufficient you can determine the maximum byte length of the user data as follows:

First read the data block size valid for communication from the following table:

Local CPU	Remote CPU	Data block size in bytes
S7-1200	Any	240
S7-1500	S7-300	240
	S7-400	480
	S7-1200	240
	S7-1500	960

Use this value in the following table to read the maximum possible user data length in bytes as total of the parameters used. It applies for even lengths of the areas SD_i, RD_i, and ADDR_i.

For each range of uneven length the maximum possible user data length is reduced by one byte.

		Number of SD_i, RD_i, ADDR_i parameters used			
Data block size	**Instruction**	**1**	**2**	**3**	**4**
240 (S7-300)	PUT/GET/ USEND	160	-	-	-
240 (S7-300 via integrated interface)	PUT	212	-	-	-
	GET	222	-	-	-
	USEND	212	-	-	-
240 (S7-400)	PUT	212	196	180	164
	GET	222	218	214	210
	USEND	212	-	-	-
480 (S7-400)	PUT	452	436	420	404
	GET	462	458	454	450
	USEND	452	448	444	440
240 (S7-1200)	PUT	212	196	180	164
	GET	222	218	214	210
960 (S7-1500)	PUT	932	916	900	884
	GET	942	938	934	930
	USEND	932	928	924	920

GET: Read data from a remote CPU (S7-1200, S7-1500)

Description

With the instruction "GET", you can read data from a remote CPU.

The instruction is started on a positive edge at control input REQ:

- The relevant pointers to the areas to be read out (ADDR_i) are then sent to the partner CPU. The partner CPU can be in RUN or STOP mode.
- The partner CPU returns the data:
  - If the reply exceeds the maximum user data length, this is displayed with error code "2" at the STATUS parameter.
  - The received data is copied to the configured receive areas (RD_i) at the next call.
- Completion of this action is indicated by the status parameter NDR having the value "1".

Reading can only be activated again after the previous reading process has been completed. Errors and warnings are output via ERROR and STATUS if access problems occurred while the data was being read or if the data type check results in an error.

Changes in the data areas addressed on the partner CPU are not registered by the "GET" instruction.

Requirements for using the instruction

- The "Permit access with PUT/GET communication from remote partner" function was activated in the properties of the partner CPU under "Protection".
- The blocks which you access with the "GET" instruction were created with the access type "standard".
- Make sure that the areas defined with the parameters ADDR_i and SD_i match in terms of number, length and data type.
- The area to be read (ADDR_i parameter) cannot be larger than the area for data storage (RD_i parameter).

Parameters

The following table shows the parameters of the "GET" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	WORD	I, Q, M, D, L or constant	Addressing parameters for specifying the connection to the partner CPU.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter NDR: • 0: Job not yet started or still running. • 1: Job successfully completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameters ERROR and STATUS, error code: • ERROR=0 STATUS has the value: – 0000H: Neither warning nor error – <> 0000H: Warning, STATUS supplies detailed information. • ERROR=1 An error has occurred. STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	
ADDR_1	InOut	REMOTE	I, Q, M, D	Pointers to the areas on the partner CPU that are to be read. When the REMOTE pointer accesses a DB, the DB must always be specified. Example: P#DB10.DBX5.0 Byte 10.
ADDR_2	InOut	REMOTE		
ADDR_3	InOut	REMOTE		
ADDR_4	InOut	REMOTE		
RD_1	InOut	VARIANT	I, Q, M, D, L	Pointers to the areas on the local CPU in which the read data is entered.
RD_2	InOut	VARIANT		
RD_3	InOut	VARIANT		
RD_4	InOut	VARIANT		

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

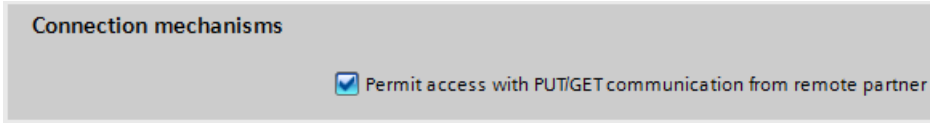
Parameters ERROR and STATUS

The following table contains all specific error information for the "GET" instruction that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problems, for example • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	2	• Negative acknowledgment from the partner device. The function cannot be executed. • Response from the remote station exceeds the maximum user data length (see: Common parameters of instructions for S7 communication (Page 4385)). • Access protection is activated on the partner CPU. Deactivate access protection in the CPU settings.
1	4	Error in the pointers to the data storage RD_i: • Data types of the parameters RD_i and ADDR_i are not compatible with each other. • The length of the area RD_i is smaller than the length of the data of the ADDR_i parameter that is to be read.
1	8	Access error on the partner CPU.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Note

Data consistency



Data is received consistently if you read the part of the receive area RD_i currently being used completely before initiating another job.

Example

In the following example use an S7 connection and in CPU 1 read out a data record of CPU 2. The data record to be sent is of the data type INT.

Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. The connection is not yet configured.
- A low protection level under “<CPU> > Properties > Protection“ ensures that read and write access is permitted for the CPUs.
- Access with the PUT/GET instruction is permitted.

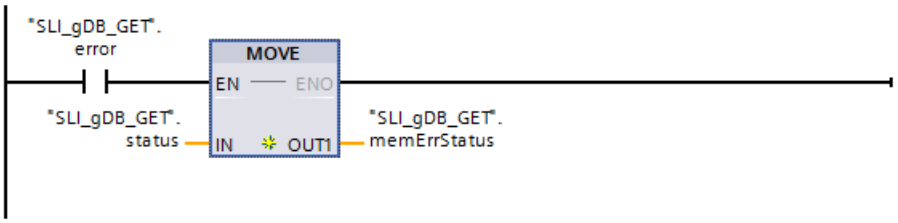
Program of CPU 1

Create six tags in a global data block for storing the data of “GET“.

SLI_gDB_GET

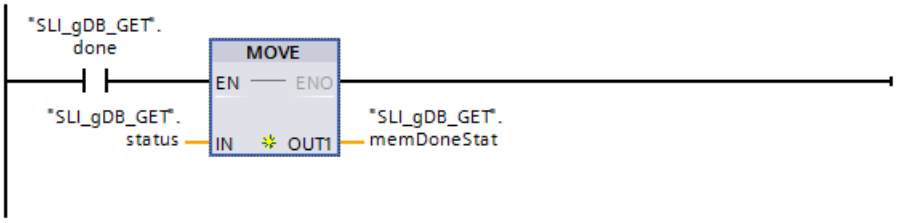
		Name	Data type	Start value
1		Static		
2		start	Bool	false
3		done	Bool	false
4		memDoneStat	Word	16#0
5		error	Bool	false
6		status	Word	16#0
7		memErrStatus	Word	16#0

Create one tag in a global data block for storing the data record to be received.



SLI_gDB_getData

		Name	Data type	Offset	Start value
1		Static			
2		readValue	Int	0.0	0

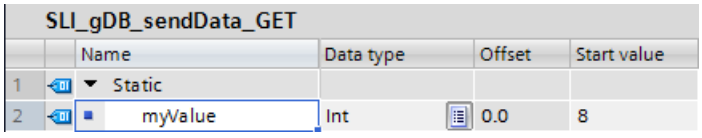


Network 1: Interconnect the parameters of the "GET" instruction as follows.

Network 2: Save the status for an error of GET as follows.

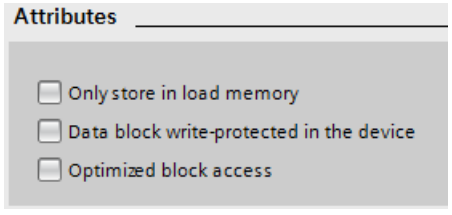
Network 3: Save the success status of GET as follows.

Configuration of GET



To interconnect the input parameter ID, open the wizard of the "GET" instruction with “Properties > Configuration“.

Make the following settings for the connection:



Section	Setting
End point	Select the communication partner. The remaining connection data will be entered automatically. An S7 connection is created automatically and its identifier entered at the input parameter ID.
Active	Make sure that the active connection goes out from CPU 1.

Program of CPU 2

Create one tag in a global data block for storing the data record to be sent.

In “Properties > Attributes“ of the data block disable the optimized block access.

Behavior of GET

When the input parameter REQ ("start") supplies the signal state "TRUE", the "GET" instruction is started. The instruction calls up the connection data and makes contact with the

communications partner of the S7 connection being used. To achieve this, the identifier of the S7 connection is stored at the input parameter ID.

Via the parameter ADDR_1 the storage location of the data record of CPU 2 to be sent (“myValue“) is identified. The data record (“myValue“) is read out and at the parameter RD_1 the identified storage location (“readValue“) is entered.

SLI_gDB_getData

		Name	Data type	Offset	Start value	Monitor value
1		Static				
2		readValue	Int	0.0	0	8

Successful processing is indicated by the output parameter NDR ("done") with the signal state "TRUE" and the output parameter STATUS ("status") with the value "16#0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "memDoneStat". The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing took place without errors.

SLI_gDB_GET

		Name	Data type	Start value	Monitor value
1		Static			
2		start	Bool	false	TRUE
3		done	Bool	false	FALSE
4		memDoneStat	Word	16#0	16#0000
5		error	Bool	false	FALSE
6		status	Word	16#0	16#0000
7		memErrStatus	Word	16#0	16#0000

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

PUT: Write data to a remote CPU (S7-1200, S7-1500)

Description

You can write data to a remote CPU with the instruction "PUT".

The instruction is started on a positive edge at control input REQ:

- The pointers to the areas to be written (ADDR_i) and the data (SD_i) are then sent to the partner CPU. The partner CPU can be in RUN or STOP mode.
- The data to be sent is copied from the configured send areas ((SD_i). The partner CPU saves the sent data under the addresses supplied with the data and returns an execution acknowledgment.
- If no errors occur, this is indicated at the next instruction call with status parameter DONE = "1". The writing process can only be activated again after the last job is complete.

Errors and warnings are output via ERROR and STATUS if access problems occurred while the data was being written or if the execution check results in an error.

Requirements for using the instruction

- The "Permit access with PUT/GET communication from remote partner" function was activated in the properties of the partner CPU under "Protection".
- The blocks which you access with the "PUT" instruction were created with the access type "standard".
- Make sure that the areas defined with the parameters ADDR_i and SD_i match in terms of number, length and data type.
- The area to be written (ADDR_i parameter) must be as large as the send area (SD_i parameter).

Parameters

The following table shows the parameters of the "PUT" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	WORD	I, Q, M, D, L or constant	Addressing parameters for specifying the connection to the partner CPU.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE: • 0: Job not yet started or still executing • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameters ERROR and STATUS, error code: • ERROR=0 STATUS has the value: – 0000H: Neither warning nor error – <> 0000H: Warning, STATUS supplies detailed information. • ERROR=1 An error has occurred, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	
ADDR_1	InOut	REMOTE	I, Q, M, D	Pointers to the areas on the partner CPU to which the data will be written. When the REMOTE pointer accesses a DB, the DB must always be specified. Example: P#DB10.DBX5.0 Byte 10. When transferring data structures (e.g., Struct) the data type CHAR must be used at the ADDR_i parameters.
ADDR_2	InOut	REMOTE		
ADDR_3	InOut	REMOTE		
ADDR_4	InOut	REMOTE		

Parameter	Declaration	Data type	Memory area	Description
SD_1	InOut	VARIANT	I, Q, M, D, L	Pointers to the areas on the local CPU which contain the data to be sent. Only the data types BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL are permitted. When transferring data structures (e.g., Struct) the data type CHAR must be used at the SD_i parameters.
SD_2	InOut	VARIANT		
SD_3	InOut	VARIANT		
SD_4	InOut	VARIANT		

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

ERROR and STATUS parameters

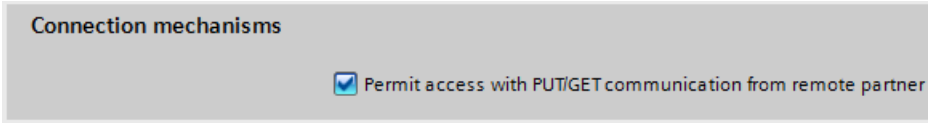
The following table contains all specific error information for the "PUT" instruction that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problems, for example • Connection description not loaded (local or remote). • Connection interrupted (for example, cable, CPU off, CP in STOP mode). • Connection to partner not yet established.
1	2	• Negative acknowledgment of partner CPU. The function cannot be executed. • Access on the partner CPU was not granted. Activate the access in the CPU settings.
1	4	Error in the pointers to the data storage: • Data types of the parameters SD_i and ADDR_i are not compatible with each other. • The length of the area SD_i is greater than the length of the data of the ADDR_i parameter that is to be written. • Not possible to access SD_i. • Maximum user data size exceeded. • Number of the parameters SD_i and ADDR_i does not match.
1	8	Access error with the partner CPU (e.g. DB not loaded or write-protected).
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Data consistency

When a send operation is activated (positive edge at REQ), the data to be sent from the send area SD_i is copied from the user program. After the block call, you can write to these areas without corrupting the current send data.

Note



The send operation is only complete when the DONE status parameter has the value "1".

Example

In the following example use an S7 connection and transfer a data record from CPU 1 to CPU 2. The data record to be sent is of the data type INT.

Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. The connection is not yet configured.
- A low protection level under “<CPU> > Properties > Protection“ ensures that read and write access is permitted for the CPUs.
- Access with the PUT/GET instruction is permitted.

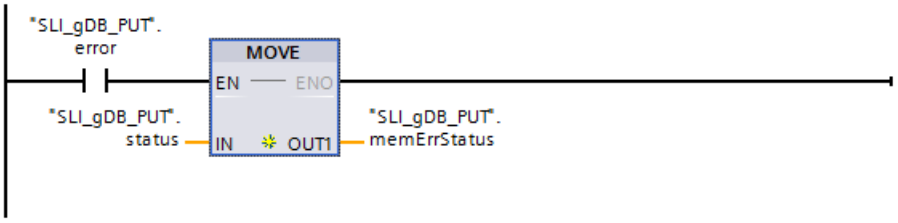
Program of CPU 1

Create six tags in a global data block for storing the data of “PUT“.

SLI_gDB_PUT

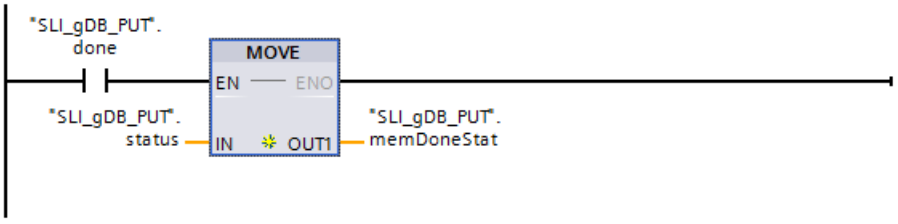
		Name	Data type	Start value
1		Static		
2		start	Bool	false
3		done	Bool	false
4		memDoneStat	Word	16#0
5		error	Bool	false
6		status	Word	16#0
7		memErrStatus	Word	16#0

Create one tag in a global data block for storing the data record to be sent.



SLI_gDB_putData

		Name	Data type	Offset	Start value
1		Static			
2		writeValue	Int	0.0	8



Network 1: Interconnect the parameters of the "PUT" instruction as follows.

Network 2: Save the status for an error of PUT as follows.

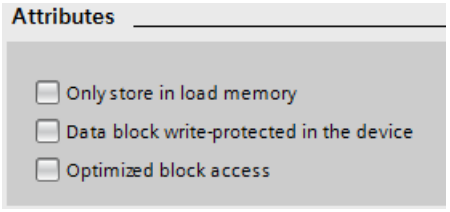
Network 3: Save the success status of PUT as follows.

Configuration of PUT

To interconnect the input parameter ID, open the wizard of the "PUT" instruction with “Properties > Configuration“.

Make the following settings for the connection:

Section	Setting
End point	Select the communication partner. The remaining connection data will be entered automatically. An S7 connection is created automatically and its identifier entered at the input parameter ID.
Active	Make sure that the active connection goes out from CPU 1.



Program of CPU 2

Create one tag in a global data block for storing the data record to be received.

SLI_gDB_rcvData_PUT

	Name	Data type	Offset	Start value
1	Static			
2	myValue	Int	0.0	0

In “Properties > Attributes“ of the data block disable the optimized block access.

Behavior of PUT

When the input parameter REQ ("start") returns the signal state "TRUE", the "PUT" instruction is started. The instruction calls up the connection data and makes contact with the communications partner of the S7 connection being used. To achieve this, the identifier of the S7 connection is stored at the input parameter ID.

At the parameter SD_1 the storage location of the data record of CPU 1 to be sent (“writeValue“) is identified. At the parameter ADDR_1 the storage location (“myValue“) of the data record in CPU 2 is identified. The data record (“writeValue“) is transferred and indicated at the storage location of CPU 2 (“myValue“).

SLI_gDB_rcvData_PUT

	Name	Data type	Offset	Start value	Monitor value
1	Static				
2	myValue	Int	0.0	0	8

Successful processing is indicated by the output parameter DONE ("done") with the signal state "TRUE" and the output parameter STATUS ("status") with the value "16#0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "memDoneStat". The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing took place without errors.

SLI_gDB_PUT

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	done	Bool	false	FALSE
4	memDoneStat	Word	16#0	16#0000
5	error	Bool	false	FALSE
6	status	Word	16#0	16#0000
7	memErrStatus	Word	16#0	16#0000

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

Other (S7-1200, S7-1500)

USEND: Send data uncoordinated (S7-1500)

Description

The "USEND" instruction sends data to a remote partner instruction of type "URCV (Page 4401)". The sending process is carried out without coordination with the partner instruction. This means that the data transfer is carried out without acknowledgment by the partner instruction.

When a send operation is activated (positive edge at REQ), the data to be sent from the send areas SD_i are copied from the user program. After the instruction call, you can write to these send areas again without corrupting the current send data.

Successful completion of the send operation is indicated by the value of the DONE status parameter being set to "1".

Parameters

The following table shows the parameters of the instruction "USEND":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange on a positive edge.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter R_ID for defining the instruction pairs "USEND" and "URCV". See also: Common parameters of instructions for S7 communication (Page 4385)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred. STATUS supplies detailed information on the type of error.

Parameter	Declaration	Data type	Memory area	Description
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.
SD_i (1≤ i ≤4)	InOut	VARIANT	I, Q, M, D, L	Pointer on the i-th send area. Only the BOOL data types are permitted (not permitted: bit array), BYTE, CHAR, WORD, INT, DWORD, DINT, REAL or STRUCT. The maximum user data size for SD_i parameters depends on the partner CPU ("URCV" instruction) and on the number of parameters used. Additional information is available in: Common parameters of instructions for S7 communication (Page 4385)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters ERROR and STATUS

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	4	• Errors in the send area pointers SD_i relating to the data length or the data type. • Maximum user data length was exceeded.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Example

You can find the example here: Program example for USEND & URCV (Page 4403).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

URCV: Receive data uncoordinated (S7-1500)

Description

The "URCV" instruction receives data asynchronously from a remote partner instruction of type "USEND (Page 4399)" and copies this data into the configured receive areas.

The instruction is ready to receive if there is a logical 1 at the EN_R input. An active job can be canceled with EN_R=0.

The receive data areas are referenced by the parameters RD_1 to RD_4. Make sure that the areas defined by the parameters RD_i / RD_1 and SD_i / SD_1 (with the associated partner instruction "USEND (Page 4399)") match in terms of number and length.

Successful completion of the copy operation is indicated when the value of the NDR status parameter is set to logical "1". Once the status parameter NDR has changed to "1", there will be new receive data in your receive areas (RD_i). A new block call may cause these data to be overwritten with new receive data. If you want to prevent this, call "URCV" (for example, during cyclic block processing) with the value 0 at EN_R until you have finished processing the received data.

Parameters

The following table shows the parameters of the instruction "URCV":

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive, signals ready to receive if the input is set.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "USEND" and "URCV". See also: Common parameters of instructions for S7 communication (Page 4385)
NDR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still running. • 1: Job successfully completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error • 1: An error has occurred, STATUS supplies detailed information on the type of error.

Parameter	Declaration	Data type	Memory area	Description
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.
RD_i (1≤ i ≤4)	InOut	VARIANT	I, Q, M, D, L	Pointer to the i-th receive area: Only the BOOL data types are permitted (not permitted: bit array), BYTE, CHAR, WORD, INT, DWORD, DINT, REAL or STRUCT. Additional information is available in: Common parameters of instructions for S7 communication (Page 4385)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters ERROR and STATUS

ERROR	STATUS (decimal)	Explanation
0	9	Warning: older received data were overwritten by newer received data.
0	11	Warning: The received data is already being processed in a priority class with lower priority (error can occur when copying data to the receive area).
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	4	Errors in the receive area pointers RD_i relating to the data length or the data type.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	19	The associated "USEND (Page 4399)" instruction sends data faster than it can be copied to the receive areas by "URCV".
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Example

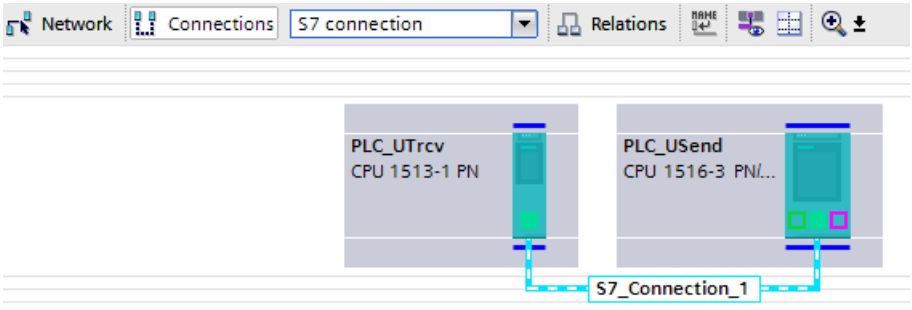
Difference between synchronous and asynchronous instructions (Page 2571)



Program example for USEND & URCV (S7-1200, S7-1500)

Introduction

In the following example you create an S7 connection between two CPUs of the S7-1500 series. You send a character string (data type STRING) from CPU 1 to CPU 2. The data transfer is carried out without acknowledgement by the communication partner.

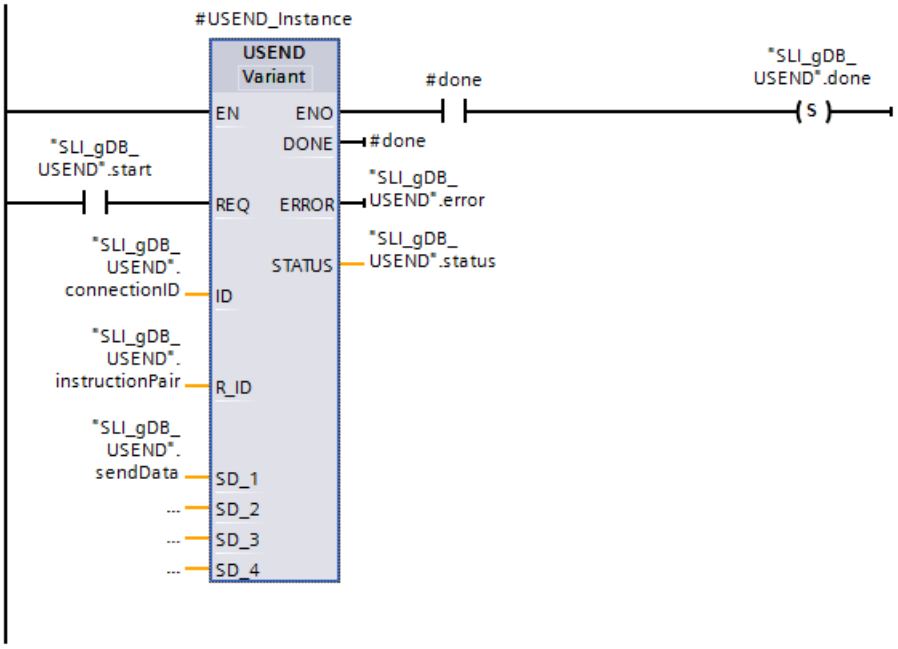
Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. An S7 connection is configured.

- A low protection level under "<CPU> > Properties > Protection" ensures that read and write access is permitted for the CPUs.

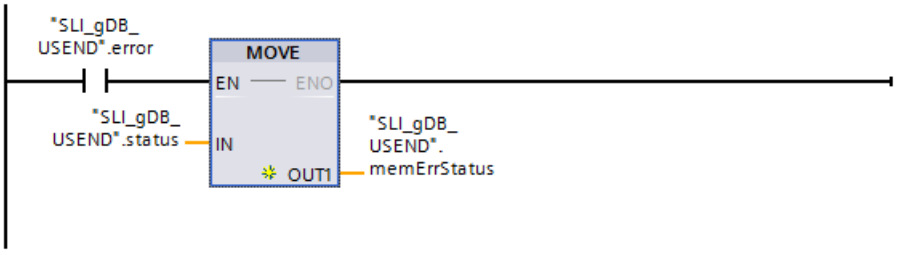
Program of CPU 1

Create the following tags for storing the data of USEND in a global data block.



SLI_gDB_USEND

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	connectionID	CONN_PRG	16#0100
4	instructionPair	CONN_R_ID	16#01
5	done	Bool	false
6	error	Bool	false
7	status	Word	16#0
8	memErrStatus	Word	16#0
9	sendData	String	'HelloData'



Create an FB "SLI_FB_USEND". Create the following local tags in it.

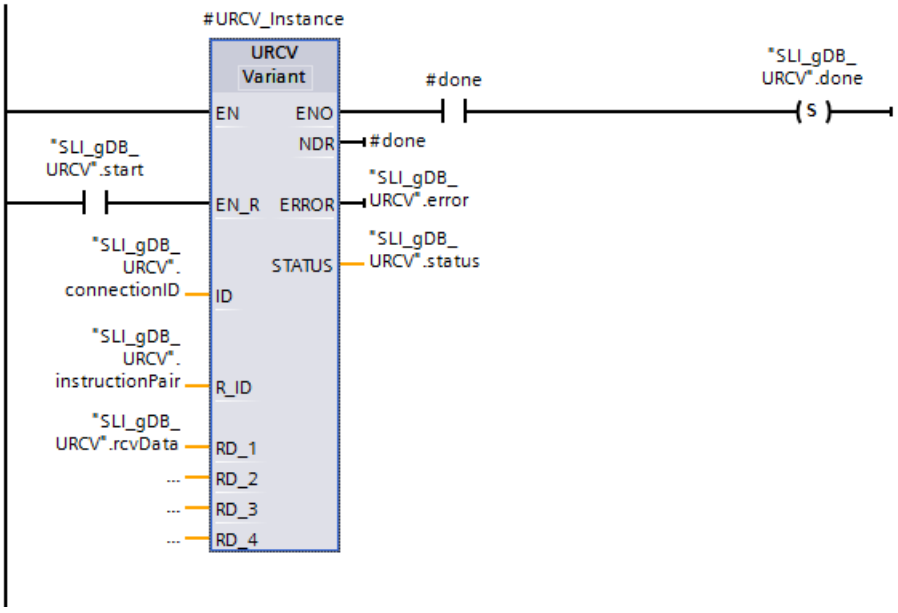
7	Static			
8	USEND_Instance	USEND		
9	done	Bool	false	Non-ret...

Network 1: Interconnect the parameter of the instruction "USEND" as follows:

Network 2: In case of error of USEND, save the status as follows.

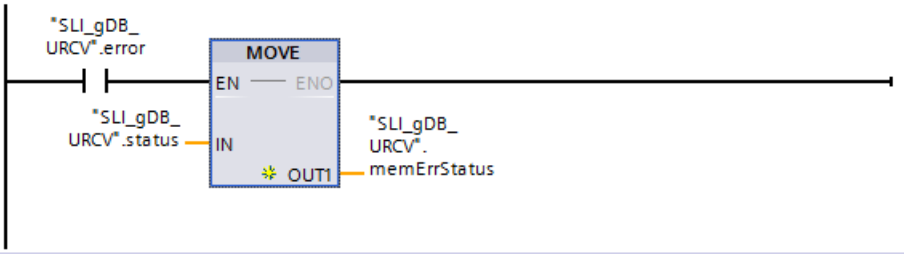
Program of CPU 2

Create the following tags for storing the data of URCV in a global data block.



SLI_gDB_URCV

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	connectionID	CONN_PRG	16#0100
4	instructionPair	CONN_R_ID	16#01
5	done	Bool	false
6	error	Bool	false
7	status	Word	16#0
8	memErrStatus	Word	16#0
9	rcvData	String	''



Create an FB "SLI_FB_URCV". Create the following local tags in it.

Network 1: Interconnect the parameter of the instruction "URCV" as follows:

Network 2: In case of error of URCV, save the status as follows.

Assigning communication connection

The addressing parameters for connecting the two CPUs and for defining the instruction pair must be uniform.

- In each case store the hexadecimal value of the hardware ID of the configured S7 connection at the input parameter ID ("connectionID").
  You can find the hardware identifier in the "Network view" under "Connections".

Network overview | Connections | Relations | I/O communication | VPN

Local connection n...	Local end point	Local ID (hex)	Partner ID (hex)	Partner	Connection type
S7_Connection_1	PLC_UTrcv	100	100	PLC_USend	S7 connection
S7_Connection_1	PLC_USend	100	100	PLC_UTrcv	S7 connection

- In each case store a self-selected identifier (as hex value, in byte size) for the instruction pair at the input parameter R_ID ("instructionPair"). The identifier must not be already assigned for another instruction pair.

Behavior of CPU 1

When the input parameter REQ ("start") supplies the signal state "TRUE", the "USEND" instruction is started. The "USEND" instruction hereby copies the data record detected at input parameter SD_1 ("sendData") to the work memory of the CPU. Successful copying of the data record is indicated by the output parameter DONE ("#done") with the signal state "TRUE". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "done".

Corresponding to the input parameter ID ("connectionID") and R_ID ("instructionPair"), the instruction "URCV" of the CPU 2 as receiver of the data record ("sendData" is addressed with the value "HelloData"). Data transfer via S7 connection continues without further participation by USEND ("start" may be set to "FALSE").

The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing of USEND in the example is taking place without errors.

SLI_gDB_USEND

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	connectionID	CONN_PRG	16#0100	16#0100
4	instructionPair	CONN_R_ID	16#01	16#0000_0001
5	done	Bool	false	TRUE
6	error	Bool	false	FALSE
7	status	Word	16#0	16#0000
8	memErrStatus	Word	16#0	16#0000
9	sendData	String	'HelloData'	'HelloData'

Behavior of CPU 2

CPU 2 receives a data record of CPU 1 via the S7 connection. Corresponding to the input parameter ID ("connectionID") and R_ID ("instructionPair"), the instruction "URCV" knows the receiver of the data record.

When the input parameter EN_R ("start") supplies the signal state "TRUE", the "URCV" instruction is started and is ready to receive. The instruction "URCV" reads out the transferred data and copies the data record into the value area at the input parameter RD_1 ("rcvData").

Successful copying of the data record is indicated by the output parameter NDR ("#done") with the signal state "TRUE". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "done".

The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing of URCV in the example is taking place without errors.

SLI_gDB_URCV

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	connectionID	CONN_PRG	16#0100	16#0100
4	instructionPair	CONN_R_ID	16#01	16#0000_0001
5	done	Bool	false	TRUE
6	error	Bool	false	FALSE
7	status	Word	16#0	16#0000
8	memErrStatus	Word	16#0	16#0000
9	rcvData	String	''	'HelloData'

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

USEND: Send data uncoordinated (Page 4399)

URCV: Receive data uncoordinated (Page 4401)

BSEND: Send data in segments (S7-1500)

Description

The "BSEND" instruction sends data to a remote partner instruction of type "BRCV (Page 4410)". With this type of data transfer, more data can be transported between the communication partners than is possible with all other communication instructions for configured S7 connections. In each case, the maximum data volume amounts to 65534 bytes (standard access) or 65535 bytes (optimized access) for the integrated interface and for SIMATIC Net CP.

Functional description

You specify the instruction pair "BSEND" and "BRCV" with the input parameter R_ID. The R_ID parameter must be identical in the related instructions.

The send job is activated after the instruction is called and a positive edge is detected at control input REQ. After the call, "BSEND" is not processed in the background, which means the data can only be read within the user program.

The data area to be transmitted is segmented. Each segment is sent individually to the partner. Each segment is acknowledged by the partner after the application of this segment by "BRCV (Page 4410)". If the data is segmented, "BSEND" must be called multiple times until all segments have been transferred.

The data area of the data to be sent is specified by SD_1. To ensure data consistency, you may only write to the part of the currently used sending area SD_1 after the current send operation is complete. This is the case when the value of the status parameter DONE changes to "1".

The length of the send data is specified by LEN based on the job. With LEN = "0", all data addressed with the SD_1 parameter is sent.

If there is a positive edge at control input R, the current sending process is canceled.

Due to the asynchronous data transfer, a new data transfer can only be initiated if the previous data has been fetched by a partner instruction call. When the data has been collected, the status parameter "NDR" is set in the partner instruction "BRCV".

Note

Migration of S7-400 user programs

An S7-400 CPU interprets the parameter SD_1 as pointer and not as data area.

With S7-1500, LEN may not exceed the area of SD1. This was permitted with S7-400. Recommendation: Use the maximum size for the LEN parameter (65534 bytes for the integrated interface) as size of the data area at the SD_1 parameter.

Parameters

The following table shows the parameters of the instruction "BSEND":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter request, activates the data exchange at a positive edge
R	Input	BOOL	I, Q, M, D, L or constant	Control parameter reset, activates an abort of the current data exchange at a positive edge
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "BSEND" and "BRCV (Page 4410)". See also: Common parameters of instructions for S7 communication (Page 4385)
SD_1	InOut	VARIANT	I, Q, M, D, L	Pointer to send area When transferring structures, the structures must be identical at the sending and receiving end.

Parameter	Declaration	Data type	Memory area	Description
LEN	InOut	WORD	I, Q, M, D, L	Length of the block of data to be sent in bytes. With LEN = "0", all data is sent by SD_1.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still executing. • 1: Job executed without errors.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error. • 1: An error has occurred, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters ERROR and STATUS

The following table contains all specific error information for "BSEND" that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	11	Warning: New job not active because the previous job is still busy.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	2	Negative acknowledgment of partner instruction. The instruction cannot be executed.
1	3	R_ID is unknown on the connection specified by the ID or the receive block has not yet been called.
1	4	• Error in the data length or data type in the send area pointer SD_1. • Value for LEN is greater than area SD_1.
1	5	Reset request was executed.
1	6	Partner instruction is in DISABLED status (EN_R has the value "0"). Also check the input parameters of "BRCV (Page 4410)" for consistency with "BSEND".
1	7	"BRCV (Page 4410)" partner instruction not called since the last data transfer.
1	8	Access to remote object in the user memory was rejected: The target range for the associated "BRCV (Page 4410)" is too small. ERROR = 1, STATUS = 4 or ERROR = 1, STATUS = 10 reported at the output parameters of "BRCV (Page 4410)".
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	R_ID already exists in the connection.

ERROR	STATUS (decimal)	Explanation
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Example

You can find the example here: Program example for BSEND & BRCV (Page 4412).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

BRCV: Receive data in segments (S7-1500)

Description

The "BRCV" instruction receives data from a remote partner instruction of type "BSEND (Page 4407)". The R_ID parameter must be identical in the related instructions.

The instruction is ready to receive data (STATUS = 25) after it is called with the value "1" at control input EN_R. An active job can be canceled with EN_R=0.

The maximum receive area is specified by RD_1. Data will be received consistently if you fully evaluate the part of the RD_1 receive area currently in use before calling the block again with value 1 at control input EN_R.

After each received data segment, an acknowledgment is sent to the partner instruction. If there are multiple segments it will be necessary to call "BRCV" several times until all of the segments have been received. Asynchronous data receipt is indicated by STATUS = 17. The amount of data currently received is indicated at the parameter LEN. The RD_1 parameter must remain constant during the operation.

Value "1" at the NDR status parameter indicates that all data segments have been received without error. The received data remains unchanged until the next call with EN_R=1.

Parameters

The following table shows the parameters of the instruction "BRCV":

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive, signals ready to receive if the input is set.
ID	Input	CONN_PRG	I, Q, M, D, L, P or constant	Addressing parameters for specifying the connection to the partner CPU.
R_ID	Input	CONN_R_ID	I, Q, M, D, L or constant	Addressing parameter for defining the instruction pairs "BSEND (Page 4407)" and "BRCV". See also: Common parameters of instructions for S7 communication (Page 4385)
RD_1	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area. When transferring structures, the structures must be identical at the sending and receiving end.
LEN	InOut	WORD	I, Q, M, D, L	Length of the data already received in bytes.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Job not yet started or still running. • 1: Job successfully completed.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter • 0: Neither warning nor error • 1: An error has occurred, STATUS supplies detailed information on the type of error.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter See "ERROR and STATUS parameters" table.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameters ERROR and STATUS

The following table contains all specific error information for "BRCV" that can be output via the ERROR and STATUS parameters.

ERROR	STATUS (decimal)	Explanation
0	17	Warning: Instruction receives data asynchronously. The LEN parameter shows the amount of data already received in bytes.
0	25	Communication has started. The job is being processed.
1	1	Communication problem has occurred. Possible causes: • Connection description not loaded (local or remote) • Connection interrupted (for example: cable, CPU off, CP in STOP mode) • Connection to partner not yet established
1	2	Function cannot be executed (protocol error)
1	4	Error in the receive area pointer RD_1 relating to the data length or data type. The block of data sent is longer than the receive area.
1	5	Reset request received, incomplete transfer.

ERROR	STATUS (decimal)	Explanation
1	8	Access error in associated "BSEND (Page 4407)": After the last valid data segment has been sent, ERROR = 1 and STATUS = 4 or ERROR = 1 and STATUS = 10 is reported.
1	10	Access to the local user memory not possible (for example, access to a deleted DB).
1	18	Value at R_ID parameter already exists in the connection specified at the ID parameter (R_ID value must be unique for the connection).
1	20	• Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with lower priority (first call).
1	W#16#80C3	(only with S7-1500) • Maximum number of parallel jobs exceeded. • The job is currently being processed in a priority class with low priority (first call).

Example

You can find the example here: Program example for BSEND & BRCV (Page 4412).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

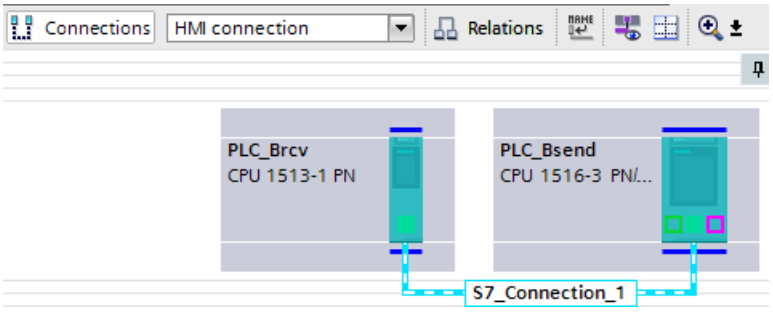
Difference between synchronous and asynchronous instructions (Page 2571)



Program example for BSEND & BRCV (S7-1200, S7-1500)

Introduction

In the following example you create an S7 connection between two CPUs of the S7-1500 series. You send a data record from CPU 1 to CPU 2 using BSEND und BRCV. The data transfer is carried out with acknowledgement by BRCV.

Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. An S7 connection is configured.

- A low protection level under "<CPU> > Properties > Protection" ensures that read and write access is permitted for the CPUs.

Program of CPU 1

Create the following tags for storing the data of BSEND in a global data block.

SLI_gDB_BSEND

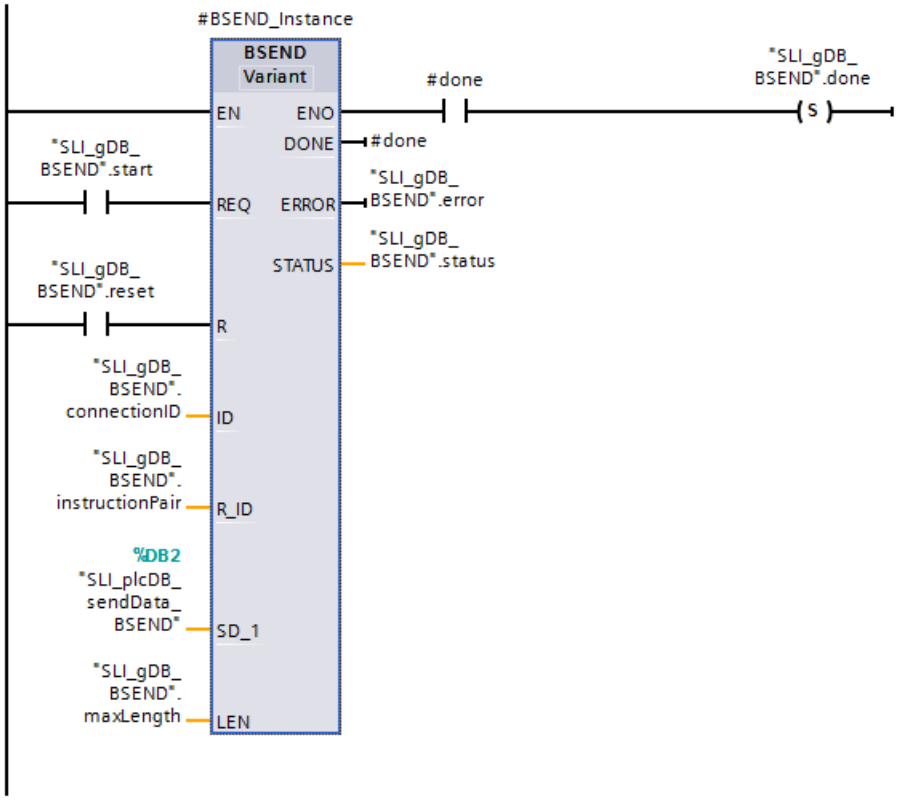
	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	reset	Bool	false
4	connectionID	CONN_PRG	16#0100
5	instructionPair	CONN_R_ID	16#02
6	maxLength	UInt	0
7	done	Bool	false
8	error	Bool	false
9	status	Word	16#0
10	memErrStatus	Word	16#0

For the data record, create the following PLC data type.

BSEND_User

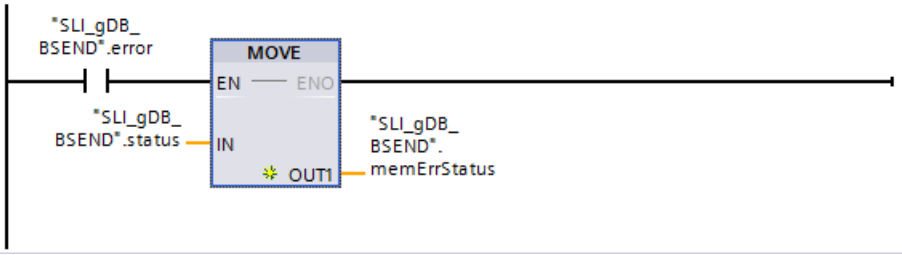
	Name	Data type	Default value
1	prename	String	''
2	lastname	String	''
3	userId	UInt	0

For the data transfer, create the following data block based on the created PLC data type ("BSEND_User").



SLI_plcDB_sendData_BSEND

	Name	Data type	Start value
1	Static		
2	prename	String	'Simon'
3	lastname	String	'Sample'
4	userId	UInt	1



Create an FB "SLI_FB_BSEND". Create the following local tags in it.

Network 1: Interconnect the parameter of the instruction "BSEND" as follows:

Network 2: In case of error of BSEND, save the status as follows.

Program of CPU 2

Create the following tags for storing the data of BRCV in a global data block.

SLI_gDB_BRCV

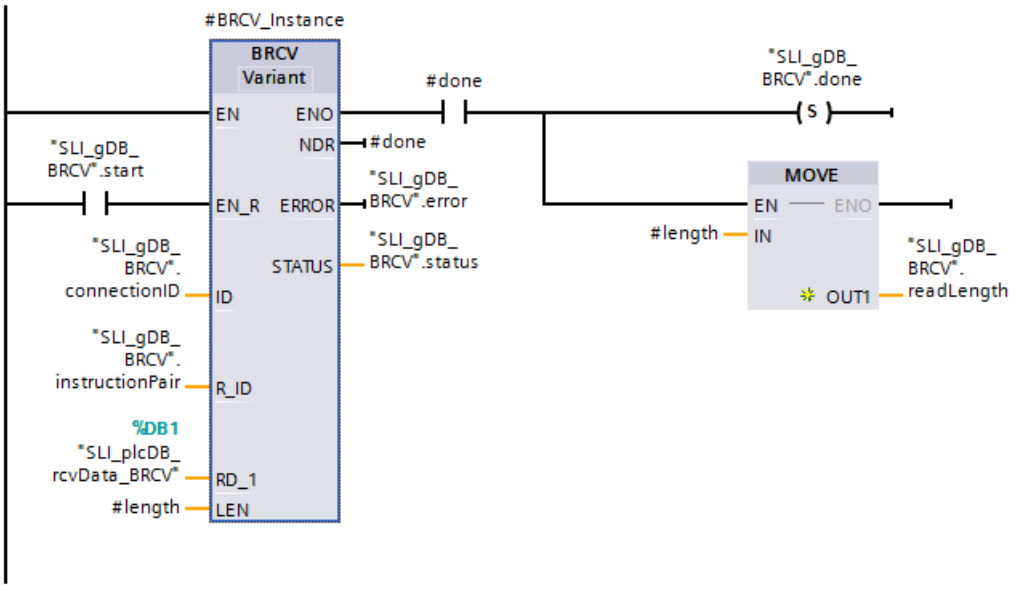
	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	connectionID	CONN_PRG	16#0100
4	instructionPair	CONN_R_ID	16#02
5	done	Bool	false
6	error	Bool	false
7	status	Word	16#0
8	memErrStatus	Word	16#0
9	readLength	UInt	0

For the data record, create the following PLC data type.

BSEND_User

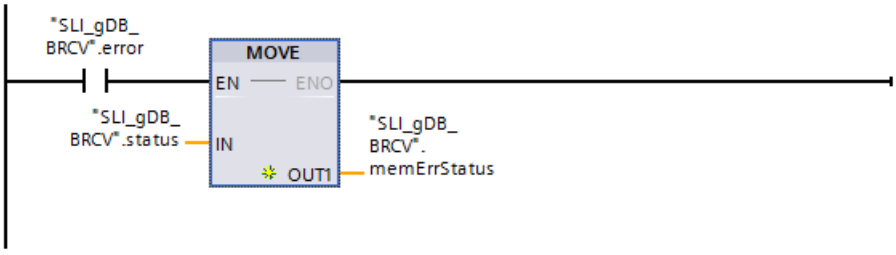
	Name	Data type	Default value
1	prename	String	''
2	lastname	String	''
3	userId	UInt	0

For the data transfer, create the following data block based on the created PLC data type ("BSEND_User").



SLI_plcDB_rcvData_BRCV

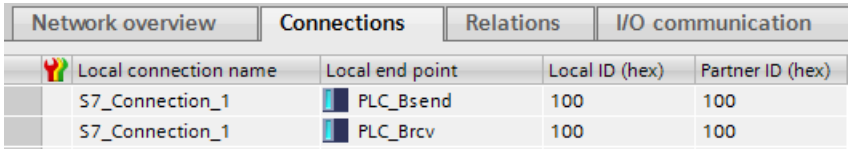
	Name	Data type	Start value
1	Static		
2	prename	String	''
3	lastname	String	''
4	userId	UInt	0



Create an FB "SLI_FB_BSEND". Create the following local tags in it.

7	Static			
8	done	Bool	false	Non-ret...
9	length	UInt	0	Non-retain
10	BRCV_Instance	BRCV		

Network 1: Interconnect the parameter of the instruction "BRCV" as follows:



Network 2: In case of error of BRCV, save the status as follows.

Assigning communication connection

The addressing parameters for connecting the two CPUs and for defining the instruction pair must be uniform.

- In each case store the hexadecimal value of the hardware ID of the configured S7 connection at the input parameter ID ("connectionID").
  You can find the hardware identifier in the "Network view" under "Connections".

- In each case store a self-selected identifier (as hex value, in byte size) for the instruction pair at the input parameter R_ID ("instructionPair"). The identifier must not be already assigned for another instruction pair.

Behavior of CPU 1

Corresponding to the input parameter ID ("connectionID") and R_ID ("instructionPair"), the instruction "BRCV" of the CPU 2 is addressed as receiver of the data record ("SLI_plcDB_sendData_BSEND").

When the input parameter REQ ("start") supplies the signal state "TRUE", the "BSEND" instruction is started. For multiple calls, the "BSEND" instruction transmits the data record detected at input parameter SD_1 ("SLI_plcDB_sendData_BSEND") in segments to the CPU 2. According to the value "0" of the input parameter LEN ("maxLength"), is the length of the data record.

Successful transfer of the data record () is indicated by the output parameter DONE ("#done") with the signal state "TRUE". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "done".

The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_BSEND

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	reset	Bool	false	FALSE
4	connectionID	CONN_PRG	16#0100	16#0100
5	instructionPair	CONN_R_ID	16#02	16#0000_0002
6	maxLength	UInt	0	0
7	done	Bool	false	TRUE
8	error	Bool	false	FALSE
9	status	Word	16#0	16#0000
10	memErrStatus	Word	16#0	16#0000

A new data transfer can only be initiated if the previous data has been fetched by calling of BRCV.

Behavior of CPU 2

CPU 2 receives a data record (in segments) of CPU 1 via the S7 connection. Corresponding to the input parameter ID ("connectionID") and R_ID ("instructionPair"), the instruction "BRCV" knows the receiver of the data record.

When the input parameter EN_R ("start") supplies the signal state "TRUE", the "BRCV" instruction is started and is ready to receive. Over several calls the "BRCV" instruction reads out the data record in segments and saves the data record at the input parameter RD_1 ("SLI_plcDB_rcvData_BRCV").

SLI_plcDB_rcvData_BRCV

	Name	Data type	Start value	Monitor value
1	Static			
2	prename	String	''	'Simon'
3	lastname	String	''	'Sample'
4	userId	UInt	0	1

Successful receipt of the entire data record is indicated by the output parameter NDR ("#done") with the signal state "TRUE". The length in BYTES of the actually transmitted data record is

detected by the output parameter LEN ("#length"). This value is only displayed during the success status. Then "0" is detected. Because the values of the output parameters are only displayed for the moment of their validity, save the success status of "#done" in the tag "done" and the length in BYTES in the tag "readLength".

The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_BRCV

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	connectionID	CONN_PRG	16#0100	16#0100
4	instructionPair	CONN_R_ID	16#02	16#0000_0002
5	done	Bool	false	TRUE
6	error	Bool	false	FALSE
7	status	Word	16#0	16#0019
8	memErrStatus	Word	16#0	16#0000
9	readLength	UInt	0	514

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

BRCV: Receive data in segments (Page 4410)

11.4.6.2 Open User Communication (S7-1200, S7-1500)

Data consistency (S7-1200, S7-1500)

Ensuring data consistency

In the S7-1500 module series, you can change parameters during ongoing operation with the instructions of the Open User Communication. Changed parameters are used immediately, even if a job is still active. Both can lead to data inconsistency! To avoid data inconsistencies, you should never change parameters while a job is running.

TSEND_C: Establishing a connection and sending data (S7-1200, S7-1500)

TSEND_C: Send data via Ethernet (S7-1200)

Validity

The following description of the "TSEND_C" instruction applies to S7-1200 CPUs with firmware version < V4.0.

Description

The "TSEND_C" instruction sets up and establishes a TCP or ISO-on-TCP communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection.

The instruction is executed asynchronously and has the following functions:

- A communication connection is set up and established:
  The communication connection is set up and established with CONT=1. Once the connection is successfully established, the DONE parameter is set to "1" for one cycle. An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TSEND_C" again. For information on the number of possible communication connections, refer to the technical specifications for your CPU.
- Sending data via an existing communication connection:
  You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. Do not use a data area with the data type BOOL or Array of BOOL at the DATA parameter. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
- The send job is executed when a rising edge is detected at the REQ parameter. With the LEN parameter, you specify the maximum number of bytes sent with a send job. When sending data (rising edge at the REQ parameter), the CONT parameter must have the value "1" in order to establish or maintain a connection. The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.
- Terminating the communication connection:
  The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transfer is not complete yet. This does not apply if you are using an already configured connection for "TSEND_C".

When setting the COM_RST parameter to "1", the currently established connection or a current data transmission can be reset at any time. This terminates the existing communication connection and a new connection is established. If data is being transferred when it executes again, this can lead to a loss of data.

To enable "TSEND_C" again after the execution (DONE = 1), call the instruction once with REQ = 0.

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and create connections of the type TCP, UDP or ISO-on-TCP and want to assign parameters to them, you can use the support of the connection parameter assignment.

You can find the connection parameter assignment the Inspector window of the program editor.

Parameters

The following table shows the parameters of the "TSEND_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Starts the send job on a rising edge.
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection • 1: Establish and maintain the communication connection When sending data (rising edge at the REQ parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum number of bytes to be sent with the job. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: AUTOHOTSPOT
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent (maximum length: 8192 bytes). When transferring structures, the structures must be identical at the sending and receiving end.
COM_RST	InOut	BOOL	I, Q, M, D, L	Restarts the instruction: • 0: Irrelevant • 1: Complete restart of the instruction causing an existing connection to be terminated and a new connection to be established.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Job completed without error.
0	0001	The connection establishment is complete.
0	0003	The connection termination is complete.
0	7000	No job processing active.
0	7001	• Start execution of the job • Establish connection • Wait for connection partner
0	7002	Data was sent.
0	7003	Connection is being terminated.
0	7004	Connection established and monitored, no job processing active.
1	80A0	Group error for error codes 80A1 and 80A2.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.

ERROR	STATUS* (W#16#...)	Description
1	80A2	Local or remote port is being used by the system.
1	80A3	Attempt being made to terminate a non-existent connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B3	Inconsistent parameter assignment: Group error for error codes 80A0 to 80A2, 80A4, 80B4 to 80B9.
1	80B4	When using the protocol variant ISO on TCP (connection_type = B#16#12) for the passive establishment of a connection (active_est = FALSE) one or both of the following conditions was violated: "local_tsap_id_len >= B#16#02" and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	8085	The LEN parameter is larger than the highest permitted value.
1	8086	The ID parameter within the CONNECT parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible.
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	The ID of the local device in the connection description does not correspond to the CPU.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST= 1.
1	80C6	Remote network error. Remote partner cannot be reached.
1	8722	Parameter CONNECT: The source area is invalid. The area does not exist in the DB.
1	873A	Parameter CONNECT: Access to the connection description is not possible (for example, DB does not exist).
1	877F	Parameter CONNECT: Internal error.

ERROR	STATUS* (W#16#...)	Description
1	8822	Parameter DATA: Invalid source area, the area does not exist in the DB.
1	8824	Parameter DATA: Area error in the VARIANT pointer.
1	8832	Parameter DATA: The DB number is too high.
1	883A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	887F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	893A	Parameter DATA: Access to send area not possible (e.g. because the DB does not exist).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TSEND", "T_DIAG" and "TDISCON"

Internally, the "TSEND_C" instruction uses the instructions "TCON (Page 4474)", "TSEND (Page 4490)", "T_DIAG (Page 4538)", "T_RESET (Page 4533)" and "TDISCON (Page 4484)". The error messages of these instructions can also be output at the STATUS parameter. The meaning of the error codes is described in the corresponding instructions. In the event of identical error codes for internally used instructions with different meanings, the instance data block of "TSEND_C" can be used to determine which instruction output the error.

See also

Difference between synchronous and asynchronous instructions (Page 2571)

TSEND_C: Establishing a connection and sending data (S7-1200, S7-1500)

Validity

The following description of the "TSEND_C" instruction is valid for:

- Ethernet
  - CPU S7-1200 with firmware version ≥ V4.0 and CPU S7-1500
  - CPU S7-1500 firmware version V2.1 and higher: UDP multicast communication
- PROFIBUS
  FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL

Description

The "TSEND_C" instruction sets up and establishes a communications connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU.

The instruction is executed asynchronously and has the following functions:

- Setting up and establishing a communication connection
- Sending data via an existing communication connection
- Terminating or resetting the communication connection

Internally, the instruction "TSEND_C" uses the communication instructions TCON", "TSEND", "T_DIAG", "T_RESET" and "TDISCON".

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and wish to create and assign parameters to connections of the type TCP, UDP, ISO-on-TCP or FDL, you can use the support of the connection parameter assignment. UDP multicast connections via the integrated PROFINET interfaces are possible for S7-1500-CPUs as of firmware version V2.1 and higher.

You can find the connection parameter assignment in the Inspector window of the program editor.

Setting up and establishing a communication connection

The communication connection is set up and established with CONT=1. For information on the number of possible communication connections, refer to the technical specifications for your CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection. The following connection types can be used:

- Programmed connections (structure of connection via "TCON"):
  - TCP / UDP: Connection description via the TCON_IP_v4 system data type
  - ISO-on-TCP: Connection description via the TCON_IP_RFC system data type
  - ISO: Connection description via the TCON_ISOnative system data type (for CP1543-1 only)
  - Telecontrol connections to SMS clients: Connection description via the TCON_PHONE system data type
    For this connection type, the station requires access to the mobile network via a mobile network CP.
  - FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL
- Configured connections
  - Specify an existing connection in the TCON_Configured system data type.

An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TSEND_C" again.

Sending data via an existing communication connection

The send job is executed when a rising edge is detected at the REQ parameter. As described above, the communication connection is established first.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. Do not use a data area with the data type BOOL or Array of BOOL at the DATA parameter. With the LEN parameter, you specify the maximum number of bytes sent with a send job. If you use a send area with optimized access at the DATA parameter, the LEN parameter must have the value "0".

The data to be sent must not be edited until the send job is completed.

Terminating and resetting the communication connection

The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transfer is not complete yet. This does not apply if you are using a configured connection for "TSEND_C".

The connection can be reset at any time by setting the parameter COM_RST to "1". This terminates the existing communication connection and a new connection is established. If data is being transferred at this time, this can lead to data loss.

Parameters

The following table shows the parameters of the "TSEND_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	Starts the send job on a rising edge.
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection. • 1: Establish and maintain the communication connection.
LEN	Input	UDINT	I, Q, M, D, L or constant	Optional parameter (hidden) Maximum number of bytes to be sent with the job. If you use a send area with optimized access at the DATA parameter, the value "0" must be used at the LEN parameter. For FDL connections of the CM 1542-5, the maximum length is 240 bytes. In this regard, note the maximum lengths that can be processed by the connection partner.

Parameter	Declaration	Data type	Memory area	Description
CONNECT	InOut	VARIANT	D	Pointer to the structure of the connection description: • Programmed connection: – For TCP or UDP, use the TCON_IP_v4 system data type. For a description, refer toAUTOHOTSPOT. – For ISO-on-TCP, use the TCON_IP_RFC system data type. For a description, refer to AUTOHOTSPOT. – For ISO, use the TCON_ISOnative system data type (for CP 1543-1 only). For description, refer to instruction "TCON (Page 4478)". – For connections to SMS clients, use the TCON_PHONE system data type. For a description, refer to AUTOHOTSPOT. – For FDL connections of the CM 1542-5, use the system data type TCON_FDL; see AUTOHOTSPOT. • Configured connection: – For existing connections, use the TCON_Configured system data type. For a description, see "System data type for configured connections" below.
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent. When transferring structures, the structures must be identical at the sending and receiving end.
ADDR	InOut	VARIANT	D	Hidden parameter that needs to be used, however, with UDP. In this case it contains a pointer to the system data type TADDR_Param. Store the address information of the recipient (IP address and port number) in a data block with the system data type TADDR_Param. See also: Structure of the address information of the remote partner with UDP (Page 4523)
COM_RST	InOut	BOOL	I, Q, M, D, L	Optional parameter (hidden) Resets the connection: • 0: Irrelevant • 1: The existing connection is reset. The COM_RST parameter is reset after evaluation by the "TSEND_C" instruction and should not, therefore, be interconnected statically.

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Send job not yet started or still in progress. • 1: Send job executed without error. This state is only displayed for one cycle. The output parameter DONE is set if an intermediate step was completed successfully during processing (connection establishment, sending, connection termination) and if the execution of "TSEND_C" was completed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Send job not yet started or already completed. • 1: Send job not yet completed. A new send job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred during connection establishment, data transfer or connection termination. The output parameter ERROR can be set due to an error in the "TSEND_C" instruction or the communication instructions used internally.
STATUS	Output	WORD	I, Q, M, D, L	Status of instruction (see the "ERROR and STATUS" parameters" description).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

REQ, CONT and COM_RST parameters

The parameter CONT controls the connection establishment of the "TSEND_C" instruction regardless of the REQ parameter. The behavior of the CONT parameter partially depends on whether a programmed or a configured connection is used:

- With CONT = "0": No data is sent (regardless of whether a programmed or a configured connection is used).
- When changing CONT = "0" to "1":
  - With a programmed connection, it is established with "TCON".
  - With a configured connection, it is checked with "T_DIAG".
- With CONT = "1":
  - As long as no data is sent (REQ="0"), the connection is checked with "T_DIAG".
  - If the internally used communication instructions signal that no connection end point exists, the connection is automatically reestablished with "TCON".
- When changing CONT = "1" to "0":
  - With a programmed connection, it is terminated with "TDISCON".
  - With a configured connection, it is reset with "T_RESET".

The parameter COM_RST resets the connection when changing from "0" to "1":

- If a connection is established, it is reset with "T_RESET" (regardless of whether a programmed or configured connection is used).
- If no connection is established, the setting of the parameter has no effect.

The REQ and COM_RST parameters only have an effect if CONT has been set to "1". The following table shows the relationship between the REQ, CONT and COM_RST parameters:

REQ	CONT	COM_ RST	Status of the instruction	Description
Irrelevant	0	Irrelevant	Not yet executed	No job active (STATUS = 7000).
Irrelevant	0	Irrelevant	Initialization	Connection is being terminated. The instruction is being reset.
Irrelevant	0 > 1	Irrelevant	Connection establishment	Connection is being established. Data is not being transferred yet.
0	1	0	Connection established	The connection is established and is monitored with the instruction "T_DIAG".
Irrelevant	1	0 > 1	Connection established	The connection is interrupted by "T_RESET" briefly and reset.
0 > 1	1	0	Connection established	Instruction starts sending.
Irrelevant	1	0 > 1	Data is being sent	Data transfer is interrupted. The connection is being reset.

System data type for configured connections

For configured connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured:

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to the connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	-	Connection type Select 254 (decimal) for a configured connection.

Note

For reasons of compatibility, the parameters InterfaceID and ConnectionType are part of the structure for the connection description to TCON_Configured. These parameters do not have an effect on the connection parameter assignment; only the parameter ID for the connection ID is evaluated in the connection parameter assignment.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a send job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

DONE	BUSY	ERROR	Description
0	0	0	The instruction has not been executed yet (no rising edge at REQ parameter).
0	1	0	The instruction is being executed and calls the internally used communication instructions.
1	0	0	The send job was completed successfully. "0000" is output at the STATUS parameter. DONE = "1" is only displayed for one cycle.
0	0	1	The execution of the instruction or an intermediate step during processing was terminated with an error. If there is a subsequent error due to an internally used communication instruction, the error that occurred first during processing is displayed. This state is only displayed for one cycle.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job was executed without error.
0	0001	Communication connection established.
0	0003	Communication connection closed.
0	7000	No active send job execution; no communication connection established.
0	7001	Initial call for establishing a connection.
0	7002	Second call for establishing a connection
0	7003	Communication connection is being terminated.
0	7004	Communication connection has been established and is being monitored. No send job execution active.
0	7005	Data transfer in progress.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A3	The nested "T_DIAG" instruction has reported that the connection has closed.
1	80A4	IP address of the remote endpoint of the connection is invalid or it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.

ERROR	STATUS* (W#16#...)	Description
1	80B3	• When using the protocol variant UDP the ADDR parameter does not contain any data. • Error in the connection description • The local port is already being used in a different connection description.
1	80B4	You have violated one or both of the following conditions for passive connection establishment (active_est = FALSE) when using the ISO-on-TCP protocol variant (connection_type = B#16#12): • local_tsap_id_len >= B#16#02 • local_tsap_id[1] = B#16#E0
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	• For system data type TCON_Param: Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len. • For system data types TCON_IP_V4 and TCON_IP_RFC: IP address of the partner end point was set to 0.0.0.0.
1	8085	The LEN parameter is larger than the highest permitted value.
1	8086	The ID parameter within the CONNECT parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible.
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	• The CONNECT parameter does not point to a data block. • The CONNECT parameter does not point to a connection description. • The manually created connection description has an incorrect structure for the selected connection type.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	InterfaceID is invalid. It is either zero or it does not point to a local CPU interface or a CP.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON (Page 4484)" instruction. • The connection used is being terminated by a call with COM_RST = 1. • Temporarily no receive resources available at the connection partner. The connection partner is not ready to receive.
1	80C5	• Connection terminated by the communication partner. • LSAP of the remote connection partner is not released

ERROR	STATUS* (W#16#...)	Description
1	80C6	Network error: • Remote partner cannot be reached. • Physical interruption on PROFIBUS
1	8722	Parameter CONNECT: The source range is invalid. The area does not exist in the DB.
1	873A	Parameter CONNECT: Access to the connection description is not possible (for example, because the DB is not available).
1	877F	Parameter CONNECT: Internal error.
1	8822	Parameter DATA: Invalid source range, the range does not exist in the DB.
1	8824	Parameter DATA: Area error in the VARIANT pointer.
1	8832	Parameter DATA: The DB number is too high.
1	883A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	887F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	893A	Parameter DATA: Access to send area not possible (e.g. because the DB does not exist).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TSEND", "T_DIAG", "T_RESET" and "TDISCON"

Internally, the "TSEND_C" instruction uses the instructions "TCON (Page 4478)", "TSEND (Page 4490)", "T_DIAG (Page 4538)", "T_RESET (Page 4533)" and "TDISCON (Page 4484)". The error messages of these instructions can also be output at the STATUS parameter. The meaning of the error codes is described in the corresponding instructions. In the event of identical error codes for internally used instructions with different meanings, the instance data block of "TSEND_C" can be used to determine which instruction output the error.

Example

You can find the example here: Program example for send functions (Page 4446).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

TRCV_C: Establishing a connection and receiving data (S7-1200, S7-1500)

TRCV_C: Receive data via Ethernet (S7-1200)

Validity

The following description of the "TRCV_C" instruction applies to S7-1200 CPUs with firmware version < V4.0.

Description

The "TRCV_C" instruction is executed asynchronously and has the following functions:

1. **Setting up and establishing a communication connection:**
   "TRCV_C" sets up and establishes a TCP or ISO-on-TCP communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU.
   The connection description specified at the CONNECT parameter is used to set up the communication connection. To establish a connection, the CONT parameter must be set to the value "1". Once the connection is successfully established, the DONE parameter is set to "1".
   An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TRCV_C" again.
   For information on the number of possible communication connections, refer to the technical specifications for your CPU.
2. **Receiving data via an existing communication connection:**
   If the EN_R parameter is set to the value "1", receipt of data is enabled. When receiving data (rising edge at the EN_R parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
   The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0) in accordance with the protocol variant used. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
   After data has been received successfully, the signal state at the DONE parameter is "1". If errors occur in the data transfer, the DONE parameter is set to "0".
3. **Terminating the communication connection:**
   The communication connection is terminated immediately when the CONT parameter is set to "0".

TRCV_C is executed again when the COM_RST parameter is set. This terminates the existing communication connection and a new connection is established. If data is being received when it executes again, this can lead to a loss of data.

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and create connections of the type TCP, UDP or ISO-on-TCP and want to assign parameters to them, you can use the support of the connection parameter assignment.

You can find the connection parameter assignment the Inspector window of the program editor.

Receive modes of TRCV_C

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type parameter of the connection description	LEN parameter
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	0
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• 1 to 1452, if a CP is used. • 1 to 8192, if no CP is used.

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "0" to the LEN parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). The data length actually received is output at the RCVD_LEN parameter.

TCP (Receipt of data with specified length)

You use the value of the LEN parameter to specify the length for the data receipt. The data receipt is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV_C" signals data receipt as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV_C" signals an error. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameters

The following table shows the parameters of the "TRCV_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L	Receive enable
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection • 1: Establish and maintain the communication connection When receiving data (rising edge at the EN_R parameter), the CONT parameter must have the value TRUE in order to establish or maintain a connection.
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the data to be received (maximum value: 8192 bytes). If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: AUTOHOTSPOT
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area When transferring structures, the structures must be identical at the sending and receiving end.
COM_RST	InOut	BOOL	I, Q, M, D, L	Restarts the instruction: • 0: Irrelevant • 1: Complete restart of the instruction causing an existing connection to be terminated
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred

Parameter	Declaration	Data type	Memory area	Description
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TRCV_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Job completed without error.
0	0001	The connection establishment is complete.
0	0003	The connection termination is complete.
0	7000	No job processing active.
0	7001	• Start execution of the job • Establish connection • Wait for connection partner
0	7002	Data is being received.
0	7003	Connection is being terminated.
0	7004	• Connection established and monitored • No job processing active
0	7006	Data is currently being received.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value at the LEN or DATA parameter was changed after the first call.
1	8086	The ID parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.

ERROR	STATUS* (W#16#...)	Description
1	8089	The CONNECT parameter does not point to a data block.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	The ID of the local device (local_device_id) in the connection description does not correspond to the CPU.
1	80A0	Group error for error codes W#16#80A1 and W#16#80A2.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.
1	80A2	Local or remote port is being used by the system.
1	80A3	• Attempt being made to re-establish an existing connection. • Attempt being made to terminate a non-existent connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B3	Inconsistent parameter assignment: Group error for error codes W#16#80A0 to W#16#80A2, W#16#80A4, W#16#80B4 to W#16#80B9.
1	80B4	When using the protocol variant ISO on TCP (connection_type = B#16#12) for the passive establishment of a connection (active_est = FALSE) one or both of the following conditions was violated: "local_tsap_id_len >= B#16#02" and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST= 1.
1	80C6	The remote partner cannot be reached (network error).
1	8722	Error in the CONNECT parameter: Invalid source area (area not declared in data block).

ERROR	STATUS* (W#16#...)	Description
1	873A	Error in the CONNECT parameter: Access to connection description is not possible (no access to data block).
1	877F	Error in the CONNECT parameter: Internal error
1	8922	Parameter DATA: Invalid destination area; the area does not exist in the DB.
1	8924	Parameter DATA: Area error in the VARIANT pointer.
1	8932	Parameter DATA: The DB number is too high.
1	893A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	897F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	8A3A	Parameter DATA: No access to the data area, for example because the data block does not exist.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Note

Error messages of the instructions "TCON", "TRCV" and "TDISCON"

Internally, the TRV_C instruction uses the "TCON (Page 4474)", "TRCV (Page 4493)" and "TDISCON (Page 4484)" instructions. The error messages of these instructions are contained in the respective descriptions.

See also

Difference between synchronous and asynchronous instructions (Page 2571)

TRCV_C: Establishing a connection and receiving data (S7-1200, S7-1500)

Validity

The following description of the "TRCV_C" instruction is valid for:

- Ethernet:
  - CPU S7-1200 with firmware version V4.0 or higher and CPU S7-1500
  - CPU S7-1500 firmware version V2.1 and higher: UDP multicast communication
- PROFIBUS: FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL

Description

The "TRCV_C" instruction is executed asynchronously and implements the following functions in sequence:

- Setting up and establishing a communication connection
- Receiving data via an existing communication connection
- Terminating or resetting the communication connection

Internally, the instruction "TRCV_C" uses the communication instructions TCON", "TRCV", "T_DIAG", "T_RESET" and "TDISCON".

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and wish to create and assign parameters to connections of the type TCP, UDP, ISO-on-TCP or FDL, you can use the support of the connection parameter assignment. UDP multicast connections via the integrated PROFINET interfaces are possible for S7-1500-CPUs as of firmware version V2.1 and higher.

You can find the connection parameter assignment in the Inspector window of the program editor.

Setting up and establishing a communication connection

The communication connection is set up and established with CONT=1. For information on the number of possible communication connections, refer to the technical specifications for your CPU. The connection description specified at the CONNECT parameter is used to set up the communication connection. The following connection types can be used:

- Programmed connections (structure of connection via "TCON"):
  - TCP / UDP: Connection description via the TCON_IP_v4 system data type
  - ISO-on-TCP: Connection description via the TCON_IP_RFC system data type
  - ISO: Connection description via the TCON_ISOnative system data type (for CP1543-1 only)
  - Telecontrol connections to SMS clients: Connection description via the TCON_PHONE system data type
    For this connection type, the station requires access to the mobile network via a mobile network CP.
  - FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL
- Configured connections
  - Specify an existing connection in the TCON_Configured system data type.

An existing connection is terminated and the connection which has been set up is removed when the CPU goes into STOP mode. To set up and establish the connection again, you must execute "TRCV_C" again.

Receiving data via an existing communication connection

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used. If you use purely symbolic values at the DATA parameter, the LEN parameter must have the value "0".

Receive modes of TRCV_C:

- **TCP (Ad-hoc mode)**
  The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV_C" instruction.
  You set ad-hoc mode by assigning the value "1" to the ADHOC parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). The data length actually received is output at the RCVD_LEN parameter.
- **TCP (Receipt of data with specified length)**
  Assign the value "0" to the ADHOC parameter for receipt of data with specified length. If ad-hoc mode is disabled, the data reception is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.
- **ISO-on-TCP (Message-oriented data transfer)**
  Complete message blocks are sent via a connection with the protocol variant ISO-on-TCP; these are recognized as such by the recipient. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV_C" signals an error. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type parameter of the connection description	Parameter LEN
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	1 up to maximum length (depending on the CPU)
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO-on-TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	1 to 8192
FDL	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#15 Decimal: 21	1 to 240

Terminating the communication connection

The communication connection is terminated when the CONT parameter is set to "0" even if an ongoing data transfer is not complete yet. This does not apply if you are using a configured connection, however.

The connection can be reset at any time by setting the parameter COM_RST to "1". This terminates the existing communication connection and a new connection is established. If data is being transferred at this time, this can lead to data loss.

Parameters

The following table shows the parameters of the "TRCV_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L, T, C or constant	Receive enable
CONT	Input	BOOL	I, Q, M, D, L	Controls the communication connection: • 0: Disconnect the communication connection. • 1: Establish communication connection and maintain after receipt of data.
LEN	Input	UDINT	I, Q, M, D, L or constant	Maximum length of the data to be received. If you use a receive area with optimized access at the DATA parameter, the value "0" must be used at the LEN parameter.
ADHOC	Input	BOOL	I, Q, M, D, L or constant	Optional parameter (hidden) Use ad-hoc mode for the TCP protocol variant.

Parameter	Declaration	Data type	Memory area	Description
CONNECT	InOut	VARIANT	D	Pointer to the connection description • Programmed connection: – For TCP or UDP, use the structure TCON_IP_v4 For description, refer to:AUTOHOTSPOT – For ISO-on-TCP, use the structure TCON_IP_RFC For a description, refer to: AUTOHOTSPOT – For ISO, use the structure TCON_ISOnative (for CP 1543-1 only) For description, refer to instruction "TCON (Page 4478)": "Structure of the connection description according to TCON_ISOnative" – For connections to SMS clients, use the TCON_PHONE system data type. For a description, refer to AUTOHOTSPOT. – For FDL connections of the CM 1542-5, use the system data type TCON_FDL; see AUTOHOTSPOT. • Configured connection: – For existing connections, use the TCON_Configured system data type. For a description, see "System data type for configured connections" below.
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area. When transferring structures, the structures must be identical at the sending and receiving end.
ADDR	InOut	VARIANT	D	Hidden parameter that needs to be used, however, with UDP. In this case it contains a pointer to the system data type TADDR_Param. Store the address information of the sender (IP address and port number) in a data block with the system data type TADDR_Param. See also: Structure of the address information of the remote partner with UDP (Page 4523)
COM_RST	InOut	BOOL	I, Q, M, D, L	Optional parameter (hidden) Resets the connection: • 0: Irrelevant • 1: The existing connection is reset. The COM_RST parameter is reset after evaluation by the "TRCV_C" instruction and should not, therefore, be interconnected statically.

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Receipt not yet started or still in progress. • 1: Receipt executed without error. This state is only displayed for one cycle. The output parameter DONE is set if an intermediate step was completed successfully during processing (connection establishment, receipt, connection termination) and if the execution of "TRCV_C" was completed successfully.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Receipt not yet started or already completed. • 1: Receipt not yet completed. A new send job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred during connection establishment, data reception or connection termination. The output parameter ERROR can be set due to an error in the "TRCV_C" instruction or the communication instructions used internally.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

EN_R, CONT and COM_RST parameters

The parameter CONT controls the connection establishment of the "TRCV_C" instruction regardless of the EN_R parameter. The behavior of the CONT parameter partially depends on whether a programmed or a configured connection is used:

- With CONT = "0": No data is received (regardless of whether a programmed or a configured connection is used).
- When changing CONT = "0" to "1":
  - With a programmed connection, it is established with "TCON".
  - With a configured connection, it is checked with "T_DIAG".
- With CONT = "1":
  - As long as no data is received (EN_R="0"), the connection is checked with "T_DIAG".
  - If the internally used communication instructions signal that no connection end point exists, the connection is automatically reestablished with "TCON".
- When changing CONT = "1" to "0":
  - With a programmed connection, it is terminated with "TDISCON".
  - With a configured connection, it is reset with "T_RESET".

The parameter COM_RST resets the connection when changing from "0" to "1":

- If a connection is established, it is reset with "T_RESET" (regardless of whether a programmed or configured connection is used).
- If no connection is established, the setting of the parameter has no effect.

The EN_R and COM_RST parameters only have an effect if CONT has been set to "1". The following table shows the relationship between the EN_R, CONT and COM_RST parameters:

EN_R	CONT	COM_RST	Status of the instruction	Description
Irrelevant	0	Irrelevant	Not yet executed	No job active (STATUS = 7000).
Irrelevant	0	Irrelevant	Initialization	Connection is being terminated. The instruction is being reset.
Irrelevant	0 > 1	Irrelevant	Connection establishment	Connection is being established. Data is not being transferred yet.
0	1	0	Connection established	The connection is established and is monitored with the instruction "T_DIAG".
Irrelevant	1	0 > 1	Connection established	The connection is interrupted by "T_RESET" briefly and reset.
0 > 1	1	0	Connection established	Instruction starts receiving.
Irrelevant	1	0 > 1	Data is being received	Data transfer is interrupted. The connection is being reset.

System data type for configured connections

For configured connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured:

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to the connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	-	Connection type Select 254 (decimal) for a configured connection.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TRCV_C". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

DONE	BUSY	ERROR	Description
0	0	0	The instruction has not been executed yet (no rising edge at EN_R parameter).
0	1	0	The instruction is being executed and calls the internally used communication instructions.
1	0	0	The receipt has been completed successfully. "0000" is output at the parameter STATUS. DONE = "1" is only displayed for one cycle.
0	0	1	The execution of the instruction or an intermediate step during processing was terminated with an error. If there is a subsequent error due to an internally used communication instruction, the error that occurred first during processing is displayed. This state is only displayed for one cycle.

ERROR and STATUS parameters

ERROR	STATUS (W#16#...)	Description
0	0000	Receive job executed without error.
0	0001	Communication connection established.
0	0003	Communication connection closed.
0	7000	No job processing active.
0	7001	Initial call for establishing a connection.
0	7002	Second call for establishing a connection.
0	7003	Communication connection is being terminated.
0	7004	Communication connection has been established and is being monitored. No receive job processing active.
0	7006	Data is currently being received.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value at the LEN or DATA parameter was changed after the first call.
1	8086	The ID parameter is outside the permitted range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8088	The value at the LEN parameter does not correspond to the receive area set at the DATA parameter.
1	8089	• The CONNECT parameter does not point to a data block. • The CONNECT parameter does not point to a connection description. • The manually created connection description has an incorrect structure for the selected connection type.
1	8091	Maximum nesting depth exceeded.
1	809A	The CONNECT parameter points to a field that does not correspond to the length of the connection description.
1	809B	InterfaceID is invalid. It is either zero or it does not point to a local CPU interface or a CP.
1	80A1	• Connection or port already being used by user. • Communication error: – The specified connection has not yet been established. – The specified connection is being terminated. Transfer via this connection is not possible. – The interface is being re-initialized.

ERROR	STATUS (W#16#...)	Description
1	80A3	The nested "T_DIAG" instruction has reported that the connection has closed.
1	80A4	IP address of the remote endpoint of the connection is invalid or it matches the IP address of the local partner.
1	80A7	Communication error: You called the instruction with COM_RST = 1 before the send job was complete.
1	80AA	A connection is currently being established with the same connection ID by another block. Repeat the job with a new rising edge at the REQ parameter.
1	80B3	• When using the protocol variant UDP the ADDR parameter does not contain any data. • Error in the connection description • The local port is already being used in a different connection description.
1	80B4	When using the protocol variant ISO on TCP (connection_type = B#16#12) for the passive establishment of a connection (active_est = FALSE) one or both of the following conditions was violated: "local_tsap_id_len >= B#16#02" and/or "local_tsap_id[1] = B#16#E0".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error in the connection_type parameter of the data block for connection description.
1	80B7	• For system data type TCON_Param: Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len. • For system data types TCON_IP_V4 and TCON_IP_RFC: IP address of the partner end point was set to 0.0.0.0.
1	80C3	• All connection resources are in use. • A block with this ID is already being processed in a different priority group.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is receiving new parameters or the connection is being established. • The configured connection is currently being removed by a "TDISCON" instruction. • The connection used is being terminated by a call with COM_RST = 1.
1	80C6	The remote partner cannot be reached (network error).
1	8722	Error in the CONNECT parameter: Invalid source range (range not declared in data block).
1	873A	Error in the CONNECT parameter: Access to connection description is not possible (no access to data block).
1	877F	Error in the CONNECT parameter: Internal error
1	8922	Parameter DATA: Invalid target range; the area does not exist in the DB.
1	8924	Parameter DATA: Area error in the VARIANT pointer.
1	8932	Parameter DATA: The DB number is too high.
1	893A	Parameter CONNECT: Access to specified connection data not possible (e.g. because the DB does not exist).
1	897F	Parameter DATA: Internal error, e.g. invalid VARIANT reference.
1	8A3A	Parameter DATA: No access to the data area, for example because the data block does not exist.

Note

Error messages of the instructions "TCON", "TRCV" and "TDISCON"

Internally, the TRV_C instruction uses the "TCON (Page 4478)", "TRCV (Page 4493)" and "TDISCON (Page 4484)" instructions. The error messages of these instructions are contained in the respective descriptions.

Example

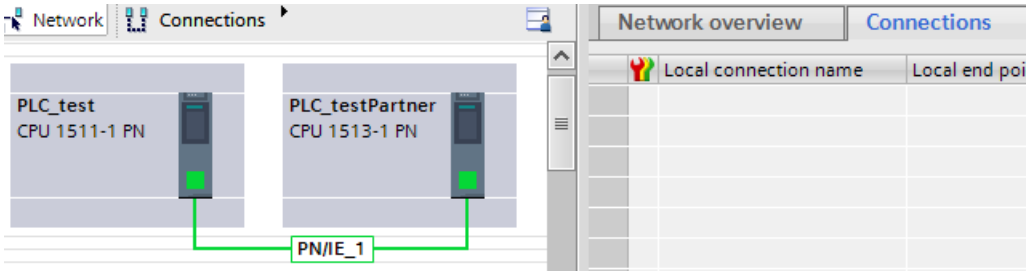
You can find the example here: Program example for send functions (Page 4446).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

TSEND_C: Establishing a connection and sending data (Page 4423)

Difference between synchronous and asynchronous instructions (Page 2571)



Program example for send functions (S7-1200, S7-1500)

Introduction

In the following example, you create a programmed connection between two CPUs of the S7-1500 series and send a character string from CPU 1 to CPU 2. The character string to be sent is of the data type STRING.

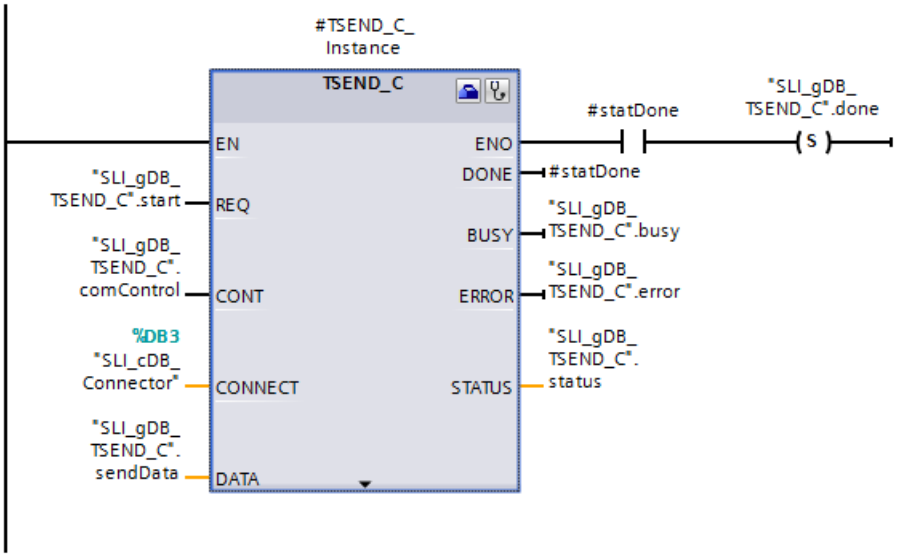
Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. Their connection is not yet configured.

- A low protection level under Properties > Protection ensures that read and write access is permitted for each CPU.

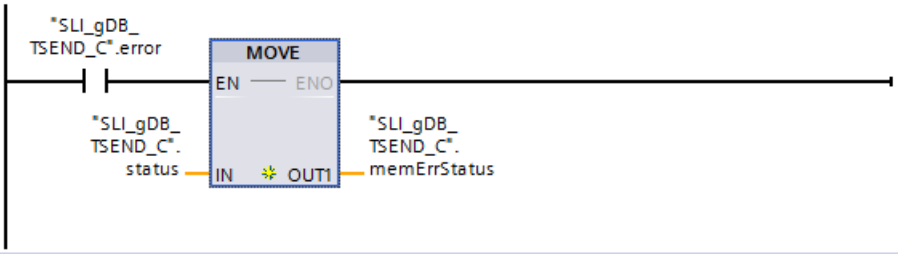
Program of CPU 1

Create nine tags in a global data block for storing the data of "TSEND_C".



SLI_gDB_TSEND_C

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	comControl	Bool	false
4	done	Bool	false
5	busy	Bool	false
6	error	Bool	false
7	status	Word	16#0
8	memErrStatus	Word	16#0
9	sendData	String	'ProcessXYZ'

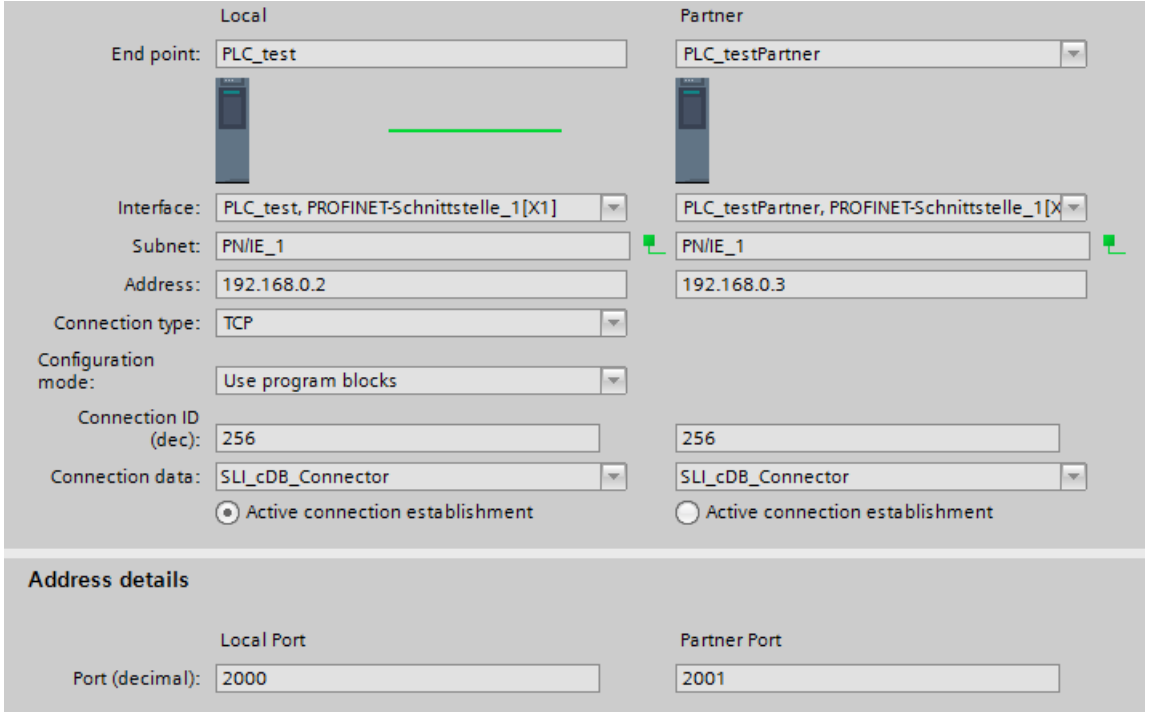


Create an FB "SLI_FB_TSEND_C" and create the following local tags in the FB.

7	Static			
8	TSEND_C_Instance	TSEND_C		
9	done	Bool	false	Non-retain

Network 1: Interconnect the parameters of the "TSEND_C" instruction as follows. Do not interconnect the parameter CONNECT yet.

Network 2: Save the status for an error of TSEND_C as follows.



Configuration of TSEND_C

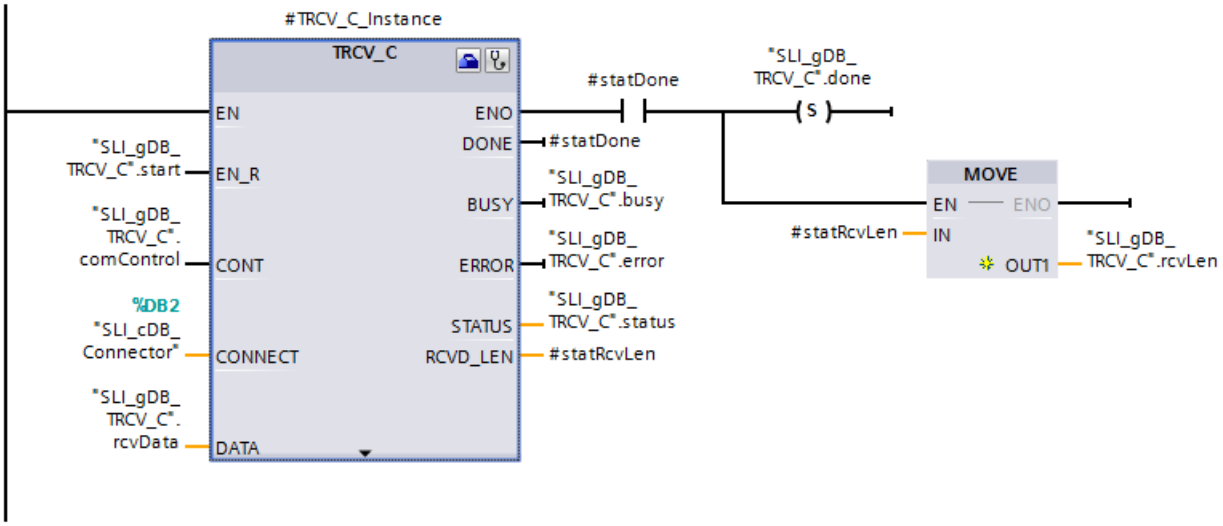
To interconnect the parameter CONNECT, open the wizard of the "TSEND_C" instruction with Properties > Configuration.

Make the following settings for the configuration of TSEND_C:

Input field	Entry
End point	Select a CPU for sender and receiver using the drop-down list. Interface, subnet and address are entered automatically.
Connection data	Use the drop-down list and the selection "New" to create one data block per CPU. This data block is required for storing the connection data. The name of the data block can be freely selected. The active connection establishment is enabled for CPU 1 (local CPU).
Connection type	Select the entry "TCP". This means an Ethernet connection with the "TCP" protocol is used for connection establishment.
Configuration mode	Select the entry "Use program block". This means connection establishment takes place by means of a programmed connection.
Connection ID	You enter a freely selected connection ID for the communication connection. The connection ID must not already be assigned in the project.
Partner port	You enter a value for the partner port. The value must be >=2000.

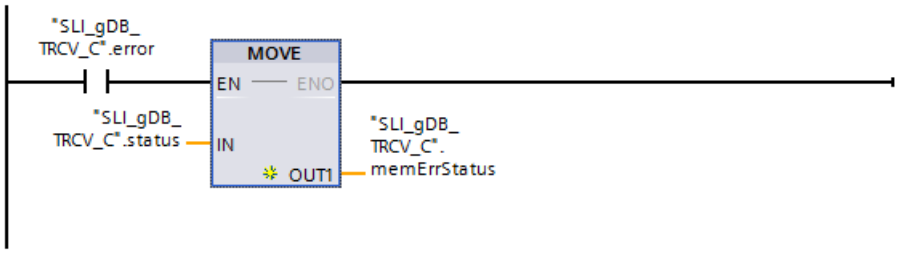
Program of CPU 2

Create ten tags in a global data block for storing the data of "TRCV_C".



SLI_gDB_TRCV_C

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	comControl	Bool	false
4	done	Bool	false
5	busy	Bool	false
6	error	Bool	false
7	status	Word	16#0
8	memErrStatus	Word	16#0
9	rcvLen	UDInt	0
10	rcvData	String	''



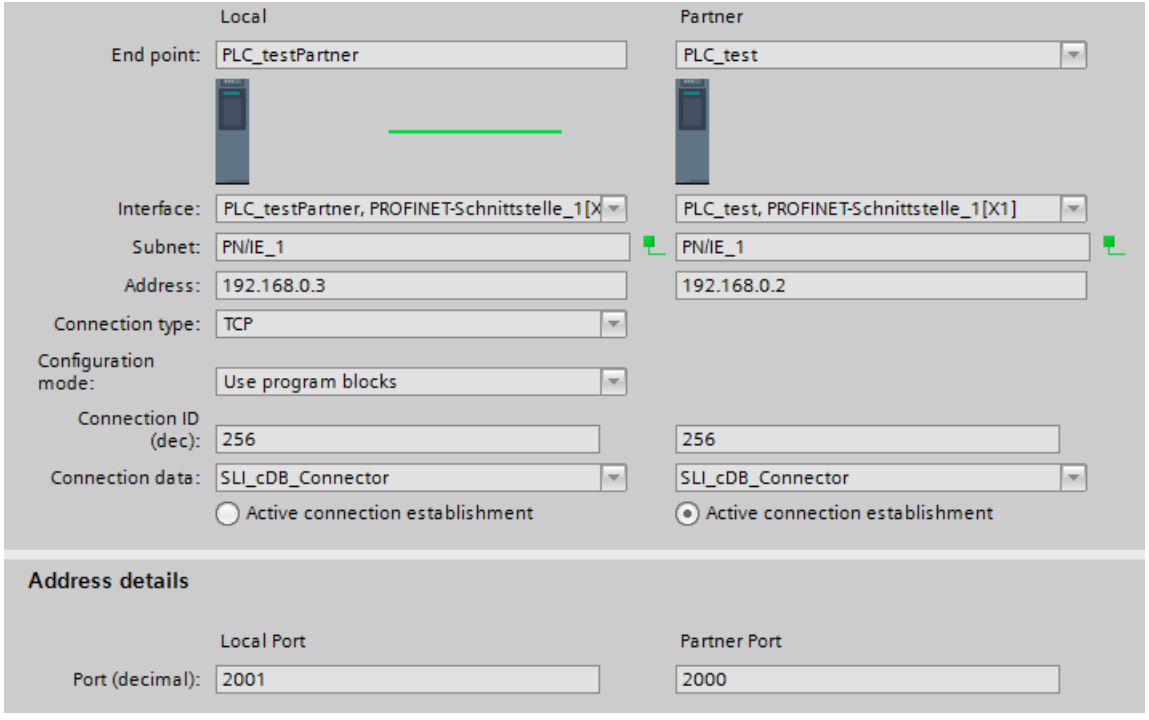
Create an FB "SLI_FB_TRCV_C" and create the following local tags in the FB.

7	Static			
8	TRCV_C_Instance	TRCV_C		
9	statDone	Bool	false	Non-retain
10	statRcvLen	UDInt	0	Non-retain

Network 1: Interconnect the parameters of the "TRCV_C" instruction as follows. Do not interconnect the parameter CONNECT yet.

Network 2: Save the status for an error of TRCV_C as follows.

Configuration of TRCV_C



Make the following settings for the configuration of TRCV_C:

Note

Connection data

By configuring TSEND_C, you have already created a data block ("SLI_cDB_Connector") with the stored connection data for each CPU. Instead of creating new data blocks and entering the connection data, you can simply use the created data blocks ("SLI_cDB_Connector").

For the created data blocks to be available for selection, they must still be available in the project tree under Program blocks > System blocks.

Procedure for connection establishment

To establish the communication connection in RUN mode, follow these steps:

1. Change the EN_R parameter to "1" for TRCV_C.
2. Change the CONT parameter to "1" for TRCV_C.
3. Change the REQ parameter to "1" for TSEND_C.
4. Change the CONT parameter to "1" for TSEND_C.

Procedure for connection termination

To terminate the communication connection in RUN mode, follow these steps:

1. Change the CONT parameter to "0" for TSEND_C.
2. Change the REQ parameter to "0" for TSEND_C.
3. Change the CONT parameter to "0" for TRCV_C.
4. Change the EN_R parameter to "0" for TRCV_C.

Behavior of CPU 1

When the input parameter REQ ("start") returns the signal state "TRUE", the "TSEND_C" instruction is started. When the input parameter CONT ("comControl") supplies the signal state "TRUE", the "TSEND_C" instruction creates a communication connection between CPU 1 and CPU 2. To do this, the connection data is retrieved with the input parameter CONNECT (or the data block "SLI_cDB_Connector").

For multiple calls, the "TSEND_C" instruction transmits the data record detected at input parameter DATA ("sendData"). Successful transfer of the data record is indicated by the output parameter DONE ("#statDone") with the signal state "TRUE" and the output parameter STATUS ("status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status of DONE ("#statDone") in the tag "done".

After transmitting the data record to CPU 2, the communication connection continues to be monitored (status "7004"). The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_TSEND_C

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	comControl	Bool	false	TRUE
4	done	Bool	false	TRUE
5	busy	Bool	false	FALSE
6	error	Bool	false	FALSE
7	status	Word	16#0	16#7004
8	memErrStatus	Word	16#0	16#0000
9	sendData	String	'ProcessXYZ'	'ProcessXYZ'

Behavior of CPU 2

When the input parameter EN_R ("start") returns the signal state "TRUE", the "TRCV_C" instruction is started. When the input parameter CONT ("comControl") supplies the signal state "TRUE", the "TRCV_C" instruction creates a communication connection between CPU 2 and CPU 1. To do this, the connection data is retrieved with the input parameter CONNECT (or the data block "SLI_cDB_Connector").

For multiple calls, the "TRCV_C" instruction receives the transmitted data record. The data record is recorded at the parameter DATA ("rcvData"). Successful transfer of the data record is indicated by the output parameter DONE ("done") with the signal state "TRUE" and the output parameter STATUS ("status") with the value "0000". The length in BYTE of the actually transmitted data record is detected with the output parameter RCVD_LEN ("#statRcvLen"). This value is only displayed during the success status. Then "0" is detected.

Because the values of the output parameters are only displayed for the moment of their validity, do the following:

- Save the value of "#statRcvLen" in "rcvLen".
- Save the value of "#statDone" in "done".
- Save the value of "#status" in "memErrStatus".

After the data record has been received by CPU 2, the communication connection continues to be monitored (status "7006"). The output parameter ERROR ("error") or the tag "memErrStatus" indicates that processing of the example is taking place without errors.

SLI_gDB_TRCV_C

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	comControl	Bool	false	TRUE
4	done	Bool	false	TRUE
5	busy	Bool	false	TRUE
6	error	Bool	false	FALSE
7	status	Word	16#0	16#7006
8	memErrStatus	Word	16#0	16#0000
9	rcvLen	UDInt	0	256
10	rcvData	String	''	'ProcessXYZ'

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

TMAIL_C: Transfer email (S7-1200, S7-1500)

Description of TMAIL_C (S7-1200, S7-1500)

Description

You can use the "TMAIL_C" instruction to send an e-mail via the Ethernet interface of the S7-1500 CPU or S7-1200 > V4.0, a communication module (CM), or a communication processor (CP).

The instruction can only be used once the hardware has been configured and if the network infrastructure allows for a communication connection to the mail server.

You define the content of the e-mail, and the connection data, using the following parameters:

- You define the recipient addresses with the parameters TO_S and CC.
- You define the content of the e-mail with the parameters SUBJECT and TEXT.
- You can define an attachment using VARIANT pointers at the ATTACHMENT and ATTACHMENT_NAME parameters.
- The connection data is defined, and addressing and authentication for the mail server executed, using the system data type TMail_V4, TMail_V6 or TMail_FQDN at the MAIL_ADDR_PARAM parameter.
  - If you are using the interface of the S7-1500 CPU, the system data type TMail_V4 must be used. In this case, the e-mail can only be sent via SMTP.
  - Any of the system data types can be used if you are using the interface of a CM/CP. The e-mail can then also be sent via SMTPS.
- You start the sending of an e-mail with an edge change from "0" to "1" for the REQ parameter.
- The job status is indicated by the output parameters "BUSY", "DONE", "ERROR" and "STATUS".

You cannot send an SMS directly with the "TMAIL_C" instruction. Whether or not the e-mail can be forwarded by the mail server as an SMS depends on your telecommunications provider.

Note

Number of e-mails to be sent

You can send more than one e-mail simultaneously using a PLC. When a CP 1243-8 or CP 1543-1 is used, you can only send one e-mail for each CP. When two CPs are used, parallel sending of two e-mails is possible.

Operation of the instruction

The "TMAIL_C" instruction works asynchronously, which means its execution extends over multiple calls. You must specify an instance when you call the instruction "TMAIL_C".

In the following cases, the connection to the mail server will be lost:

- If the CPU switches to STOP while "TMAIL_C" is active.
- If communication problems occur at the Industrial Ethernet bus.

In this case, the transfer of the e-mail will be interrupted and it will not reach its recipient. The connection is also canceled once the instruction has been successfully executed and the e-mail sent.

NOTICE
Changing user programs You can change the parts of your user program that directly affect calls of "TMAIL_C" only: • The CPU is in "STOP" mode. • No e-mail is being sent (REQ = 0 and BUSY = 0). This relates, in particular, to deleting and replacing program blocks that contain "TMAIL_C" calls or calls for the instance of "TMAIL_C". Ignoring this restriction can tie up connection resources. The automation system can change to an undefined status with the TCP/IP communication functions via Industrial Ethernet. A warm or cold restart of the CPU is required after the changes are transferred.

Data consistency

The TO_S, CC, SUBJECT, TEXT, ATTACHMENT and MAIL_ADDR_PARAM parameters are applied by the "TMAIL_C" instruction while it is running, which means that they may only be changed after the job has been completed (BUSY = 0).

SMTP authentication

Authentication refers here to a procedure for verifying identity, for example, with a password query.

If you are using the S7-1500 CPU interface, the instruction "TMAIL_C" supports the SMTP authentication procedure AUTH-LOGIN which is required by most mail servers. For information about the authentication procedure of your mail server, please refer to your mail server manual or the website of your Internet service provider.

- Before you can use the AUTH-LOGIN authentication procedure, the "TMAIL_C" instruction requires the user name with which it is to log on to the mail server. This user name corresponds to the user name with which you set up a mail account on your mail server. It is transferred via the UserName parameter to the structure at parameter MAIL_ADDR_PARAM.
  If no user name is specified at the MAIL_ADDR_PARAM parameter, the AUTH-LOGIN authentication procedure is not used. The e-mail is then sent without authentication.
- To log on, the "TMAIL_C" instruction also requires the associated password. This password corresponds to the password you specified when you set up your mail account. It is transferred via the PassWord parameter to the structure at parameter MAIL_ADDR_PARAM.

Parameters

The following table shows the parameters of the "TMAIL_C" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	Control parameter REQUEST: Activates the sending of an e-mail upon a rising edge.
TO_S (Page 4458)	Input	STRING	D, L or constant	Recipient addresses STRING with a maximum length of 240 characters (bytes). For the e-mail address format, see the example in the parameter description.
CC (Page 4458)	Input	STRING	D, L or constant	CC recipient addresses (optional) STRING with a maximum length of 240 characters (bytes). Same e-mail address format as for the TO_S parameter. If an empty string is assigned here, the e-mail is not sent to a CC recipient.
SUBJECT	Input	STRING	D, L or constant	Subject of the e-mail STRING with a maximum length of 240 characters (bytes).
TEXT	Input	STRING	D, L or constant	Text of the e-mail (optional) STRING with a maximum length of 240 characters (bytes). If an empty string is assigned at this parameter, the e-mail is sent without text.
ATTACHMENT	Input	VARIANT	D	E-mail attachment (optional) Reference to a byte/word/double word field (ArrayOfByte, ArrayOfWord or ArrayOfDWord) with a maximum length of 64 Kb. If no value is assigned, the e-mail is sent without an attachment.
ATTACHMENT_NAME	Input	STRING	D, L or constant	E-mail attachment name (optional) Reference to a character string with a maximum length of 50 characters (bytes) to define the file name of the attachment. If an empty string is assigned at this parameter, the attachment of the e-mail is received with a file name assigned by the e-mail receiving program. It is therefore recommended to use a defined file name.
MAIL_ADDR_PARAM (Page 4459)	Input	VARIANT	D	Connection parameter and address of the e-mail server To define the connection parameters, use the structure TMail_V4, TMail_V6 or TMail_FQDN (see parameter description).

Parameter	Declaration	Data type	Memory area	Description
DONE (Page 4468)	Output	BOOL	I, Q, M, D, L	Status parameter • DONE = 0: Job not yet started or still executing. • DONE = 1: Job executed without errors.
BUSY (Page 4468)	Output	BOOL	I, Q, M, D, L	Status parameter • BUSY = 0: Processing of "TMAIL_C" was terminated • BUSY = 1: Sending of an e-mail is not yet complete.
ERROR (Page 4468)	Output	BOOL	I, Q, M, D, L	Status parameter • ERROR = 0: No error occurred. • ERROR = 1: An error occurred during processing. STATUS supplies detailed information on the type of error.
STATUS (Page 4469)	Output	WORD	I, Q, M, D, L	Status parameter Return value or error information of the "TMAIL_C" instruction (see parameter description).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Optional parameters

The optional parameters CC, TEXT, and ATTACHMENT are only sent with the e-mail if the corresponding parameters contain a string of length > 0.

Example

You will find an example of sending e-mails with the TMAIL_CExample: Sending an e-mail with TMAIL_C (Page 4472) instruction with the following link:

Difference between synchronous and asynchronous instructions (Page 2571)

Description TMAIL_C as of version V4.0 (S7-1200, S7-1500)

Introduction

The instruction TMAIL_C as of version V4.0 is described below. This description does not include all details, but instead explains the differences as compared to the instruction versions < V4.0.

The handling of the required certificates is also not described here.

Description

You use the instruction TMAIL_C as of version V4.0 to send an e-mail using Secure Communication via the Ethernet interface of the following modules:

- CP 1543-1 V2.0
- CP 1542SP-1 IRC V1.0
- CP 1543SP-1 V1.0
- CP 1242-7 GPRS V2, Firmware version V2.1
- CP 1243-7 LTE V2.1
- CP 1243-8 V2.1

The files required for the sending process including the TCP port of the e-mail server are defined with one of the system data types TMAIL_V4_SEC, TMAIL_V6_SEC or TMAIL_QDN_SEC at the parameter MAIL_ADDR_PARAM.

Note

Compatibility with the TMAIL_C versions < V4.0

For reasons of compatibility, you can also use the existing system data types TMAIL_V4 and TMAIL_FQDN. In this case, you can also send an email via the Ethernet interfaces of the CPU and the Ethernet interface of the CP 1543-1.

Restrictions for the CP

You must observe the following rules:

- You may use only one CP as email client for each TMAIL_C instance.
- All email servers to which emails are to be sent must be reachable via the IP network from a CP that is used as email client.
- If an email server is to be reached via its fully qualified domain name, the DNS servers, which are configured in the CP, must also be reachable in the IP network.

Parameters

Parameter	Declaration	Data type	Memory area	Description
...				
MAIL_ADDR_PARAM (Page 4462)	Input	VARIANT	D	The data required for the send process (including the connection parameters, the address of the email server and the TCP port used) Select one of the following system data types for this: • TMail_V4_SEC • TMail_V6_SEC • TMail_QDN_SEC
...				

Diagnostic options when an error occurs

You have the following two diagnostic options when an error occurs:

- Evaluation of the STATUS parameter
  The same values can occur as with the instruction-versions < V4.0.
  Only the value W#16#8015 receives an extension. It also occurs if you specify the hardware identifier of a CPU interface at the parameter InterfaceId.
- Evaluation of the MS_STATUS tag in the instance data of TMAIL_C. This tag has been added in the version V4.0 of TMAIL_C. It contains both the protocol codes and their associated textual descriptions as they are defined in RFC 3207 "SMTP Service Extension for Secure SMTP over Transport Layer Security".
  Examples of diagnostic information in MS_STATUS:
  - 550 SMTP AUTH required before submission
  - 550 StartTLS required
  - 550 Requested action not taken

TO_S and CC parameters (S7-1200, S7-1500)

Description

The TO_S and CC parameters are strings, for example, with the following content:

- <wenna@mydomain.com>, <ruby@mydomain.com>
- <admin@mydomain.com>, <judy@mydomain.com>

Note the following rules when entering the parameters:

- A space and an opening pointed bracket "<" must be entered before each address.
- A closing pointed bracket ">" must be entered after each address.
- A comma must be entered between the addresses in TO and CC.

For runtime and memory space reasons, the "TMAIL_C" instruction does not perform a syntax check of parameter TO_S or CC.

MAIL_ADDR_PARAM parameter (S7-1200, S7-1500)

Description

At the MAIL_ADDR_PARAM parameter, you define the connection for sending the e-mail in the structure TMail_V4, TMail_V6 or Tmail_FQDN, and save the e-mail server address and login details.

The structure you use at the MAIL_ADDR_PARAM parameter depends on the format in which the e-mail server is to be addressed:

- TMail_V4: Addressing by IP address to IPv4.
- TMail_V6: Addressing by IP address to IPv6.
- TMail_FQDN: Addressing by fully qualified domain name (FQDN).

Which structure you can use depends on the interface addressed at the InterfaceId parameter:

- If you want to use the "TMAIL_C" instruction with the internal interface, the TMail_V4 structure must be used at the MAIL_ADDR_PARAM parameter.
- If you are using a communication processor (CP) or communication module (CM), you can use all three addressing options (IPv4, IPv6 and FQDN).

Table 11-79 **TMail_V4: Addressing the mail server by IP address (IPv4)**

Parameter	Data type	Description
TMail_V4	Struct	
InterfaceId	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#20 as the connection type for IPv4.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs).
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V4	IP address of the mail server. IPv4 in the following format: XXX.XXX.XXX.XXX (decimal). Example: 192.142.131.237.
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"

Table 11-80 **TMail_V6: Addressing the mail server by IP address to IPv6**

Parameter	Data type	Description
TMail_V6	Struct	
InterfaceId	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#21 as the connection type for IPv6.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs). You use the CertIndex parameter to specify the certificate to be used (see "Project navigation" > "Global security settings" > "Certificate manager").
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V6	IP address of the mail server (IPv6) in the following format: XXXX.XXXX.XXXX.XXXX.XXXX.XXXX.XXXX.XXXX (hexadecimal). The address is divided into 8 blocks of 2 bytes each (16 bytes in total). Example: 2001:db8:1f11:08d3:290:27ff:0370:2093
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"

Table 11-81 **TMail_FQDN: Addressing the mail server via the FQDN**

Parameter	Data type	Description
TMail_FQDN	Struct	
InterfaceId	LADDR	Hardware identifier of the interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#22 as the connection type for FQDN.
ActiveEstablished	BOOL	Status bit. Set to "1" once the connection is established.
CertIndex	BYTE	• =0: SMTP used (**S**imple **M**ail **T**ransfer **P**rotocol). SMTP must be used if the e-mail is being sent via the interface of an S7-1500 CPU. • ≠0: SMTPS used to secure the connection before it is established (with CPs/CMs). You use the CertIndex parameter to specify the certificate to be used (see "Project navigation" > "Global security settings" > "Certificate manager").
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	STRING[254]	FQDN (**F**ully **Q**ualified **D**omain **N**ame) of the mail server. The mail server is addressed using the fully qualified domain name. Example: "www.mymailserver.com."
UserName	STRING[254]	Mail server login name
PassWord	STRING[254]	Mail server password
From	Struct	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"

Parameter MAIL_ADDR_PARAM as of Version 4.0 of TMAIL_C (S7-1200, S7-1500)

Description

You use the MAIL_ADDR_PARAM parameter to specify the data required for the send process, for example the connection parameters, the address of the email server and the TCP port used.

Depending on the format in which the e-mail server is to be addressed, you use one of the following structures at the MAIL_ADDR_PARAM parameter:

- TMail_V4_SEC: Addressing via the IP address in IPv4 format
- TMail_V6_SEC: Addressing via the IP address in IPv6 format
- TMail_QDN_SEC: Addressing via the fully qualified host name (FQDN)

TMail_V4_SEC: Addressing of the mail server via the IP address in IPv4 format

Parameter	Data type	Description
TMail_V4_SEC	Struct	
InterfaceId	LADDR	Hardware identifier of the Ethernet interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#20 as the connection type for IPv4.
ActiveEstablishment	BOOL	Active/passive connection establishment. Because the CP is always the SMTP client, this parameter must be set to "1".
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WatchDog-Time parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V4	IP address of the mail server intrinsic in IPv4 format: XXX.XXX.XXX.XXX (decimal place). Example: 192.142.131.237.
UserName	STRING[254]	User name. This is required if users wants to access their email inbox in order to identify themselves as the owner of the email inbox to the email provider.
PassWord	STRING[254]	User password. This is required if users wants to access their email inbox in order to identify themselves as the owner of the email inbox to the email provider.
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"

Parameter		Data type	Description
	FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"
RemotePort		UINT	TCP port of the mail server
ActivateSecureConn		BOOL	• 1: Secure SMTP connection • 0: SMTP connection (non-secure). In this case, the following parameters are irrelevant.
ExtTLSCapabilities		BYTE	Not currently used
TLSServerCertRef		UDINT	Reference to the X.509 V3 (CA) certificate of the mail server, which is used by the TLS client to validate the authentication of the TLS server.

TMail_V6_SEC: Addressing of the e-mail server via the IP address in IPv6 format

Parameter	Data type	Description
TMail_V6_SEC	Struct	
InterfaceId	LADDR	Hardware identifier of the Ethernet interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#21 as the connection type for IPv6.
ActiveEstablishment	BOOL	Active/passive connection establishment. Because the CP is always the SMTP client, this parameter must be set to "1".
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WatchDog-Time parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerAddress	IP_V6	IP address of the mail server in IPv6 format: XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX (hexadecimal). The address is divided into 8 blocks of 2 bytes each (16 bytes in total). Example: 2001:db8:1f11:08d3:290:27ff:0370:2093
UserName	STRING[254]	User name. This is required if users wants to access their e-mail inbox in order to identify themselves as the owner of the e-mail inbox to the e-mail provider.
PassWord	STRING[254]	User password. This is required if users wants to access their e-mail inbox in order to identify themselves as the owner of the e-mail inbox to the e-mail provider.
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"

Parameter	Data type	Description
RemotePort	UINT	TCP port of the mail server
ActivateSecureConn	BOOL	• 1: Secure SMTP connection • 0: SMTP connection (non-secure). In this case, the following parameters are irrelevant.
ExtTLSCapabilities	BYTE	Not currently used
TLSServerCertRef	UDINT	Reference to the X.509 V3 (CA) certificate of the mail server, which is used by the TLS client to validate the authentication of the TLS server.

TMail_QDN_SEC: Addressing of the mail server via FQDN

Parameter	Data type	Description
TMail_QDN_SEC	Struct	
InterfaceId	LADDR	Hardware identifier of the Ethernet interface
ID	CONN_OUC	Connection ID
ConnectionType	BYTE	Connection type. Select 16#22 as the connection type for FQDN.
ActiveEstablishment	BOOL	Active/passive connection establishment. Because the S7-CP is always the SMTP client, this parameter must be set to "1".
WatchDogTime	TIME	Execution watchdog. Use this parameter to define the maximum execution time for the send operation. Note: Connection establishment can take longer (approx. one minute) if the connection is slow. When you specify the WatchDogTime parameter, remember to allow for the time required to establish the connection. The connection is terminated once the specified time has elapsed.
MailServerQDN	STRING[254]	FQDN (Fully Qualified Domain Name) of the mail server. The mail server is addressed using the fully qualified domain name, which must be end with "." Example: "www.mymailserver.com"
UserName	STRING[254]	User name This is required if users wants to access their email inbox in order to identify themselves as the owner of the email inbox to the email provider.
PassWord	STRING[254]	User password This is required if users wants to access their email inbox in order to identify themselves as the owner of the email inbox to the email provider.
From	EMAIL_ADDR	E-mail sender address, which is defined using the following two STRING parameters. For example: "myname@mymailserver.com".
LocalPartPlusAtSign	STRING[64]	Local part of sender address, including @ sign. Example: "myname@"
FullQualifiedDomainName	STRING[254]	Fully Qualified Domain Name (abbreviated to FQDN) of the mail server. Example: "mymailserver.com"

Parameter	Data type	Description
RemotePort	UINT	TCP port of the mail server
ActivateSecureConn	BOOL	• 1: Secure SMTP connection • 0: Unsecured SMTP connection In this case, the following parameters are irrelevant.
ExtTLSCapabilities	BYTE	Not currently used
TLSServerCertRef	UDINT	Reference to the X.509 V3 (CA) certificate of the mail server, which is used by the TLS client to validate the authentication of the TLS server.

DONE, BUSY and ERROR parameters (S7-1200, S7-1500)

Description

The output parameters DONE, BUSY and ERROR are each displayed for only one cycle if the status of the BUSY output parameter changes from "1" to "0".

The following table shows the relationship between DONE, BUSY, and ERROR. Using this table, you can determine the current status of the instruction "TMAIL_C and when the sending of the e-mail is complete.

DONE	BUSY	ER-ROR	Description
0	1	0	The job is being processed.
1	0	0	Job successfully completed.
0	0	1	The job ended with an error. The cause of the error can be found in the STATUS (Page 4469) parameter.
0	0	0	The "TMAIL_C" instruction was not assigned a (new) job.

STATUS parameter (S7-1200, S7-1500)

Description

The following table shows the return values of "TMAIL_C" at the STATUS parameter:

Return value STATUS* (W#16#...):	Explanation	Notes
0000	The processing of "TMAIL_C" was completed without errors.	Error-free completion of "TMAIL_C" does not mean that the e-mail sent will necessarily arrive. Incorrectly entering the recipient addresses does not generate a status error of the "TMAIL_C" instruction. In this case, there is no guarantee that the e-mail will be sent to other recipients, even if these were entered correctly.
7001	"TMAIL_C" is active (BUSY = 1).	First call: Job triggered.
7002	"TMAIL_C" is active (BUSY = 1).	Intermediate call: Job already active.
8xxx	The processing of "TMAIL_C" was completed with an error code of the communication instructions called internally.	For detailed information, please refer to the STATUS parameter descriptions for the "TCON (Page 4478)", "TDISCON (Page 4484)", "TSEND (Page 4490)" and "TRCV (Page 4493)" communication instructions.
8010	Error during connection establishment	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TCON (Page 4478)" instruction.
8011	Error sending the data	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TSEND (Page 4490)" instruction.
8012	Error receiving the data	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the "TRCV (Page 4493)" instruction.
8013	Error during connection establishment	You can find further information on evaluation in the SFB_STATUS parameter of the instance data block. The error code displayed at the SFB_STATUS parameter is explained in the STATUS parameter description for the TCON (Page 4478)" and "TDISCON (Page 4484)" instructions.

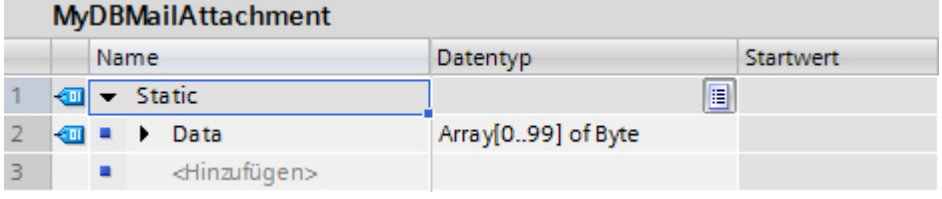
Return value STATUS* (W#16#...):	Explanation	Notes
8014	Establishment of a connection is not possible.	You may have entered an incorrect mail server IP address (MailServerAddress (Page 4459)) or too short a time span (WatchDogTime (Page 4459)) for connection establishment. It is also possible that the CPU has no connection to the network or that the CPU configuration is incorrect.
8015	Incorrect data type for MAIL_ADDR_PARAM	The only valid data types are the system data types (structures) TMail_V4, TMail_V6 and TMail_FQDN.
8016	Incorrect data type for the ATTACHMENT parameter	The only valid data types are ArrayOfByte, ArrayOfWord and ArrayOfDWord.
8017	Incorrect data length for the ATTACHMENT parameter	Data length must be <= 65534 bytes.
8401	No channels available. Possible cause: There is already an e-mail connection via the CP. A second connection cannot be established in parallel.	Specific error for CP 1543
8403	A TCP/IP connection to the mail server was not possible.	Specific error for CP 1543
8405	Server has denied login request.	Specific error for CP 1543
8406	SMTP client has detected an internal SSL error or a problem with the certificate structure.	Specific error for CP 1543
8407	Request to use SSL denied.	Specific error for CP 1543
8408	Client unable to identify socket for establishing a TCP/IP connection to the mail server.	Specific error for CP 1543
8409	Writing via the connection not possible. Possible cause: The communication partner has reset the connection or the connection has been lost.	Specific error for CP 1543
8410	Reading via the connection not possible. Possible cause: The communication partner has reset the connection or the connection has been lost.	Specific error for CP 1543
8411	E-mail could not be sent. Cause: Insufficient memory space to execute the send operation.	Specific error for CP 1543
8412	Configured DNS server was unable to resolve the specified domain name.	Specific error for CP 1543
8413	An internal error in the DNS subsystem prevented domain name resolution.	Specific error for CP 1543
8414	Empty character string entered as domain name.	Specific error for CP 1543
8415	An internal error has occurred in the cURL module. Execution was stopped.	Specific error for CP 1543

Return value STATUS* (W#16#...):	Explanation	Notes
8416	An internal error has occurred in the SMTP module. Execution was stopped.	Specific error for CP 1543
8417	Request to SMTP on a channel already in use or invalid channel ID. Execution was stopped.	Specific error for CP 1543
8418	E-mail send job aborted. Possible causes: Execution time exceeded (WatchDogTime parameter) or CP transition from start to stop.	Specific error for CP 1543
8419	Channel interrupted and cannot be used before the connection is closed.	Specific error for CP 1543
8420	Server certificate string could not be verified with CP root certificate.	Specific error for CP 1543
8421	Internal error occurred. Execution was stopped.	Specific error for CP 1543
82xx, 84xx, or 85xx	The error message originates from the mail server and corresponds, except for the "8", to the error number of the SMTP protocol. The following lines list several error codes that can occur.	You can find more detailed information on the SMTP error code and other error codes in the SMTP protocol on the Internet or in the error documentation of the mail server. You can also view the most recent error message from the mail server in your instance DB in the BUFFER1 parameter. You can find the last data sent by the "TMAIL_C" instruction under DATEN in the instance DB.
8450	Action not executed: Mailbox not available/cannot be reached	Try again later.
8451	Action aborted: Local processing error	Try again later.
8500	Syntax error: Error not recognized. This also includes the error when a command string is too long. This can also occur when the e-mail server does not support the LOGIN authentication procedure.	Check the parameters of "TMAIL_C". Try to send an e-mail without authentication. To do this, replace the content of the UserName parameter with an empty string. If no user name is specified, the LOGIN authentication procedure is not used.
8501	Syntax error: Incorrect input at a parameter	Possible cause: Incorrect address at the parameters TO_S or CC (see also: TO_S and CC parameters (Page 4458)).
8502	Command unknown or not implemented	Check your entries, in particular the FROM parameter. It may be incomplete and you may have forgotten the "@" or "." (see also: TO_S and CC parameters (Page 4458)).
8504	Command parameters not implemented	Check your entries, in particular the FROM parameter. It may be incomplete and you may have forgotten the "@" (see also: TO_S and CC parameters (Page 4458)).
8535	SMTP authentication incomplete	You have possibly entered an incorrect user name or incorrect password.

Return value STATUS* (W#16#...):	Explanation	Notes
8550	Mail server cannot be reached. You have no access rights.	You may have entered an incorrect user name or password, or the mail server may not support your login. Another cause of error could be an incorrect entry of the domain name after the "@" or a missing "." at the TO_S, CC and FROM parameters (see also: TO_S and CC parameters (Page 4458)).
8552	Action aborted: Assigned memory size has been exceeded	Try again later.
8554	Transfer failed	Try again later.
8555	Error due to incorrect entry of the e-mail address.	If multiple addresses were entered, these need to be separated by a comma.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example: Sending an e-mail with TMAIL_C (S7-1200, S7-1500)

Introduction



The following call example shows you how the TMAIL_C instruction works.

Requirements

Hardware must be configured beforehand for sending e-mail and the infrastructure of the network must allow a communication connection to the mail server. In addition, you need to create two structures to supply the input parameters of TMAIL_C: One for the e-mail attachment, the other for the connection information and address data.

E-mail attachment

The e-mail should be sent with an attachment. Create an Array of Byte with the name "Data" in a global data block as a source for the attachment. The array will be interconnected with the ATTACHMENT input parameter at a later time.

Connection information and address data

You enter the connection information of the CPU and address data of the mail server in the TMail_V4 system data type:

- Create a "Par1" tag with the "TMail_V4" data type in a global data block.
- In the following structure, enter the parameters of your CPU based on the configuration and the connection data of your mail server. For more information, refer to the description of the MAIL_ADDR_PARAM (Page 4459) input parameter.

The "Par1" tag will be interconnected with the MAIL_ADDR_PARAM input parameter later.

MyDBSendMail

	Name	Datentyp	Startwert
1	Static		
2	Par1	TMail_V4	
3	InterfaceId	HW_ANY	64
4	ID	CONN_OUC	100
5	ConnectionType	Byte	16#20
6	ActiveEstablished	Bool	false
7	CertIndex	Byte	16#0
8	WatchDogTime	Time	T#5s
9	MailServerAddress	IP_V4	
10	ADDR	Array[1..4] of Byte	
11	ADDR[1]	Byte	192
12	ADDR[2]	Byte	168
13	ADDR[3]	Byte	100
14	ADDR[4]	Byte	10
15	UserName	String[254]	'myusername'
16	PassWord	String[254]	'mypassword'
17	From	EMAIL_ADDR	
18	LocalPartPlusAt...	String[64]	'station1@'
19	FullQualifiedD...	String[254]	'mycpu.com'

Calling the instruction

Create a new function block in the SCL language with the following interfaces:

- InOut
  - Name: SendEMail
  - Data type: Bool
- Static
  - Name: STATUS
  - Data type: Word

Copy the following source code with the call for TMAIL_C to the programming window:

Call TMAIL_C

```
BEGIN
    IF #SendEMail = true THEN
     "TMAIL_C_DB"(REQ := NOT "TMAIL_C_DB".BUSY,
                  TEXT := 'The cpu switched to run',
                  ATTACHMENT := "MyDBMailAttachment".Data,
                  MAIL_ADDR_PARAM := "MyDBSendMail".Par1);
     IF ("TMAIL_C_DB".BUSY = false) AND ("TMAIL_C_DB".DONE = false)
AND
     ("TMAIL_C_DB".ERROR = false) THEN
         #SendEMail := false;
     END_IF;
     IF ("TMAIL_C_DB".DONE = false) OR ("TMAIL_C_DB".ERROR = true) THEN
         #STATUS := "TMAIL_C_DB".STATUS;
       END_IF;
    END_IF;
```

Result

This instruction must be called once with SendEMail = true. In the following calls, SendEMail should not be allocated when calling. SendEMail is reset by the instruction shown, as soon as an e-mail has been sent or an error has occurred during sending.

If the email was not sent successfully, the STATUS parameter contains the corresponding value of the STATUS parameter from the TMAIL_C instruction.

Description of TMAIL_C (Page 4453)

Other (S7-1200, S7-1500)

TCON: Establishing a communication connection (S7-1200, S7-1500)

TCON: Establish communication connection (S7-1200)

Validity

The following description of the "TCON" instruction applies to S7-1200 CPUs with firmware version < V4.0.

Description

You use the "TCON" instruction to set up and establish a communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. "TCON" executes asynchronously.

The connection data specified for the CONNECT and ID parameters are used to set up the communication connection. To establish the connection, a rising edge must be detected at the REQ parameter. Once the connection is successfully established, the DONE parameter is set to "1".

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and create connections of the type TCP, UDP or ISO-on-TCP and want to assign parameters to them, you can use the support of the connection parameter assignment.

You can find the connection parameter assignment the Inspector window of the program editor.

Number of possible connections

For information on the number of possible communication connections, refer to the technical specifications for your CPU.

TCP and ISO-on-TCP connections

Both communication partners call the "TCON" instruction to set up and establish the communication connection. During parameter assignment, you specify which partner is the active communication end point and which is the passive one.

If the connection aborts, for example due to a line break or due to the remote communication partner, the active partner attempts to reestablish the configured connection. You do not have to call "TCON" again. This applies only if "TCON" has been executed successfully once (DONE = 1).

An existing connection is terminated and the connection set up is removed when the "TDISCON (Page 4484)" instruction is executed or when the CPU changes to STOP mode. To set up and establish the connection again, you will need to execute "TCON" again.

Parameters

The following table shows the parameters of the "TCON" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the job to establish the connection specified in the ID upon a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the assigned connection. Value range: W#16#0001 to W#16#0FFF
CONNECT	InOut	TCON_Param	D	Pointer to the connection description See also: AUTOHOTSPOT

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not a job has been executed successfully. The ERROR parameter is set when errors occurred during execution of "TCON". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection successfully established.
0	7000	No job processing active
0	7001	Start job execution, establish connection.
0	7002	Connection is being established (REQ irrelevant).
1	8085	Connection ID (ID parameter) is already being used by a configured connection.
1	8086	The ID parameter is outside the valid range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8089	The CONNECT parameter does not point to a data block.
1	809A	The structure at the CONNECT parameter is not supported on an integrated interface or the length is invalid or an incorrect "InterfaceID" is specified in the connection description (SDT).

ERROR	STATUS* (W#16#...)	Explanation
1	809B	The element InterfaceId within the TCON_xxx structure does not reference a hardware identifier of a CPU or CM/CP interface or has the value "0".
1	80A0	Group error for error codes W#16#80A1 and W#16#80A2.
1	80A1	The specified connection or the port is already being used.
1	80A2	Local or remote port is being used by the system.
1	80A3	Attempt being made to re-establish an existing connection.
1	80A4	IP address of the remote endpoint of the connection is invalid, in other words, it matches the IP address of the local partner.
1	80A5	Connection ID is already in use.
1	80A7	Communication error: You executed "TDISCON (Page 4484)" before "TCON" had completed.
1	80B2	The CONNECT parameter points to a data block that was generated with the attribute "Only store in load memory".
1	80B4	You have violated one or more of the following conditions for passive connection establishment with the ISO-on-TCP protocol variant (connection_type = B#16#12): • local_tsap_id_len >= B#16#02 • local_tsap_id[1] = B#16#E0 • With local_tsap_id_len >= B#16#03, local_tsap_id[1] is an ASCII character. • local_tsap_id[1] is an ASCII character and local_tsap_id_len >= B#16#03.
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP.
1	80B6	Parameter assignment error at the connection_type parameter of the SDT TCON_Param.
1	80B7	Error in one of the following parameters of the data block for connection description: block_length, local_tsap_id_len, rem_subnet_id_len, rem_staddr_len, rem_tsap_id_len, next_staddr_len. Note: If you call TCON in TCP for the passive end, local_tsap_id_len must have the value 2 and rem_tsap_id_len the value 0.
1	80B8	Connection description of the structure element ID and the block parameter ID are not identical.
1	80C3	All connection resources are in use.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is currently receiving new parameters. • The configured connection is currently being removed by a "TDISCON (Page 4484)" instruction.
* The error codes in the program editor can be displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Difference between synchronous and asynchronous instructions (Page 2571)

TCON: Establish communication connection (S7-1200, S7-1500)

Description

You use the "TCON" instruction to set up and establish a communication connection. Once the connection has been set up and established, it is automatically maintained and monitored by the CPU. "TCON" executes asynchronously.

For S7-1500-CPUs as of firmware version V2.0 and higher, you can set up an access point for IPv4 multicast communication with the instruction "TCON" via the integrated PROFINET interfaces.

The connection data specified for the CONNECT and ID parameters are used to set up the communication connection. At the CONNECT parameter, if possible, only use the predefined structures as created by the connection parameter assignment in the Inspector window of the program editor.

To establish the connection, a rising edge must be detected at the REQ parameter. Once the connection is successfully established, the DONE parameter is set to "1".

Note

Support when programming connections

If you select an instruction for communication TCON, TSEND_C or TRCV_C in a program block and wish to create and assign parameters to connections of the type TCP, UDP, ISO-on-TCP or FDL, you can use the support of the connection parameter assignment.

You can find the connection parameter assignment in the Inspector window of the program editor.

Number of possible connections

For information on the number of possible communication connections, refer to the technical specifications for your CPU.

Connection with TCP and ISO-on-TCP

Both communication partners call the "TCON" instruction to set up and establish the communication connection. During parameter assignment, you specify which partner is the active communication end point and which is the passive one.

If the connection aborts, for example due to a line break or due to the remote communication partner, the active partner attempts to reestablish the configured connection. You do not have to call "TCON" again. This applies only if "TCON" has been executed successfully once (DONE = 1).

An existing connection is terminated and the connection set up is removed when the "TDISCON (Page 4484)" instruction is executed or when the CPU changes to STOP mode. To set up and establish the connection again, you will need to execute "TCON" again.

Telecontrol connections between CP and SMS client

Use the TCON_PHONE system data type for connection description in the CONNECT parameter.

For this connection type, the station requires access to the mobile network via a mobile network CP.

FDL connections

To set up the FDL connections of the CM 1542-5, see AUTOHOTSPOT.

Parameter

The following table shows the parameters of the instruction "TCON":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the job to establish the connection specified on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the assigned connection. Value range: W#16#0001 to W#16#0FFF
CONNECT	InOut	VARIANT	D	Pointer to the connection description • For TCP or UDP, use the structure TCON_IP_v4 or TCON_QDN For description, refer to: AUTOHOTSPOT or AUTOHOTSPOT • For TCP or UDP using secure communication, use the structure TCON_IP_V4_SEC or TCON_QDN_SEC For description, refer to: AUTOHOTSPOT or AUTOHOTSPOT • For ISO-on-TCP, use the structure TCON_IP_RFC For a description, refer to: AUTOHOTSPOT • For ISO connections of the CP 1543-1, use the structure TCON_ISOnative. For description, refer to: "Structure of the connection description according to TCON_ISOnative" • For connections to SMS clients, use the TCON_PHONE system data type. For a description, refer to AUTOHOTSPOT. • For FDL connections of the CM 1542-5, use the system data type TCON_FDL; see AUTOHOTSPOT.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error

Parameter	Declaration	Data type	Memory area	Description
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not a job has been executed successfully. The ERROR parameter is set if errors occur during execution of "TCON". The error information is output at the STATUS parameter.

The instruction "TCON" generates an error message in version 3.0 if an active connection establishment to a remote partner fails. Create a rising edge at the REQ parameter to establish a connection once again.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Structure of the connection description according to TCON_ISOnative

A connection description DB with a structure according to TCON_ISOnative is used to assign the communication connection parameters for ISO. The fixed data structure of the TCON_ISOnative contains all parameters that are required to establish the connection.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceId	HW_ANY	0	Hardware identifier of the CP interface
2 … 3	ID	CONN_OUC	1	Reference to this connection (unique ID in the value range: 1 to 4095).
4	ConnectionType	BYTE	16#16	Connection type: ISO
5	ActiveEstablished	BOOL	TRUE	ID for the manner in which the connection is established: • FALSE: Passive connection establishment • TRUE: Active connection establishment

Byte	Parameter	Data type	Start value	Description
8 to 13	RemoteMacAddress	ARRAY [1..6] of BYTE	-	MAC address of the partner end point, for example, for 00-74-41-FD-AE-84: • MacAddr[1] = 00 • MacAddr[2] = 74 • MacAddr[3] = 41 • MacAddr[4] = FD • MacAddr[5] = AE • MacAddr[6] = 84
14 - 19	LocalMacAddress	ARRAY [1..6] of BYTE	-	MAC address of the local end point, for example, for 00-74-41-FD-AE-84: • MacAddr[1] = 00 • MacAddr[2] = 74 • MacAddr[3] = 41 • MacAddr[4] = FD • MacAddr[5] = AE • MacAddr[6] = 84
20 - 53	RemoteTSelector	Struct	-	TSelector of the remote connection partner: • Bytes 20 to 21 = TSelLength • Bytes 22 to 53 = TSel[1-32]
	TSelLength	UINT	-	Value range from 0 to 32
	TSel	ARRAY [1..32] of BYTE	-	Value range in each case 0 to 255 in bytes
54 - 87	LocalTSelector	Struct	-	TSelector of the remote connection partner: • Bytes 20 to 21 = TSelLength • Bytes 22 to 53 = TSel[1-32]
	TSelLength	UINT		Value range from 0 to 32
	TSel	ARRAY [1..32] of BYTE	-	Value range in each case 0 to 255 in bytes
88 - 89	CrRetransmitionTime	UINT	-	Duration until connection attempt is repeated in seconds.
90 - 91	DataRetransmition-Time	UINT	100 ms	Duration until data transfer is repeated in milliseconds.
92 - 93	MaxRetransmition-Count	UINT	-	Maximum number of repetitions.
94 - 95	InactivityTime	UINT	-	in seconds
96 - 97	WindowTime	UINT		in seconds

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection successfully established.
0	7000	No job processing active
0	7001	Start job execution, establish connection.
0	7002	Connection is being established (REQ irrelevant).
1	8085	Connection ID (ID parameter) is already being used by a configured connection.
1	8086	The ID parameter is outside the valid range.
1	8087	Maximum number of connections reached; no additional connection possible
1	8089	The CONNECT parameter does not point to a connection description or the connection description was created manually.
1	809A	The structure at the CONNECT parameter is not supported on an integrated interface or the length is invalid.
1	809B	The element InterfaceId within the TCON_xxx structure does not reference a hardware identifier of a CPU or CM/CP interface or has the value "0".
1	80A1	The specified connection or the port is already being used.
1	80A2	Local or remote port is being used by the system. The following ports are reserved locally: 20, 21, 80, 102, 135, 161, 162, 443, 34962, 34963, 34964 as well as the area 49152 to 65535.
1	80A3	ID is used by a connection created by the user program, which uses the same connection description at the CONNECT parameter.
1	80A4	IP address of the remote endpoint of the connection is invalid or it corresponds to the IP address of the local partner.
1	80A7	Communication error: You executed "TDISCON (Page 4484)" before "TCON" had completed.
1	80B4	Only with TCON_IP_RFC: The local T selector was not specified or the first byte does not contain the value 0x0E (only with a length of T selector = 2) or the local T selector starts with "SIMATIC-".
1	80B5	Only passive connection establishment is permitted for connection type 13 = UDP (parameter ActiveEstablished of the structure TCON_IP_v4 / TCON_PARAM has the value TRUE).
1	80B6	Parameter assignment error in the ConnectionType parameter of the data block for connection description. • Only valid with TCON_IP_v4: 0x11, 0x0B and 0x13. • Only valid with TCON_IP_RFC: 0x0C and 0x12
1	80B7	With TCON_IP_v4: • TCP (active connection establishment): Remote port is "0". • TCP (passive connection establishment): Local port is "0". • UDP: Local port is "0". • IP address of the partner end point was set to 0.0.0.0. With TCON_IP_RFC: • Local (LocalTSelector) or remote (RemoteTSelector) T selector was specified with a length of more than 32 bytes. • For TSelLength of the T selector (local or remote), a length greater than 32 was entered. • Error in the length of the IP address of the specific connection partner. • IP address of the partner end point was set to 0.0.0.0.
1	80B8	Parameter ID in the local connection description (structure at CONNECT parameter) and parameter ID of the instruction are different.

ERROR	STATUS* (W#16#...)	Explanation
1	80C3	All connection resources are assigned, or ports may be dynamically used by other applications or connections.
1	80C4	Temporary communication error: • The connection cannot be established at this time. • The connection cannot be established because the firewalls on the connection path are not open for the required ports. • The interface is currently receiving new parameters. • The configured connection is currently being removed by a "TDISCON (Page 4484)" instruction.
1	80C5	The connection partner refuses to establish the connection, has terminated the connection or actively ended it.
1	80C6	The connection partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C8	Value at the ID parameter is already being used by a connection that was created using the user program. The connection uses the identical ID, but different connection settings at the parameter CONNECT.
1	80C9	Validation of the connection partner failed. The connection partner that wants to establish the connection does not match the defined partner of the structure at the CONNECT parameter.
1	80CE	The IP address of the local interface is 0.0.0.0.
1	80D0	In connection with TCP and the active connection end point: The remote_qdn parameter is an empty string. In this case, no connection can be established.
1	80D1	The remote_qdn parameter is not a fully qualified domain name. The period at the end may be missing.
1	80D2	No DNS server address is configured.
1	80D3	The fully qualified domain name could not be resolved. Possible causes: • The DNS server is not reachable, for example, because it has been shut down or the remote port is not reachable. • An error occurred during communication with the DNS server. • The DNS server returned a valid DNS answer, but the answer contained no IPv4 address.
1	80E0	Unsuitable or poor message was received.
1	80E1	Error during the handshake. Possible causes: • Abort by the user • Security not high enough • Renewed negotiation is not supported • SSL/TLS version is not supported • Validation of the host name failed
1	80E2	Not supported / invalid certificate Possible cause: The time-of-day of the module concerned is not set or the module is not synchronized. Example: The default setting for the date of the module is 1/1/2012 and it was not set during commissioning. The validity period of the certificate starts on 20 August 2016 and ends on 20 August 2024. In this case, the date of the module is outside the validity period of the certificate; the certificate is invalid for the module.
1	80E3	Certificate was discarded.

ERROR	STATUS* (W#16#...)	Explanation
1	80E4	No valid certification authority found.
1	80E5	Certificate expired.
1	80E6	Integrity errors in the Transport Layer Security Protocol
1	80E7	Not supported extension in X.509-V3 certificate
1	80E9	TLS server without server certificate is not supported.
1	80EA	DTLS (UDP) protocol is not supported.
1	80EB	A client cannot request a client certificate.
1	80EC	The server cannot perform validation based on the subjectAlternateName (only clients can do this).
1	80ED	TLSServerCertRef_m-ID invalid
* The error codes in the program editor can be displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

Example

Difference between synchronous and asynchronous instructions (Page 2571)

TDISCON: Terminate communication connection (S7-1200, S7-1500)

Description

The "TDISCON" instruction terminates a communications connection from the CPU to a connection partner.

Functional description

"TDISCON" is an instruction that works asynchronously, which means its job processing extends over multiple calls. You start the job for terminating a connection by calling the "TDISCON" instruction with REQ = 1.

After "TDISCON" has been successfully executed, the ID specified for "TCON" is no longer valid and cannot be used for sending or receiving.

The job status is indicated by the output parameters BUSY and STATUS. Here, STATUS corresponds to the output parameter RET_VAL of the asynchronous instructions (see also: Difference between synchronous and asynchronous instructions (Page 2571)).

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can recognize the current status of "TDISCON" or when the establishment of the connection is completed.

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	Job successfully completed.
0	0	1	The job ended with an error. The cause of the error can be found in the STATUS parameter.
0	0	0	The instruction was not assigned a (new) job.

Parameters

The following table shows the parameters of the instruction "TDISCON":

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
REQ	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Control parameter REQUEST starts the job for terminating the connection specified by ID. The job starts on a rising edge.
ID	Input	CONN_OUC (WORD)	D, L or constant	I, Q, M, D, L or constant	Reference to the connection to be terminated (connection ID) Value range: W#16#0001 to W#16#0FFF
DONE	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • 0: Job not yet started or still executing. • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • BUSY = 1: The job is not yet complete. • BUSY = 0: The job has been completed or has not yet started.
ERROR	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status parameter: • ERROR = 0: No error. • ERROR=1: An error occurred during processing. STATUS supplies detailed information on the type of error
STATUS	Output	WORD	I, Q, M, D, L	I, Q, M, D, L	Status parameter: Error information (see "Parameters ERROR and STATUS")

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Connection terminated successfully.
0	7000	No job processing active.
0	7001	Start of job processing, connection being terminated.
0	7002	Intermediate call (REQ irrelevant), connection being terminated.
1	8086	The ID parameter is not in the permitted value range.
1	80A3	Attempt is being made to terminate a non-existent connection or the connection is already terminated.
1	80C4	Temporary communication error: New parameters are being assigned to the interface or the connection is currently being established.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

You can find the example here: Program example for TCON, TDISCON, TSEND & TRCV (Page 4502).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

TSEND: Send data via communication connection (S7-1200, S7-1500)

TSEND: Send data via communication connection (S7-1200)

Description

The following description of the "TSEND" instruction is valid for the CPU S7-1200 to version 3.0.

You use the "TSEND" instruction to send data over an existing communication connection. TSEND executes asynchronously.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. All data types except BOOL and Array of BOOL can be used for the data to be sent.

The send job is executed when a rising edge is detected at the REQ parameter.

With the LEN parameter, you specify the maximum number of bytes sent with a send job.

- When data is transferred with TCP (streaming protocol), the "TSEND" instruction provides no information about the length of the data sent to "TRCV (Page 4493)".
- When data is transferred with ISO-on-TCP (message-oriented protocol), the length of the data sent is communicated to "TRCV (Page 4493)". The amount of data sent with "TSEND" as packet must also be received again at the receiving end ("TRCV (Page 4493)"):
  - If the receive buffer is too small for the sent data, an error occurs at the receiving end.
  - If the receive buffer is sufficiently large, "TRCV" returns with DONE=1 as soon as the data packet is received.

The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.

Parameter

The following table shows the parameters of the "TSEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the send job on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum number of bytes to be sent with the job.
DATA	InOut	VARIANT	I, Q, M, D	Pointer to the send area containing the address and the length of the data to be sent. The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block When transferring structures, the structures must be identical at the sending and receiving end.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

LEN and DATA parameters

- With LEN = 0 , all the data specified with the DATA parameter is sent.
- If the number of bytes at the LEN parameter is larger than the length of the data to be sent that was defined with the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS parameter below).
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- With data types STRING and WSTRING, all data is transferred if the parameter LEN = 0. When LEN > 0, the length must be at least the maximum number of bytes plus two additional bytes which contain the length information. You will find more detailed information on the structure of the data types in: "Overview of the valid data types (Page 2239)".
- The maximum number of bytes that can be transmitted is 65534.
- When you use structured tags from optimized DBs, the address of the structured tag should be interconnected at the DATA parameter and the parameter LEN = 0. This guarantees type-safe transmission of the entire structure if the same structure is used at the receiving end.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of "TSEND". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TSEND" is executed asynchronously, you must keep the data in the send area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job completed without error.
0	7000	No job processing active.
0	7001	Start of job execution, data is being sent. When processing this job, the operating system accesses the data in the DATA send area.
0	7002	Job executing (REQ irrelevant). When processing this job, the operating system accesses the data in the DATA send area.
1	8085	• The LEN parameter is greater than the highest permitted value (65536). • DATA and LEN parameters both have the value "0".
1	8086	The ID parameter is outside the permitted address range (1..0xFFF).
1	8088	The LEN parameter is greater than the area specified in DATA.
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Transfer via this connection is not possible. • The interface is being re-initialized.
1	80B3	The protocol variant (ConnectionType parameter in the connection description) is set to UDP. Use the instruction "TUSEND" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	Connection terminated by the communication partner.
1	80C6	Network error. Communication partner cannot be reached.
1	80C7	Execution timeout.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

Difference between synchronous and asynchronous instructions (Page 2571)

TSEND: Send data via communication connection (S7-1200, S7-1500)

Description

The following description of the "TSEND" instruction is valid for:

- Ethernet
  CPU S7-1200 with firmware version ≥ V4.0 and CPU S7-1500
- PROFIBUS
  FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL

You use the "TSEND" instruction to send data over an existing communication connection. TSEND executes asynchronously.

You specify the send area with the DATA parameter. This includes the address and the length of the data to be sent. All data types except BOOL and Array of BOOL can be used for the data to be sent.

The send job is executed when a rising edge is detected at the REQ parameter.

With the LEN parameter, you specify the maximum number of bytes sent with a send job.

- When data is transferred with TCP (streaming protocol), the "TSEND" instruction provides no information about the length of the data sent to "TRCV (Page 4493)".
- When data is transferred with ISO-on-TCP (message-oriented protocol), the length of the data sent is communicated to "TRCV (Page 4493)". The amount of data sent with "TSEND" as packet must also be received again at the receiving end ("TRCV (Page 4493)"):
  - If the receive buffer is too small for the sent data, an error occurs at the receiving end.
  - If the receive buffer is sufficiently large, "TRCV" returns with DONE=1 as soon as the data packet is received.

The data to be sent must not be edited until the send job is completed. If the send job executes successfully, the DONE parameter is set to "1". Signal state "1" at the DONE parameter is not confirmation that the data sent has already been read by the communication partner.

Parameter

The following table shows the parameters of the "TSEND" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the send job on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Maximum number of bytes that are sent with the job (maximum permissible value for S7-1200: 8192, maximum permissible value for S7-1500: 65536). For FDL connections of the CM 1542-5, the maximum length is 240 bytes. In this regard, note the maximum lengths that can be processed by the connection partner.

Parameter	Declaration	Data type	Memory area	Description
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the send area containing the address and the length of the data to be sent. The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block • Local data When transferring structures, the structures must be identical at the sending and receiving end.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

LEN and DATA parameters

- With LEN = 0 , all the data specified with the DATA parameter is sent.
- If the number of bytes at the LEN parameter is larger than the length of the data to be sent that was defined with the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS parameter below).
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- With data types STRING and WSTRING, all data is transferred if the parameter LEN = 0. When LEN > 0, the length must be at least the maximum number of bytes plus two additional bytes which contain the length information. You will find more detailed information on the structure of the data types in: "Overview of the valid data types (Page 2239)".
- The maximum number of bytes that can be transmitted depends on the device.
- When you use structured tags from optimized DBs, the address of the structured tag should be interconnected at the DATA parameter and the parameter LEN = 0. This guarantees type-safe transmission of the entire structure if the same structure is used at the receiving end.

BUSY, DONE and ERROR parameters

You can check the status of the job with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the DONE parameter, you can check whether or not a job executed successfully. The ERROR parameter is set if errors occur during execution of "TSEND". The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ERROR	Description
1	0	0	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is specified in the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TSEND" is executed asynchronously, you must keep the data in the send area consistent until the DONE parameter or the ERROR parameter changes to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Description
0	0000	Send job completed without error.
0	7000	No job processing active.
0	7001	Start of job execution, data is being sent. When processing this job, the operating system accesses the data in the DATA send area.
0	7002	Job executing (REQ irrelevant). When processing this job, the operating system accesses the data in the DATA send area.
1	8085	• The LEN parameter is larger than the highest permitted value. For S7-1200: 8192; for S7-1500 (TCP): 65536; for S7-1500 (FDL): 240 / 236 • DATA and LEN parameters both have the value "0".
1	8086	The ID parameter is outside the permitted address range (1..0xFFF).
1	8088	The LEN parameter is greater than the area specified in DATA.
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Transfer via this connection is not possible. • The interface is being re-initialized.
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (ConnectionType parameter in the connection description) is set to UDP. Use the instruction "TUSEND" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.

ERROR	STATUS* (W#16#...)	Description
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established. • Temporarily no receive resources available at the connection partner. The connection partner is not ready to receive.
1	80C5	• Connection terminated by the communication partner. • LSAP of the remote connection partner is not released
1	80C6	Network error: • Remote partner cannot be reached. • Physical interruption on PROFIBUS
1	80C7	Execution timeout.
1	80EE	Handshake not yet completed
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

You can find the example here: Program example for TCON, TDISCON, TSEND & TRCV (Page 4502).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Difference between synchronous and asynchronous instructions (Page 2571)

TRCV: Receive data via communication connection (S7-1200, S7-1500)

TRCV: Receive data via communication connection (S7-1200)

Description

The following description of the "TRCV" instruction is valid for the CPU S7-1200 up to version 3.0.

You use the "TRCV" instruction to receive data over an existing communication connection. "TRCV" executes asynchronously.

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used.

While data is being received, you cannot make changes to the DATA parameter or the defined receive area to ensure consistency of the received data.

After successful receipt of data, the NDR parameter is set to the value "1". You can query the amount of data actually received at the RCVD_LEN parameter.

Receive modes of "TRCV"

The following table shows how the received data is entered in the receive area.

Protocol variant	Availability of data in the receive area	connection_type* parameter of the connection description	Parameter LEN
TCP (Ad-hoc mode)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	0
TCP (Receipt of data with specified length)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	1 to 8192
ISO on TCP (Message-oriented data transfer)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• 1 to 1452, if a CP is used. • 1 to 8192, if no CP is used.
* See "AUTOHOTSPOT".			

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "0" to the LEN parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.). When ad-hoc mode is active, receipt of data is already signaled after a received byte at the NDR parameter.

TCP (Receipt of data with specified length)

For receipt of data with a specified length, enter the length of the data at the LEN parameter. The data receipt is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV" signals data receipt as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV" signals an error. The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameter

The following table shows the parameters of the "TRCV" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Receive enable
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON (Page 4474)". Value range: W#16#0001 (1) to W#16#0FFF (4095)
LEN	Input	UINT	I, Q, M, D, L or constant	Length of the receive area in bytes (hidden). If you use a memory area with optimized access at the DATA parameter, the LEN parameter must have the value "0".
DATA	InOut	VARIANT	I, Q, M, D	Pointer to the receive area When transferring structures, the structures must be identical at the sending and receiving end.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter (New Data Received): • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error. • 1: An error occurred during execution of the instruction. Detailed information is output via the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter: Output of status and error information.
RCVD_LEN	Output	UINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

LEN, DATA and RCVD_LEN parameters

- If LEN = 0, the received data is saved in the receive area specified at the DATA parameter. The number of bytes received is indicated at the RCVD_LEN parameter.
  With LEN = 0 (default setting of the LEN parameter), the length of the data to be received is defined by the DATA parameter. It is recommended that the receive area (DATA parameter) has the same size as the data to be transmitted by TSEND.
  If LEN has the value 0 and the sent data was transferred in segments that are smaller than the DATA receive area, the following applies. It is recommended to keep EN_R set until the associated TSEND instruction has sent all data. STATUS shows the value 7002 as long as the size of the data sent by TSEND is not equal to the size of the DATA receive area. EN_R must be set until the amount of the received data is equal to the size of the DATA receive area. If you pulse EN_R, you must do so until BUSY=0 or ERROR <> 0.
  The data in the DATA receive area is only valid when BUSY has the value 0.
- If the length specified at the LEN parameter is greater than the length of the data received at the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS) parameter in the following.
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- If the DATA parameter references a data block with optimized access, the LEN parameter must be set to "0".
- If a STRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=2 (LEN = 1 is not permitted).
- If a WSTRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=5.

BUSY, NDR and ERROR parameters

You can check the status of the job with the BUSY, NDR, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the NDR parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of TRCV. The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, NDR and ERROR parameters:

BUSY	NDR	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TRCV" is executed asynchronously, the data in the receive area is only consistent when the NDR parameter is set to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Job completed successfully. The current length of the received data is output at the RCVD_LEN parameter.
0	7000	Block not ready to receive.
0	7001	Block is ready to receive, receive job was activated.
0	7002	Interim call, the receive job is executing. Note: While the job is being processed, data is written to the receive area. Access to the receive area during this time may provide inconsistent data.
1	8085	• The LEN parameter is larger than the highest permitted value. • The value of the LEN or DATA parameter was changed after the first call. • Both LEN parameters and the DATA parameter have the value "0" or LEN is longer than the maximum permitted value (65536).
1	8086	The ID parameter is outside the permitted address range (1 .. 0x0FFF).
1	8088	• Receive area is too small. • The value at the LEN parameter is larger than the receive area set at the DATA parameter.
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Receive job over this connection is not possible. • The connection is being re-initialized.
1	80B3	The protocol variant (connection_type parameter in the connection description) is set to UDP. Use the instruction "TURCV" with a UDP connection.
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	The remote partner has terminated the connection.
1	80C6	The remote partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C9	The length of the receive area is smaller than the length of the sent data.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".

Difference between synchronous and asynchronous instructions (Page 2571)

TRCV: Receive data via communication connection (S7-1200, S7-1500)

Description

The following description of the "TRCV" instruction is valid for:

- Ethernet
  CPU S7-1200 with firmware version ≥ V4.0 and CPU S7-1500
- PROFIBUS
  FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL

You use the "TRCV" instruction to receive data over an existing communication connection. "TRCV" executes asynchronously.

Receipt of data is enabled when the EN_R parameter is set to the value "1". The received data is entered in a receive area. You specify the length of the receive area either with the LEN parameter (if LEN <> 0) or with the length information of the DATA parameter (if LEN = 0), depending on the protocol variant being used.

While data is being received, you cannot make changes to the DATA parameter or the defined receive area to ensure consistency of the received data.

After successful receipt of data, the NDR parameter is set to the value "1". You can query the amount of data actually received at the RCVD_LEN parameter.

Receive modes of "TRCV"

The following table shows how the received data is entered in the receive area.

Protocol variant	Parameter ADHOC	Availability of data in the receive area	connection_type parameter of the connection description	Parameter LEN
TCP (Ad-hoc mode)	1 (ad-hoc activated)	The data is immediately available.	Hexadecimal value: B#16#11 Integer value: 17	As much data will be read as is currently available; not exceeding the data length specified by LEN. LEN = 0 (recommended): Length of the receive area referenced by DATA
TCP (Receipt of data with specified length)	0 (ad-hoc deactivated)	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#11 Integer value: 17	• S7-1200: 1 to 8192 • S7-1500: 1 to 65536
ISO on TCP (Message-oriented data transfer)	-	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#12 Integer value: 18	• S7-1200: 1 to 8192 • S7-1500: 1 to 65536
FDL	-	The data is available as soon as the data length specified at the LEN parameter has been fully received.	Hexadecimal value: B#16#15 Decimal: 21	1 to 240

TCP (Ad-hoc mode)

The ad-hoc mode is only available with the TCP protocol variant. You use the ad-hoc mode to receive data with dynamic length with the "TRCV" instruction.

You set ad-hoc mode by assigning the value "1" to the ADHOC parameter. When ad-hoc mode is active, receipt of data is already signaled after a received byte at the NDR parameter. All data types can be used for data blocks with standard access when you use ad-hoc mode. Only ARRAY of BYTE or data types with a length of 8 bits can be used for data blocks with optimized access (e.g., CHAR, USINT, SINT, etc.).

TCP (Receipt of data with specified length)

Assign the value "0" to the ADHOC parameter for receipt of data with specified length. If ad-hoc mode is disabled, the data reception is not complete until the length of data specified at the LEN parameter has been completely received. Only then is the data available in the receive area (DATA parameter). The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

ISO on TCP (Message-oriented data transfer)

Complete message blocks are sent via a connection with the protocol variant ISO on TCP; these are recognized as such by the recipient. When using ISO on TCP, "TRCV" signals data receipt as soon as the message block has been completely received. The receive area is defined by the LEN and DATA parameters. If the receive buffer (DATA parameter) is too small for the sent data, "TRCV" signals an error. The successful receipt of data is signaled by the NDR output parameter. The actually received data length in bytes at the RCVD_LEN parameter corresponds to the data length at the LEN parameter after receipt.

Parameter

The following table shows the parameters of the instruction "TRCV":

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Receive enable
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection established with "TCON". Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Length of the receive area in bytes (hidden) Maximum value for S7-1200: 8192; maximum value for S7-1500: 65536; maximum value for CM 1542-5 (FDL): 240. If you use a receive area with optimized access at the DATA parameter, the LEN parameter must have the value "0".
ADHOC	Input	BOOL	I, Q, M, D, L or constant	Use ad-hoc mode for the TCP protocol variant (hidden).

Parameter	Declaration	Data type	Memory area	Description
DATA	InOut	VARIANT	I, Q, M, D, L	Pointer to the receive area When transferring structures, the structures must be identical at the sending and receiving end.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter (New Data Received): • 0: Job not yet started or still in progress • 1: New data received
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

LEN, DATA and RCVD_LEN parameters

- If LEN = 0, the received data is saved in the receive area specified at the DATA parameter. The number of bytes received is indicated at the RCVD_LEN parameter.
  With LEN = 0 (default setting of the LEN parameter), the length of the data to be received is defined by the DATA parameter. It is recommended that the receive area (DATA parameter) has the same size as the data to be transmitted by TSEND.
  If LEN has the value 0 and the sent data was transferred in segments that are smaller than the DATA receive area, the following applies. It is recommended to keep EN_R set until the associated TSEND instruction has sent all data. STATUS shows the value 7002 as long as the size of the data sent by TSEND is not equal to the size of the DATA receive area. EN_R must be set until the amount of the received data is equal to the size of the DATA receive area. If you pulse EN_R, you must do so until BUSY=0 or ERROR <> 0.
  The data in the DATA receive area is only valid when BUSY has the value 0.
- If the length specified at the LEN parameter is greater than the length of the data received at the DATA parameter, the error code 8088 is output at the STATUS parameter (see description of the STATUS) parameter in the following.
- If a structure (Struct) is referenced via the DATA parameter, LEN can be shorter than the structure. In this case, only the data up to the length of the LEN parameter is transferred.
- If the DATA parameter references a data block with optimized access, the LEN parameter must be set to "0". If the length of the data does not match for elementary data types, the data will not be received and the error code 8088 is output at the STATUS parameter.
- If a STRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=2 (LEN = 1 is not permitted).
- If a WSTRING data type is referenced via the DATA parameter, the length specified at the LEN parameter must be 0 or >=5.

BUSY, NDR and ERROR parameters

You can check the status of the job with the BUSY, NDR, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. With the NDR parameter, you can check whether or not a job executed successfully. The ERROR parameter is set when errors occurred during execution of TRCV. The error information is output at the STATUS parameter.

The following table shows the relationship between the BUSY, NDR and ERROR parameters:

BUSY	NDR	ERROR	Description
1	-	-	The job is being processed.
0	1	0	The job was completed successfully.
0	0	1	The job ended with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new job was assigned.

Note

Because "TRCV" is executed asynchronously, the data in the receive area is only consistent when the NDR parameter is set to the value "1".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Job completed successfully. The current length of the received data is output at the RCVD_LEN parameter.
0	7000	Block not ready to receive.
0	7001	Block is ready to receive, receive job was activated.
0	7002	Interim call, the receive job is executing. Note: While the job is being processed, data is written to the receive area. Access to the receive area during this time may provide inconsistent data.
1	8085	• The LEN parameter is greater than the maximum permissible value (for S7-1200: 8192 bytes, for S7-1500: 65536 bytes). • The value of the LEN or DATA parameter was changed after the first call. • Both LEN parameters and the DATA parameter have the value "0" or LEN is longer than the maximum permissible value (for S7-1200): 8192 bytes, for S7-1500: 65536 bytes).
1	8086	The ID parameter is outside the permitted value range (1 .. 0x0FFF).
1	8088	• Receive area is too small. • The value at the LEN parameter is larger than the receive area set at the DATA parameter.
1	80A1	Communication error: • The specified connection has not yet been established. • The specified connection is being terminated. Receive job over this connection is not possible. • The connection is being re-initialized.
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (connection_type parameter in the connection description) is set to UDP. Use the instruction "TURCV" with a UDP connection.

ERROR	STATUS* (W#16#...)	Explanation
1	80C3	• A block with this ID is already being processed in a different priority group. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection cannot be established to the partner at this time. • The interface is receiving new parameter settings or the connection is being established.
1	80C5	The remote partner has terminated the connection.
1	80C6	The remote partner cannot be reached (network error).
1	80C7	Execution timeout.
1	80C9	The length of the receive area is smaller than the length of the sent data.
1	80EE	Handshake not yet completed
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

You can find the example here: Program example for TCON, TDISCON, TSEND & TRCV (Page 4502).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

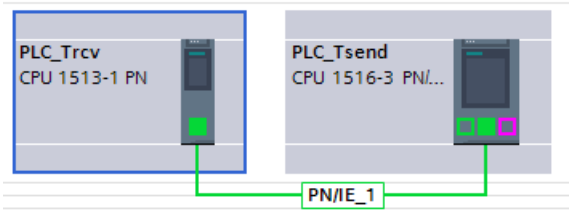
Difference between synchronous and asynchronous instructions (Page 2571)



Program example for TCON, TDISCON, TSEND & TRCV (S7-1200, S7-1500)

Introduction

In the following example, you create a programmed connection between two CPUs of the S7-1500 series and send a data record from CPU 1 to CPU 2.

Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. Their connection is not yet configured.

- A low protection level under Properties > Protection ensures that read and write access is permitted for each CPU.

Program of CPU 1: Storage of data

For the data record, create the following PLC data type.

TSEND_User

	Name	Data type	Default value
1	prename	String	''
2	lastname	String	''
3	userId	UInt	0

For the data transfer, create the following data block ("SLI_plcDB_sendData_TSEND") based on the created PLC data type.

SLI_plcDB_sendData_TSEND

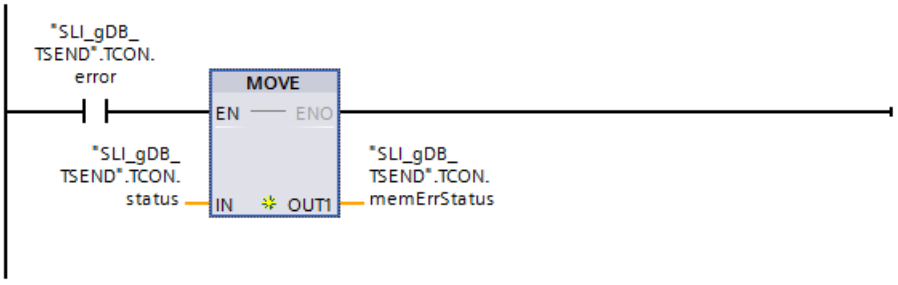
	Name	Data type	Start value
1	Static		
2	prename	String	'Simon'
3	lastname	String	'Sample'
4	userId	UInt	1

To store the data, create a global data block ("SLI_gDB_TSEND") with the following structures and tags.

SLI_gDB_TSEND

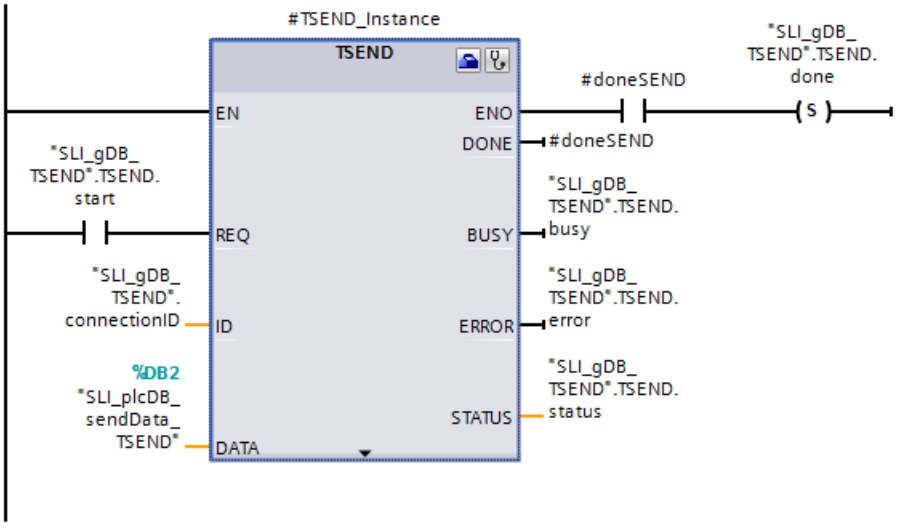
	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	1
3	TCON	Struct	
4	start	Bool	false
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStatus	Word	16#0
10	TSEND	Struct	
11	start	Bool	false
12	maxLength	UInt	0
13	busy	Bool	false
14	done	Bool	false
15	error	Bool	false
16	status	Word	16#0
17	memErrStatus	Word	16#0
18	TDISCON	Struct	
19	start	Bool	false
20	busy	Bool	false
21	done	Bool	false
22	error	Bool	false
23	status	Word	16#0
24	memErrStatus	Word	16#0

Program of CPU 1: Interconnect parameters

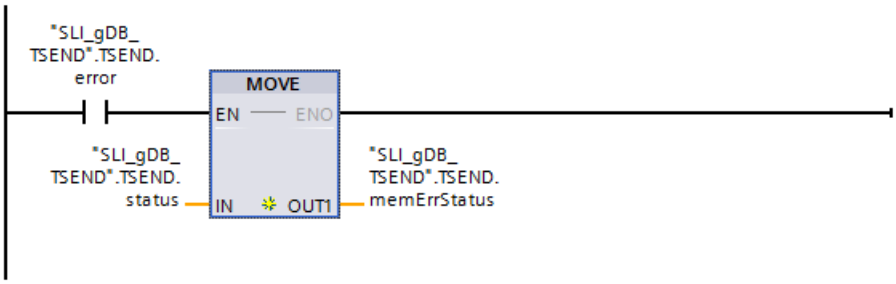


Create the FB "SLI_FB_TSEND" Create the following local tags in it.

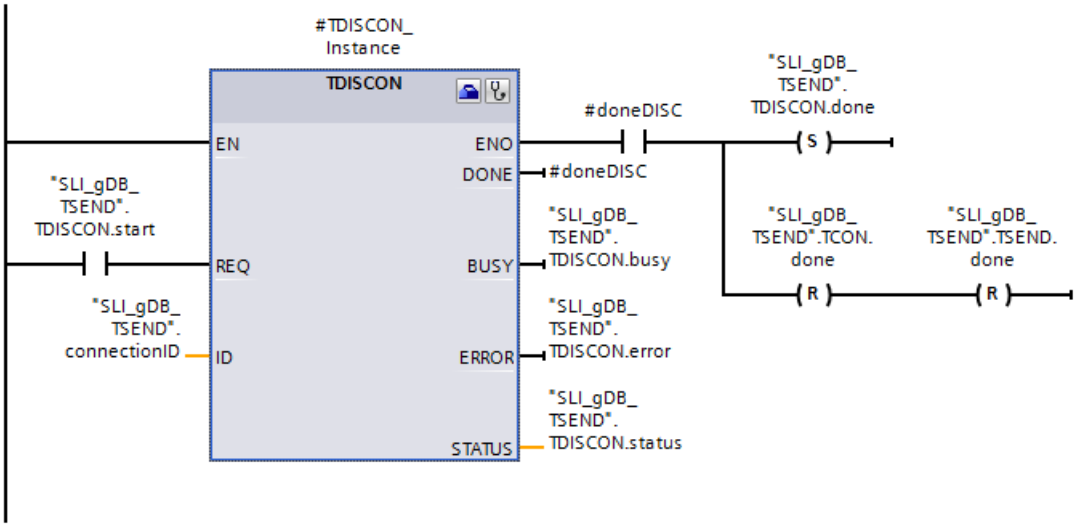
7	Static			
8	TCON_Instance	TCON		
9	TSEND_Instance	TSEND		
10	TDISCON_Instance	TDISCON		
11	doneCON	Bool	false	Non-retain
12	doneSEND	Bool	false	Non-retain
13	doneDISC	Bool	false	Non-retain



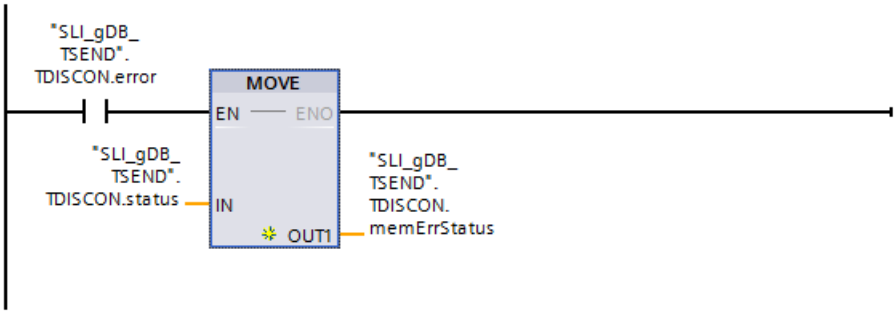
Network 1: Interconnect the parameter of the instruction "TCON" as follows:



Network 2: In case of error of TCON, save the status as follows.



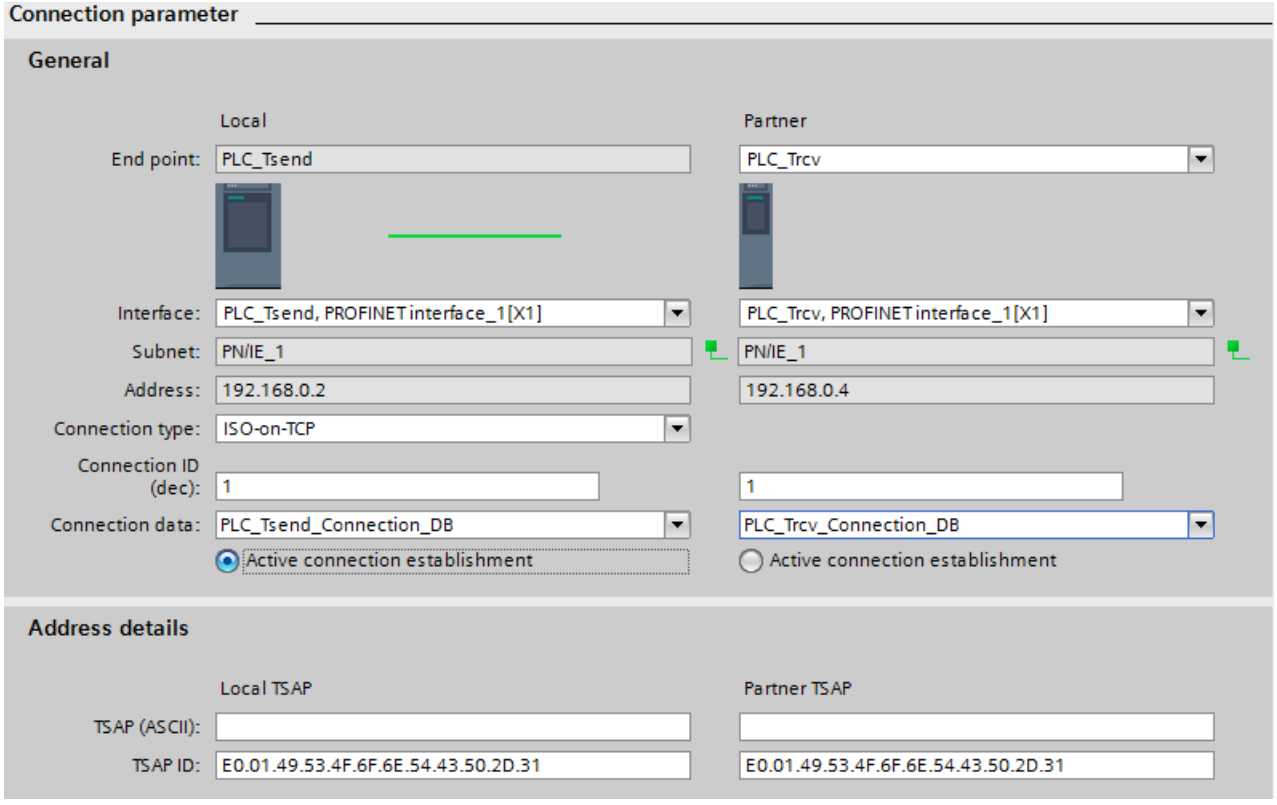
Network 3: Interconnect the parameter of the instruction "TSEND" as follows:



Network 4: In case of error of TSEND, save the status as follows.

Network 5: Interconnect the parameter of the instruction "TDISCON" as follows:

Network 6: In case of error of TDISCON, save the status as follows.



Program of CPU 1: Configuration of TCON

To interconnect the input parameter CONNECT, open the wizard of the "TCON" instruction with its Properties > Configuration.

Make the following settings for the configuration of TCON:

Input field	Entry
End point	Select a CPU for sender and receiver using the drop-down list. Interface, subnet and address are entered automatically.
Connection data	Use the drop-down list and the selection "New" to create one data block per CPU. This data block is required for storing the connection data. The name of the data block can be freely selected. The active connection establishment is enabled for CPU 1 (local CPU).
Connection type	Select the entry "ISO-on-TCP". This means an Ethernet connection with the "ISO-on-TCP" protocol is used for connection setup.
Connection ID	You enter a freely selected connection ID for the communication connection. The connection ID must not already be assigned in the project. Ensure that the value matches the value of the "connectionID" tag that is used.
TSAP ID	The address details are automatically entered during the selection of the connection type "ISO-on-TCP".

Program of CPU 2: Storage of data

For the data record, create the following PLC data type.

TSEND_User

	Name	Data type	Default value
1	prename	String	''
2	lastname	String	''
3	userId	UInt	0

For the data transfer, create the following data block ("SLI_plcDB_rcvData_TRCV") based on the created PLC data type.

SLI_plcDB_rcvData_TRCV

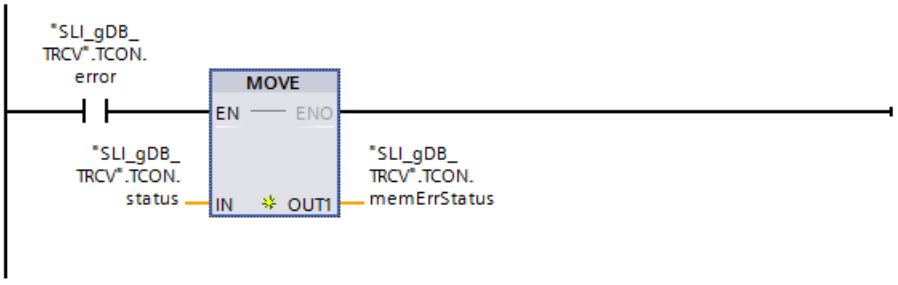
	Name	Data type	Start value
1	Static		
2	prename	String	''
3	lastname	String	''
4	userId	UInt	0

To store the data, create a global data block ("SLI_gDB_TRCV") with the following structures and tags.

SLI_gDB_TRCV

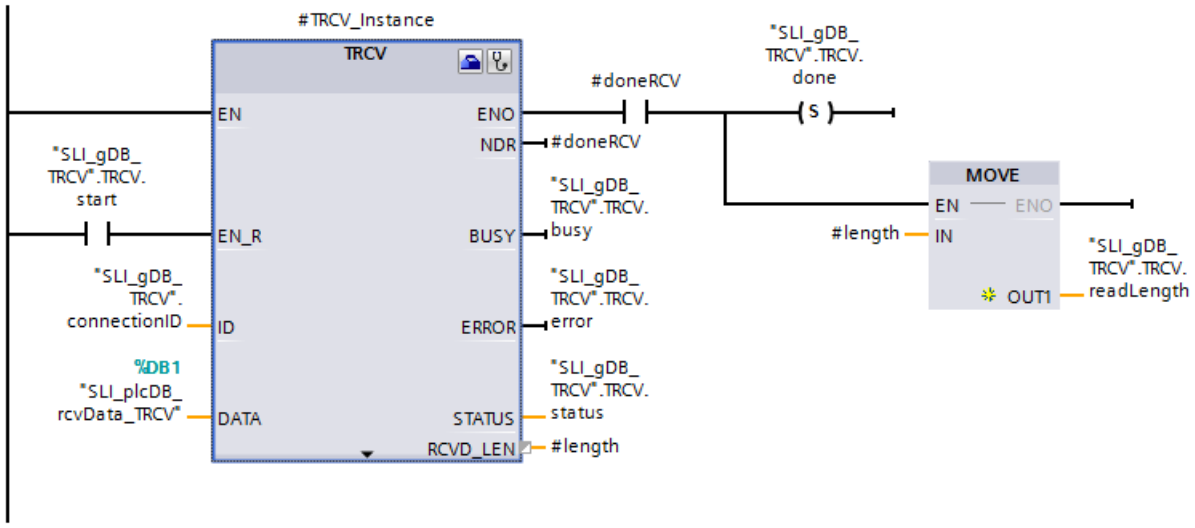
	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	1
3	TCON	Struct	
4	start	Bool	false
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStatus	Word	16#0
10	TRCV	Struct	
11	start	Bool	false
12	busy	Bool	false
13	done	Bool	false
14	error	Bool	false
15	status	Word	16#0
16	memErrStatus	Word	16#0
17	readLength	UInt	0
18	TDISCON	Struct	
19	start	Bool	false
20	busy	Bool	false
21	done	Bool	false
22	error	Bool	false
23	status	Word	16#0
24	memErrStatus	Word	16#0

Program of CPU 2: Interconnect parameters

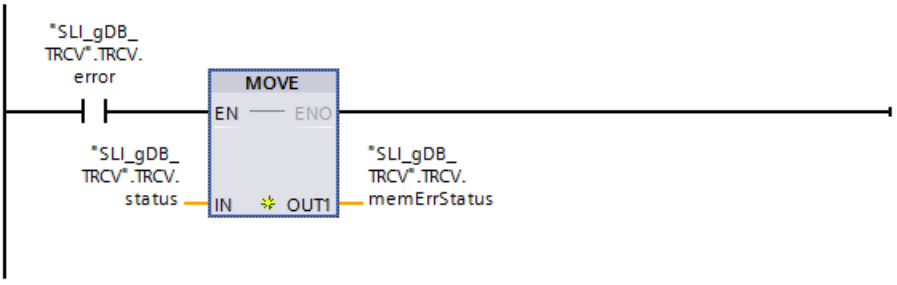


Create the FB "SLI_FB_TRCV" Create the following local tags in it.

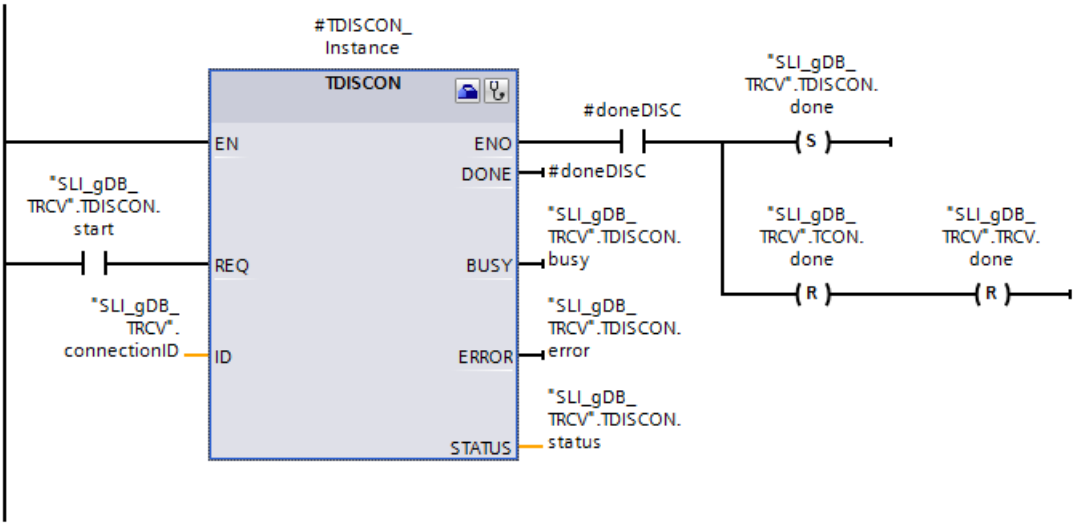
7		Static			
8		doneCON	Bool	false	Non-ret...
9		doneRCV	Bool	false	Non-retain
10		doneDISC	Bool	false	Non-retain
11		length	UInt	0	Non-retain
12		TCON_Instance	TCON		
13		TRCV_Instance	TRCV		
14		TDISCON_Instance	TDISCON		



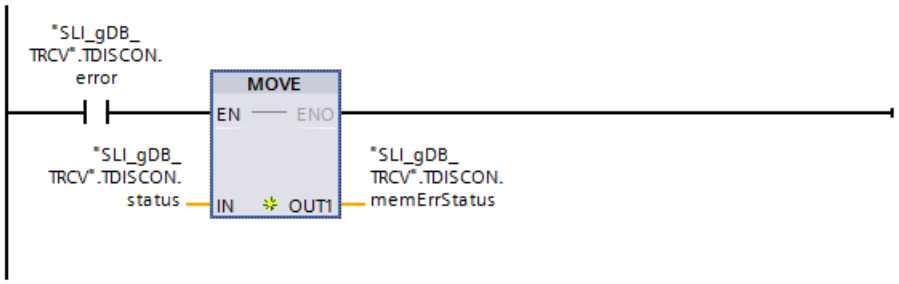
Network 1: Interconnect the parameter of the instruction "TCON" as follows:



Network 2: In case of error of TCON, save the status as follows.



Network 3: Interconnect the parameter of the instruction "TRCV" as follows:

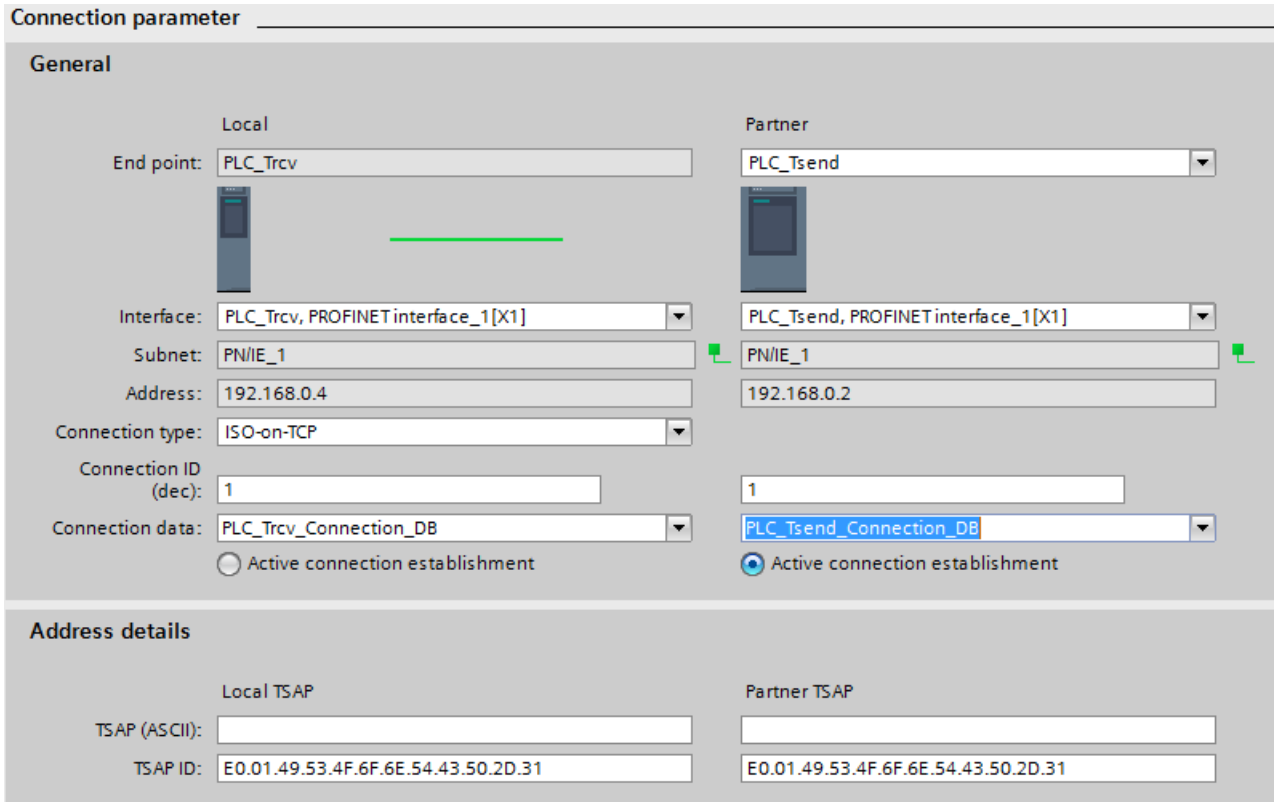


Network 4: In case of error of TRCV, save the status as follows.

Network 5: Interconnect the parameter of the instruction "TDISCON" as follows:

Network 6: In case of error of TDISCON, save the status as follows.

Program of CPU 2: Configuration of TCON



You make the following settings for the connection of CPU 2 / TCON according to the example of CPU 1 / TCON:

Note

Connection data

By configuring CPU 1 / TCON, you have already created a data block ("PLC_Tsend_Connection_DB", "PLC_Trcv_Connection_DB") with the stored connection data for each CPU. Instead of creating new data blocks and entering the connection data, you can simply use the created data blocks ("PLC_Tsend_Connection_DB", "PLC_Trcv_Connection_DB").

For the created data blocks to be available for selection, they must still be available in the project tree under Program blocks > System blocks.

Procedure for establishing connection

Observe the order of the action steps:

1. Change the parameter REQ to "TRUE" for CPU 2 / TCON.
2. Change the parameter REQ to "TRUE" for CPU 1 / TCON.
3. Change the parameter REQ to "FALSE" for CPU 2 / TCON.
4. Change the parameter REQ to "FALSE" for CPU 1 / TCON.

Procedure for terminating connection

Observe the order of the action steps:

1. Change the parameter REQ to "TRUE" for CPU 1 / TDISCON.
2. Change the parameter REQ to "TRUE" for CPU 2 / TDISCON.
3. Change the parameter REQ to "FALSE" for CPU 1 / TDISCON.
4. Change the parameter REQ to "FALSE" for CPU 2 / TDISCON.

Behavior of CPU 1

Network 1 (TCON):

When the input parameter REQ ("TCON.start") supplies the signal state "TRUE", the "TCON" instruction is started. For multiple calls, the "TCON" instruction creates a communication connection to the partner CPU. To do this, the connection data is retrieved with the input parameter CONNECT (data block "PLC_Trcv_Connection_DB").

Successful connection setup is indicated by the output parameter DONE ("#doneCON") with the signal state "TRUE" and the output parameter STATUS ("TCON.status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "TCON.done". Reset the success status of any previous connection termination ("TDISCON.done").

The output parameter ERROR ("TCON.error") or the tag "TCON.memErrStatus" indicates that processing in the example is taking place without errors.

3		TCON	Struct		
4		start	Bool	false	TRUE
5		busy	Bool	false	FALSE
6		done	Bool	false	TRUE
7		error	Bool	false	FALSE
8		status	Word	16#0	16#7000
9		memErrStatus	Word	16#0	16#0000

Network 2 (TCON):

When TCON signals an error ("TCON.error" is "TRUE"), the reported status ("TCON.status") is stored permanently ("TCON.memErrStatus").

Network 3 (TSEND):

Based on the input parameter ID ("connectionID"), the "TSEND" instruction knows the communication connection to be used.

When the input parameter REQ ("TSEND.start") supplies the signal state "TRUE", the "TSEND" instruction is started. For multiple calls, the "TSEND" instruction transmits the data record detected at input parameter DATA ("SLI_plcDB_sendData_TSEND").

Successful transfer of the data record is indicated by the output parameter DONE ("#doneSEND") with the signal state "TRUE" and the output parameter STATUS ("TSEND.status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "TSEND.done".

The output parameter ERROR ("TSEND.error") or the tag "TSEND.memErrStatus" indicates that processing in the example is taking place without errors.

10		TSEND	Struct		
11		start	Bool	false	TRUE
12		maxLength	UInt	0	0
13		busy	Bool	false	FALSE
14		done	Bool	false	TRUE
15		error	Bool	false	FALSE
16		status	Word	16#0	16#7000
17		memErrStatus	Word	16#0	16#0000

Network 4 (TSEND):

When TSEND signals an error ("TSEND.error" is "TRUE"), the reported status ("TSEND.status") is stored permanently ("TSEND.memErrStatus").

Network 5 (TDISCON):

When the input parameter REQ ("TDISCON.start") supplies the signal state "TRUE", the "TDISCON" instruction is started. For multiple calls, the instruction "TDISCON" terminates the communication connection. The communication connection used at the input parameter ID ("connectionID") is retrieved for this purpose.

Successful connection termination is indicated by the output parameter DONE ("#doneDISC") with the signal state "TRUE" and the output parameter STATUS ("TDISCON.status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "TDISCON.done". Reset the success messages for connection setup ("TCON.done") and for data transfer ("TSEND.done").

The output parameter ERROR ("TDISCON.error") or the tag "TDISCON.memErrStatus" indicates that processing in the example is taking place without errors.

18		TDISCON	Struct		
19		start	Bool	false	TRUE
20		busy	Bool	false	FALSE
21		done	Bool	false	TRUE
22		error	Bool	false	FALSE
23		status	Word	16#0	16#7000
24		memErrStatus	Word	16#0	16#0000

Network 6 (TDISCON):

When TDISCON signals an error ("TDISCON.error" is "TRUE"), the reported status ("TDISCON.status") is stored permanently ("TDISCON.memErrStatus").

Behavior of CPU 2

For TCON and TDISCON, the behavior is the same as that for CPU 1.

3		TCON	Struct		
4		start	Bool	false	TRUE
5		busy	Bool	false	FALSE
6		done	Bool	false	TRUE
7		error	Bool	false	FALSE
8		status	Word	16#0	16#7000
9		memErrStatus	Word	16#0	16#0000

18		TDISCON	Struct		
19		start	Bool	false	TRUE
20		busy	Bool	false	FALSE
21		done	Bool	false	TRUE
22		error	Bool	false	FALSE
23		status	Word	16#0	16#7000
24		memErrStatus	Word	16#0	16#0000

Network 3 (TRCV):

Based on the input parameter ID ("connectionID"), the "TRCV" instruction knows the communication connection to be used.

When the input parameter EN_R ("TRCV.start") supplies the signal state "TRUE", the "TRCV" instruction is started. For multiple calls, the "TRCV" instruction receives the transmitted data record. The data record is detected at the input parameter DATA ("SLI_plcDB_rcvData_TRCV").

SLI_plcDB_rcvData_TRCV

	Name	Data type	Start value	Monitor value
1	Static			
2	prename	String	''	'Simon'
3	lastname	String	''	'Sample'
4	userId	UInt	0	1

The length in BYTE of the actually transmitted data record is detected with the output parameter LEN ("#length"). This value is only displayed during the success status. Then "0" is detected. Successful receipt of the data record is indicated by the output parameter DONE ("#doneRCV") with the signal state "TRUE" and the output parameter STATUS ("TRCV.status") with the value "0000".

Because the values of the output parameters are only displayed for the moment of their validity, do the following:

- Save the success status in the tag "TRCV.done"
- Save the length in BYTE in the tag "TRCV.readLength".

The output parameter ERROR ("TRCV.error") or the tag "TRCV.memErrStatus" indicates that processing in the example is taking place without errors.

10	TRCV	Struct		
11	start	Bool	false	TRUE
12	busy	Bool	false	TRUE
13	done	Bool	false	TRUE
14	error	Bool	false	FALSE
15	status	Word	16#0	16#7002
16	memErrStatus	Word	16#0	16#0000
17	readLength	UInt	0	514

Network 4 (TRCV):

When TRCV signals an error ("TRCV.error" is "TRUE"), the reported status ("TRCV.status") is stored permanently ("TRCV.memErrStatus").

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

TCON: Establish communication connection (Page 4478)

TDISCON: Terminate communication connection (Page 4484)

TSEND: Send data via communication connection (Page 4490)

TRCV: Receive data via communication connection (Page 4498)

Sending and receiving data via Ethernet (UDP) or FDL (S7-1200, S7-1500)

TUSEND: Sending data (S7-1200, S7-1500)

Description

TUSEND supports data transfer via UDP (for S7-1500-CPUs as of firmware version V2.0 and higher via the integrated PROFINET interfaces also as multicast communication) and via FDL connections of the S7-1500 with CM 1542-5 as of V2.0 with the system data type TCON_FDL.

The "TUSEND" instruction sends data to the communication partner addressed by the ADDR parameter.

WARNING

Data transfer via UDP

When transferring data with UDP according to RFC 768, the data is transferred to the partner without acknowledgement and therefore non-securely. This means that data can be lost without this being indicated by the block.

Note

For sequential send operations to different partners, you only need to adjust the ADDR parameter when calling "TUSEND". You do not need to call the "TCON (Page 4474)" and "TDISCON (Page 4484)" instructions again. The UDP port must be set up at the specific partner in order for this partner to receive data.

Functional description

The TUSEND" instruction works asynchronously, which means its job processing extends over multiple calls. Create a rising edge at the REQ parameter to establish a connection once again.

The output parameters BUSY, DONE, ERROR and STATUS indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571).

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can determine the current status of "TUSEND" or when the send process is concluded.

BUSY	DONE	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the STATUS parameter.
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Note

Due to the asynchronous operation of "TUSEND", make sure the data in the send area remains consistent until the DONE parameter or the ERROR parameter has the value TRUE.

Parameter

The following table shows the parameters of the instruction "TUSEND":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter REQUEST starts the send job on a rising edge. The data is transferred from the area specified by DATA and LEN.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the associated connection between the user program and the communication layer of the operating system. ID must be identical to the associated parameter ID in the local connection description with the .TCON instruction: Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Number of bytes to be sent with the job Value range for Ethernet/UDP: 1 to 1472 For FDL connections of the CM 1542-5, the maximum length is 240 bytes. In this regard, note the maximum lengths that can be processed by the connection partner.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE: • 0: Job not yet started or still executing. • 1: Job executed without errors. This value is only displayed for one cycle.
BUSY	Output	BOOL	I, Q, M, D, L	• BUSY = 1: The job is not yet complete. A new job cannot be triggered. • BUSY = 0: Job is complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • ERROR = 1: An error occurred during processing. STATUS supplies detailed information on the type of error

Parameter	Declaration	Data type	Memory area	Description
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS: Error information
DATA	InOut	VARIANT	I, Q, M, D	Send area, contains address and length The address refers to: • The process image of the inputs • The process image of the outputs • A bit memory • A data block When transferring structures, the structures must be identical at the sending and receiving end.
ADDR	InOut	VARIANT	D	Address information of the communication partner See also: Addressing the remote partner via TADDR_Param (Page 4523) and Addressing the remote partner via TADDR_SEND_QDN and TADDR_RCV_IP (Page 4525) and AUTOHOTSPOT

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	Send job completed without error
0	7000	No job processing active
0	7001	Start of job processing, data being sent Note: During this processing phase, the operating system accesses the data in the DATA send area.
0	7002	Intermediate call (REQ irrelevant), job is being processed Note: During this processing phase, the operating system accesses the data in the DATA send area.
1	8085	The LEN parameter has the value "0" or is greater than the highest permitted value.
1	8086	The ID parameter is not in the permitted value range.
0	8088	The LEN parameter is greater than the memory area specified in DATA.
1	8089	The parameter ADDR does not point to a data block with the structure TADDR_Param or TADDR_SEND_QDN.
1	80A1	Communication error: • The specified connection between user program and communication layer of the operating system has not yet been established. • The specified connection between the user program and the communication layer of the operating system is currently being terminated. Transmission over this connection is not possible. • The interface is being reinitialized.
1	80B1	You changed the DATA parameter before the current job finished.

ERROR	STATUS* (W#16#...)	Explanation
1	80A4	IP address (at the ADDR parameter) of the remote connection end point is invalid; it may correspond to the local partner's own IP address.
1	80B3	• The protocol variant (connection_type parameter in the connection description) is not set to UDP. Please use "TSEND (Page 4490)". • Parameter ADDR: Invalid information for port no.
1	80B7	The length of the structure referenced by the parameter ADDR is not 8 bytes.
1	80C3	• A block with this ID is already being processed in a different priority class. • Internal lack of resources.
1	80C4	Temporary communication error: • The connection between the user program and the communication layer of the operating system cannot be established at this time. • New parameter settings are being assigned to the interface. • Temporarily no receive resources available at the connection partner. The connection partner is not ready to receive.
1	80C5	• Connection terminated by the communication partner. • LSAP of the remote connection partner is not released
1	80C6	Network error: • Remote partner cannot be reached. • Physical interruption on PROFIBUS
1	80C7	Execution timeout.
1	80D3	The fully qualified domain name could not be resolved. Possible causes: • The DNS server is not reachable, for example, because it has been shut down or the remote port is not reachable. • An error occurred during communication with the DNS server. • The DNS server returned a valid DNS answer, but the answer contained no IPv4 address.
1	80EA	DTLS (UDP) protocol is not supported
-	General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

You can find the example here: Program example for TUSEND & TURCV (Page 4526).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

TURCV: Receiving data (S7-1200, S7-1500)

Description

The "TURCV" instruction receives data via UDP (for S7-1500-CPUs as of firmware version V2.0 and higher via the integrated PROFINET interfaces also as multicast communication) and via FDL connections of the S7-1500 with CM 1542-5 as of V2.0. After successful completion of "TURCV", the ADDR parameter will show you the address of the remote partner (the sender).

⚠ WARNING

Unsecured data transfer

When transferring data with UDP according to RFC 768, the data is transferred to the remote partner without acknowledgement and is therefore unreliable. This means that data can be lost without this being indicated by the block.

Functional description

"TURCV" is an instruction that works asynchronously, which means its job processing extends over multiple calls. You start the receive job by calling "TURCV" with EN_R = 1.

The output parameters BUSY, DONE, ERROR and STATUS indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571).

The following table shows the relationship between BUSY, NDR and ERROR. Using this table, you can determine the current status of TURCV or when the receive process is concluded.

BUSY	NDR	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed. New data was received.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the STATUS parameter.
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Note

Due to the asynchronous operation of "TURCV", the data in the receive area is only consistent when the NDR parameter has the value TRUE.

Parameter

The following table shows the parameters of the instruction "TURCV":

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Control parameter enabled to receive When EN_R = 1, "TURCV" is ready to receive. The receive job is being processed.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the associated connection between the user program and the communication layer of the operating system. ID must be identical to the associated ID parameter in the local connection description. Value range: W#16#0001 to W#16#0FFF
LEN	Input	UDINT	I, Q, M, D, L or constant	Length of the receive area in bytes: 0 (recommended) or 1 to 1472 Maximum value for CM 1542-5 (FDL): 240
NDR	Output	BOOL	I, Q, M, D, L	Status parameter NDR: • NDR = 0: Job not yet started or still running. • NDR = 1: Job successfully completed
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR: • ERROR=1: An error occurred during processing. STATUS supplies detailed information on the type of error
BUSY	Output	BOOL	I, Q, M, D, L	• BUSY = 1: The job is not yet complete. A new job cannot be triggered. • BUSY = 0: Job is complete.
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS: Error information
RCVD_LEN	Output	UDINT	I, Q, M, D, L	Amount of data actually received in bytes
DATA	InOut	VARIANT	I, Q, M, D, L	Receive area The address references: • The process image of the inputs • The process image of the outputs • A bit memory • A data block When transferring structures, the structures must be identical at the sending and receiving end.
ADDR	InOut	VARIANT	D	Address information of the remote partner See also: Addressing the remote partner via TADDR_Param (Page 4523) and Addressing the remote partner via TADDR_SEND_QDN and TADDR_RCV_IP (Page 4525) and AUTOHOTSPOT

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

ERROR and STATUS parameters

ERROR	STATUS* (W#16#...)	Explanation
0	0000	New data was accepted. The current length of the received data is shown in RCVD_LEN.
0	7000	Block not ready to receive
0	7001	Block is ready to receive, receive job was activated
0	7002	Intermediate call, receive job being processed Note: During this processing phase, "TURCV" writes data to the receive area. For this reason, an error could result in inconsistent data in the receive area.
1	8085	The LEN parameter is greater than the largest permitted value, or you changed the value of the LEN or DATA parameter since the first call
1	8086	The ID parameter is not in the permitted value range
1	8088	• Receive area is too small • Value in LEN is higher than the receive area specified by DATA
1	8089	The parameter ADDR does not point to a data block with the structure TADDR_Param or TADDR_RCV_IP.
1	80A1	Communication error: • The specified connection between user program and communication layer of the operating system has not yet been established. • The specified connection between the user program and the communication layer of the operating system is currently being terminated. A receive job over this connection is not possible. • New parameter settings are being assigned to the interface.
1	80B1	You changed the DATA parameter before the current job finished.
1	80B3	The protocol variant (connection_type parameter in the connection description) is not set to UDP. Please use "TRCV (Page 4493)".
1	80B7	The length at ADDR parameter does not correspond to 8 bytes.
1	80C3	• A block with this ID is already being processed in a different priority class. • Internal lack of resources.
1	80C4	Temporary communication error: New parameter settings are being assigned to the interface.
1	80C5	The remote partner has terminated the connection.
1	80C7	Execution timeout.
1	80C9	With RFC1006 / UDP: The received data is longer than expected (size of receive buffer exceeded).
1	80EA	DTLS (UDP) protocol is not supported
-	General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Example

You can find the example here: Program example for TUSEND & TURCV (Page 4526).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

TDISCON: Terminate communication connection (Page 4484)

Addressing the remote partner via TADDR_Param (S7-1200, S7-1500)

Overview

When using a UDP connection, you can store the address information for the remote partner in the system data type TADDR_Param:

- With the "TUSEND (Page 4516)" instruction, you transfer the address information of the recipient at the parameter ADDR via TADDR_Param.
  The stored address data of the remote partner are read from the system data type by the instruction.

  Note

  Supporting a limited broadcast

  For S7-1500 CPUs as of firmware version V2.0, the following applies to the instruction "TUSEND": When addressing the remote partner via the "TADDR_Param" system data type, a limited broadcast (255.255.255.255 as the IP address of the remote partner) is supported with consistent compliance to IP routing rules. Accordingly, limited broadcasts are only sent over an interface through which a default router is accessible according to configuration.

  It is recommended to use of directed broadcast addresses because they - according to the IP standards - are not subject to this restriction.

- With the "TURCV (Page 4520)" instruction, you receive the address of the sender at the parameter ADDR via TADDR_Param.
  The address data is written by the instruction in the system data type.

Structure of the address information according to TADDR_Param

The system data type TADDR_Param contains the address information of the remote partner and consists of the IP address and the port number.

The system data type TADDR_Param has the following structure:

Byte	Parameter	Data type	Start value	Description
0 to 3	rem_ip_addr	ARRAY [1..4] of USINT	B#16#00 ...	• IP address of the remote partner, e.g. 192.168.002.003: – rem_ip_addr[1] = B#16#C0 (192) – rem_ip_addr[2] = B#16#A8 (168) – rem_ip_addr[3] = B#16#02 (002) – rem_ip_addr[4] = B#16#03 (003) The IP address can be taken from the Devices & networks view in the interface properties of the remote partner. As an alternative these are also displayed in the properties of the UDP connection under Address details. • Multicast address of an IPv4 multicast group (for the "TUSEND" instruction with S7-1500-CPUs as of firmware version V2.0 and higher. Note: For the "TURCV" instruction, the IP address of the sender must also be specified in case of multicast communication.)
4 to 5	rem_port_nr	UINT	B#16#00 ...	Remote port-number (for possible values, see: AUTOHOT-SPOT): • rem_port_nr[1] = high byte of the port no. in hexadecimal notation • rem_port_nr[2] = low byte of port no. in hexadecimal notation The port number can be taken from the Devices & networks view in the UDP connection properties. The port number is indicated under Address details as a decimal value. Example: Port number = 2000 (decimal) / W#16#07D0 (hexadecimal) • rem_port_nr[1] = 07 (high byte) • rem_port_nr[2] = D0 (low byte)
6 to 7	reserved	WORD	B#16#00 ...	Not used. Leave the value "0" at this parameter.

Creating TADDR_Param in a data block

You have the following options for creating TADDR_Param:

- Create a new data block and select TADDR_Param as type in the dialog "Add new data block".
- Open an existing data block create a new tag and enter in the column Data type TADDR_Param.

A data block can contain several system data types TADDR_Param.

Addressing the remote partner via TADDR_SEND_QDN and TADDR_RCV_IP (S7-1500)

Overview

For S7-1500 CPUs as of firmware version V2.0, you can address the recipient with its fully qualified domain name when sending data via UDP. With the instruction TUSEND at the parameter ADDR, you hereby reference a structure of the type TADDR_SEND_QDN.

The receiver can return an IPv4 or an IPv6 address. With the TURCV instruction at the ADDR parameter, you therefore reference a structure of the type TADDR_RCV_IP. Only this can include both IP address types.

Structure of the address information according to TADDR_SEND_QDN

The system data type TADDR_SEND_QDN contains the address information of the remote partner (of the receiver) and consists of the fully qualified domain name and port number.

It has the following structure:

Byte	Parameter	Data type	Start value	Description
0 to 255	RemoteQDN	ARRAY of STRING[1..254]	-	Fully qualified domain name of the partner end point, which must finish with "." Please note that the name including the concluding period must not exceed 254 characters in a SIMATIC environment.
256 to 257	RemotePort	UINT	B#16#00 ...	Remote port-number (for possible values, see: AUTOHOTSPOT): • RemotePort[1] = high byte of the port no. in hexadecimal notation • RemotePort[2] = low byte of port no. in hexadecimal notation Example: Port number = 2000 (decimal) / W#16#07D0 (hexadecimal) • RemotePort[1] = 07 (high byte) • RemotePort[2] = D0 (low byte)
258 to 259	reserved	WORD	W#16#00	Not used. Leave the value "0" at this parameter.

Note

Runtime of the instruction TUSEND

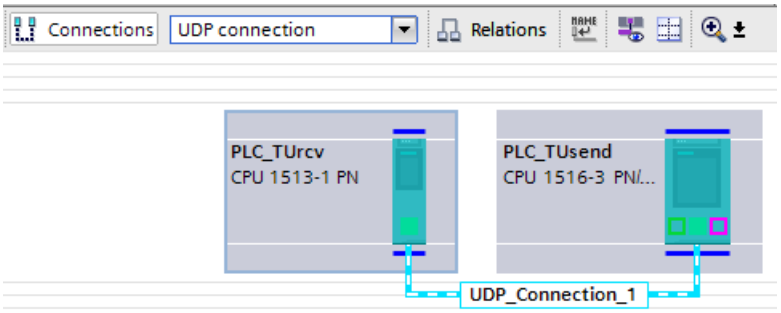
With each call of TUSEND, the fully qualified domain name is resolved in the IP address. As a result, the execution time of TUSEND is longer than if you address the receiver directly via its IPv4 address.

Structure of the address information according to TADDR_RCV_IP

The system data type TADDR_RCV_IP contains the address information of the remote partner (of the sender) and consists of the IP address, the port number and the information on whether the IP address is an IPv4 or IPv6 address.

It has the following structure:

Byte	Parameter	Data type	Start value	Description
0 to 15	RemoteAd-dress	ARRAY [1..16] of BYTE	B#16#00 ...	IP address of the remote partner, e.g. for the IPv4 address 192.168.002.003: • RemoteAddress[1] = B#16#C0 (192) • RemoteAddress[2] = B#16#A8 (168) • RemoteAddress[3] = B#16#02 (002) • RemoteAddress[4] = B#16#03 (003) The following applies to the IPv6 address.
16 to 17	RemotePort	UINT	B#16#00 ...	Remote port-number (for possible values, see: AUTOHOT-SPOT): • RemotePort[1] = high byte of the port no. in hexadecimal notation • RemotePort[2] = low byte of port no. in hexadecimal notation Example: Port number = 2000 (decimal) / W#16#07D0 (hex-adecimal) • RemotePort[1] = 07 (high byte) • RemotePort[2] = D0 (low byte)
18	RemAddr-Type	BYTE	B#16#00	Type of the remote address: • B#16#03: IPv4 • B#16#04: IPv6
19	reserved	BYTE	B#16#00	Not used. Leave the value "0" at this parameter.



Program example for TUSEND & TURCV (S7-1200, S7-1500)

Introduction

In the following example you create a configured UDP connection between two CPUs of the S7-1500 series. Transmit a data record from CPU1 to CPU2 using the instructions "TUSEND" and "TURCV".

Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. A UDP connection is configured.

- A low protection level under "<CPU> > Properties > Protection" ensures that read and write access is permitted for the CPUs.

Program of CPU 1

For the data record, create the following PLC data type "TUSEND_User".

TUSEND_User

	Name	Data type	Default value
1	prename	String	''
2	lastname	String	''
3	userId	UInt	0

For the data transfer, create the following data block ("SLI_plcDB_sendData_TUSEND") based on the PLC data type "TUSEND_User".

SLI_plcDB_sendData_TUSEND

	Name	Data type	Start value
1	Static		
2	prename	String	'Simon'
3	lastname	String	'Sample'
4	userId	UInt	1

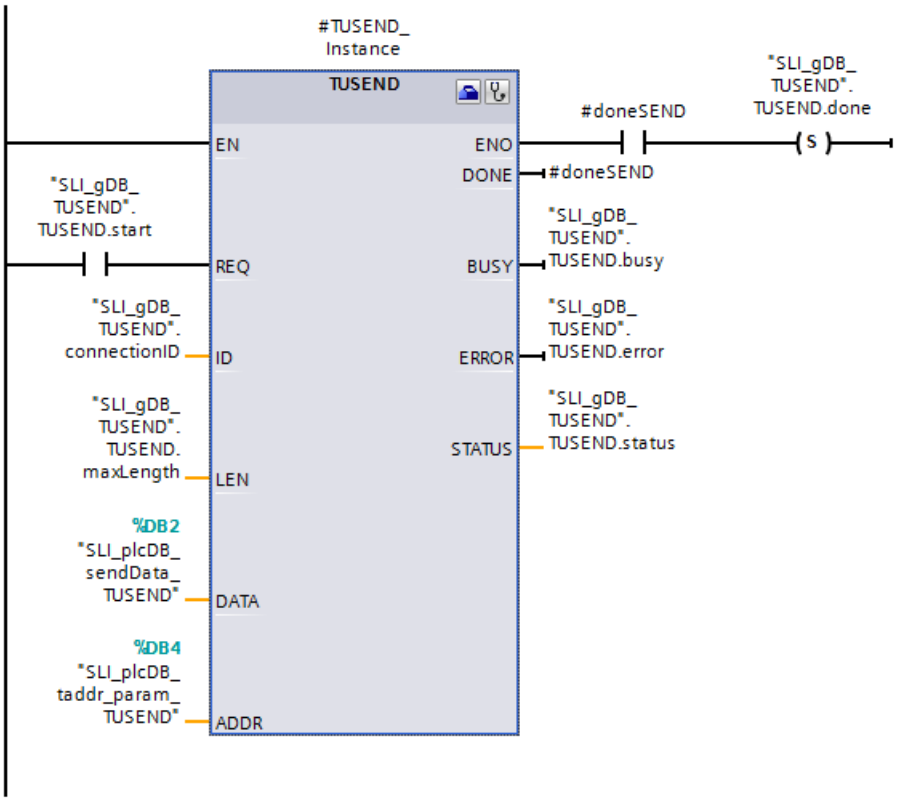
For addressing the communication partner, create the following data block ("SLI_plcDB_taddr_param_TUSEND") based on the system data type "TADDR_Param.

SLI_plcDB_taddr_param_TUSEND

	Name	Data type	Start value
1	Static		
2	REM_IP_ADDR	Array[1..4] of USInt	
3	REM_IP_ADDR[1]	USInt	192
4	REM_IP_ADDR[2]	USInt	168
5	REM_IP_ADDR[3]	USInt	0
6	REM_IP_ADDR[4]	USInt	3
7	REM_PORT_NR	UInt	2000
8	RESERVED	Word	16#0

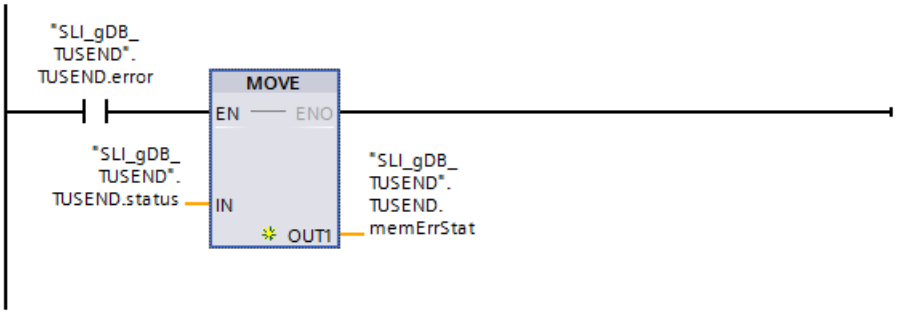
You can find the address date in the "Network view" under "Connections > Properties > Address details". The data of the CPU that had been selected previously are specified in the address details under "Local". In the following figure, CPU 1 "TUsend") is selected.

To store the data, create a global data block ("SLI_gDB_TUSEND") with the following structures and tags.



SLI_gDB_TUSEND

	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	16#0100
3	TUSEND	Struct	
4	start	Bool	false
5	maxLength	UDInt	0
6	busy	Bool	false
7	done	Bool	false
8	error	Bool	false
9	status	Word	16#0
10	memErrStat	Word	16#0



Create the FB "SLI_FB_TUSEND" Create the following local tags in it.

7	Static			
8	doneSEND	Bool	false	Non-ret...
9	TUSEND_Instance	TUSEND		

Network 1: Interconnect the parameter of the instruction "TUSEND" as follows:

Network 2: In case of error of TUSEND, save the status as follows.

Program of CPU 2

For the data record, create the PLC data type "TUSEND_User" based on the example of CPU 1.

For receiving data, create the following data block ("SLI_plcDB_rcvData_TURCV") based on the created PLC data type ("TUSEND_User").

SLI_plcDB_rcvData_TURCV

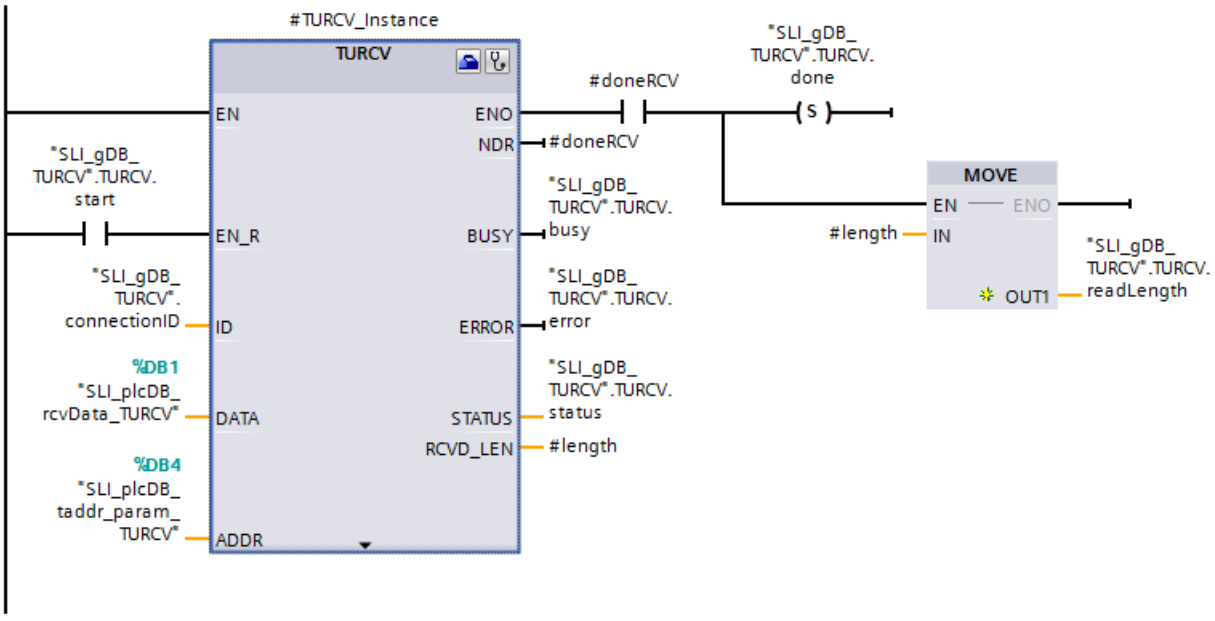
	Name	Data type	Start value
1	Static		
2	prename	String	''
3	lastname	String	''
4	userId	UInt	0

For addressing the communication partner, create the following data block ("SLI_plcDB_taddr_param_TURCV") based on the system data type "TADDR_Param.

SLI_plcDB_taddr_param_TURCV

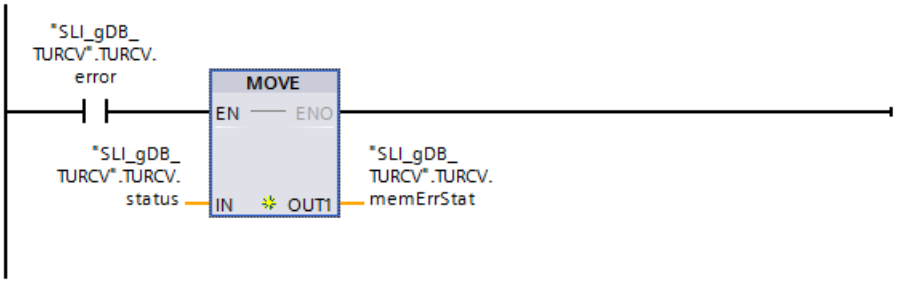
	Name	Data type	Start value
1	Static		
2	REM_IP_ADDR	Array[1..4] of USInt	
3	REM_IP_ADDR[1]	USInt	192
4	REM_IP_ADDR[2]	USInt	168
5	REM_IP_ADDR[3]	USInt	0
6	REM_IP_ADDR[4]	USInt	2
7	REM_PORT_NR	UInt	2000
8	RESERVED	Word	16#0

To store the data, create a global data block ("SLI_gDB_TURCV") with the following structures and tags.



SLI_gDB_TURCV

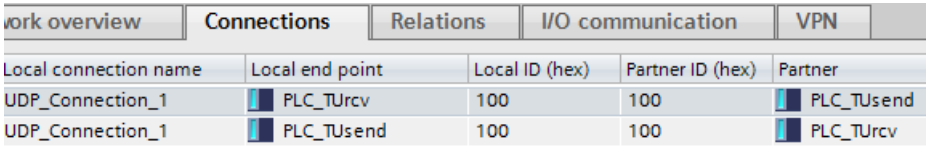
	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	16#0100
3	TURCV	Struct	
4	start	Bool	false
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStat	Word	16#0
10	readLength	UDInt	0



Create the FB "SLI_FB_TURCV" Create the following local tags in it.

7	Static			
8	doneRCV	Bool	false	Non-ret...
9	length	UDInt	0	Non-retain
10	TURCV_Instance	TURCV		

Network 1: Interconnect the parameter of the instruction "TURCV" as follows:



Network 2: In case of error of TURCV, save the status as follows.

Assigning communication connection

The address parameters for the connection of the two CPUs must be uniform.

- In each case store the hexadecimal value of the hardware identifier of the configured UDP connection at the input parameter ID ("connectionID").
  You can find the hardware identifier in the "Network view" under "Connections".

ork overview | Connections | Relations | I/O communication | VPN

Local connection name	Local end point	Local ID (hex)	Partner ID (hex)	Partner
UDP_Connection_1	PLC_TUrcv	100	100	PLC_TUsend
UDP_Connection_1	PLC_TUsend	100	100	PLC_TUrcv

Result of CPU 1

Network 1 (TUSEND):

Based on the input parameter ID ("connectionID"), the "TUSEND" instruction knows the communication connection to be used. Based on the input parameter ADDR

("SLI_plcDB_taddr_param_TUSEND"), the communication partner (CPU 2) can be addressed.

When the input parameter REQ ("TUSEND.start") supplies the signal state "TRUE", the "TUSEND" instruction is started. For multiple calls, the "TUSEND" instruction transmits the data record detected at input parameter DATA ("SLI_plcDB_sendData_TUSEND"). The size of the data record to be transmitted is restricted by the value of the input parameter LEN ("TUSEND.maxLength").

Successful transfer of the data record is indicated by the output parameter DONE ("#doneSEND") with the signal state "TRUE" and the output parameter STATUS ("TUSEND.status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "TUSEND.done".

The output parameter ERROR ("TUSEND.error") or the tag "TUSEND.memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_TUSEND

	Name	Data type	Start value	Monitor value
1	Static			
2	connectionID	CONN_OUC	16#0100	16#0100
3	TUSEND	Struct		
4	start	Bool	false	TRUE
5	maxLength	UDInt	0	0
6	busy	Bool	false	FALSE
7	done	Bool	false	TRUE
8	error	Bool	false	FALSE
9	status	Word	16#0	16#7000
10	memErrStat	Word	16#0	16#0000

Network 2 (TUSEND):

When TUSEND signals an error ("TUSEND.error" is "TRUE"), the reported status ("TUSEND.status") is stored permanently ("TUSEND.memErrStatus").

Result of CPU 2

Network 1 (TURCV):

Based on the input parameter ID ("connectionID"), the "TURCV" instruction knows the communication connection to be used. The communication partner (CPU 1) can be addressed based on the input parameter ADDR ("SLI_plcDB_taddr_param_TURCV").

When the input parameter EN_R ("TURCV.start") supplies the signal state "TRUE", the "TURCV" instruction is started. For multiple calls, the "TURCV" instruction receives the transmitted data record. The data record is detected at the input parameter DATA ("SLI_plcDB_rcvData_TURCV").

SLI_plcDB_rcvData_TURCV

	Name	Data type	Start value	Monitor value
1	Static			
2	prename	String	''	'Simon'
3	lastname	String	''	'Sample'
4	userId	UInt	0	1

The length in BYTES of the actually transmitted data record is detected with the output parameter LEN ("#length"). This value is only displayed during the success status. Then "0" is detected. Successful receipt of the data record is indicated by the output parameter DONE ("#doneRCV") with the signal state "TRUE" and the output parameter STATUS ("TURCV.status") with the value "0000".

Because the values of the output parameters are only displayed for the moment of their validity, do the following:

- Save the success status in the tag "TURCV.done"
- Save the length in BYTES in the tag "TURCV.readLength".

The output parameter ERROR ("TURCV.error") or the tag "TURCV.memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_TURCV

	Name	Data type	Start value	Monitor value
1	Static			
2	connectionID	CONN_OUC	16#0100	16#0100
3	TURCV	Struct		
4	start	Bool	false	TRUE
5	busy	Bool	false	TRUE
6	done	Bool	false	TRUE
7	error	Bool	false	FALSE
8	status	Word	16#0	16#7002
9	memErrStat	Word	16#0	16#0000
10	readLength	UDInt	0	514

Network 2 (TURCV):

When TURCV signals an error ("TURCV.error" is "TRUE"), the reported status ("TURCV.status") is stored permanently ("TURCV.memErrStatus").

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

TUSEND: Sending data (Page 4516)

TURCV: Receiving data (Page 4520)

T_RESET: Resetting the connection (S7-1200, S7-1500)

Description

The "T_RESET" instruction terminates and then reestablishes an existing connection.

The local end points of the connection are retained. They are generated automatically:

- If a connection has been configured and loaded to the CPU.
- If a connection has been generated by the user program, for example, by calling the instruction "TCON (Page 4474)".

The instruction "T_RESET" can be executed for all connection types (TCP, UDP, ISO-on-TCP, etc.). It does not matter whether the local interface of the CPU or the interface of a CM/CP was used for the connection.

Once the instruction "T_RESET" has been called using the REQ parameter, the connection specified with the ID parameter is terminated and, if necessary, the data send and receive buffer cleared. Canceling the connection also cancels any data transfer in progress. There is therefore a risk of losing data if data transfer is in progress. The CPU defined as the active connection partner will then automatically attempt to restore the interrupted communication connection. You therefore do not need to call the "TCON (Page 4474)" instruction to reestablish the communication connection.

The output parameters DONE, BUSY and STATUS indicate the status of the job.

Parameter

The following table shows the parameters of the instruction "T_RESET":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter REQUEST starts the job for terminating the connection specified by ID. The job starts on a rising edge.
ID	Input	CONN_OUC	I, Q, M, D, L or constant	Reference to the connection to the passive partner ID being interrupted must be identical to the corresponding parameter ID in the local connection description. Value range: W#16#0001 to W#16#0FFF
DONE	Output	BOOL	I, Q, M, D, L	Status parameter DONE • 0: Job not yet started or still executing. • 1: Job executed without errors
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter BUSY • 0: Job is complete. • 1: The job is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter ERROR • 0: No error occurred. • 1: Error occurred during processing. The STATUS parameter supplies detailed information on the type of error
STATUS	Output	WORD	I, Q, M, D, L	Status parameter STATUS Error information (see "STATUS parameter" table).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

STATUS* (W#16#...)	Explanation
0000	No error.
0001	Connection has not been established.
7000	No job processing active.
7001	Connection termination launched.
7002	Connection being terminated.
8081	Unknown connection specified at the ID parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example

You can find the example here: Program example for T_RESET (Page 4535).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

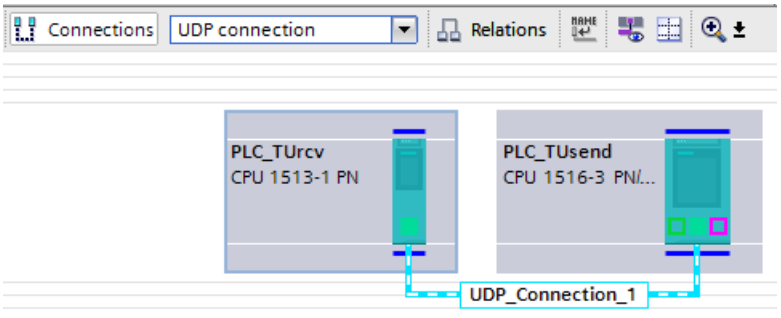
Difference between synchronous and asynchronous instructions (Page 2571)



Program example for T_RESET (S7-1200, S7-1500)

Introduction

In the following example you use a configured connection (by UDP for example) between two CPUs (S7-1500). Reset the connection using instruction "T_RESET".

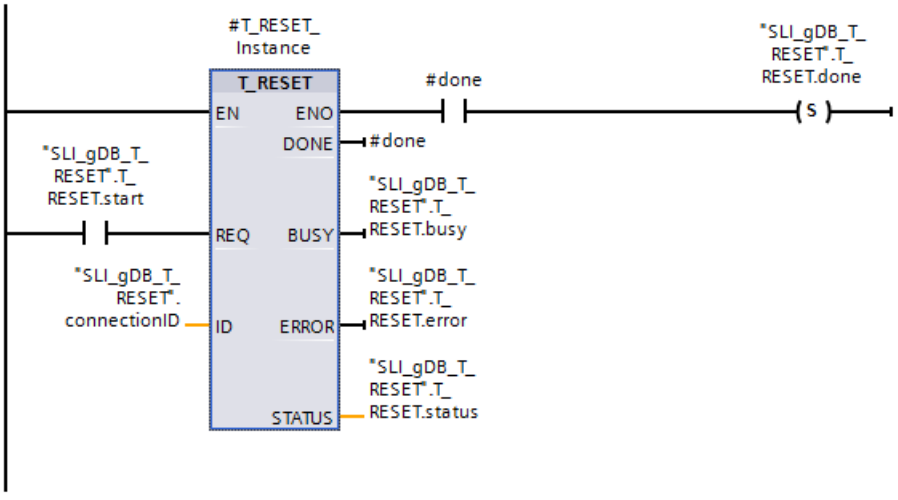
Requirement

- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. A UDP connection is configured.

- A low protection level under "<CPU> > Properties > Protection" ensures that read and write access is permitted for the CPUs.

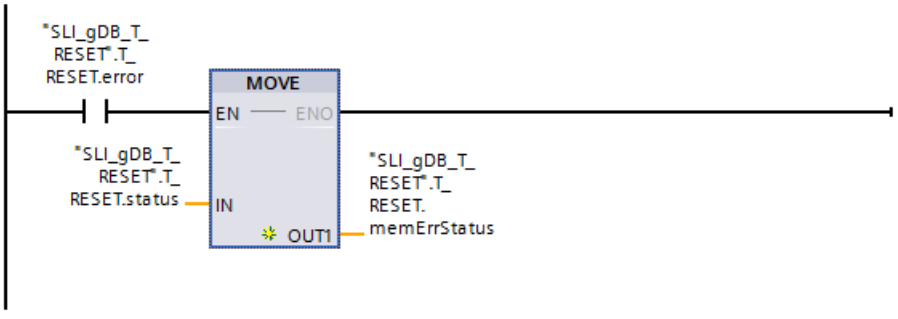
Create tags and interconnect parameters (program of CPU 1)

To store the data, create a global data block ("SLI_gDB_T_RESET") with the following structures and tags.



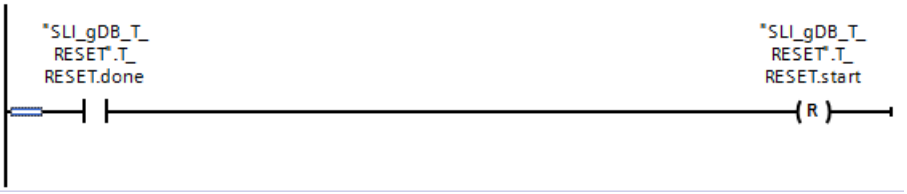
SLI_gDB_T_RESET

	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	16#0100
3	T_RESET	Struct	
4	start	Bool	false
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStatus	Word	16#0



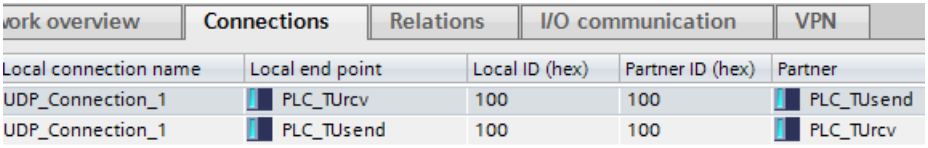
Create the FB "SLI_FB_T_RESET" Create the following local tags in it.

7	Static			
8	done	Bool	false	Non-ret...
9	T_RESET_Instance	T_RESET		



Network 1: Interconnect the parameter of the instruction "T_RESET" as follows:

Network 2: In case of error of T_RESET, save the status as follows.



Network 3: To reset the "REQ" parameter, create the following interconnections.

Assigning communication connection

The addressing parameters must be adapted for the connection.

- Store the hexadecimal value of the hardware identifier of the configured UDP connection at the input parameter ID ("connectionID").
  You can find the hardware identifier in the "Network view" under "Connections".

Local connection name	Local end point	Local ID (hex)	Partner ID (hex)	Partner
UDP_Connection_1	PLC_TUrcv	100	100	PLC_TUsend
UDP_Connection_1	PLC_TUsend	100	100	PLC_TUrcv

Result

Network 1:

Based on the input parameter ID ("connectionID"), the "T_RESET" instruction knows the communication connection to be used.

When the input parameter REQ ("T_RESET.start") supplies the signal state "TRUE", the "T_RESET" instruction is started. The "T_RESET" instruction terminates the specified communication connection. All jobs that use the connection are terminated. The active connection partner (CPU 1) then re-establishes the connection automatically.

Successful transfer of the data record is indicated by the output parameter DONE ("#done") with the signal state "TRUE" and the output parameter STATUS ("T_RESET.status") with the value "0000".
Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "T_RESET.done".

The output parameter ERROR ("T_RESET.error") or the tag "T_RESET.memErrStatus" indicates that processing in the example is taking place without errors.

SLI_gDB_T_RESET

	Name	Data type	Start value	Monitor value
1	Static			
2	connectionID	CONN_OUC	16#0100	16#0100
3	T_RESET	Struct		
4	start	Bool	false	FALSE
5	busy	Bool	false	FALSE
6	done	Bool	false	TRUE
7	error	Bool	false	FALSE
8	status	Word	16#0	16#7000
9	memErrStatus	Word	16#0	16#0000

Network 2:

When T_RESET signals an error ("T_RESET.error" is "TRUE"), the reported status ("T_RESET.status") is stored permanently ("T_RESET.memErrStatus").

Network 3:

After the successful processing of T_RESET ("T_RESET.done"), T_RESET is stopped.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

T_RESET: Resetting the connection (Page 4533)

T_DIAG: Checking the connection (S7-1200, S7-1500)

Description

You use the "T_DIAG" instruction to check the status of a connection and read further information on the local end point of this connection.

- The connection is referenced by the ID parameter. You can read both connection end points configured in the connection editor and programmed connection end points (e.g. with the "TCON" instruction).
  Temporary connection end points (for example end points created when you connect to an engineering station) cannot be diagnosed, as no connection ID is generated in this process.
- The connection information read is stored in a structure referenced by the RESULT parameter.
- The output parameter STATUS indicates whether it was possible to read the connection information. The connection information in the structure at the RESULT parameter is only valid if the "T_DIAG" instruction has been completed with STATUS = W#16#0000 and ERROR = FALSE.
  Connection information cannot be evaluated if an error occurs.

Possible connection information

Two different structures can be used to read the connection information at the RESULT parameter:

- The "TDiag_Status" structure only contains the most important information about a connection end point, for example the protocol used, the connection status and the number of data bytes sent or received.
- The structure "TDiag_StatusExt" supplies not just the most important information, but also the number of connection attempts, the reason for a connection abort, etc.

The structure and parameters of the two structures are described below (see the "TDIAG_Status and TDIAG_StatusExt structures" table).

Parameters

The following table shows the parameters of the instruction "T_DIAG":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Starts the instruction to check the connection specified in the ID parameter when there is a positive edge.
ID	Input	CONN_OUC (WORD)	I, Q, M, D, L or constant	Reference to the assigned connection. Value range: W#16#0001 to W#16#0FFF
RESULT	InOut	VARIANT	D	Pointer to the structure in which the connection information is stored. The structure TDiag_Status or TDiag_StatusExt can be used at the RESULT parameter (for a description, see the "TDIAG_Status and TDIAG_StatusExt structures" table).
DONE	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Instruction not yet started or still in progress. • 1: Instruction executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Instruction not yet started or already completed. • 1: Instruction not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error. • 1: Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

BUSY, DONE and ERROR parameters

You can check the status of "T_DIAG" instruction execution with the BUSY, DONE, ERROR and STATUS parameters. The BUSY parameter indicates the processing status. You use the DONE parameter to check whether or not an instruction has been executed successfully. The ERROR parameter is set if errors occur during execution of "T_DIAG".

The following table shows the relationship between the BUSY, DONE and ERROR parameters:

BUSY	DONE	ER-ROR	Description
1	-	-	The instruction is being processed.
0	1	0	The instruction has been executed successfully. The data in the structure referenced by RESULT are only valid if this is the case.
0	0	1	Instruction completed with an error. The cause of the error is output at the STATUS parameter.
0	0	0	No new instruction has been assigned.

Parameter STATUS

The following table shows the meaning of the values at the STATUS parameter:

STA-TUS* (W#16#...)	Explanation
0000	The instruction "T_DIAG" has been executed successfully. The data in the structure referenced at the RESULT parameter can be evaluated.
7000	No instruction processing active.
7001	Instruction processing launched.
7002	Connection information is being read (REQ parameter irrelevant).
8086	The value at the ID parameter is outside the valid range (W#16#0001 ... W#16#0FFF).
8089	The RESULT parameter points to an invalid data type (structures TDIAG_Status and TDIAG_StatusExt only).
80A3	The ID parameter references a connection end point which does not exist. With programmed connections, this error can also occur after the "TDISCON" instruction is called.
80B1	The RESULT parameter was changed before the execution of T_DIAG was completed. A change of RESULT is not permitted during execution of T_DIAG.
80C4	Internal error. Access to the connection end point is temporarily unavailable.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Structures TDIAG_Status and TDIAG_StatusExt

The table below details the form of the TDIAG_Status and TDIAG_StatusExt structures:

- From the InterfaceID to the ReceivedBytes parameter, the "TDIAG_StatusExt" and "TDIAG_Status" structures are identical.
- The structure TDIAG_StatusExt also includes the parameters ConnTrials to LastDisconnTimeStamp.

The value of each element is only valid if the instruction has been executed without errors. If an error occurs, the content of the parameters will not change.

Name	Data type	Description
The following parameters are in both the TDIAG_Status and the TDIAG_StatusExt structure:		
InterfaceID	HW_ANY	Interface ID (LADDR) of the CPU or the CM/CP.
ID	CONN_OUC	ID of the connection diagnosed. Following a successful call, the value of this element is identical to the parameter ID of the "T_DIAG" instruction.
ConnectionType	BYTE	Protocol type used for connection: • 0x01: Not used. • ... • 0x0B: TCP protocol (IP_v4) • 0x0C: ISO-on-TCP protocol (RFC1006) • 0x0D: TCP protocol (DNS) • 0x0E: Dial-in protocol • 0x0F: WDC protocol • 0x10: SMTP protocol • 0x11: TCP protocol • 0x12: TCP and ISO-on-TCP protocol (RFC1006) • 0x13: UDP protocol • 0x14: Reserved • 0x15: PROFIBUS bus access protocol (FDL) • 0x16: ISO 8073 transport protocol (ISO native) • ... • 0x20: SMTP or SMTPS protocol - based on IPv4 • 0x21 SMTP or SMTPS protocol - based on IPv6 • 0x22: SMTP or SMTPS protocol based on FQDN (**F**ully **Q**ualified **D**omain **N**ame) • ... • 0x70: S7 connection • Other: Reserved
ActiveEstablished	BOOL	• FALSE: Locally, the passive connection end point • TRUE: Locally, the active connection end point

Name	Data type	Description
State	BYTE	Current status of the connection end point • 0x00: Not used. • 0x01: Connection terminated. Temporary status, for example, after the "T_RESET" instruction is called. The system then automatically attempts to reestablish the connection. • 0x02: The active connection end point is attempting to establish a connection to the remote communication partner. • 0x03: The passive connection end point is waiting for establishment of the connection to the remote communication partner. • 0x04: Connection established. • 0x05: The connection is being terminated. This may be because the "T_RESET" or "T_DISCON" instruction has been called. Other possible reasons are protocol errors and line breaks. • 0x06..0xFF: Not used.
Kind	BYTE	Mode of the connection end point: • 0x00: Not used. • 0x01: Configured, static connection which has been configured and loaded to the CPU. • 0x02: Configured, dynamic connection which has been configured and loaded to the CPU (not currently supported). • 0x03: Programmed connection generated in the user program with the instruction "TCON". A call of the instruction "TDISCON" or a transition to CPU STOP status has destroyed the connection end point. • 0x04: Temporary, dynamic connection established by the engineering station (ES) or operator station (OS) (this connection currently not be diagnosed due to the missing ID). • 0x05..0xFF: Not used.
SentBytes	UDINT	Number of data bytes sent.
ReceivedBytes	UDINT	Number of data bytes received.
The following parameters only occur in the TDiag_StatusExt structure:		
ConnTrials	UDINT	Number of connection attempts. Once a connection has been successfully established, ConnTrials has the value 0. If this element is not equal to 0, this indicates that there are connection problems. Note: With a passive connection end point, this value is never greater than 1.
ConnTrialsSuccess	UDINT	Number of successful connection attempts. This element is never reset during the life cycle of a connection end point, and returns to 0 after reaching 0xFFFF FFFF. Note: This parameter is 1 if there has never been a problem in this connection.

Name	Data type	Description
LastConnErrReason	UDINT	Error ID output during the last connection attempt with errors (the error messages are identical to those at the LastDisconnReason parameter): • 0x4F01: Remote connection end point cannot be reached (this error usually occurs during connection establishment). • 0x4F02: Connection terminated locally. • 0x4F03: Connection terminated by remote communication partner. • 0x4F04: Connection terminated by a protocol error. • 0x4F05: Connection terminated by a network problem detected locally. • 0x4F06: Connection terminated by a network problem detected remotely. • 0x4F07: Connected terminated due to timeout in protocol. • 0x4F08: Incorrect parameter assignment: Connection to be established to local partner's own address. • 0x4F09: Connection temporarily reset by a call of the instruction "T_RESET". • 0x4F0A: Insufficient connection resources available (quantity exceeded) • 0x4F0B: Internal error: Incorrect addressing parameters • 0x4F0C: Internal CPU communication error • 0x4F0D: Internal AS communication error between CPU and CM/CP • 0x4F0E: The local TCP/UDP port (or RFC1006-T selector) specified is already in use.
LastConnErrTimeStamp	LDT	Time of the last connection attempt with errors.
LastDisconnReason	UDINT	Error ID which led to the last connection termination (the error messages are identical to those at the LastConnErrReason parameter): • 0x4F01: Remote connection end point cannot be reached (this error usually occurs during connection establishment). • 0x4F02: Connection terminated locally. • 0x4F03: Connection terminated by remote communication partner. • 0x4F04: Connection terminated by a protocol error. • 0x4F05: Connection terminated by a network problem detected locally. • 0x4F06: Connection terminated by a network problem detected remotely. • 0x4F07: Connected terminated due to timeout in protocol. • 0x4F08: Incorrect parameter assignment: Connection to be established to local partner's own address. • 0x4F09: Connection temporarily reset by a call of the instruction "T_RESET". • 0x4F0A: Insufficient connection resources available (quantity exceeded) • 0x4F0B: Internal error: Incorrect addressing parameters • 0x4F0C: Internal CPU communication error • 0x4F0D: Internal AS communication error between CPU and CM/CP • 0x4F0E: The local TCP/UDP port (or RFC1006-T selector) specified is already in use.
LastDisconnTimeStamp	LDT	Time of the last connection termination.

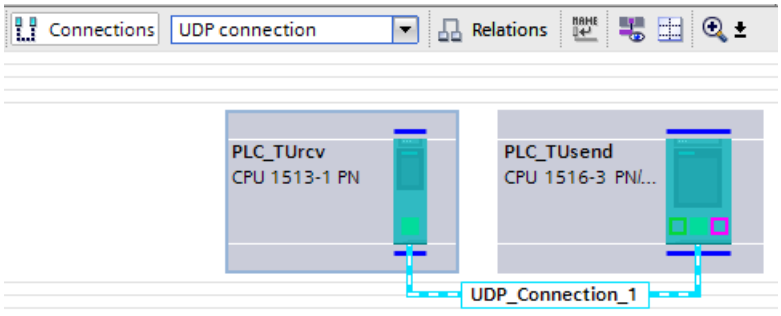
Example

You can find the example here: Program example for T_DIAG (Page 4544).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

Difference between synchronous and asynchronous instructions (Page 2571)



Program example for T_DIAG (S7-1200, S7-1500)

Introduction

In the following example you use a configured connection (by UDP for example) between two CPUs (S7-1500). The instruction "T_DIAG" is used to diagnose the connection and read information from the local end point of the connection.

Requirement

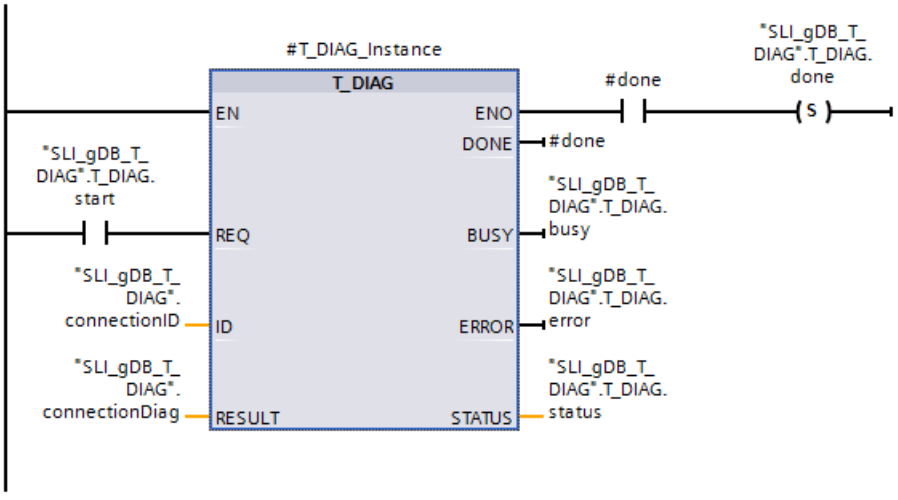
- Two CPUs of the S7-1500 series are available and connected to each other over PROFINET. A UDP connection is configured.

- A low protection level under "<CPU> > Properties > Protection" ensures that read and write access is permitted for the CPUs.

Create tags and interconnect parameters (program of CPU 1)

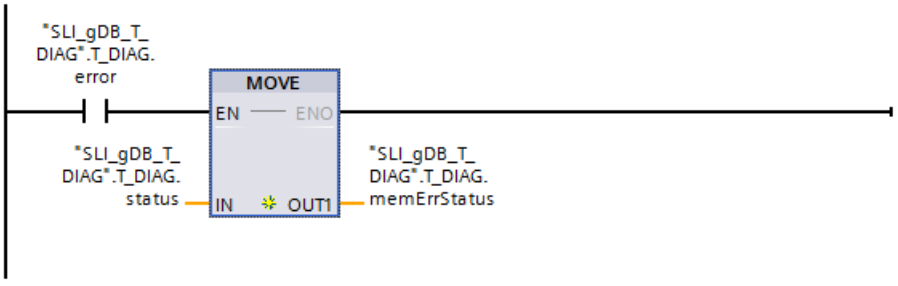
To store the data, create a global data block ("SLI_gDB_T_DIAG") with the following structures and tags.

Note: "TDiag_StatusExt" is a system data type for recorded the diagnostics data.



SLI_gDB_T_DIAG

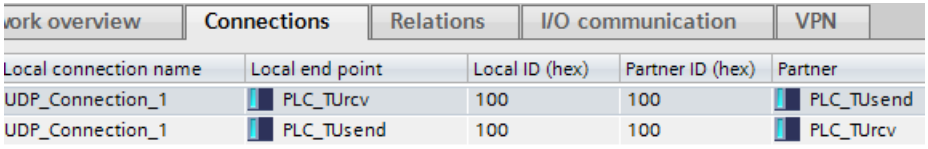
	Name	Data type	Start value
1	Static		
2	connectionID	CONN_OUC	16#0100
3	T_DIAG	Struct	
4	start	Bool	false
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	status	Word	16#0
9	memErrStatus	Word	16#0
10	connectionDiag	TDiag_StatusExt	



Create the FB "SLI_FB_T_DIAG" Create the following local tags in it.

7	Static			
8	T_DIAG_Instance	T_DIAG		
9	done	Bool	false	Non-retain

Network 1: Interconnect the parameter of the instruction "T_DIAG" as follows:



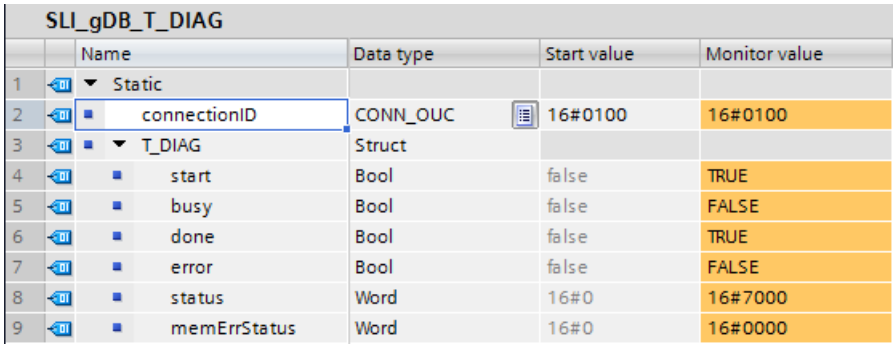
Network 2: In case of error of T_DIAG, save the status as follows.

Assigning communication connection

The addressing parameters must be adapted for the connection.

- Store the hexadecimal value of the hardware identifier of the configured UDP connection at the input parameter ID ("connectionID").
  You can find the hardware identifier in the "Network view" under "Connections".

Result



Network 1:

Based on the input parameter ID ("connectionID"), the "T_DIAG" instruction knows the communication connection to be used.

When the input parameter REQ ("T_DIAG.start") supplies the signal state "TRUE", the "T_DIAG" instruction is started. The instruction "T_DIAG" reads the status of the connection and the status of the local end point of the connection.

Successful transfer of the data record is indicated by the output parameter DONE ("#done") with the signal state "TRUE" and the output parameter STATUS ("T_DIAG.status") with the value "0000". Because the values of the output parameters are only displayed for the moment of their validity, save the success status in the tag "T_DIAG.done".

The output parameter ERROR ("T_DIAG.error") or the tag "T_DIAG.memErrStatus" indicates that processing in the example is taking place without errors.

The diagnostics data are recorded at the RESULT parameter ("TDiag_StatusExt").

10	connectionDiag	TDiag_StatusExt		
11	InterfaceId	HW_ANY	16#0	16#0040
12	ID	CONN_OUC	16#0	16#0100
13	ConnectionType	Byte	0	16#13
14	ActiveEstablished	Bool	false	FALSE
15	State	Byte	0	16#04
16	Kind	Byte	0	16#01
17	SentBytes	UDInt	0	0
18	ReceivedBytes	UDInt	0	0
19	ConnTrials	UDInt	0	0
20	ConnTrialsSuccess	UDInt	0	2
21	LastConnErrReason	UDInt	0	0
22	LastConnErrTimeSt..	LDT	LDT#1970-01-01-0	LDT#1970-01-01-0...
23	LastDisconnReason	UDInt	0	20226
24	LastDisconnTimeS...	LDT	LDT#1970-01-01-0	LDT#2012-01-21-0...

Network 2:

When T_DIAG signals an error ("T_DIAG.error" is "TRUE"), the reported status ("T_DIAG.status") is stored permanently ("T_DIAG.memErrStatus").

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

T_DIAG: Checking the connection (Page 4538)

T_CONFIG: Configure interface (S7-1200, S7-1500)

Description T_CONFIG (S7-1200, S7-1500)

Description

The "T_CONFIG" instruction is used for the program-controlled configuration of the integrated PROFINET interfaces of the CPU or the interface of a CP/CM.

Configuration of the integrated PROFINET interfaces of the CPU

With the "T_CONFIG" instruction, you can change the Ethernet address, the PROFINET device name or the IP addresses of the NTP servers for time-of-day synchronization from within the user program. The existing configuration data is overwritten.

You can make the following changes:

- Settings for the IP protocol
  - IP address
  - Subnet mask
  - Router address
- Settings for PROFINET
  - Assignment of the PROFINET device name

  Note

  Dependency between device names and IP protocol

  The IP protocol must also be set when a new device name is assigned.
- Settings for time-of-day synchronization
  - Assignment of the IP addresses of the NTP servers for time-of-day synchronization (only with S7-1500 and there only for the PROFINET interface [X1} of a modular CPU)

These settings correspond to the configuration options under "IP protocol" and "PROFINET" in the "Ethernet addresses " dialog or the "NTP mode" in the "Time synchronization" dialog. This is displayed in the "Devices & Networks" view under the properties of the PROFINET interface.

⚠ WARNING

Restart of CPU after execution of the "T_CONFIG" instruction (only S7-1200 CPUs with firmware versions V2.0 to V4.1.2)

The CPU is restarted after you have executed the instruction to change an IP parameter. The CPU goes to STOP mode, a warm restart is carried out and the CPU starts up again (RUN mode).

Make sure that the control process is in a secure operating mode after the CPU has been restarted following execution of the instruction. Uncontrolled operation can result in serious material damage or personal injury due to malfunctions or programming errors, for example. Non-retentive data could be lost.

Configuration of the PROFINET interface of a CP 1543-1

With the "T_CONFIG" instruction you can change the IPv6 address, the MAC address or the IP addresses of up to two DNS servers of the PROFINET interface of a CP 1543-1 from within the user program. The existing configuration data is overwritten.

Requirement

In order to use the instruction must be explicitly specified in the hardware configuration that the assignment of IP address parameters and device name must be made by the user program.

- For this purpose open the properties of the PROFINET interface in the device view. In the "Ethernet addresses" or "Time synchronization" dialog, enable the following options:
  - In order to change the IP address parameters with "T_CONFIG": Select the setting "IP address is set directly at the device" under "IP protocol".
  - In order to change the PROFINET device name with "T_CONFIG":
    Select the setting "PROFINET device name is set directly at the device" under "PROFINET".
    Also select the setting "IP address is set directly at the device" under "IP protocol".
  - To change the IP addresses of the NTP servers with "T_CONFIG". Select "Enabled time synchronization via NTP server" and specify the IP address of at least one NTP server.
- The configuration data must be stored in the following system data types and assigned at the parameter CONF_DATA (Page 4551):
  - Store the IP address, subnet mask, and the router address in the system data type IF_CONF_V4.
  - Store the device name in the system type IF_CONF_NOS. Observe the restrictions that exist for assigning the name of the device (see parameter CONF_DATA (Page 4551)).
  - Use store the IP addresses for the NTP time synchronization in the system data type IF_CONF_NTP.
  - Store the IPv6 address of the PROFINET interface of a CP 1543-1 in the system data type IF_CONF_IPV6.
  - Store the MAC address of the PROFINET interface of a CP 1543-1 in the system data type IF_CONF_MAC.
  - Store the IP addresses of up to two DNS servers for the PROFINET interface of a CP 1543-1 in the system data type IF_CONF_DNS.

Functional description

The "T_CONFIG" instruction works asynchronously, which means its execution extends over multiple calls. The configuration process is started by calling "T_CONFIG" with REQ = 1. Only one job can be active at any time.

The block is edge triggered which means that after BUSY= FALSE the block must be re-called with REQ=FALSE to enable the instance.

Parameter

The following table shows the parameters of the instruction "T_CONFIG":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Calling the instruction with REQ = 1 starts processing of the instruction.
INTERFACE	Input	HW_INTERFACE	I, Q, M, D, L or constant	Hardware identifier of the interface The hardware ID is displayed in the properties of the interface in the device view, and in the system constants of the PLC tags.
CONF_DATA (Page 4551)	Input	VARIANT	D, L	Pointer to the higher-level structure that contains the system data types IF_CONF_HEADER, IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC and IF_CONF_DNS (see description of the parameters CONF_DATA).
DONE (Page 4556)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Processing not yet complete. • 1: Processing of instruction finished successfully.
BUSY (Page 4556)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: Processing of the instruction has not started, completed or canceled yet. • 1: Processing of instruction is in progress
ERROR (Page 4556)	Output	BOOL	I, Q, M, D, L	Status parameter: • 0: No error • 1: Error
STATUS (Page 4556)	Output	DWORD	I, Q, M, D, L	Detailed status information: Detailed error and status information in the form of an error code are output at the parameter STATUS.
ERR_LOC (Page 4556)	Output	DWORD	I, Q, M, D, L	Error location: • 0: Error during execution of the instruction or when assigning parameters. • > 0: Errors in the structure or content of the configuration data at the parameter CONF_DATA.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example

You will find the example here: Program example for T_CONFIG (Page 4558).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Difference between synchronous and asynchronous instructions (Page 2571)

Parameter CONF_DATA (S7-1200, S7-1500)

Structure of the configuration data

The configuration data at the parameter CONF_DATA can be stored in a global data block or in the section "Static" of the block interface.

The configuration data must be stored according to the following structure:

Name	Data type	Description
ConfData	Struct	Parent structure that is assigned at the parameter CONF_DATA.
Header	IF_CONF_HEADER	The header is used to define the number of these system data types. The system data type IF_CONF_HEADER must always be included.
IPData	IF_CONF_V4	The IP address, subnet mask and router address are stored in this system data type.
NoS	IF_CONF_NOS	The PROFINET device names are stored in this system data type. Only create IF_CONF_NOS if you also want to change the device names with "T_CONFIG".
NTP	IF_CONF_NTP	In this system data type, use store the IP addresses of the NTP servers for time synchronization.
IP_V6	IF_CONF_V6	Store the IPv6 address of a CP 1543-1 in this system data type.
MAC	IF_CONF_MAC	Store the MAC address of a CP 1543-1 in this system data type.
DNS	IF_CONF_DNS	Store the IP addresses of up to two DNS servers for a CP 1543-1 in this system data type .

Create the system data types IF_CONF_HEADER, IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC and IF_CONF_DNS be entering the name of the system data type in the "Data type " column of the data block or the block interface. The name for the system data types can be freely assigned. The system data types can be combined in any order.

System data type IF_CONF_Header

Use the system data type IF_CONF_Header to specify the number of system data types IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC and IF_CONF_DNS that are used when executing "T_CONFIG".

Byte	Parameter	Data type	Start value	Description
0 ... 1	FieldType	UINT	0	Field type: Must always have the value "0".
2 ... 3	FieldId	UINT	0	Error ID: Must always have the value "0".
4 ... 5	SubfieldCount	UINT	0	Number of system data types IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC and IF_CONF_DNS used

System data type IF_CONF_V4

The IP address, subnet mask and router address are defined with the system data type IF_CONF_V4.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	30	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	18	Length of the system data type IF_CONF_V4 The start value must be used for the length specification since the parameters of IF_CONF_V4 have a fixed length and structure.
4 ... 5	Mode	UINT	0	Validity of addressing: • 1: Permanent validity of the configuration data • 2: Temporary validity of the configuration data including the deletion of existing permanent configuration data
6 ... 9	InterfaceAddress	IP_V4 *	0.0.0.0	IP address
10 - 12	SubnetMask	IP_V4 *	0.0.0.0	Subnet mask
14 - 16	DefaultRouter	IP_V4 *	0.0.0.0	Router address
* The data type IP_V4 is a structure of 4 BYTE, which includes the respective address of the respective parameter (e.g. at parameter SubnetMask the four-digit address of the subnet mask of the IP protocol).				

System data type IF_CONF_NOS

With the system data type IF_CONF_NOS you specify the station name to be assigned when the "T_CONFIG" instruction executes.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	40	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	246	Length of the system data type IF_CONF_NOS in bytes. • For an absolute length, the value for the Lenght parameter consists of: – 6 bytes for the parameter Id, Length and Mode. – up to 240 bytes for the device name (parameter NOS). Example: An overall length of 10 is the result for the device name "plc1" with a length of 4 characters (=4 bytes). • Use the default start value 246 at the Lenght parameter for a dynamic length. Make sure that you enter the value "0" after the name (see description for NOS parameter).

Byte	Parameter	Data type	Start value	Description
4 ... 5	Mode	UINT	0	Validity of the device name change: • 1: Permanent validity of the device name. • 2: Temporary validity of the device name.
6 ... 244	NOS	ARRAY [1...240] of Byte	0	Device name (Name of Station) • You must occupy the ARRAY from the first byte. The station name is deleted if "0" is assigned as the first byte. • The minimum length for the name is 2 bytes. The maximum length for a name is 240 bytes. • If the device name is shorter than specified at the parameter Length then a zero byte (16#0 hex) must be entered after the actual station name (according to IEC 61185-6-10). Otherwise NOS will be rejected and the instruction "T_CONFIG" outputs the error codeDW#16#C0809400 at the parameter STATUS. • If the device name is longer than specified at the parameter Length then the device name will only be written up to to specified length. The following restrictions apply for the device name: • The name must be specified in ASCII code. • Only lowercase letters, numbers, hyphen or dots may be used for the name. – The name may not begin or end with a hyphen. – The name may not begin with numbers. – The name may not have the form n.n.n.n (n = 0, ... 999). – The name may not begin with the string "port-xyz" or "port-xyz-abcde" (a, b, c, d, e, x, y, z = 0, ... 9). • A name component between two points may be up to 63 characters long. • No special characters such as umlauts, brackets, underscore, slash, blank etc. The error code C080_9400 is output at the parameter STATUS if an invalid character is used.

System data type IF_CONF_NTP

Using the system data type IF_CONF_NTP you specify the IP addresses of the NTP servers for time synchronization.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	17	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	22	Length of the system data type IF_CONF_NTP in bytes The start value must be used for the length specification since the parameters of IF_CONF_NTP have a fixed length and structure.
4 ... 5	Mode	UINT	2	Validity: • 1: Permanent validity (not permitted) • 2: Temporary validity
6 ... 9	NTP_IP[1]	ARRAY [1...4] of IP_V4		IP address of NTP server 1
...	...			IP address of NTP server 2 ... 3
18 ... 21	NTP_IP[4]	ARRAY [1...4] of IP_V4		IP address of NTP server 4

System data type IF_CONF_V6 (only when using a CP 1543-1)

With the system data type IF_CONF_V6 you define an IPv6 address for the interface selected with INTERFACE.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	22	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	22	Length of the system data type IF_CONF_V6 in bytes The start value must be used for the length specification since the parameters of IF_CONF_V6 have a fixed length and structure.
4 ... 5	Mode	UINT	0	Validity of the IPv6 address: • 1: Permanent validity • 2: Temporary validity
6 ... 21	InterfaceAddress	IP_V6 *		IPv6 address
* The data type IP_V6 is a structure of 16 bytes.				

System data type IF_CONF_MAC (only when using a CP 1543-1)

With the system data type IF_CONF_MAC you set a MAC address for the interface selected with INTERFACE.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	3	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	12	Length of the system data type IF_CONF_MAC in bytes The start value must be used for the length specification since the parameters of IF_CONF_MAC have a fixed length and structure.
4 ... 5	Mode	UINT	0	Validity of MAC address: • 1: Permanent validity • 2: Temporary validity
6 ... 11	Mac	ARRAY [1...6] of Byte		MAC address Note that by changing the MAC address, connections can abort.

System data type IF_CONF_DNS (only when using a CP 1543-1)

With the system data type IF_CONF_DNS you set IP addresses of up to two DNS servers for the interface selected with INTERFACE.

Byte	Parameter	Data type	Start value	Description
0 ... 1	Id	UINT	16	System data type ID The start value of this parameter must not be changed.
2 ... 3	Length	UINT	14	Length of the system data type IF_CONF_DNS in bytes The start value must be used for the length specification since the parameters of IF_CONF_DNS have a fixed length and structure.
4 ... 5	Mode	UINT	0	Validity: • 1: Permanent validity • 2: Temporary validity
6 ... 9	DNS_IP1	IP_V4		IP address of DNS server 1
10 ... 13	DNS_IP2	IP_V4		IP address of DNS server 2 If only one address is to be set, the IP address of DNS server 2 must be set to 0.0.0.0.

DONE, BUSY and ERROR parameters (S7-1200, S7-1500)

Description

The following table shows the relationship between BUSY, DONE and ERROR. Using this table, you can determine the current status of the instruction and when the transfer of configuration data is concluded.

BUSY	DONE	ERROR	Description
TRUE	FALSE	FALSE	The job is being processed.
FALSE	TRUE	FALSE	Job successfully completed.
FALSE	FALSE	TRUE	The job ended with an error. The cause of the error can be found in the parameter STATUS (Page 4556).
FALSE	FALSE	FALSE	The instruction was not assigned a (new) job.

Parameter STATUS and ERR_LOC (S7-1200, S7-1500)

Description

The status and error messages of the instruction "T_CONFIG" are output at the parameters STATUS and ERR_LOC.

- The cause of the error is output at the parameter STATUS.
- The location of the error that occurred is output at the parameter ERR_LOC. The following options are available here:
  - 16#0000_0000: Error when calling the instruction (e.g. errors when assigning parameters to the instruction or in communication with the PROFINET interface).
  - 16#0001_0000: Error with the configuration data in the parameters of the system data type IF_CONF_HEADER.
  - 16#0001_000x: Error in the configuration data in the parameters of system data type IF_CONF_V4 or IF_CONF_NOS or IF_CONF_NTP or IF_CONF_V6 or IF_CONF_MAC or IF_CONF_DNS (x specifies the position of the bad sub block in the T_CONFIG structure. If the T_CONFIG structure contains, for example a sub block for the IP address and a sub block for the station name and the error is located in the sub block for the station name, ERR_LOC has the value 0001_0002.)

The following table shows the possible values for the parameters STATUS and ERR_LOC:

STATUS*	ERR_LOC*	Explanation
0000_0000	0000_0000	Order processing completed without errors.
0070_0000	0000_0000	No job processing active.
0070_0100	0000_0000	Start of the order processing.
0070_0200	0000_0000	Intermediate call (REQ irrelevant).
C08x_yy00	0000_0000	General error information. See also: GET_ERR_ID: Get error ID locally (Page 2840)
C080_8000	0000_0000	Error at call of the instruction: The hardware ID at the parameter Interface is invalid.

STATUS*	ERR_LOC*	Explanation
C080_8100	0000_0000	Error at call of the instruction: The hardware ID at the parameter Interface does not address a PROFINET interface.
C080_8700	0000_0000	Error at call of the instruction: Incorrect length of the data block at the parameter CONF_DATA.
C080_8800	0001_0000	Error in the system data type IF_CONF_HEADER: The parameter FieldType has an invalid value. Use the value "0" for FieldType.
C080_8900	0001_0000	Error in the system data type IF_CONF_HEADER: The parameter FieldId has an invalid value. Use the value "0" for FieldId.
C080_8A00	0001_0000	Error in the system data type IF_CONF_HEADER: Incorrect number at the parameter SubfieldCount. Enter the correct number of system data types IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS being used.
C080_8B00	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: The parameter Id has an invalid value. For IF_CONF_V4 use "30", for IF_CONF_NOS "40", for IF_CONF_NTP "17", for IF_CONF_V6 "22", for IF_CONF_MAC "3", for IF_CONF_DNS "16". Note: IF_CONF_NTP is only permitted if T_CONFIG is used on the first interface [X1] of an S7-1500 modular CPU.
C080_8C00	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: Incorrect data type system used, wrong order or multiple use of a system data type.
C080_8D00	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: The parameter Length has an incorrect or invalid value.
C080_8E00	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: The parameter Mode has an incorrect or invalid value. • With IF_CONF_V4 and IF_CONF_NOS only the values "1" (permanent) or "2" (temporary) are permitted. • With IF_CONF_NTP only the value "2" (temporary) is permitted.
C080_9000	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: Configuration data cannot be applied. Possible cause: • With IF_CONF_V4: In the hardware configuration, the setting "Set IP address on the device" was not selected.. • With IF_CONF_NOS: In the hardware configuration, the setting "Set PROFINET device name on the device" was not selected.. • With IF_CONF_NTP: In the hardware configuration, the setting "Enable time synchronization via NTP server " was not selected and no IP address was set for NTP servers..
C080_9400	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: A parameter value is undefined or invalid.
C080_9500	0001_000x	Error in the system data type IF_CONF_V4, IF_CONF_NOS, IF_CONF_NTP, IF_CONF_V6, IF_CONF_MAC or IF_CONF_DNS: The values of two parameters are inconsistent.

STATUS*	ERR_LOC*	Explanation
C080_C200	0000_0000	Error at call of the instruction: The configuration data can not be transferred. Possible cause: The PROFINET interface is not accessible.
C080_C300	0000_0000	Error at call of the instruction: Insufficient resources (e.g., multiple calling of "T_CONFIG" with different parameters).
C080_C400	0000_0000	Error at call of the instruction: Temporary communication error. Time indication for change to daylight saving time.
C080_D200	0000_0000	Error at call of the instruction: Call not possible. Instruction is not supported by the selected PROFINET interface.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Program example for T_CONFIG (S7-1200, S7-1500)

Introduction

In the following example you use a configured connection (by UDP for example) between two CPUs. Configure the IP address and the PROFINET device name of CPU 1 using the instruction "T_CONFIG".

Requirements

Set connection:

- Two CPUs (for example, S7-1513-1 PN) are available and connected to each other via PROFINET.
- A configured connection is not required.

Setting up PROFINET of CPU 1:

1. Open the device view of the CPU 1 "> Properties > PROFINET interface > Ethernet addresses > PROFINET".
2. To set the device names, select the following options:
   - "IP address is set directly at the device".
   - "PROFINET device name is set directly at the device".

Adjust the value of "hwid":

- Change the value of "hwid" according to the hardware identifier of the PROFINET interface of your local device (CPU 1).

Note

Open "PLC tags > Show all tags > System constants". Find the entry "<Local~PROFINET_interface_1>", with the data type "Hw_Interface". The "value" cell contains the hardware identifier.

Create tags and interconnect parameters (program of CPU 1)

To store the data, create a global data block ("SLI_gDB_T_CONFIG") with the following structures and tags.

SLI_gDB_T_CONFIG

	Name	Data type	Start value
1	Static		
2	T_CONFIG	Struct	
3	start	Bool	false
4	hwid	HW_INTERFACE	64
5	busy	Bool	false
6	done	Bool	false
7	error	Bool	false
8	errorLocation	DWord	16#0
9	status	DWord	16#0
10	memErrStat	DWord	16#0
11	configData	Struct	
12	header	IF_CONF_Header	
13	deviceIP	IF_CONF_v4	
14	deviceName	IF_CONF_NOS	

In the structure "configData": Assign parameters for the system data type "IF_CONF_Header" for specifying the size of the PROFINET data, as follows:

12	header	IF_CONF_Header	
13	FieldType	UInt	0
14	FieldId	UInt	0
15	SubfieldCount	UInt	2

In the structure "configData": Assign parameters for the system data type "IF_CONF_v4" for defining the IP address, as follows:

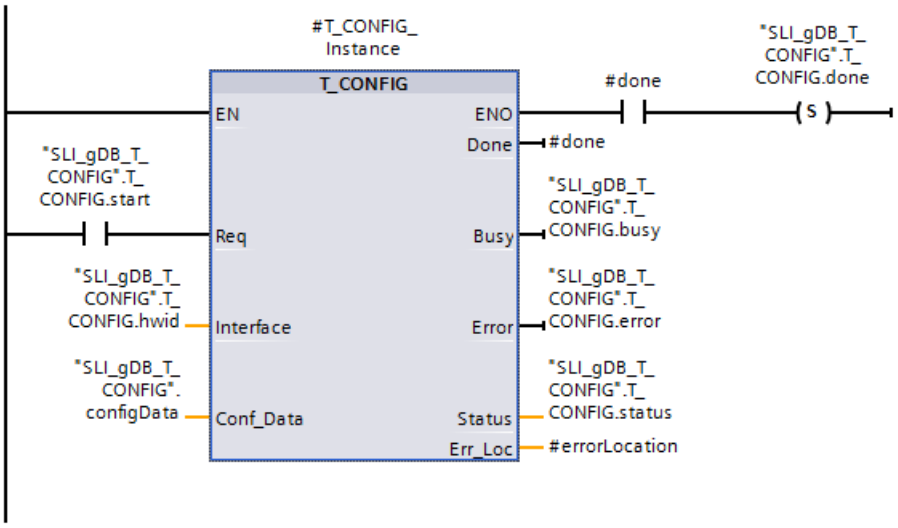
16	deviceIP	IF_CONF_v4	
17	Id	UInt	30
18	Length	UInt	18
19	Mode	UInt	1
20	InterfaceAddress	IP_V4	
21	ADDR	Array[1..4] of Byte	
22	ADDR[1]	Byte	192
23	ADDR[2]	Byte	168
24	ADDR[3]	Byte	0
25	ADDR[4]	Byte	3
26	SubnetMask	IP_V4	
27	ADDR	Array[1..4] of Byte	
28	ADDR[1]	Byte	255
29	ADDR[2]	Byte	255
30	ADDR[3]	Byte	255
31	ADDR[4]	Byte	0
32	DefaultRouter	IP_V4	
33	ADDR	Array[1..4] of Byte	
34	ADDR[1]	Byte	16#0
35	ADDR[2]	Byte	16#0
36	ADDR[3]	Byte	16#0
37	ADDR[4]	Byte	16#0

In the structure "configData": Assign parameters for the system data type "IF_CONF_NOS" for defining the PROFINET device name, as follows:

38	deviceName	IF_CONF_NOS	
39	Id	UInt	40
40	Length	UInt	11
41	Mode	UInt	1
42	NOS	Array[1..240] of Byte	
43	NOS[1]	Byte	'm'
44	NOS[2]	Byte	'y'
45	NOS[3]	Byte	'p'
46	NOS[4]	Byte	'l'
47	NOS[5]	Byte	'c'

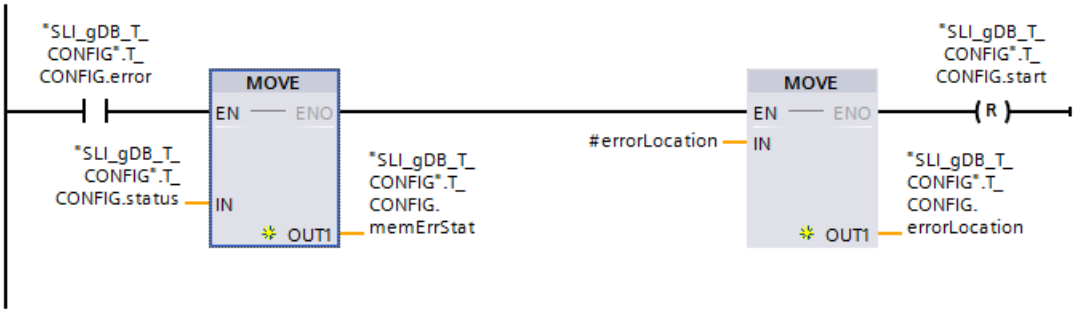
Note

Structure of "configData"



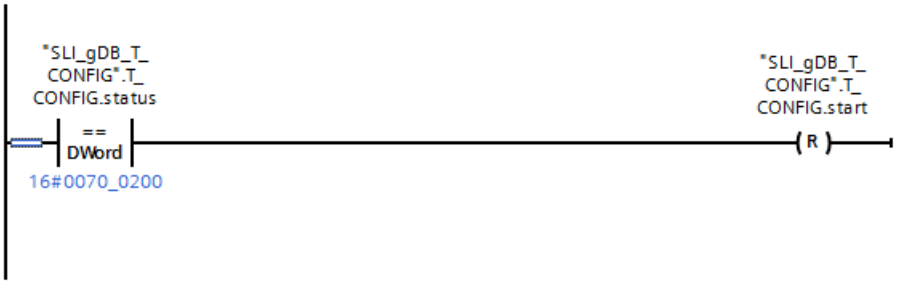
The information of the structure "configData" can be interpreted as follows:

- In the Header (IF_CONF_Header).
  SubfieldCount = 2: The value means: Two additional structures ("deviceIP", "deviceName") (*) are used below.
  *Make sure to maintain the order of both structures.
- For In the structure "deviceName" (system data type IF_CONF_NOS)
  - Lenght = 11 (*). The value corresponds to the overall length of the structure NOS (5 bytes for the device name"myplc" + 6 bytes for the parameters Id, Length and Mode)
    *Instead of an absolute length, you can use the default start value (Lenght = 0) for a dynamic length.
  - Mode = 1. The value causes a permanent change of the device name in "myplc".
  - NOS[1] ... NOS[5]. The NOS array contains the new device name (1 character / byte).



Create the FB "SLI_FB_T_CONFIG" Create the following local tags in it.

7	Static			
8	T_CONFIG_Instance	T_CONFIG		
9	done	Bool	false	Non-retain
10	errorLocation	DWord	16#0	Non-retain



Network 1: Interconnect the parameter of the instruction "T_CONFIG" as follows:

Network 2: In case of error of T_CONFIG, save the status as follows.

Network 3: To exit T_CONFIG, create the following interconnections.

Result

Network 1:

When the input parameter REQ ("T_CONFIG.start") supplies the signal state "TRUE", the "T_CONFIG" instruction is started. The instruction "T_CONFIG" configures the integrated PROFINET interface of the CPU for multiple calls. Based on the input parameter INTERFACE ("T_CONFIG.hwid"), the "T_CONFIG" instruction knows the interface to be used.

Successful transfer of the data record () is indicated by the output parameter DONE ("#done") with the signal state "TRUE". At the same time the value "0000_0000" is displayed at the output

parameter STATUS ("T_CONFIG.status"). Because the values of the output parameters are only displayed for the moment of their validity, save the success message in the tag "T_CONFIG.done".

The output parameter ERROR ("T_CONFIG.error") or the tag "T_CONFIG.memErrStat" indicates that processing in the example is taking place without errors.

SLI_gDB_T_CONFIG

	Name	Data type	Start value	Monitor value
1	Static			
2	T_CONFIG	Struct		
3	start	Bool	false	FALSE
4	hwid	HW_INTERFACE	64	16#0040
5	busy	Bool	false	FALSE
6	done	Bool	false	TRUE
7	error	Bool	false	FALSE
8	errorLocation	DWord	16#0	16#0000_0000
9	status	DWord	16#0	16#0070_0000
10	memErrStat	DWord	16#0	16#0000_0000
11	configData	Struct		

Network 2:

If T_CONFIG signals an error ("T_CONFIG.error", "TRUE"), save the alarm as follows:

- Save the status ("T_CONFIG.status") in the "T_CONFIG.memErrStat" tag.
- Save the error location, output at the output parameter ERR_LOC ("#errorLocation") from T_CONFIG, in the tag "T_CONFIG.errorLocation".

Online & diagnostics

To check whether the PROFINET data were changed, open the path "Online & Diagnostics > Functions > Assign name" in the project tree.

Accessible devices in the network:

IP address	MAC address	Device	PROFINET device name
192.168.0.2	28-63-36-8D-BB-49	S7-1500	simaticplc
192.168.0.3	00-1B-1B-22-63-D0	S7-1500	myplc

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Description T_CONFIG (Page 4547)

Changes to the communications instructions (S7-1200, S7-1500)

Differences between the versions <= V3.x and >= V4.1 of the OUC library (S7-1200, S7-1500)

Introduction

CPU S7-1200 as of firmware version 4.1 supports new instruction versions for Open User Communication (OUC). The new instructions are included in the library with version 4.1.

If you want to use this library, changes must be made to the user program, since some of the new instructions for Open User Communication behave differently.

This section describes the differences in detail, especially in the call behavior of the instructions.

Note

Description only relevant when upgrading from the CPU S7-1200 ≤ V4.0 to S7-1200 ≥ V4.1

If you are using an S7-1500 CPU, changes between the library versions are not relevant. The same applies if you are using an S7-1200 ≥ Version 4.1 and do not convert the library for the Open User Communication to versvon <4.1.

Differences between the versions <= V3.x and >= V4.1 of the Open User Communication library

The following table shows the instruction that have differences between the versions <= V3.x and >= V4.1 of the Open User Communication library Click on the name of the instruction for detailed information.

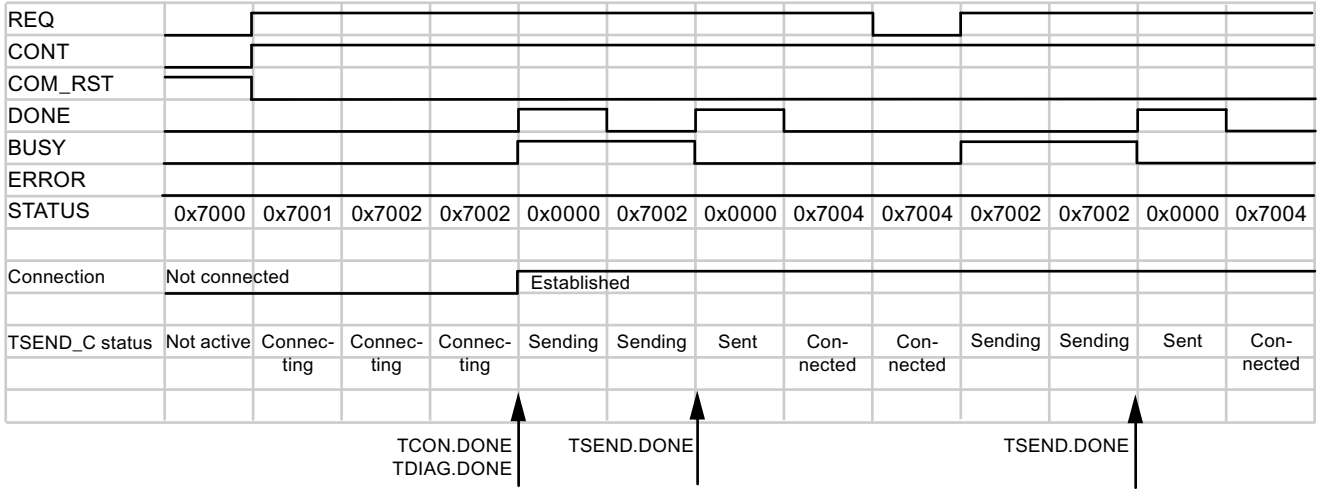
Instruction	Version in library <= V3.x (CPU FW ≤ V4.0)	Version in library >= V4.1 (CPU FW ≥ V4.1)
TSEND_C (Page 4564)	V2.1	V3.0
TRCV_C (Page 4565)	V2.1	V3.0
TMAIL_C *	V2.1	V3.0
TCON (Page 4567)	V3.0	V4.0
TDISCON	V2.1	V2.1 (identical to library <= V3.x)
TSEND (Page 4569)	V3.0	V4.0
TRCV (Page 4571)	V3.0	V4.0
TUSEND (Page 4569)	V3.0	V4.0
TURCV (Page 4571)	V3.0	V4.0
T_RESET *	V1.1	V1.2
T_DIAG *	V1.1	V1.2
T_CONFIG	V1.0	V1.0 (identical to library <= V3.x)
* There are no differences in the versions that affect the user program.		

Note

Changing the Open User Communication library from a version <= V3.x to a version >= V4.1

When replacing the Open User Communication library from a version <= V3.x to a version >= V4.1 you also need to replace the Modbus TCP library. Afterwards check all the instructions relevant for your program.

See also

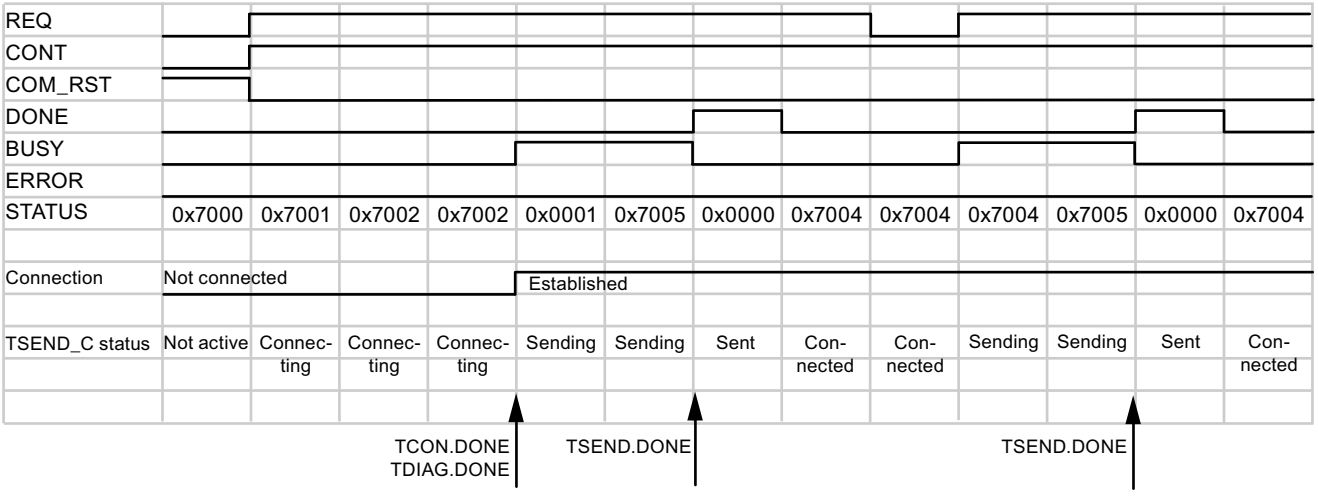


Differences between the versions <= V3.x and >= V4.0 of the Modbus TCP library (Page 4675)

Changes with the TSEND_C instruction (S7-1200, S7-1500)

Call behavior of TSEND_C (V<3.0)

Up to version 2.1 of the TSEND_C instruction, the DONE output parameter is set twice: Once when a connection is established by the internally used TCON instruction and then after a send operation by the internally used TSEND instruction.



The following diagram shows the connection establishment and the sending of data with TSEND_C V2.1:

When setting the COM_RST parameter to "1", the current connection establishment or a current data transmission can be reset at any time. This terminates the existing communication connection and a new connection is established.

Call behavior of TSEND_C (V≥3.0)

As of the TSEND_C version, the DONE parameter is only set when data transfer has been completed by the internally used TSEND instruction (STATUS = 0000).

The existing connection is temporarily interrupted and reset when the COM_RST parameter is set to "1". However, unlike TSEND_C V2.1, the connection endpoint is retained.

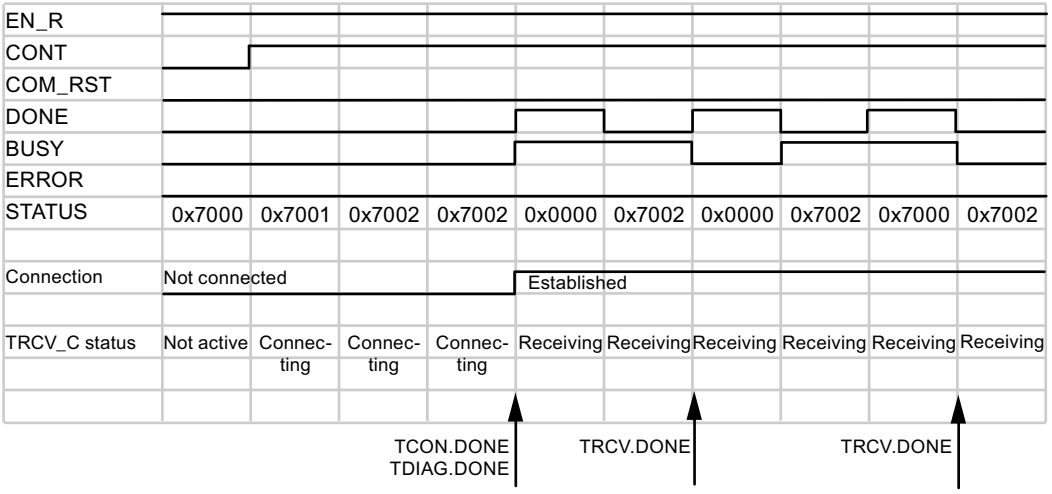
Note

Additional protocols with TSEND_C as of version 3.0

Version 3.0 of the TSEND_C instruction also supports UDP and UDP Broadcast via the interface of the CPU and via CM/CP.

See also

TSEND_C: Send data via Ethernet (Page 4419)

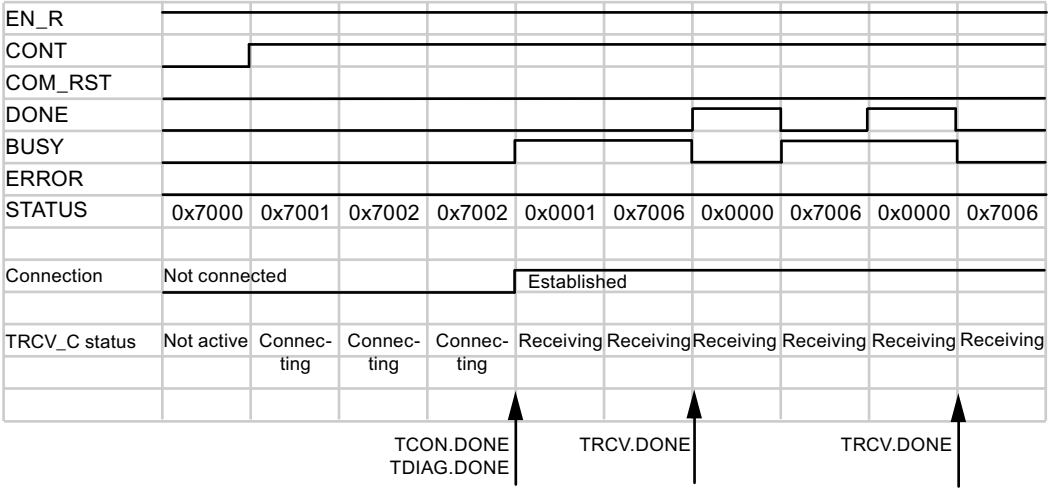


TSEND_C: Establishing a connection and sending data (Page 4423)

Changes with the TRCV_C instruction (S7-1200, S7-1500)

Call behavior of TRCV_C (V<3.0)

Up to version 2.1 of the TRCV_C instruction, the DONE output parameter is set after the connection is established. The STATUS output parameter does not distinguish whether the connection or the data transfer has been completed.



The following diagram shows the connection establishment and the sending of data with TRCV_C V2.1:

The current connection establishment or a current data transmission can be reset at any time by setting the COM_RST parameter to "1". This terminates the existing communication connection and a new connection is established.

Call behavior of TRCV_C (V≥3.0)

As of the TRCV_C version, the DONE parameter is only set when data transfer has been completed by the internally used TRCV instruction (STATUS = 0000). The completion of the connection establishment by the internally used TCON instruction is displayed by the output value 0x0001 at the STATUS parameter.

The existing connection is temporarily interrupted and reset when the COM_RST parameter is set to "1". However, unlike TSEND_C V2.1, the connection endpoint is retained.

Note

Additional protocols with TRCV_C as of version 3.0

Version 3.0 of the TRCV_C instruction also supports UDP and UDP Broadcast via the interface of the CPU and via CM/CP.

Note

ADHOC mode for the TCP protocol variant

In accordance with the TRCV instruction, with TRCV_C up to version 2.1, ADHOC mode is activated by assigning the value "0" to the LEN parameter. As of version 3.0 of the instruction, you use the ADHOC parameter for this. You can find detailed information in the descriptions of the instructions.

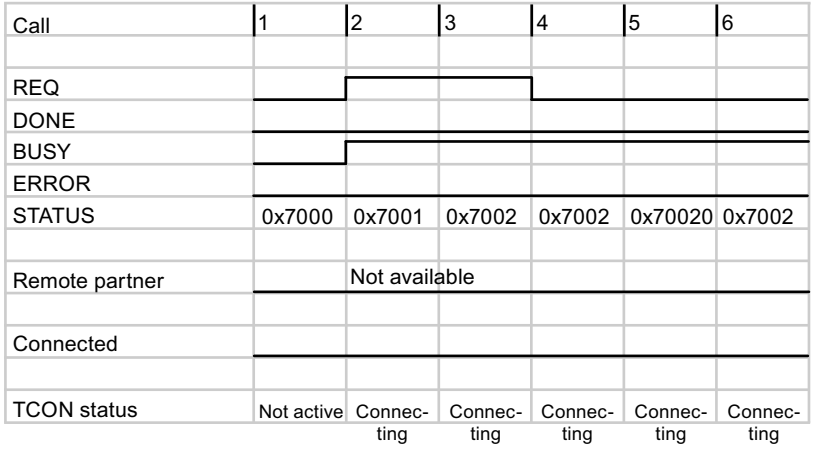
TRCV_C: Receive data via Ethernet (Page 4432)

TRCV_C: Establishing a connection and receiving data (Page 4437)

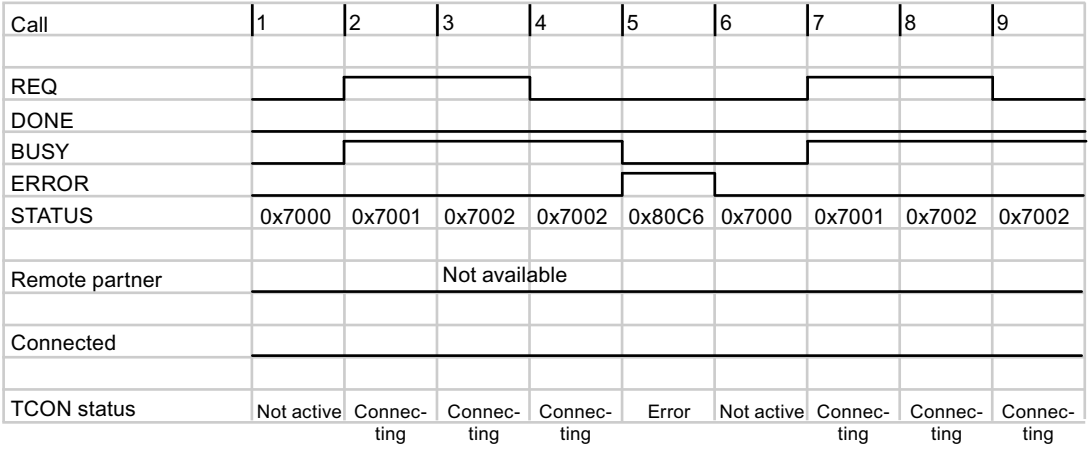


Changes with the TCON instruction (S7-1200, S7-1500)

Changed call behavior with connection errors

Previous call behavior of TCON (V<4.0)

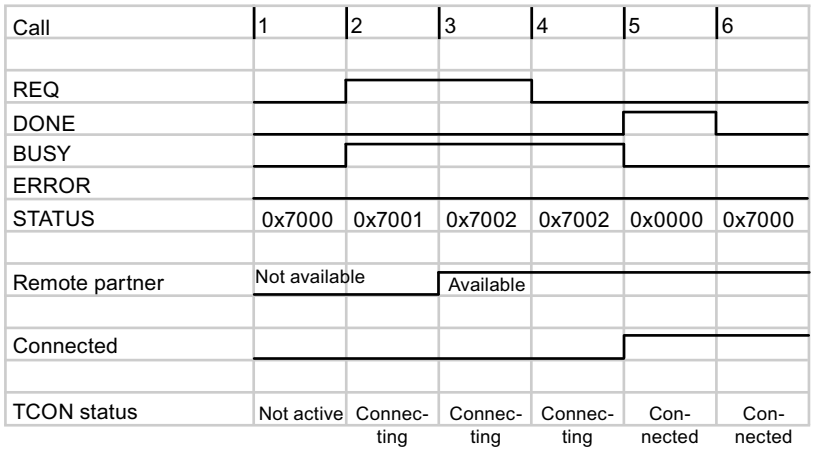
- The previous TCON instruction (V<4.0) is activated with a rising edge at the REQ input parameter.
- If the remote communication partner cannot be reached, the instruction sets the BUSY output parameter.
- An error message is not output.



The following diagram shows the behavior of TCON on the part of the active connection partner. If no connection is made, the instruction is not called again.

New call behavior of TCON (V≥4.0)

- The new TCON instruction is also activated with a rising edge at the REQ input parameter.
- Unlike before, an error message is output when the remote communication partner cannot be reached. The error can be queried and the call started again by a new edge at the REQ parameter.
- The following changes result for the user program:
  - Additional error messages of TCON that can be evaluated (see description of TCON (Page 4478)).
  - The connection establishment can be re-initialized via a new rising edge. To do this, query the DONE and ERROR parameters to ensure that an error is present.



The following diagram shows the behavior of TCON on the part of the active connection partner. The instruction is called again after a network error (error code 80C6).

Call behavior without communication errors

If there is no connection error, the TCON versions have the same behavior.

The following diagram shows the behavior of TCON on the part of the active connection partner.

TCON: Establish communication connection (Page 4474)

Changes with the TSEND/TUSEND instructions (S7-1200, S7-1500)

Send operation with an established connection

If no delay or interruption occurs during sending, versions 3.0 and 4.0 of the TSEND/TUSEND instructions behave the same way:

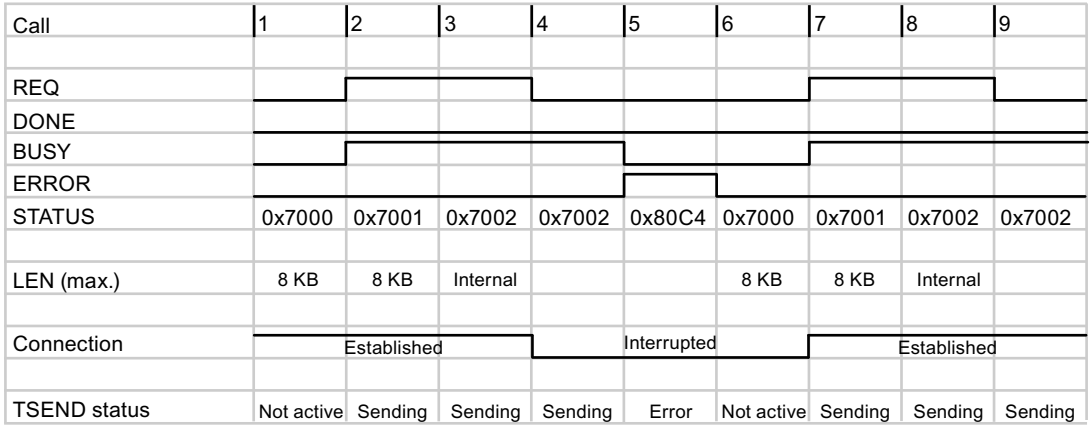
- The instruction is started with a positive edge at the "REQ" parameter. The instruction is executed asynchronously, i.e. it must be called until the full execution is indicated by the DONE parameter.
- A maximum of 8 KB of data can be sent with TSEND. A maximum of 1472 bytes can be sent with TUSEND. The amounts are based on the full execution of the instruction, i.e. all required calls until the DONE parameter is set.
- Data transmission takes place in three steps:
  - The data is written from the operand area to an internal buffer (indicated by STATUS=7001).
  - The transmission to the remote communication partner follows.
  - If the transmission is successful, DONE is set to "1" and STATUS is reset to "0" (see call 5 in the diagram below).

Call	1	2	3	4	5	6
REQ						
DONE						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
LEN (max.)	8 KB	8 KB	Internal			
Connected						
TSEND status	Not active	Sending	Sending	Sending	Sent	Not active

Send operation with time-delayed call

If the send operation is not performed via a communication module (CM) or a communication processor (CP), versions 3.0 and 4.0 of the TSEND/TUSEND instructions behave the same way:

- In the following example, TSEND or TUSEND are only called once with a rising edge at the REQ parameter (see call 2 in the diagram below).
- If the time delay is sufficiently long and the data could be transferred, the DONE parameter is set directly to "1" in the next call (call 3 here).



Call	1	2 → Time delay / No call		3	4
REQ					
DONE					
BUSY					
ERROR					
STATUS	0x7000	0x7001		0x0000	0x7000
LEN (max.)	8 KB	8 KB	Internal		
Connected					
TSEND status	Not active	Sending	Sending	Sent	Not active

If the send operation is performed via a CM/CP, version 4.0 of the TSEND/TUSEND instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter of the TRCV/TURCV instructions.

Send operation with interrupted connection

If the connection is interrupted during the send operation, the ERROR and STATUS parameters indicate the error and its cause. In the following example, the connection was interrupted during call number 5 and this error is indicated accordingly with the STATUS parameter.

As of version 4.0 of the TSEND/TUSEND instructions, more STATUS alarms are available that can be correspondingly evaluated (see description of TSEND (Page 4490)/TUSEND (Page 4516)) .

See also

TSEND: Send data via communication connection (Page 4486)

Changes with the TRCV/TURCV instructions (S7-1200, S7-1500)

Receive operation with an established connection

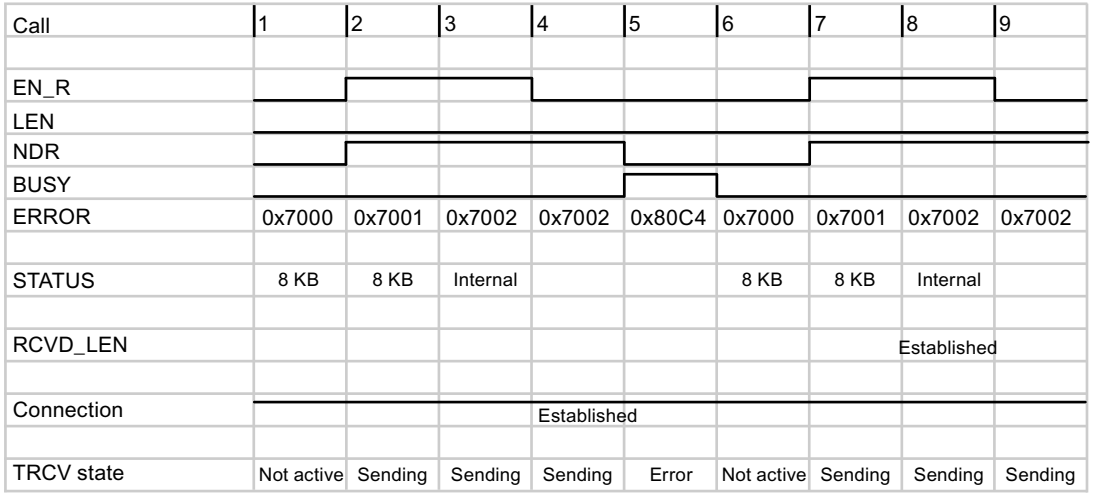
If no delay or interruption occurs during sending, version 3.0 and 4.0 of the TRCV/TURCV instructions behave the same way:

- A maximum of 8 KB of data can be sent with TRCV. A maximum of 1472 bytes can be received with TURCV. The amounts are based on the full execution of the instruction, i.e. all required calls until the DONE parameter is set.
- The instruction receives data if the EN_R parameter is set to "1".
- The data reception is not complete until the length of data specified at the the LEN parameter has been completely received. The length of the received data is output at the RCVD_LEN output parameter. Only then does the data in the area defined at the DATA parameter become available.

Call	1	2	3	4	5	6
EN_R						
LEN (max.)	8 KB	8 KB	Internal			
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
RCVD_LEN	0	0	0	0	max. 8 KB	0
Connection	Established					
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

Receive operation with time-delayed call

If the send operation is not performed via a communication module (CM) or a communication processor (CP), versions 3.0 and 4.0 of the TRCV/TURCV instructions behave the same way:



- In the following example, TRCV or TURCV are only called once with a rising edge at the EN_R parameter (see call 2 in the diagram below).
- If the time delay is sufficiently long and the data could be transferred, the NDR parameter is set directly to "1" in the next call (call 3 here).

Call	1	2	Delay No call		3	4
EN_R						
LEN (max.)	8 KB	8 KB	Internal			
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001			0x0000	0x7000
RCVD_LEN	0	0	0	0	max. 8 kB	0
Connection	Established					
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

If the send operation is performed via a CM/CP, version 4.0 of the TSEND/TUSEND instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter.

Receive operation with interrupted connection

If the connection is interrupted during receiving, the ERROR and STATUS parameters indicate the error and its cause. In the following example, call number 5 resulted in a temporary communication error, which is accordingly indicated by the STATUS parameter.

As of version 4.0 of the TRCV/TURCV instructions, more STATUS alarms are available that can be correspondingly evaluated (see description of TRCV (Page 4498)/TURCV (Page 4520)).

Receive operation using ADHOC mode

ADHOC mode is only available with the TCP protocol variant. You can use ADHOC mode to receive data of variable length with the TRCV/TURCV instruction. If ADHOC mode is active, the receipt of data is confirmed at the NDR parameter when at least one byte has been transferred.

Data reception in ADHOC mode with TRCV < 3.0 (S7-1200 < V4.0)

In the older version of TRCV (Page 4493), ADHOC mode was activated by setting the LEN parameter to "0". In the following example, 10 bytes of data are transferred with call 5.

Call	1	2	3	4	5	6
EN_R						
LEN (max.)	0 = Activation of the ADHOC mode					
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
RCVD_LEN	0	0	0	0	10 bytes	0
Connection	Established					
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

Data receipt in ADHOC mode with TRCV ≥ 3.0 (S7-1200 ≥ V4.0 or S7-1500)

As of version 3.0 of the TRCV instruction, ADHOC mode is activated with its own parameter (ADHOC).

Call	1	2	3	4	5	6
EN_R						
LEN	Max. 8 KB	Max. 8 KB	Internal			
ADHOC						
NDR						
BUSY						
ERROR						
STATUS	0x7000	0x7001	0x7002	0x7002	0x0000	0x7000
RCVD_LEN	0	0	0	0	10 bytes	0
Connection	Established					
TRCV status	Not active	Receiving	Receiving	Receiving	Receiving	Not active

If an error occurs during execution, as of version 4.0 of the TRCV instructions, there are more STATUS alarms available which can be evaluated accordingly.

If the send operation is performed via a CM/CP, version 4.0 of the TRCV/TURCV instructions behaves differently. In this case, the instruction must be called multiple times until the receipt of data is confirmed by the NDR parameter.

11.4.6.3 Web server (S7-1200, S7-1500)

WWW: Synchronizing user pages (S7-1200, S7-1500)

WWW: Synchronizing user pages (S7-1200, S7-1500)

Description

The instruction WWW initializes the web server of the CPU or synchronizes user-defined web pages, in short: "user pages", with the user program in the CPU.

Together with the Web server, user web pages make it possible for the CPU to access freely designed web pages of the CPU with a web browser.

Use script instructions (such as Javascript) and HTML code in user web pages to transfer data via a web browser for further processing to the CPU and to display data from the operand area of the CPU in the web browser. To synchronize the user program and the Web server, but also to initialize, call the instruction "WWW" in the user program.

Initialization

User web pages are "packaged" in data blocks for processing by the CPU. You will have to generate appropriate data blocks from the source files (HTML files, screens, Javascript files, ...) during configuration. The Web Control DB takes on a special role (default: DB 333). It contains status and control information as well as links to additional data blocks with coded web pages. The data blocks with coded web pages are called fragment DBs.

When the data blocks are downloaded into the CPU, the CPU does not "know" that user web pages are coded inside it. The instruction "WWW" in the startup OB, for example, will inform the CPU which DB is the Web Control DB. After this initialization, the user pages are accessible via a web browser.

Synchronization

If you want the user program to interact with the user pages, then the instruction "WWW" must be used in the cyclical program part.

Examples of interaction between user program and web page:

- Check received data
- Assemble and send back data to the web browser making the request

In this case it must be possible to evaluate the current status information and the Web server must receive control information, such as release of a web page requested by a web browser.

Parameter

The following table shows the parameters of the "WWW" instruction:

Parameter	Declaration	Data type	Memory area	Description
CTRL_DB	Input	DB_WWW	I, Q, M, D, L or constant	Data block that describes the user pages (Web control DB)
RET_VAL	Output	INT	I, Q, M, D, L	Error information

For additional information on valid data types, refer to Overview of the valid data types (Page 2239).

Parameter RET_VAL

Error code (W#16#...)	Explanation
0000	No error occurred. There are no web page requests that have to be released by the user program.
00xy	x: indicates whether an error has occurred during initialization of the Web Control DB (CTRL_DB): x=0: No errors occurred. x=1: Error occurred. The error is coded in the byte "CTRL_DB.last_error" of the Web Control DB, see description of Web Control DB. y: Number of the pending request. Several requests are possible (e. g. requests "0" and "1" are pending: y="3". y="1": Request "0" y="2": Request "1" y="4": Request "2" y="8": Request "3"
803A	The specified Web Control DB does not exist on the CPU.
8081	Incorrect version or incorrect format of the Web Control DB.
80C1	There are no resources to initialize the web application, for example, because only two or four web applications may be running.

Example

You will find the example here: Program example of WWW (Page 4577).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

See also

Overview of the valid data types (Page 2239)

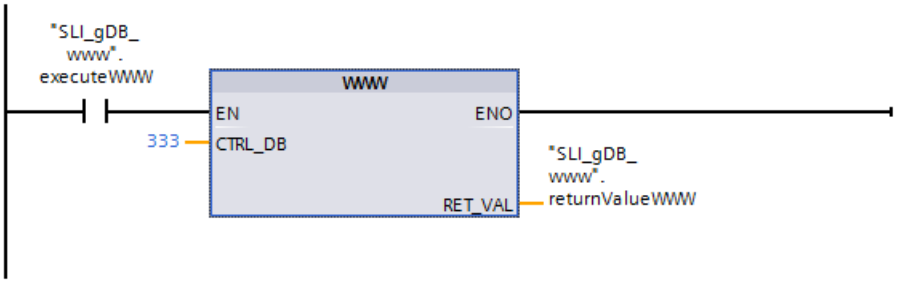
Program example of WWW (S7-1200, S7-1500)

Introduction

In the following example, you synchronize a user-defined Website with the program example in a CPU S7-1500 and test the program example via a Web server.

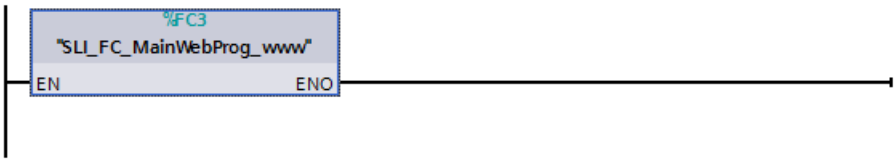
Requirement

Create nineteen tags in a global data block for storing the data.



SLI_gDB_www

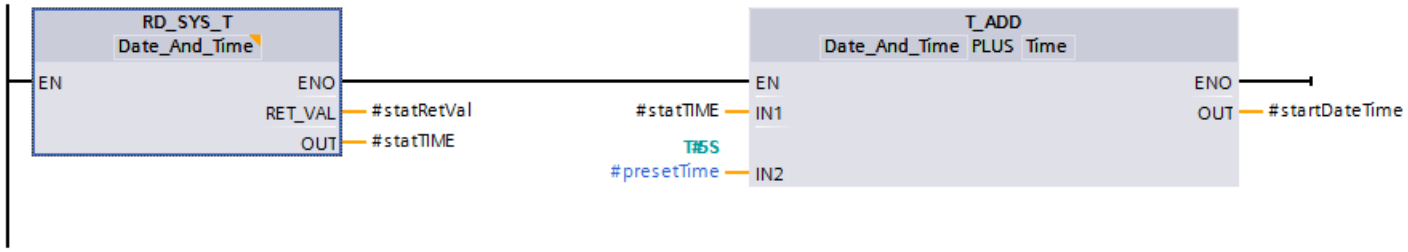
	Name	Data type	Start value
1	Static		
2	executeWWW	Bool	false
3	returnValueWWW	Word	16#0
4	executeSetOB	Bool	false
5	setDone	Bool	false
6	start	Bool	false
7	stop	Bool	false
8	engineStarted	Bool	false
9	reset	Bool	false
10	tempReset	Bool	false
11	openValve	Bool	false
12	closeValve	Bool	false
13	valveOutput	Bool	false
14	flowrate	Int	1
15	tankLevel	Int	0
16	alarm	Int	0
17	tankLevelOverflow	Int	160
18	tankLevelMax	Int	150
19	tankLevelMidth	Int	75
20	tankLevelMin	Int	5



Interconnect parameters - in FB “SLI_FB_www“

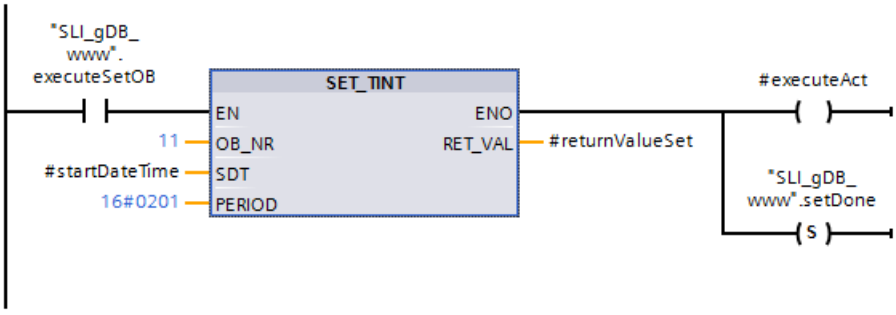
You create the following interconnections in an FB "SLI_FB_www": You call the FB in an OB1.

Network 1: Interconnect the parameters of the "WWW" instruction as follows.



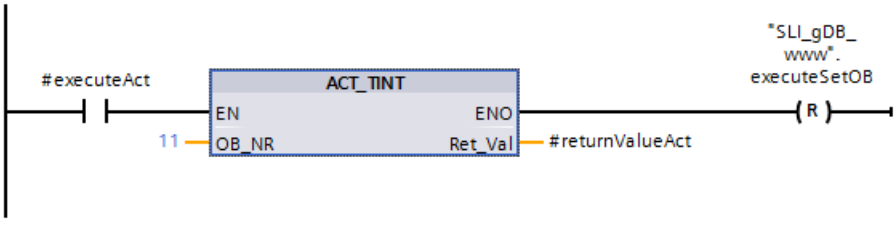
Network 2: You create the program for the Website in the FC “SLI_FC_MainWebProg_www“. You then call the FC “SLI_FC_MainWebProg_www“ in network 2 of the FB.

Interconnecting parameters - in FC "SLI_FC_SetTOD_www"



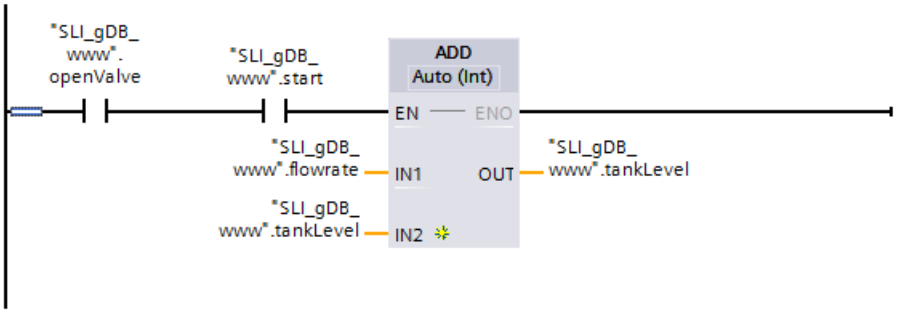
In an FC “SLI_FC_SetTOD_www“ you create a program for using a time-of-day interrupt OB (OB11). You create the following interconnections:

Network 1: In the FC you interconnect the following local tags with the instructions “RD_SYS_T“ and “T_ADD“.



Network 2: This is followed by interconnecting the tags for setting the time-of-day interrupt OB.

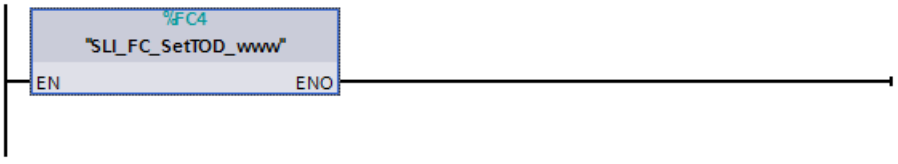
The local tag “#startDateTime“ (data type “Date_And_Time”) transfers the start time to the time-of-day interrupt OB.



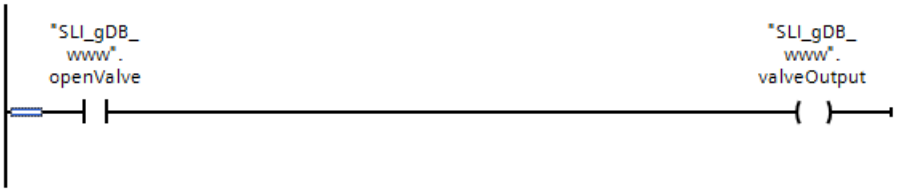
Network 3: This is followed by interconnecting the tags for activating the time-of-day interrupt OB.

Interconnecting parameters - in the OB “SLI_todOB_www“

In the time-of-day interrupt OB “SLI_todOB_www“ (OB11) you create the following interconnections for cyclic increasing of the tag “tankLevel“.

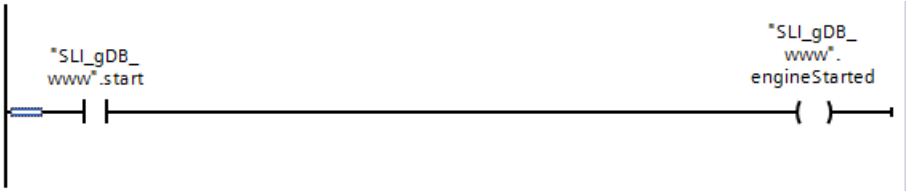


Interconnecting parameters - in FC "SLI_FC_MainWebProg_www"

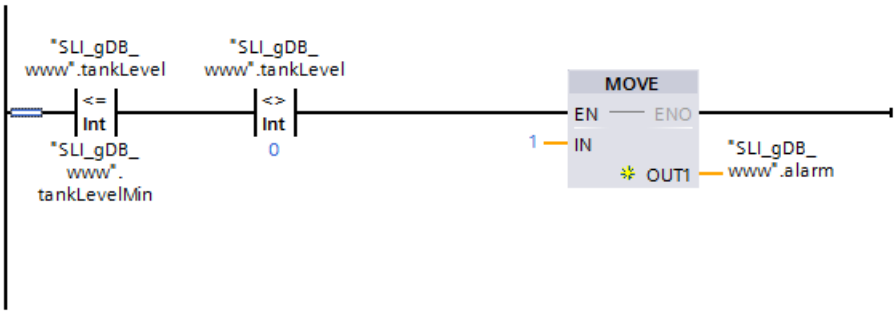


You create the following interconnections in the FC "SLI_FC_MainWebProg_www“.

The program “SLI_FC_MainWebProg_www“ allows control of a motor, a valve and the tank filling. In addition to this the output of various interrupt statuses is made possible. The program is controlled via the Web server.

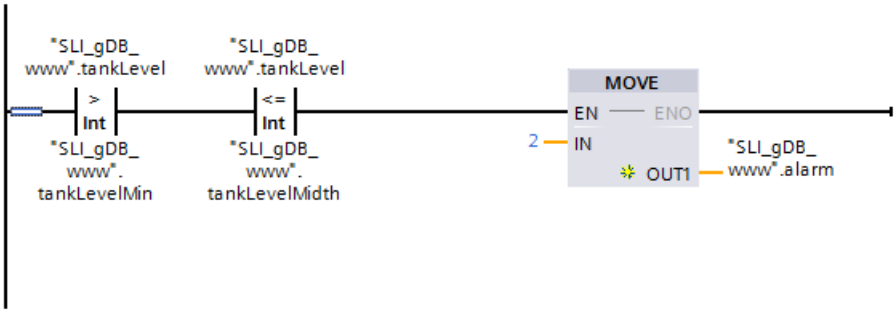


Network 1: You call the FC “SLI_FC_SetTOD_www“ in the FC “SLI_FC_MainWebProg_www“.

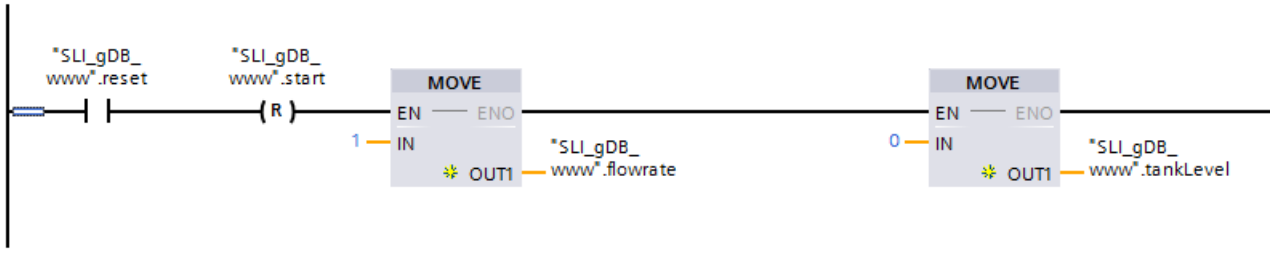


Network 2: This is followed by interconnecting the tags for opening the valve.

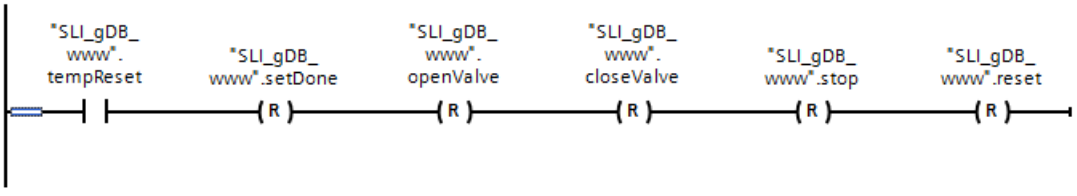
Network 3: This is followed by interconnecting the tags for starting the motor.



Network 4: This is followed by interconnecting the tags for querying the interrupt status “1“.



Networks 5 to 8: This is followed by interconnecting the tags for querying the interrupt status "2".



Interconnect the tags for querying the other interrupt statuses in the same way.

Network 9: This is followed by interconnecting the tags for resetting the the motor and the filling of the tank..

Network 10: This is followed by interconnecting the tags for resetting all the other values (BOOL).

Setting CPU properties

Make the following settings in the CPU properties:

- Activate web server access under "... > PROFINET interface > Access to the web server".
- In “CPU properties > Web server enable the Web server for the module,
- In the section “User administration“ create a new user with read and write rights.
- Make the following settings in the section "User pages":
  - You set the “HTML file path”.

    Note

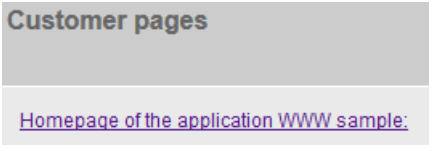
    The storage path should be the same as the path of the Sample Library for Instructions (SLI). The folder name is “SLI_html“. For example: “C:\TIA_library\SLI_html“.

  - Enter the text "index.html" for the Start HTML page.
  - For the application you enter the name “WWW sample“.
  - Click the "Create block" button. The Web DB (333) and the Fragment DB (334) are then created.

Result for WWW

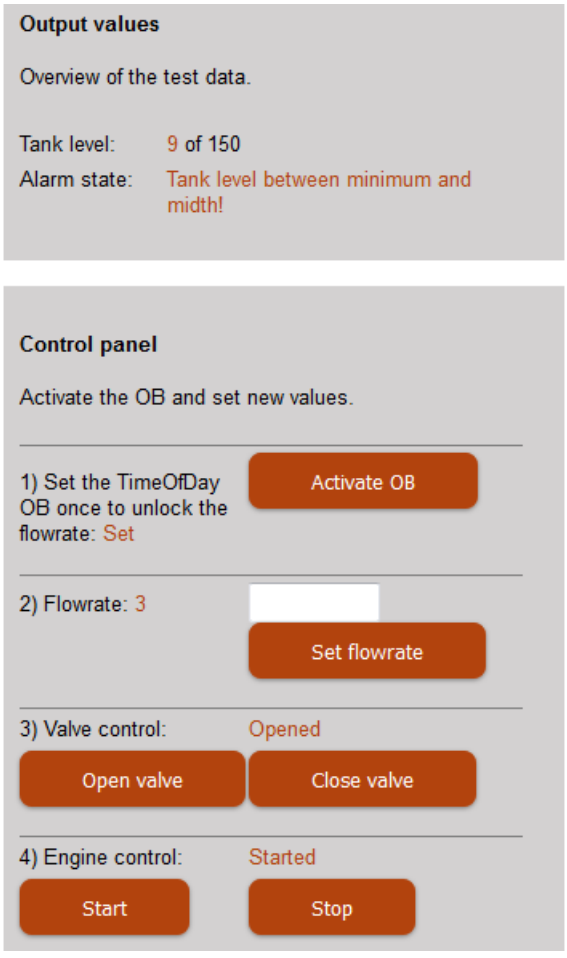
If the normally open contact ("executeWWW") supplies the signal state "TRUE", the "WWW" instruction is executed. The number of the data block that describes user defined Website is stored via the the input parameter CTRL_DB ("333"). The “WWW“ instruction initializes the user defined Website in the Web server of the CPU and immediately synchronizes the program example.

The output parameter RET_VAL ("returnValueWWW") indicates that the processing is running without errors.



SLI_gDB_www

	Name	Data type	Start value	Monitor value
1	Static			
2	executeWWW	Bool	false	TRUE
3	returnValueWWW	Word	16#0	16#0000
4	executeSetOB	Bool	false	FALSE
5	setDone	Bool	false	TRUE
6	start	Bool	false	TRUE
7	stop	Bool	false	FALSE
8	engineStarted	Bool	false	TRUE
9	reset	Bool	false	FALSE
10	tempReset	Bool	false	FALSE
11	openValve	Bool	false	TRUE
12	closeValve	Bool	false	FALSE
13	valveOutput	Bool	false	TRUE
14	flowrate	Int	1	3
15	tankLevel	Int	0	3
16	alarm	Int	0	1
17	tankLevelOverflow	Int	160	160
18	tankLevelMax	Int	150	150
19	tankLevelMidth	Int	75	75
20	tankLevelMin	Int	5	5



Result for the Web server

You call the Web server via the “Internet browser > IP of the Web server”. You log in with your user name user name and -password.

In the Web server in “User pages” a link to the website defined by the user is displayed.

On the Website of the program example it is possible for you to output tags and transfer new values to the tags.

Functions used in the HTML document

Below you will see excerpts of the functions used in the program example with which the tags are transferred to the source code in the HTML document. For each function a tag is implemented via a call in the HTML document and at the relevant location in the HTML document is used with a further call.

Function	To call in the HTML document	To output in the HTML element
Data output:	`<!-- AWP_In_Variable Name='"SLI_gDB_www".tankLevel' -->`	`:="SLI_gDB_www".tankLevel:`
Enumeration (value replacement):	`<!-- AWP_Enum_Def Name="OpValvValue" Values='0:"Closed", 1:"Opened"' -->`	`<!-- AWP_Enum_Ref Name='"SLI_gDB_www".valveOutput' Enum="OpValvValue" -->:="SLI_gDB_www".valveOutput:`

Function	To call in the HTML document	To output in the HTML element
Value change (from INT):	`<!-- AWP_In_Variable Name='"SLI_gDB_www".flowrate' -->`	`<form method="post" action="" onsubmit="return check();"> <input type="text" name='"SLI_gDB_www".flowrate' size="10px"/> <input class="button1" type="submit" value="Set flowrate"/> </form>`
Value change (from BOOL):	`<!-- AWP_Enum_Def Name="ResetValue" Values='0:"Off", 1:"On"' -->`	`<form method="post" action=""> <input class="button1" type="submit" value="Reset"/> <input type="hidden" name='"SLI_gDB_www".reset' size="34px" value="1"/> </form>`

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

11.4.6.4 Communications processor (S7-1200, S7-1500)

SIMATIC NET CM/CP (S7-1200, S7-1500)

Point-to-point (S7-1200)

PORT_CFG: Configure communication parameters dynamically (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The instruction "PORT_CFG" allows dynamic configuration of communications parameters for a point-to-point communications port.

You set up the original static configuration of the port in the hardware configuration. You can change this configuration by executing the "PORT_CFG" instruction. You can also use this

function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it.

With "PORT_CFG" you can influence the following communications parameter settings:

- Parity
- Baud rate
- Number of bits per character
- Number of stop bits
- Type and properties of flow control

The changes made by the "PORT_CFG" instruction are not stored permanently on the target system.

You can transfer serial data via the electrical connections RS-232 (half and full duplex) and RS-485 (half duplex).

Parameters

The following table shows the parameters of the "PORT_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
PROTOCOL	Input	UINT	I, Q, M, D, L or constant	Transmission protocol: • 0: Point-to-point communication protocol • 1..n: Future definition for specific transmission protocols
BAUD	Input	UINT	I, Q, M, D, L or constant	Baud rate of the port: • 1: 300 baud • 2: 600 baud • 3: 1200 baud • 4: 2400 baud • 5: 4800 baud • 6: 9600 baud (default) • 7: 19200 baud • 8: 38400 baud • 9: 57600 baud • 10: 76800 baud • 11: 115200 baud

Parameter	Declaration	Data type	Memory area	Description
PARITY	Input	UINT	I, Q, M, D, L or constant	Parity of the port: • 1: No parity (default) • 2: Even parity • 3: Odd parity • 4: Mark parity • 5: Space parity
DATABITS	Input	UINT	I, Q, M, D, L or constant	Bits per character: • 1: 8 bits per character (default) • 2: 7 bits per character
STOPBITS	Input	UINT	I, Q, M, D, L or constant	Number of stop bits: • 1: 1 stop bit (default) • 2: 2 stop bits
FLOWCTRL	Input	UINT	I, Q, M, D, L or constant	Data flow control: • 1: None (default) • 2: XON/XOFF • 3: Hardware flow control (RTS always activated) • 4: Hardware flow control (RTS can be deactivated during transmission)
XONCHAR	Input	CHAR	I, Q, M, D, L or constant	Indicates the character used as XON character. The character DC1 (11H) is set as default.
XOFFCHAR	Input	CHAR	I, Q, M, D, L or constant	Indicates the character used as XOFF character. The character DC3 (13H) is set as default.
WAITTIME	Input	UINT	I, Q, M, D, L or constant	Specifies the wait time for XON or CTS after the start of the transmission. The specified value must be greater than 0. 2000 milliseconds are set as default.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
80A0	The specified protocol is invalid.
80A1	The specified baud rate is invalid.

Error code* (W#16#...)	Description
80A2	The specified parity rate is invalid.
80A3	The specified number of bits per character is invalid.
80A4	The specified number of stop bits is invalid.
80A5	The specified type of flow control is invalid.
80A6	Incorrect value at the WAITTIME parameter When the data flow control is enabled, the value at the WAITTIME parameter must be greater than zero.
80A7	Invalid values at XONCHAR and XOFFCHAR parameters.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

SEND_CFG: Configure serial transmission parameters dynamically (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The instruction "SEND_CFG" allows dynamic configuration of serial transmission parameters for a point-to-point communications port. All the messages waiting for transfer are discarded after execution of SEND_CFG.

You set up the original static configuration of the port in the hardware configuration. You can change this configuration by executing the "SEND_CFG" instruction. You can also use this function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it. With "SEND_CFG" you can influence the following transmission parameter settings:

- Time between the activation of RTS (Request to Send) and the start of the transmission
- Time between the end of transmission and the deactivation of RTS
- Define bit times for breaks

The changes made by the "SEND_CFG" instruction are not stored permanently on the target system.

You can transfer serial data via the electrical connections RS-232 (half and full duplex) and RS-485 (half duplex).

Parameters

The following table shows the parameters of the "SEND_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
RTSONDLY	Input	UINT	I, Q, M, D, L or constant	The time that should elapse after activating RTS until the start of transmission. Valid values for this parameter are as follows: • 0 (default) • 0 to 65535 ms in steps of 1 ms This parameter does not apply to RS-485 modules.
RTSOFFDLY	Input	UINT	I, Q, M, D, L or constant	Time that should elapse after the end of transmission until deactivation of RTS. Valid values for this parameter are as follows: • 0 (default) • 0 to 65535 ms in steps of 1 ms This parameter does not apply to RS-485 modules.
BREAK	Input	UINT	I, Q, M, D, L or constant	Specifies the bit times for a break, which are sent at the start of the message. 12 bit times are set as default. A maximum of 25000 bit times can be specified.
IDLELINE	Input	UINT	I, Q, M, D, L or constant	Specifies the bit times for idle line after the break at the start of the message. 12 bit times are set as default. A maximum of 25000 bit times can be specified.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
80B0	The configuration of a transmission interruption is not permitted.
80B1	The specified break time exceeds the permitted maximum of 25000 bit times.

Error code* (W#16#...)	Description
80B2	The specified time for idle line exceeds the permitted maximum of 25000 bit times.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

RCV_CFG: Configure serial receive parameters dynamically (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The instruction "RCV_CFG" allows dynamic configuration of serial receive parameters for a point-to-point communications port. You can use this instruction to configure the conditions that specify the start and end of the message to be transmitted. The receipt of messages that correspond to these conditions can be enabled by the "RCV_PTP (Page 4599)" instruction.

You set up the original static configuration of the port in the properties of the hardware configuration. Execute the "RCV_CFG" instruction in your program to change the configuration. You can also use this function to save created blocks in libraries and to avoid configuration in the hardware configuration when you reuse it. The changes made by the "RCV_CFG" instruction are not stored permanently on the target system.

All the messages waiting for transfer are discarded after execution of the "RCV_CFG" instruction.

Parameters

The following table shows the parameters of the "RCV_CFG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the configuration change on a rising edge.
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
CONDITIONS	Input	CONDITIONS	D, L	Data structure defining the conditions for start and end of data transmission.
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred.
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Data type CONDITIONS

You can use the CONDITIONS structure to define the start and end conditions for the message transmission. The structure CONDITIONS is included in the instance DB of the "RCV_CFG" instruction. Use the structure CONDITIONS to define the start and end conditions when the transmission of a message is complete and when the next message transfer is to start:

- You define the start conditions for the data transfer in the START structure.
- You define the end conditions for the data transfer in the END structure.

You can define one or more start and end conditions for this. If you specify multiple start or end conditions these are linked by an OR logic instruction.

The following table shows the "CONDITIONS" structure:

Parameters		Data type	Description
START		STRUCT	Start conditions
	STARTCOND	UINT	Specifies the start condition (details, see below). The start condition can be specified as a 16-bit hexadecimal value. Possible values for the start condition are: • 1: Start character • 2: Any character (default) • 4: Line break • 8: Idle line • 16: Character string 1 • 32: Character string 2 • 64: Character string 3 • 128: Character string 4 Multiple start conditions can also be defined at the STARTCOND parameter. The total from the values of the individual conditions is specified for this. If, for example, you want to define "Idle line" OR "Character string 1" OR "Character string 4" as start condition, the value "152" must be specified.
	IDLETIME	UINT	Specifies the maximum idle time of the line before receipt is started. Valid values for this parameter are as follows: • 40 bit times (default) • 0 to 2500 bit times
	STARTCHAR	BYTE	Specifies the start character. This setting is only enabled when the configured start condition is "Start character". Valid values for this parameter are as follows: • 02 (STX): Default setting • B#16#00 to B#16#FF
	SEQ[1].CTL	BYTE	Character string 1: Control sequence for each character You can use the bit position of the character to define which characters of the character string will be considered or ignored. To evaluate the characters, the corresponding bits have to be set. • Bit 0: 1 character • Bit 1: 2 characters • Bit 2: 3 characters • Bit 3: 4 characters • Bit 4: 5 characters A character is ignored when the corresponding bit is reset.
	SEQ[1].STR	CHAR[5]	Character string 1: Start character (5 characters)
	SEQ[2].CTL	BYTE	Character string 2: Ignore/compare control sequence for each character
	SEQ[2].STR	CHAR[5]	Character string 2: Start character (5 characters)
	SEQ[3].CTL	BYTE	Character string 3: Ignore/compare control sequence for each character
	SEQ[3].STR	CHAR[5]	Character string 3: Start character (5 characters)
	SEQ[4].CTL	BYTE	Character string 4: Ignore/compare control sequence for each character
	SEQ[4].STR	CHAR[5]	Character string 4: Start character (5 characters)

Parameters	Data type	Description
END	STRUCT	End conditions

Parameters		Data type	Description
	ENDCOND	UINT	Specifies the end condition (details, see below). The end condition can be specified as a 16-bit hexadecimal value. Possible values for the end condition are: • 1: Reply timeout • 2: Message timeout • 4: Timeout within the character string • 8: Maximum length • 16: N+LEN+M; the information on the message length in integrated in the message and will be evaluated. • 32: Character string 1 Multiple end conditions can also be defined at the ENDCOND parameter. The total from the values of the individual end conditions is specified for this. If, for example, you want to define the end condition "Maximum length" OR "Sequence 1", the value "40" must be specified.
	MAXLEN	UINT	Specifies the maximum number of characters in a message. Valid values* for this parameter are as follows: • 1 character (default) • 0 to 1024 characters This setting is only enabled if the "Maximum length" end condition is set at the ENDCOND parameter.
	N	UINT	Offset of the length field in the message Valid values for this parameter are as follows: • 0 characters (default) • 0 to 1024 characters This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	LENGTHSIZE	UINT	Size of the length field in bytes Valid values* for this parameter are as follows: • 0 bytes (default) • 1 byte • 2 bytes • 4 bytes This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	LENGTHM	UINT	Specifies the number of end characters that follow the length field but are not contained in the length of the message. Valid values for this parameter are as follows: • 0 characters (default) • 0 to 255 characters This setting is only enabled if the "N+LEN+M" end condition is set at the END-COND parameter.
	RCVTIME	UINT	Specifies the maximum duration for the receipt of the first character of a message. Valid values for this parameter are as follows: • 200 ms (default)

Parameters		Data type	Description
			• 0 to 65535 ms in steps of 1 ms This setting is only enabled if the "Reply timeout" end condition is set at the ENDCOND parameter.
	MSGTIME	UINT	Specifies the maximum duration of the receipt of a message. Valid values for this parameter are as follows: • 200 ms (default) • 0 to 65535 ms in steps of 1 ms This setting is only enabled if the "Message timeout" end condition is set at the ENDCOND parameter.
	CHARGAP	UINT	Specifies the time interval between received consecutive characters. Valid values for this parameter are as follows: • 12 bit times (default) • 0 to 2500 bit times This setting is only enabled if the "Timeout within the character string" end condition is set at the ENDCOND parameter.
	SEQ.CTL	BYTE	Character string: Control sequence for each character You can use the bit position of the character to define which characters of the character string will be considered or ignored. To evaluate the characters, the corresponding bits have to be set. • Bit 0: 1 character • Bit 1: 2 characters • Bit 2: 3 characters • Bit 3: 4 characters • Bit 4: 5 characters A character is ignored when the corresponding bit is reset.
	SEQ.STR	CHAR[5]	Character string: Start character (5 characters)
	* These value ranges also apply to the corresponding hardware settings for specifying the end of message.		

Start conditions for the message receipt (STARTCOND parameter)

The start of the message is recognized by the receiver if a configured start condition applies. The following conditions can be defined as start conditions for message receipt:

- Start character: The start of a message is recognized when a certain character occurs. This character is stored as first character of the message. All characters received before the start character are rejected.
- Any character: Any character can define the start of a message. This character is stored as first character of the message.
- Line break: The start of a message is recognized if the received data stream is interrupted for longer than one character length.

- Idle line: The start of a message is recognized when the send transmission line is in the idle state for a certain time (specified in bit times) followed by renewed transmission of characters.
- Character string (sequence): The start of a message is recognized when a specified character sequence occurs in the data stream. You can specify up to four character sequences with up to five characters each.
  Example: A received hexadecimal message includes the following characters: "68 10 aa 68 bb 10 aa 16". The configured start character sequences are listed in the following table. Start character sequences will be evaluated once the first character 68H has been received successfully. After the fourth character has been received successfully (the second 68H), the start condition "1" has been met. Once the start conditions have been met, evaluation of the end conditions will start.
  Processing of the start character sequence can end due to different errors in parity, framing or time intervals between characters. These errors will prevent reception of the message, because the start condition has not been met.

Start condition	First character	First character +1	First character +2	First character +3	First character +4
1	68H	xx	xx	68H	xx
2	10H	aaH	xx	xx	xx
3	dcH	aaH	xx	xx	xx
4	e5H	xx	xx	xx	xx

End conditions for the message receipt (ENDCOND parameter)

The start of a message is recognized by the receiver if a configured end condition applies. The following conditions can be defined as end conditions for message receipt:

- Reply timeout: The receipt of messages will end when the specified maximum duration for the receipt of a character is exceeded. The maximum duration is defined at the RCVTIME parameter. The defined time starts to run down as soon at the last transmission is completed and the RCV_PTP instruction enables the receipt of the message. If no character was received within the defined time (RCVTIME), the RCV_PTP instruction reports an error.
- Message timeout: The receipt of messages will end when the specified maximum duration for the receipt of a message is exceeded. The maximum duration is defined at the MSGTIME parameter. The defined time starts to run down as soon as the first character of the message is received.
- Timeout within the character string: The receipt of messages will end when the time interval between the receipt of two consecutive characters is longer than the value at the CHARGAP parameter.
- Maximum length: The receipt of messages will end when the length of the message defined at the MAXLEN parameter is exceeded.

- Reading message length (N+LEN+M): The receipt of messages will end when a certain message length is reached. This length is calculated by the values of the following parameters:
  - N: Position of the character in the message, as of which the length field begins.
  - LENGTHSIZE: Size of the length field in bytes
  - LENGTHM: Number of end characters that follow the length field. These characters are not taken into account in the evaluation of the message length.
- Character string: The receipt of messages will end when a defined character sequence is received. The character string can contain a maximum of five characters. For each character of the character string, you can use the bit position to define if this will be considered or ignored in the evaluation.

STATUS parameter

Error code* (W#16#...)	Description
80C0	Error in start condition
80C1	• Error in end condition • No end condition defined
80C2	Receive interrupt enabled
80C3	A value that is equal to 0 or greater than 4132 was entered at the MAXLEN parameter while the "Maximum length" end condition was set.
80C4	A value that is greater than 4131 was entered at the N parameter while the "N+LEN+M" end condition was set.
80C5	A value that is equal to 0 or invalid was entered at the LENGTHSIZE parameter while the "N+LEN+M" end condition was set.
80C6	A value that is greater than 255 was entered at the LENGTHM parameter while the "N+LEN+M" end condition was set.
80C7	A message length greater than 4132 was calculated while the "N+LEN+M" end condition was set.
80C8	A value that is equal to 0 was entered at the RCVTIME parameter while the "Reply timeout" end condition was set.
80C9	A value that is equal to 0 or greater than 2500 was entered at the CHARGAP parameter while the "Timeout within a character string" end condition was set.
80CA	A value that is equal to 0 or greater than 2500 was entered at the IDLETIME parameter while the "Idle line" start condition was set.
80CB	All characters of the character string are marked as "Don't care" even though "Character string" is set as the end condition.
80CC	All characters of the character string are marked as "Don't care" even though "Character string" is set as the start condition.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

SEND_PTP: Transmit send buffer data (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

You use the "SEND_PTP" instruction to start the transmission of data. The "SEND_PTP" instruction does not execute the actual transmission of the data. The data of the send buffer is transmitted to the relevant point-to-point communication module (CM). The CM executes the actual transmission.

Parameters

The following table shows the parameters of the "SEND_PTP" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Enables the requested transmission on a rising edge of this enable input. The content of buffer is transmitted to the point-to-point communication module (CM).
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
BUFFER	Input	VARIANT	I, Q, M, D, L or constant	Pointer to the start address of the send buffer. Boolean values or Array of BOOL are not supported.
LENGTH	Input	UINT	I, Q, M, D, L or constant	Length of the send buffer
PTRCL	Input	BOOL	I, Q, M, D, L or constant	This parameter selects the buffer for normal point-to-point communication or for specific Siemens protocols implemented in the connected CM. FALSE = point-to-point operations controlled by the user program (only valid option)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
7000	The send operation is not active.
7001	The send operation is processing the first call.
7002	The send operation is processing subsequent calls (queries following the first call).
8080	The identifier entered for the communications port number is invalid.
8088	The length of the LENGHT parameter does not correspond to the length of data to be sent. See also: Parameters LENGHT and BUFFER.
80D0	A new send request was received while a transmission was taking place.
80D1	The transmission was interrupted because the CTS signal was not confirmed within the specified wait time.
80D2	The send request was interrupted because the communications partner (DCE) signaled that it was not willing to receive (DSR).
80D3	The send request was interrupted because the maximum size of the waiting loop was exceeded (more than 1024 Byte).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

LENGTH and BUFFER parameters

The minimum data size that can be sent by the "PTP_SEND" instruction is one byte. The parameter BUFFER defines the size of the data to be sent. You can use neither the BOOL nor the Array of BOOL data type for the BUFFER parameter.

LENGTH parameter	BUFFER parameter	Description
LENGTH = 0	Not used	The complete data is sent as defined by the BUFFER parameter. If LENGTH = 0, you do not need to specify the number of bytes transferred.
LENGTH > 0	Elementary data type	The LENGTH value must contain the byte count of this data type. Otherwise, data is not transferred and error 8088 is output.
	STRUCT	The LENGTH value can contain a byte count that is smaller than the complete byte length of the structure. In this case, only the first LENGTH bytes are transferred.
	ARRAY	The LENGTH value can contain a byte count that is smaller than the complete byte length of the field. In this case, only the field elements that fit completely in the LENGTH bytes are transferred. The LENGTH value must be a multiple of the byte count of the data elements. Otherwise, STATUS = 8088, ERROR = 1, and no data is transferred.
	STRING	The complete memory arrangement of the character sequence format will be transmitted as well as the information about maximum length of the character string and the actual length of the character string. The LENGTH value must contain bytes for maximum length, actual length, and the characters of the character string. With the data type STRING, all lengths and characters have the size of one byte. If a character string is used for the BUFFER parameter, the LENGTH value must also contain two bytes for the two length fields.

RCV_PTP: Enable receive messages (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

With the RCV_PTP instruction you enable receipt of a sent message. Each message must be enabled individually. The sent data is only available in the receive area when the message has been acknowledged by the relevant communications partner.

Parameters

The following table shows the parameters of the "RCV_PTP" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN_R	Input	BOOL	I, Q, M, D, L or constant	Enables receipt on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
BUFFER	Input	VARIANT	I, Q, M, D, L or constant	Points to the start address of the receive buffer. Do not use a tag of the type STRING in the receive buffer.
NDR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction
LENGTH	Output	UINT	I, Q, M, D, L	Length of the message in the receive buffer

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#....)	Description
80E0	Receipt of messages was terminated because the receive buffer is full.
80E1	Receipt of messages was terminated as a result of a parity error.
80E2	Receipt of messages was terminated as a result of a framing error.
80E3	Receipt of messages was terminated as a result of an overflow error.
80E4	Receipt of messages was terminated because the calculated message length (N+LEN+M) exceeds the size of the receive buffer.
8080	The identifier entered for the communications port number is invalid.
8088	A data type STRING is referenced via the BUFFER parameter.
0094	Receipt of messages was terminated because the maximum character length was received.
0095	Receipt of messages was terminated as a result of a timeout.
0096	Receipt of messages was terminated because of a timeout within the character string.
0097	Receipt of messages was terminated as a result of a reply timeout.
0098	Receipt of messages was terminated because the "N+LEN+M" length condition has been satisfied.
0099	Receipt of messages was terminated because the character string defined as the end condition was received.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

RCV_RST: Delete receive buffer (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

With the "RCV_RST" instruction, you delete the receive buffer of a communications partner.

Parameters

The following table shows the parameters of the "RCV_RST" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Enables deleting of the receive buffer on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

SGN_GET: Query RS-232 signals (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

With the "SGN_GET" instruction, you query the current state of several signals of an RS-232 communications module.

Parameters

The following table shows the parameters of the "SGN_GET" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Enables the query on a rising edge
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID)
NDR	Output	BOOL	I, Q, M, D, L	Is set for one cycle if new data are ready for sending and the instruction was executed error-free.
DTR	Output	BOOL	I, Q, M, D, L	Data terminal ready, module ready
DSR	Output	BOOL	I, Q, M, D, L	Data set ready, communications partner ready
RTS	Output	BOOL	I, Q, M, D, L	Send request, module ready to send
CTS	Output	BOOL	I, Q, M, D, L	Clear to send, communications partner can receive data (reaction to RTS = ON of the module).
DCD	Output	BOOL	I, Q, M, D, L	Data carrier detect, received signal level
RING	Output	BOOL	I, Q, M, D, L	Ring display, display of an incoming call
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#....)	Description
80F0	The communication module is an RS-485 module and no signals are available.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

SGN_SET: Set RS-232 signals (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

With the "SGN_SET" instruction, you set the status of the output signals of an RS-232 communications module.

Parameters

The following table shows the parameters of the "SGN_SET" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Activates the action on a rising edge Initial value: FALSE
PORT	Input	PORT	I, Q, M, D, L or constant	Identification of the communication port (HW-ID) Initial value: FALSE
SIGNAL	Input	BYTE	I, Q, M, D, L or constant	Specifies the signals to be set: • Set 01H = RTS • Set 02H = DTR • Set 04H = DSR Initial value: FALSE
RTS	Input	BOOL	I, Q, M, D, L or constant	Send request, module ready to send Initial value: FALSE
DTR	Input	BOOL	I, Q, M, D, L or constant	Data terminal ready, module ready Initial value: FALSE
DSR	Input	BOOL	I, Q, M, D, L or constant	Data set ready (applies only to interfaces of the DCE type) Initial value: FALSE
DONE	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: Job not yet started or is still executing • 1: Job executed without errors Initial value: FALSE
ERROR	Output	BOOL	I, Q, M, D, L	Status parameter with the following values: • 0: No error • 1: Error occurred Initial value: FALSE
STATUS	Output	WORD	I, Q, M, D, L	Status of the instruction Initial value: 0

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
80F0	The communication module is an RS-485 module and no signals are available.
80F1	No signals are settable because H/W flow control is enabled.
80F2	The DSR signal cannot be set because the module is a DTE device.
80F3	The DTR signal cannot be set because the module is a DCE device.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

You will find more detailed information on general error codes of the communication instructions in “General status information of the communications blocks (Page 4604)“.

General status information of the communications blocks (S7-1200)

General information on execution status of the communications blocks

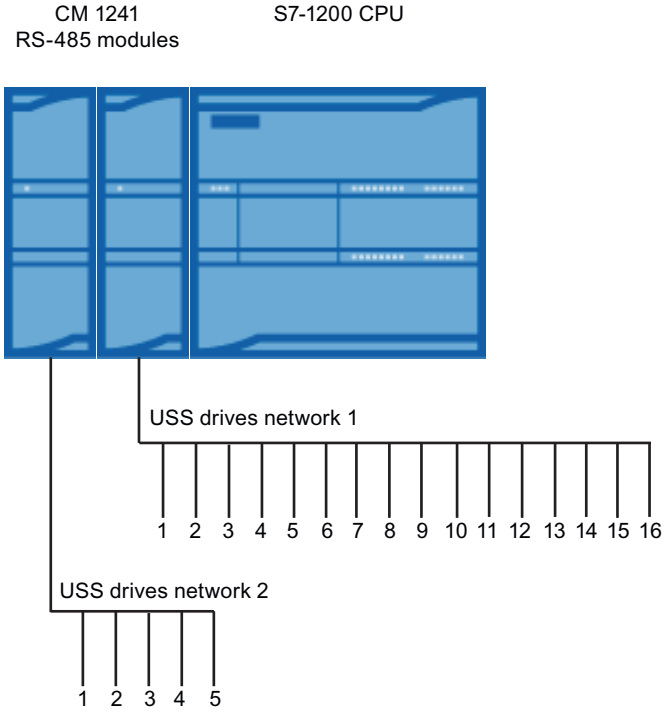
The following table shows which general information can be output at the STATUS parameter of the communications blocks:

Error code* (W#16#....)	Description
0000	No error
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0.
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
8x3A	Invalid pointer at parameter x.
8070	All internal instance memories are in use.
8080	The identifier entered for the communications port is invalid
8081	Timeout, module error, internal error
8082	Parameter assignment failed because parameter assignment is currently being performed in the background.
8083	Buffer overflow: The CM or CB has returned a receipt message with a length that is greater than permitted by the length parameter.
8085	Error specifying the length at the LENGHT parameter. The specified length is "0" or greater than the maximum permitted value.
8090	Message length invalid, module invalid, message invalid
8091	Incorrect version in parameterization message
8092	Invalid record length in parameterization message
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

USS (S7-1200)

Overview of USS instructions (S7-1200)

Introduction



The USS instructions control the operation of drives that support the universal serial interface (USS). With the USS instructions, you can communicate with more than one drive via an RS-485 connection.

To do this, you require a CM 1241 RS-485 communications module or a CB 1241 RS-485 communications board. Up to three CM 1241 RS-485 modules and one CB 1241 RS-485 board can be installed in an S7-1200 CPU.

Each RS-485 port can operate up to sixteen drives.

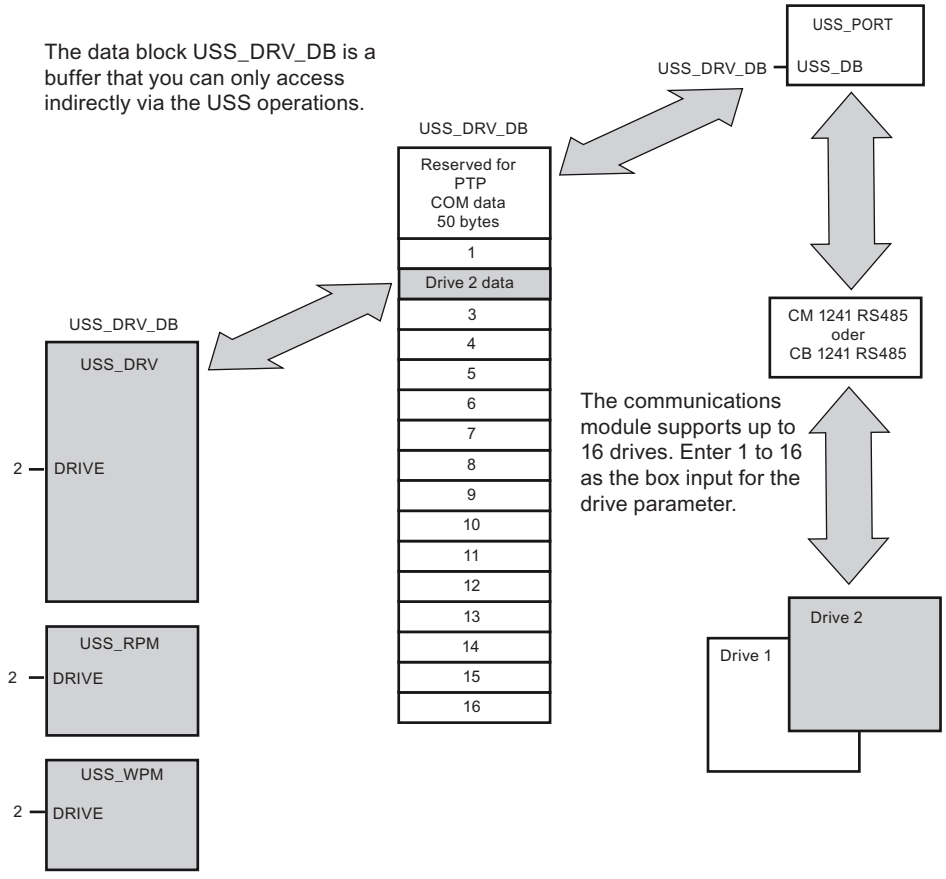
The USS protocol uses a master/slave network for communication via a serial bus. The master uses an address parameter to send a message to a selected slave. A slave itself can never send without previously receiving a request. Direct exchange of messages between slaves is not possible. USS communication works in half duplex mode.

The following figure shows an example of a USS network diagram:

Requirements for using the USS protocol (S7-1200)

General requirements for setting up a drive

- The use of 4 PKW words must be set up for the drives.
- The drives can be configured for 2, 4, 6 or 8 PZD words.
- The number of PZD words in the drive must correspond to the PZD_LEN input of the "USS_DRIVE (Page 4610)" instruction of the drive.
- The baud rate of all drives must match the baud rate of the BAUD input parameter of the "USS_PORT (Page 4609)" instruction.
- The drive must be set up for remote control.
- USS must be specified for the desired frequency value on the COM connection of the drive.
- 1 to 16 must be set as the drive address. This address must correspond to the address of the DRIVE input parameter of the "USS_DRIVE (Page 4610)" instruction.
- To control the direction of the drive, the polarity of the drive desired value must be set up.
- The RS-485 network must be connected correctly.



Definition: PKW / PZD area

- The PKW area relates to the handling of the parameter-identifier-value interface.
  The PKW interface is not a physical interface but describes a mechanism that controls the exchange of parameters between two communications partners, in other words, reading and writing parameter values, parameter descriptions and corresponding texts and the handling of parameter changes due to spontaneous messages. All the tasks handled via the PKW interface are essentially tasks for operator control and monitoring, service and diagnostics.
- The PZD area includes the signals required for automation:
  - Control word(s), and setpoint(s) from the master to the slave
  - Status word(s), and actual value(s) from the slave to the master.

Both areas together result in the user data field. This is transferred by the master to the slave as a job frame or by the slave to the master as a reply frame.

Description

Each communication module CM 1241 RS485 supports a maximum of 16 drives. A single instance data block contains temporary memory and buffer functions for all drives in the USS network that are connected to a PtP communications module you installed. The USS instructions for these drives have shared access to the information in this data block.

- All drives (max. 16) that are connected to an RS485 port are part of the same USS network. All drives that are connected to a different RS485 port are part of a different USS network. As the S7-1200 supports up to three CM 1241 RS485 modules, you can set up up to three USS networks, each having a maximum of 16 drives, thus a total of 48 USS drives are supported.
- Each USS network is managed via a unique data block (three data blocks are required for three USS networks with three CM 1241 RS485 modules). All instructions that belong to a USS network must share this data block. This includes all "USS_DRIVE (Page 4610)", "USS_PORT (Page 4609)", "USS_RPM (Page 4613)", and "USS_WPM (Page 4614)" instructions for controlling all drives in a USS network.

- The instruction "USS_DRIVE (Page 4610)" is a function block (FB). When you insert the instruction "USS_DRIVE" in the editor, the "Call options" dialog will ask you to assign a DB to the instruction.
  - If this is the first "USS_DRIVE" instruction in this program for this USS network, you can accept the default DB assignment (or, if necessary, change the name) and the new DB will be created.
  - If, however, this is not the first "USS_DRIVE" instruction for this network, you must select the DB that was previously assigned to this USS network in the drop-down list in the "Call options" dialog.
- All "USS_PORT (Page 4609), USS_RPM (Page 4613)", and "USS_WPM (Page 4614)" instructions are functions (FCs). When you insert these FCs in the editor, no DB is assigned. Instead, you have to assign the DB in question to the USS_DB input of these instructions (double-click on the parameter field and then on the icon to display the available DBs).
- The instruction "USS_PORT (Page 4609)" controls communication between the CPU and the drives via the PtP communications module. Whenever this instruction is called, communication with a drive is processed. Your program must call this function quickly enough so that the drives do not report a timeout. The instruction can be called from the main program or any interrupt OB.
- The function block "USS_DRIVE (Page 4610)" gives your program access to a specified drive in the USS network. Its inputs and outputs correspond to the states and operating functions of the drive. If there are 16 drives in the network, "USS_DRIVE" must be called at least 16 times in your program, i.e., once for each drive. How quickly these blocks are called depends on the required speed for controlling drive functions.
  You can only call the instruction "USS_DRIVE" from the main program OB.

  CAUTION

  Call "USS_DRIVE", "USS_RPM", "USS_WPM" only from the main program OB. The instruction "USS_PORT" can be called from any OB, it is usually called from a time-delay interrupt OB. If the instruction "USS_PORT" is interrupted during execution, this may result in unexpected errors.

The "USS_RPM" and "USS_WPM" instructions are used to read and write the operating parameters of the drive. These parameters control the internal mode of operation of the drive. A definition of these parameters can be found in the drive manual.

Your program may also contain any number of these instructions; however only one read or write request can be active for a drive. You may only call the instructions "USS_RPM" and "USS_WPM" from the main program OB.

Calculating the time for communication with the drive

Communication with the drive is runs asynchronous to the cycle of the S7-1200. The S7-1200 runs through several cycles before communication with a drive is completed.

The interval of "USS_PORT" is the time required for a drive transaction. The following table shows the minimum intervals for "USS_PORT" for each baud rate. Calling the "USS_PORT" more frequently than the "USS_PORT" interval will not increase the number of transactions. The timeout interval of the drive is the period of time available to a transaction if 3 attempts

are required to complete the transaction due to communications errors. By default, up to 2 further attempts are made for each transaction with the USS protocol.

Baud rate	Calculated minimum interval for calling USS_PORT (ms)	Drive message interval timeout per drive (ms)
1200	790	2370
2400	405	1215
4800	212.5	638
9600	116.3	349
19200	68.2	205
38400	44.1	133
57600	36.1	109
115200	28.1	85

USS_PORT: Edit communication via USS network (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "USS_PORT" instruction handles communication over the USS network. In the program, use one "USS_PORT" instruction per PtP communications port to control the transmission to or from one drive.

All USS instructions that are assigned to one USS network and one PtP communications port must use the same instance data block.

Call

Your program must execute the "USS_PORT" instruction often enough to prevent timeouts in the drive. You should therefore call the "USS_PORT" instruction from a cyclic interrupt OB to prevent drive timeouts and keep the most recent USS data updates available for "USS_DRIVE (Page 4610)" calls.

Parameters

The following table shows the parameters of the "USS_PORT" instruction:

Parameter	Declaration	Data type	Memory area	Description
PORT	Input	PORT	D, L or constant	PtP communications port identifier Constant that can be referenced within the "Constants" tab of the default tag table.
BAUD	Input	DINT	I, Q, M, D, L or constant	Baud rate for USS communication.
USS_DB	InOut	USS_BASE	D	Reference to the instance DB of the "USS_DRIVE (Page 4610)" instruction.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR is set to TRUE if an error occurs. A corresponding error code will be output at the STATUS output.
STATUS (Page 4616)	Output	WORD	I, Q, M, D, L	Status value of the request. It indicates the result of the cycle or initialization. Additional information is available in the "USS_Extended_Error (Page 4616)" tag for some status codes.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

USS_DRIVE: Swap data with drive (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "USS_DRIVE" instruction exchanges data with the drive by creating request messages and interpreting the drive response messages. A separate instruction must be used for each drive, but all USS instructions assigned to one USS network and one PtP communications module must use the same instance data block. You must create the DB name when you place the first "USS_DRIVE" instruction. Then reuse this DB that was created when the initial instruction was inserted.

When the "USS_DRIVE" instruction is executed the first time, the drive indicated by the USS address (parameter DRIVE) is initialized in the instance DB. After this initialization, subsequent "USS_PORT (Page 4609)" instructions can start communication with the drive at this drive number.

Changing the drive number requires a PLC STOP to RUN mode transition that initializes the instance DB. Input parameters are configured in the USS send buffer, and outputs are read from a "previous" valid response buffer if any exists. There is no data transmission during execution of the "USS_DRIVE" instruction. After executing “USS_PORT (Page 4609) there is communication with the drives, “USS_DRIVE" only configures the messages to be sent and evaluates data received in a previous request.

You can control the drive direction of rotation using either the DIR (BOOL) input or using the sign (positive or negative) at the SPEED_SP (REAL) input. The following table explains how these inputs work together to determine the drive direction, assuming the motor is wired for forward rotation.

SPEED_SP	DIR	Direction of rotation of drive
Value > 0	0	Reverse
Value > 0	1	Forward
Value < 0	0	Forward
Value < 0	1	Reverse

Parameters

Expand the box to display all the parameters by clicking the bottom of the box. The parameter connections that are grayed are optional and do not need to be assigned.

The following table shows the parameters of the "USS_DRIVE" instruction:

Parameter	Declaration	Data type	Memory area	Description
RUN	Input	BOOL	I, Q, M, D, L or constant	Drive start bit: If this parameter has the value TRUE, this input enables the drive to run at the preset speed.
OFF2	Input	BOOL	I, Q, M, D, L or constant	"Electrical stop" bit: If this parameter has the value FALSE, this bit cause the drive to coast to a stop without braking.
OFF3	Input	BOOL	I, Q, M, D, L or constant	Fast stop bit - If this parameter has the value FALSE, this bit causes a fast stop by braking the drive.
F_ACK	Input	BOOL	I, Q, M, D, L or constant	Fault acknowledge bit - This bit resets the fault bit on a drive. This bit is set after the fault is cleared to indicate to the drive that it no longer needs to indicate the previous fault.
DIR	Input	BOOL	I, Q, M, D, L or constant	Drive direction control - This bit is set to indicate that the direction is forward (when SPEED_SP is positive).
DRIVE	Input	USINT	I, Q, M, D, L or constant	Drive address: This input is the address of the USS drive. The valid range is drive 1 to drive 16.
PZD_LEN	Input	USINT	I, Q, M, D, L or constant	Word length - This is the number of words of PZD data. Valid values are 2, 4, 6, or 8 words. The default is 2.
SPEED_SP	Input	REAL	I, Q, M, D, L or constant	Speed setpoint - This is the speed of the drive as a percentage of configured frequency. A positive value specifies forward direction (when DIR has the value TRUE).
CTRL3	Input	WORD	I, Q, M, D, L or constant	Control word 3 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive. Optional parameter
CTRL4	Input	WORD	I, Q, M, D, L or constant	Control word 4 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive. Optional parameter
CTRL5	Input	WORD	I, Q, M, D, L or constant	Control word 5 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive. Optional parameter

Parameter	Declaration	Data type	Memory area	Description
CTRL6	Input	WORD	I, Q, M, D, L or constant	Control word 6 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive.
CTRL7	Input	WORD	I, Q, M, D, L or constant	Control word 7 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive. Optional parameter
CTRL8	Input	WORD	I, Q, M, D, L or constant	Control word 8 - A value written to a user-configurable parameter on the drive. The user must configure this on the drive. Optional parameter
NDR	Output	BOOL	I, Q, M, D, L	New data ready - If this parameter has the value TRUE, the bit indicates that the output contains data from a new communication request.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred - If this parameter has the value TRUE, this indicates that an error has occurred and the STATUS output is valid. All other outputs are set to zero on an error. Communication errors are only reported at the ERROR and STATUS outputs of the "USS_PORT" instruction.
STATUS (Page 4616)	Output	WORD	I, Q, M, D, L	Status value of the request. It indicates the result of the cycle. This is not a status word returned from the drive.
RUN_EN	Output	BOOL	I, Q, M, D, L	Run enabled - This bit indicates whether the drive is running.
D_DIR	Output	BOOL	I, Q, M, D, L	Drive direction - This bit indicates whether the drive is running forward.
INHIBIT	Output	BOOL	I, Q, M, D, L	Drive inhibited - This bit indicates the state of the inhibit bit on the drive.
FAULT	Output	BOOL	I, Q, M, D, L	Drive fault - This bit indicates that the drive has registered a fault. The user must eliminate the fault and then set the F_ACK bit to clear this bit.
SPEED	Output	REAL	I, Q, M, D, L	Drive current speed (scaled value of drive status word 2) - The value of the speed of the drive as a percentage of configured speed.
STATUS1	Output	WORD	I, Q, M, D, L	Drive status word 1 - This value contains fixed status bits of a drive.
STATUS3	Output	WORD	I, Q, M, D, L	Drive status word 3 - This value contains a user-configurable status word on the drive.
STATUS4	Output	WORD	I, Q, M, D, L	Drive status word 4 - This value contains a user-configurable status word on the drive.
STATUS5	Output	WORD	I, Q, M, D, L	Drive status word 5 - This value contains a user-configurable status word on the drive.
STATUS6	Output	WORD	I, Q, M, D, L	Drive status word 6 - This value contains a user-configurable status word on the drive.
STATUS7	Output	WORD	I, Q, M, D, L	Drive status word 7 - This value contains a user-configurable status word on the drive.
STATUS8	Output	WORD	I, Q, M, D, L	Drive status word 8 - This value contains a user-configurable status word on the drive.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

USS_RPM: Readout parameters from the drive (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "USS_RPM" instruction reads a parameter from the drive. All USS functions that are assigned to one USS network and one PtP communications module must use the same data block. "USS_RPM" must be called from the main program OB.

Parameter

The following table shows the parameters of the "USS_RPM" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Send request: If this parameter has the value TRUE, it indicates that a new read request is desired. This is ignored if the request for this parameter is already pending.
DRIVE	Input	USINT	I, Q, M, D, L or constant	Drive address: This input is the address of the USS drive. The valid range is drive 1 to drive 16.
PARAM	Input	UINT	I, Q, M, D, L or constant	Parameter number: This input specifies which drive parameter is written. The range of this parameter is 0 to 2047. See your drive manual for details on how to access any parameters above this range.
INDEX	Input	UINT	I, Q, M, D, L or constant	Parameter index: This input specifies which drive parameter index is to be written. This is a 16-bit value where the least significant byte is the actual index value with a range of (0 to 255). The most significant byte may also be used by the drive and is drive-specific. See your drive manual for additional information.
USS_DB	InOut	USS_BASE	D	Reference to the instance DB that is created and initialized when a "USS_DRIVE" instruction is inserted in your program.
DONE	Output	BOOL	I, Q, M, D, L	If this parameter has the value TRUE, it indicates that the VALUE output holds the previously requested read parameter value. This bit is set when the "USS_DRIVE" instruction recognizes the read response from the drive. This bit is reset when either: • you request the response data via another "USS_RPM" poll or • the second of the next two calls of "USS_DRIVE (Page 4610)" is executed

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred - If this parameter has the value TRUE, this indicates that an error has occurred and the STATUS output is valid. All other outputs are set to zero on an error. Communication errors are only reported at the ERROR and STATUS outputs of the "USS_PORT (Page 4609)" instruction.
STATUS (Page 4616)	Output	WORD	I, Q, M, D, L	This is the status value of the request. It indicates the result of the read request. Additional information is available in the "USS_Extended_Error (Page 4616)" tag for some status codes.
VALUE	Output	VARIANT	I, Q, M, D, L	This is the value of the parameter that was read and is valid only when the DONE bit has the value TRUE.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

USS_WPM: Change parameters in the drive (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "USS_WPM" instruction modifies a parameter in the drive. All USS functions that are assigned to one USS network and one PtP communications module must use the same data block. "USS_WPM" must be called from the main program OB.

Note

EEPROM write operations

Beware of overusing the EEPROM write operation. Minimize the number of EEPROM write operations to extend the EEPROM life.

Parameter

The following table shows the parameters of the "USS_WPM" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Send request: If this parameter has the value TRUE, it indicates that a new write request is desired. This is ignored if the request for this parameter is already pending.
DRIVE	Input	USINT	I, Q, M, D, L or constant	Drive address: This input is the address of the USS drive. The valid range is drive 1 to drive 16.

Parameter	Declaration	Data type	Memory area	Description
PARAM	Input	UINT	I, Q, M, D, L or constant	Parameter number: This input specifies which drive parameter is written. The range of this parameter is 0 to 2047. See your drive manual for details on how to access any parameters above this range.
INDEX	Input	UINT	I, Q, M, D, L or constant	Parameter index: This input specifies which drive parameter index is to be written. This is a 16-bit value where the least significant byte is the actual index value with a range of (0 to 255). The most significant byte may also be used by the drive and is drive-specific. See your drive manual for additional information.
EEPROM	Input	BOOL	I, Q, M, D, L or constant	Store to drive EEPROM: If this parameter has the value TRUE, values written to the drive parameter will be stored in the drive EEPROM. If this parameter has the value FALSE, the value written is only temporarily saved and will be lost the next time the drive is switched on.
VALUE	Input	VARIANT	I, Q, M, D, L or constant	The value of the parameter that is to be written. It must be valid on the transition of REQ.
USS_DB	InOut	USS_BASE	D	This is a reference to the instance DB that is created and initialized when a "USS_DRIVE (Page 4610)" instruction is inserted in your program.
DONE	Output	BOOL	I, Q, M, D, L	If this parameter has the value TRUE, the VALUE input was written to the drive. This bit is set when the "USS_DRIVE (Page 4610)" instruction recognizes the write response from the drive. This bit is reset when either: You request the drive's confirmation that the write operation has been completed via another "USS_WPM" query or when the second of the next two calls of "USS_DRIVE (Page 4610)" is executed.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred: If this parameter has the value TRUE, this indicates that an error has occurred and the STATUS output is valid. All other outputs are set to zero on an error. Communication errors are only reported at the ERROR and STATUS outputs of the "USS_PORT (Page 4609)" instruction.
STATUS (Page 4616)	Output	WORD	I, Q, M, D, L	This is the status value of the request. It indicates the result of the write request. Additional information is available in the "USS_Extended_Error (Page 4616)" tag for some status codes.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS of USS instructions (S7-1200)

STATUS parameter

The following table contains the status codes of the USS operation that are output at the STATUS output of the USS instructions:

STATUS* (W#16#....)	Description
0000	No error
8180	The length of the drive response did not match the characters received from the drive. The drive number where the error occurred is returned in the "USS_Extended_Error" tag. See the extended error description below this table.
8181	The parameter VALUE is not of the data type WORD, REAL, or DWORD
8182	User supplied a parameter value of the type word and received a DWORD or REAL from the drive in the response
8183	User supplied a parameter value of the type DWORD or REAL and received a word from the drive in the response
8184	Response telegram from drive had a bad checksum. The drive number where the error occurred is returned in the "USS_Extended_Error" tag. See the extended error description below this table.
8185	Illegal drive address (valid drive address range: 1-16)
8186	Speed set point out of valid range (valid speed SP range: -200% to 200%)
8187	Wrong drive number responded to the request sent. The drive number where the error occurred is returned in the "USS_Extended_Error" tag. See the extended error description below this table.
8188	Illegal PZD word length specified (valid range = 2, 4, 6 or 8 words)
8189	Illegal baud rate was specified
818A	Parameter request channel is in use by another request for this drive
818B	Drive has not responded to requests and retries. The drive number where the error occurred is returned in the "USS_Extended_Error" tag. See the extended error description below this table.
818C	Drive returned an extended error on a parameter request operation. See the extended error description below this table.
818D	Drive returned an invalid access error on a parameter request operation. See your drive manual for information of why parameter access may be limited
818E	Drive has not been initialized: This error code is output at "USS_RPM (Page 4613)" or "USS_WPM (Page 4614)" if the "USS_DRIVE (Page 4610)" instruction has not been called at least once for this drive. This prevents the initialization of the first cycle of "USS_DRIVE (Page 4610)" from overwriting a pending parameter read or write request since it initializes the drive as a new entry. To eliminate this error, call the "USS_DRIVE (Page 4610)" instruction for this drive.
80Ax-80Fx	Specific errors returned from PtP (Point-to-Point) communication instructions called by the USS library: These error code values are not modified by the USS library and are defined in the PtP instruction descriptions.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".	

USS_Extended_Error - USS drive extended error codes

USS drives support read and write access to a drive's internal parameters. This feature allows distributed control and configuration of the drive. Drive parameter access operations can fail due to errors such as values out of range or invalid requests in a drive's current mode. The drive generates an error code that is output in the "USS_Extended_Error" variable in the instance DB of the "USS_DRIVE (Page 4610)" instruction. This error code value is only valid for the last execution of the "USS_RPM (Page 4613)" or "USS_WPM (Page 4614)" instruction. The drive error code is put into the "USS_Extended_Error" tag when the value of STATUS is hexadecimal 818C. The error code of "USS_Extended_Error" depends on the drive variant. See the drive's manual for a description of the extended error codes for read and write parameter operations.

MODBUS (RTU) (S7-1200)

MB_COMM_LOAD: Configure port on the PtP module for Modbus RTU (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "MB_COMM_LOAD" instruction configures a port for communication using the Modbus RTU protocol. The following hardware can be used for this:

- Up to three point-to-point modules (PtP) CM 1241 RS485 or CM 1241 RS232
- A communications board CB 1241 RS485 in addition to this

After configuration of the port, you communicate over Modbus by executing the "MB_SLAVE" or "MB_MASTER" instruction.

Call

"MB_COMM_LOAD" must be called once to configure the port for the Modbus RTU protocol. On completion of the configuration, the port can be used by the "MB_MASTER (Page 4620)" and "MB_SLAVE (Page 4628)" instructions.

"MB_COMM_LOAD" only needs to be called again if one of the communication parameters has to be modified. Each "MB_COMM_LOAD" call deletes the communications buffer. To avoid data loss during communication, you should not call the instruction unnecessarily.

One instance of "MB_COMM_LOAD" must be used to configure the port of each communication module that is used for Modbus communication. You assign a unique "MB_COMM_LOAD" instance data block for each port that you use. The S7-1200 CPU is limited to three communication modules.

An instance data block is assigned when you insert the "MB_MASTER (Page 4620)" or "MB_SLAVE (Page 4628)" instruction. This instance data block is referenced when you specify the MB_DB parameter on the "MB_COMM_LOAD" instruction.

Parameters

The following table shows the parameters of the instruction "MB_COMM_LOAD":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	Execution of the instruction upon a rising edge.
PORT	Input	PORT	I, Q, M, D, L or constant	ID of the communications port: After you have inserted the communications module in the device configuration, the port ID appears in the drop-down list at the PORT box connection. This constant can also be referenced within the "Constants" tab of the tag table.
BAUD	Input	UDINT	I, Q, M, D, L or constant	Baud rate selection: 300, 600, 1200, 2400, 4800, 9600, 19200, 38400, 57600, 76800, 115200 All other values are invalid.
PARITY	Input	UINT	I, Q, M, D, L or constant	Parity selection: • 0 – None • 1 – Odd • 2 – Even
FLOW_CTRL	Input	UINT	I, Q, M, D, L or constant	Flow control selection: • 0 – (default) No flow control • 1 – Hardware flow control with RTS always ON (does not apply to RS485 ports) • 2 - Hardware flow control with RTS switched
RTS_ON_DLY	Input	UINT	I, Q, M, D, L or constant	RTS on-delay selection: • 0 – (default) No delay of RTS active until the first character of the message is transmitted. • 1 to 65535 – Delay in milliseconds of "RTS active" until the first character of the message is transmitted (does not apply to RS-485 ports). RTS delays must be used depending on the selection of FLOW_CTRL.
RTS_OFF_DLY	Input	UINT	I, Q, M, D, L or constant	RTS off-delay selection: • 0 – (default) No delay after the last character transmitted until "RTS inactive" • 1 to 65535 – Delay in milliseconds after the last character transmitted until "RTS inactive" (does not apply to RS-485 ports). RTS delays must be used regardless of the selection of FLOW_CTRL.

Parameter	Declaration	Data type	Memory area	Description
RESP_TO	Input	UINT	I, Q, M, D, L or constant	Response timeout: Time in milliseconds allowed by "MB_MASTER (Page 4620)" for the slave to respond. If the slave does not respond in this time, "MB_MASTER (Page 4620)" repeats the request or terminates the request with an error if the specified number of retries has been sent. 5 ms to 65535 ms (default = 1000 ms).
MB_DB	Input	MB_BASE	D	A reference to the instance data block of the "MB_MASTER (Page 4620)" or "MB_SLAVE (Page 4628)" instructions. After you insert "MB_SLAVE (Page 4628)" or "MB_MASTER (Page 4620)" in your program, the DB identifier appears in the drop-down list at the MB_DB box connection.
DONE	Output	BOOL	I, Q, M, D, L	Execution of instruction completed without error.
ERROR	Output	BOOL	I, Q, M, D, L	Error: • 0 – No error detected • 1 – Indicates that an error was detected. An error code is output in the STATUS parameter.
STATUS	Output	WORD	I, Q, M, D, L	Port configuration error code

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Error code* (W#16#...)	Description
0000	No error
8180	Invalid value for the port ID (wrong address for the communications module).
8181	Invalid baud rate value.
8182	Invalid parity value.
8183	Invalid flow control value.
8184	Invalid value for the timeout of the response (the time before which a timeout is reported must be at least 25 ms).
8185	Incorrect pointer in the MB_DB parameter to the instance DB of the "MB_MASTER (Page 4620)" or "MB_SLAVE (Page 4628)" instruction.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

MB_COMM_LOAD data block tags

The table below shows the public static tags in the instance DB of MB_COMM_LOAD that you can use in your program.

Table 11-82 Static tags in the instance DB

Tag	Data type	Default	Description
ICHAR_GAP	WORD	0	Delay for the character spacing between characters. This parameter is specified in milliseconds and is used to increase the anticipated period between the received characters. The corresponding number of bit times for this parameter is added to the Modbus standard value of 35 bit times (3.5 character times).
RETRIES	WORD	2	The number of repeated attempts by the master before the error code 0x80C8 is returned for "No response".
STOP_BITS	USINT	1	Number of stop bits per character Valid values 1 and 2

MB_MASTER: Communicate via the PtP port as Modbus master (S7-1200)

Description of MB_MASTER (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "MB_MASTER" instruction allows your program to communicate as a Modbus master using a port on a point-to-point module (CM) or a communications board (CB). You can access data in one or more Modbus slave devices.

Before the "MB_MASTER" instruction can communicate with a port, "MB_COMM_LOAD (Page 4617)" must first execute.

An instance DB is created when you insert the "MB_MASTER" instruction in your program. You specify this instance DB in the MB_DB input parameter of the "MB_COMM_LOAD (Page 4617)" instruction.

Rules for Modbus master communication

- A port used for Modbus master requests cannot be used for "MB_SLAVE".
- A port can be used for one or more "MB_MASTER" calls if the same instance DB is used.
- The Modbus instructions do not use communication interrupt events to control the communication process. Your program must poll the "MB_MASTER" instruction for completed send and receive operations.

- Calling the instruction:
  - Call the "MB_MASTER" instruction if possible in a cyclic program OB. The instruction can only be called in a time delay or cyclic interrupt OB.
  - Do not call more than one "MB_MASTER" instruction in organization blocks with different priority classes. If a "MB_MASTER" instruction executes "preemptively" from a higher priority class, the instruction may execute incorrectly.
  - Do not call the "MB_MASTER" instruction in a startup, diagnostics or time error OB.
- After a transfer has started, the EN parameter (LAD/FBD) must remain set to the value "1" until the DONE or ERROR output parameter is set to "1" by the instruction. A renewed call by the REQ parameter while the instruction is executing causes an error. After the instruction executes, the bit in the REQ parameter remains set for the time specified by the BLOCKED_PROC_TIMEOUT parameter in the instance DB.
- If "MB_MASTER" sends a request to a slave, make sure that "MB_MASTER" continues to execute until the response from the slave arrives.

Parameters

The following table shows the parameters of the "MB_MASTER" instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ (Page 4623)	Input	BOOL	I, Q, M, D, L	Request input: • 0 – No request • 1 – Request to transmit data to Modbus slave(s)
MB_ADDR	Input	UINT	I, Q, M, D, L or constant	Modbus RTU station address: • Default address range: 0 to 247 • Extended address range: 0 to 65535 The value "0" is reserved for broadcasting a message to all Modbus slaves. Modbus function codes 05, 06, 15, and 16 are the only function codes supported for broadcast.
MODE (Page 4623)	Input	USINT	I, Q, M, D, L or constant	Mode selection: Specifies the type of request: Read, write, or diagnostics: Refer to the Modbus functions table for details.
DATA_ADDR (Page 4623)	Input	UDINT	I, Q, M, D, L or constant	Starting address in the slave: Specifies the starting address of the data to be accessed in the Modbus slave. You will find the valid addresses in the Modbus functions table.
DATA_LEN	Input	UINT	I, Q, M, D, L or constant	Data length: Specifies the number of bits or words to be accessed in this request. You will find the valid lengths in the Modbus functions table.
DATA_PTR (Page 4625)	Input	VARIANT	M, D	Points to the DB or bit memory address of the CPU for the data to be written or read. For a DB, this must be created with the "Standard - compatible with S7-300/400" access type.
DONE	Output	BOOL	I, Q, M, D, L	• 0: Transaction not completed • 1: Transaction completed without error

Parameters	Declaration	Data type	Memory area	Description
BUSY	Output	BOOL	I, Q, M, D, L	• 0: No "MB_MASTER" transaction in progress • 1: "MB_MASTER" transaction in progress
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error • 1: Error, the error code is indicated by the STATUS parameter
STATUS	Output	WORD	I, Q, M, D, L	Execution condition code

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

Table 11-83 Communications and configuration error messages of the instruction

Error code* (W#16#....)	Description
0000	No error
80C8	Slave timeout. Check the baud rate, parity and the connectors on the slave.
80D1	The receiver issued a flow control request to suspend an active transmission and never re-enabled the transmission within the wait time. This error is also generated during hardware flow control if the recipient does not detect CTS within the wait time.
80D2	The send request was aborted because no DSR signal is received from the DCE.
80E0	The message was terminated because the receive buffer is full.
80E1	The message was terminated as a result of a parity error.
80E2	The message was terminated as a result of a framing error.
80E3	The message was terminated as a result of an overrun error.
80E4	The message was terminated as a result of the specified length exceeding the total buffer size.
8180	Invalid value for the port ID.
8186	Invalid Modbus station address
8188	The MODE parameter has an invalid value for a broadcast call.
8189	Invalid data address value.
818A	Invalid data length value.
818B	Invalid pointer to the local data source/destination: Size not correct
818C	The DATA_PTR parameter has an invalid pointer. Use a pointer to a bit memory area or a DB with the "Standard - compatible with S7-300/400" access type.
8200	Port is busy processing a send request
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Table 11-84 Error messages of the Modbus protocol

Error code* (W#16#....)	Response code of slave	Description
8380	-	CRC error
8381	01	Function code not supported
8382	03	Data length error
8383	02	Error in the data address or address outside the valid range of DATA_PTR
8384	> 03	Data value error
8385	03	Data diagnostic code value not supported (function code 08)
8386	-	Function code of the response does not match the function code of the query.
8387	-	Response from wrong slave
8388	-	The response of the slave to a write call is not correct. The data sent by the slave does not match the query from the master.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Parameter REQ (S7-1200)

Description

- REQ = FALSE: No request
- REQ = TRUE: Request to transmit data to Modbus slave(s)

You can control this input by means of a level-controlled or edge-controlled contact.

A state machine is started every time this input is activated to ensure that another instruction "MB_MASTER" that uses the same instance DB can only issue a request when the current request has been processed. All other input states are recorded and saved internally for the current request until the reply has been received or an error has been detected.

If the same instance of "MB_MASTER" is executed again with REQ input = 1 before the current request is completely processed, no subsequent transfers are made. However, if the request has been processed, a new request is issued at the time when "MB_MASTER" is executed again with REQ input = 1.

DATA_ADDR and MODE parameters (S7-1200)

Description

You specify the start address for data access to the Modbus slave using the DATA_ADDR parameter.

With the MODE parameter and the Modbus address, you specify the function code to be transferred to the Modbus slave. The following table shows the relationship between the MODE parameter, the function code and Modbus address range.

MODE	Modbus function	Data length	Operation and data	Modbus address
0	01	1 to 2000 1 to 1992 (1)	Read output bits: 1 to (1992 or 2000) bits per query	1 to 9999
0	02	1 to 2000 1 to 1992 (1)	Read input bits: 1 to (1992 or 2000) bits per query	10001 to 19999
0	03	1 to 125 1 to 124 (1)	Read holding register: 1 to (124 or 125) WORD per query	40001 to 49999 or 400001 to 465535
0	04	1 to 125 1 to 124 (1)	Read input WORD: 1 to (124 or 125) WORD per query	30001 to 39999
1	05	1	Writing an output bit: One bit per query	1 to 9999
1	06	1	Writing a holding register: 1 WORD per query	40001 to 49999 or 400001 to 465535
1	15	2 to 1968 2 to 1960 (1)	Writing multiple output bits: 2 to (1960 or 1968) bits per query	1 to 9999
1	16	2 to 123 2 to 122 (1)	Writing multiple holding registers: 2 to (122 or 123) WORD per query	40001 to 49999 or 400001 to 465535
2	15	1 to 1968 2 to 1960 (1)	Writing one or more output bits: 1 to (1960 or 1968) bits per query	1 to 9999
2	16	1 to 123 2 to 122 (1)	Writing one or more holding registers: 1 to (122 or 123) WORD per query	40001 to 49999 or 400001 to 465535
11	11	0	Reading out the communications status word of the slaves and the event counter: The status word indicates execution of the instruction (0: is not executing; 0xFFFF: is executing). The event counter is incremented each time a message is transferred successfully. The DATA_ADDR and DATA_LEN parameters of the "MB_MASTER" instruction are ignored with this function.	-
80	08	1	Checking the slave status by reading the error code (0x0000): 1 WORD per query	-
81	08	1	Resetting the event counter of the slave with the diagnostics code 0x000A: 1 WORD per query	-
3 to 10, 12 to 79, 82 to 2555			Reserved	-
(1) For the "Extended address range", the maximum data length is reduced by one byte or one WORD depending on which data type is used for the function.				

Parameter DATA_PTR (S7-1200)

Description

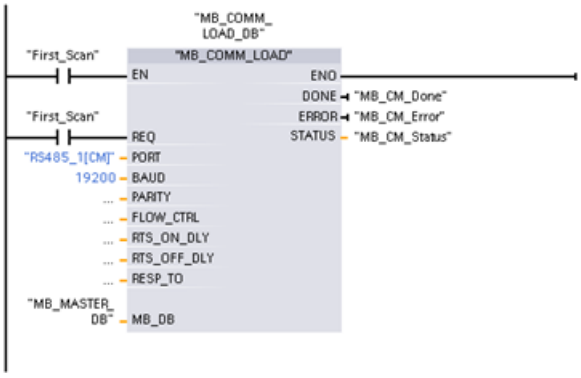
The DATA_PTR parameter is a pointer to a data block or bit memory from which the data should be written or read. If you use a data block, create a global data block with the "Standard - compatible with S7-300/400" access type.

Data block structures for the DATA_PTR parameter

- These data types are valid for **reading of words** of Modbus addresses 30001 to 39999, 40001 to 49999, and 400001 to 465536 and also for **writing of words** to Modbus addresses 40001 to 49999 and 400001 to 465536.
  - Standard array of WORD, UINT, or INT data types (see below).
  - Named WORD, UINT, or INT structure where each element has a unique name and 16 bit data type.
  - Named complex structure where each element has a unique name and 16 bit or 32 bit data type.
- For reading and writing of bits of Modbus addresses 00001 to 09999 and 10001 to 19999.
  - Standard array of Boolean data types.
  - Named Boolean structure of uniquely named Boolean variables.
- Although not required, it is recommended that each "MB_MASTER" instruction has its own separate memory area in a global data block. The reason for this recommendation is that there is a greater possibility of data corruption if multiple "MB_MASTER" instructions are reading and writing the same area of a global data block.
- The memory areas for DATA_PTR do not need to be in the same global data block. You can create one data block with multiple areas for Modbus read operations, one data block for Modbus write operations, or one data block for each slave station.

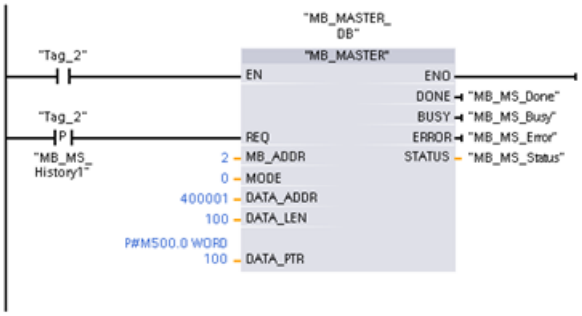
Instance DB of the "MB_MASTER" instruction (S7-1200)

Static variables of the instance DB



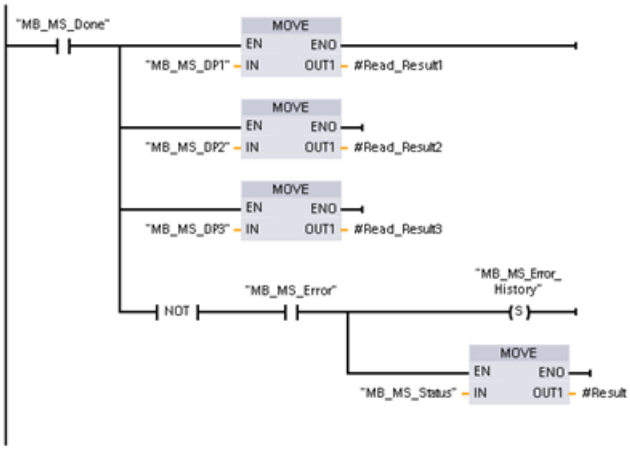
The following table describes the static variables of the instance DB of the instruction that you can use in the user program.

Variable	Data type	Description
MB_STATE	UINT	Internal status of the Modbus instruction
BLOCKED_ PROC_TIMEOUT	REAL	Time between completion of the instruction call and resetting the ACTIVE bit in the instance DB. The time buffer is used to avoid execution of the instruction being terminated before a job has been sent completely. The default time is 500 ms.
EXTENDED_ AD-DRESSING	BOOL	Configuring addressing: • 0: Default address area (1 byte) • 1: Extended address area (2 bytes) For additional information, refer to the section EXTENDED_AD-DRESSING: Instance DB of the "MB_SLAVE" instruction (Page 4631)

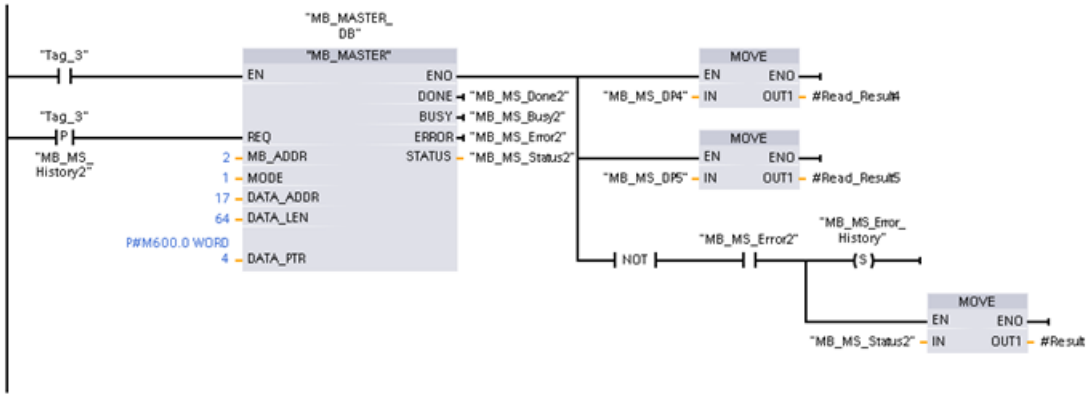


Sample program for a Modbus master (S7-1200)

Networks (LAD)



Network 1: Initialize parameters of the RS-485 module only once during the first cycle.



Network 2: Read 100 words from the holding register of the slave.

Network 3: This is an optional network that displays the values of the first 3 words as soon as the read operation has executed.

Network 4: Write 64 bits to the process image output, starting at slave address Q2.0.

MB_SLAVE: Communicate via the PtP port as Modbus slave (S7-1200)

Description of MB_SLAVE (S7-1200)

Note

Use with CM1241

The use of this instruction with a CM1241 is possible only as of firmware version V2.1 of the module.

Description

The "MB_SLAVE" instruction allows your program to communicate as a Modbus slave using a port on a point-to-point module (PtP) or a communications board (CB). A Modbus RTU master can issue a request and then your program responds via "MB_SLAVE" execution.

You must assign a unique instance data block when you insert the "MB_SLAVE" instruction in your program. This instance data block is used when you specify it at the MB_DB parameter of the "MB_COMM_LOAD (Page 4617)" instruction.

Modbus communication function codes (1, 2, 4, 5, and 15) can read and write bits and words directly in the process image input and process image output in the target system. The following table shows the mapping of Modbus addresses to the process image in the CPU.

Modbus functions of "MB_SLAVE"						S7-1200	
Codes	Function	Data area	Address range			Data area	CPU address
01	Read bits	Output	1	to	8192	Process image output	Q0.0 to Q1023.7
02	Read bits	Input	10001	to	18192	Process image input	I0.0 to I1023.7
04	Read words	Input	30001	to	30512	Process image input	IW0 to IW1022
05	Write bit	Output	1	to	8192	Process image output	Q0.0 to Q1023.7
15	Write bits	Output	1	to	8192	Process image output	Q0.0 to Q1023.7

Modbus communication function codes (function codes 3, 6, 16) use a separate holding register. To do this, you can use bit memory or a data block with the "Standard - compatible with S7-300/400" access type.

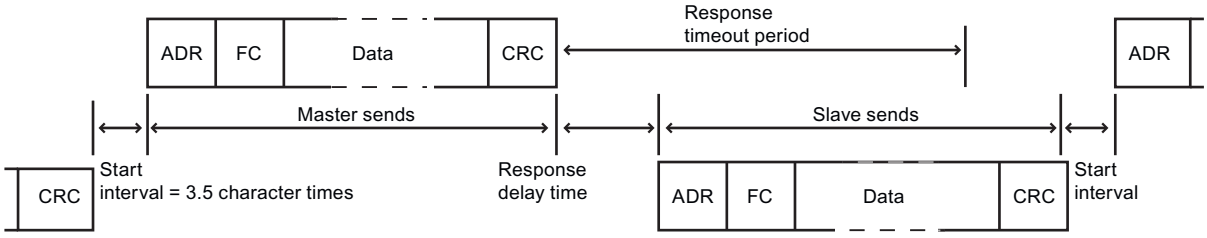
You specify the type of the holding register using the MB_HOLD_REG parameter of the MB_SLAVE instruction. The following table shows the mapping of the Modbus holding register to the DB address of MB_HOLD_REG in the target system.

Modbus functions of "MB_SLAVE"				S7-1200	
Codes	Function	Data area	Address range (WORD number)	Address in the DB (BYTE number)	Bit memory address (BYTE number)
03	Read words	Holding register	40001 to 49999 or	DW0 to DW19998 or	MW0 to CPU limit
			400001 to 465535	DW0 to DW131068	
06	Write word	Holding register	40001 to 49999 or	DW0 to DW19998 or	
			400001 to 465535	DW0 to DW131068	
16	Write words	Holding register	40001 to 49999 or	DW0 to DW19998 or	
			400001 to 465535	DW0 to DW131068	

The table below shows the supported Modbus diagnostic functions.

S7-1200 "MB_SLAVE" Modbus diagnostic functions		
Codes	Subfunction	Description
08	0000H	Return query data echo test: The "MB_SLAVE" instruction returns the echo of a received data word to a Modbus master.
08	000AH	Clear communication event counter: The "MB_SLAVE" instruction clears the communication event counter that is used for Modbus function 11.
11	-	Get communication event counter: The "MB_SLAVE" instruction uses an internal communication event counter for recording the number of successful Modbus read and write requests that are sent to the Modbus slave. The counter is not incremented on any Function 8, Function 11, or broadcast requests. It is also not incremented on any requests that result in a communication error (for example, parity or CRC errors).

The "MB_SLAVE" instruction supports broadcast write requests from Modbus masters as long as the requests include access to valid addresses.



Regardless of the validity of a request, "MB_SLAVE" gives no response to a Modbus master as the result of a broadcast request.

Rules of Modbus slave communication

- "MB_COMM_LOAD" must be executed to configure a port, before the "MB_SLAVE" instruction can communicate with this port.
- If a port is to respond as a slave to a Modbus master, then that port cannot be used by "MB_MASTER (Page 4620)". Only one instance of "MB_SLAVE" can be used with a given port.
- The Modbus instructions do not use communication interrupt events to control the communication process. Your program must control the communication process by polling the "MB_SLAVE" instruction for completed send and receive operations.
- The "MB_SLAVE" instruction must be executed periodically at a rate that allows it to make a timely response to incoming requests from a Modbus master. It is therefore advisable to call the instruction in a cyclic program OB. Calling the "MB_SLAVE" instruction in an interrupt OB is possible but not advisable since it can lead to long delays in execution.

Frequency of execution of "MB_SLAVE"

The "MB_SLAVE" instruction must be executed periodically to receive each request from the Modbus master and to respond as required. The frequency of execution of "MB_SLAVE" is dependent upon the specified response timeout period of the Modbus master. This is illustrated in the following diagram.

The response timeout period is the amount of time a Modbus master waits for the start of a response from a Modbus slave. This time period is not defined by the Modbus protocol, but rather by a parameter of each Modbus master. The frequency of execution (time between one execution and the next execution) of "MB_SLAVE" must be based on the particular parameters of your Modbus master. As a minimum, you should execute "MB_SLAVE" twice within the response timeout period of the Modbus master.

Parameter

The following table shows the parameters of the "MB_SLAVE" instruction:

Parameter	Declaration	Data type	Memory area	Description
MB_ADDR	Input	V1.0: USINT V2.0: UINT	I, Q, M, D, L or constant	Station address of the Modbus slave (address range: 0 to 255)
MB_HOLD_REG	Input	VARIANT	D	Pointer to the Modbus holding register DB. The DB must be created with the "Standard - compatible with S7-300/400" access type.
NDR	Output	BOOL	I, Q, M, D, L	New data ready: • 0: No new data • 1: Indicates that new data has been written by the Modbus master
DR	Output	BOOL	I, Q, M, D, L	Read data: • 0: No data read • 1: Indicates that data has been read by the Modbus master
ERROR	Output	BOOL	I, Q, M, D, L	• 0: No error detected • 1: Error, a corresponding error code is output in the STATUS
STATUS	Output	WORD	I, Q, M, D, L	Error code

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

STATUS parameter

STATUS* (W#16#....)	Description	
80C8	The specified response timeout (refer to RCVTIME or MSGTIME) is "0".	
80D1	The receiver issued a flow control request to suspend an active transmission and never re-enabled the transmission within the wait time. This error is also generated during hardware flow control if the recipient does not detect CTS within the wait time.	
80D2	The send request was aborted because no DSR signal is received from the DCE.	
80E0	The message was terminated because the receive buffer is full	
80E1	The message was terminated as a result of a parity error	
80E2	The message was terminated as a result of a message frame error	
80E3	The message was terminated as a result of a overrun error	
80E4	The message was terminated as a result of the specified length exceeding the total buffer size	
8180	Invalid value for the port ID.	
8186	Invalid Modbus station address	
8187	Invalid pointer to MB_HOLD_REG-DB	
818C	Pointer to a type safe DB type MB_HOLD_REG (must be a Classic DB type)	
Response code sent to Modbus master (B#16#...)		
8380	No response	CRC error
8381	01	Function code not supported or not supported in a broadcast
8382	03	Data length error
8383	02	Error in the data address or address outside the valid range of MB_HOLD_REG
8384	03	Data value error
8385	03	Data diagnostic code value not supported (function code 08)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".		

Instance DB of the "MB_SLAVE" instruction (S7-1200)

Static variables of the instance DB

The following table describes the static variables of the instance DB of the instruction that you can use in the user program. Your program can write values to the HR_Start_Offset and Extended_Addressing variables and control the Modbus slave operations.

The other variables can be read to monitor the Modbus status.

Variable	Data type	Description
HR_Start_Offset	WORD	Start address of the Modbus holding register (default = " 0")
Extended_ Addressing	BOOL	Configuring addressing: • 0: Default address area (1 byte) • 1: Extended address area (2 bytes)
Request_Count	WORD	Total number of queries received by the slave

Variable	Data type	Description
Slave_Message_Count	WORD	Number of queries sent to this specific slave
Bad_CRC_Count	WORD	Number of received queries with CRC errors
Broadcast_Count	WORD	Number of received broadcast queries
Exception_Count	WORD	Number of Modbus-specific errors that require the return of an exception
Success_Count	WORD	The number of requests received for this specific slave without protocol errors

HR_Start_Offset

The addresses of the Modbus holding register start at 40001 or 400001. These addresses correspond to the start address of the holding register in the target system memory. Using the HR_Start_Offset variable, you can set the offset to a different start address.

Example: A holding register starts at MW 100 and has a length of 100 WORD. With an offset of 20 in the HR_Start_Offset parameter, the holding register begins at address 40021 instead of 40001. Each address below 40021 and above 400119 causes an addressing error.

	HR_Start_Offset = 0			HR_Start_Offset = 20	
	Modbus word address	S7-1200 byte address		Modbus word address	S7-1200 byte address
Minimum	40001	MW100		40021	MW100
Maximum	40099	MW198		40119	MW198

Extended_Addressing

To address the Modbus slave, a single byte (default address range) or a double byte (extended address range) can be configured. Extended addressing is used to address more than 247 devices in a single network. If you decide on extended addressing, you can address a maximum of 64,000 addresses. Below, you will see a frame of Modbus function 1 as an example.

Table 11-85 Slave address with one byte (byte 0)

Function 1	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	
Request	Slave address	F code	Start address		Length of the coils		
Valid response	Slave address	F code	Length	Coil data			
Error response	Slave address	0x81	E code				

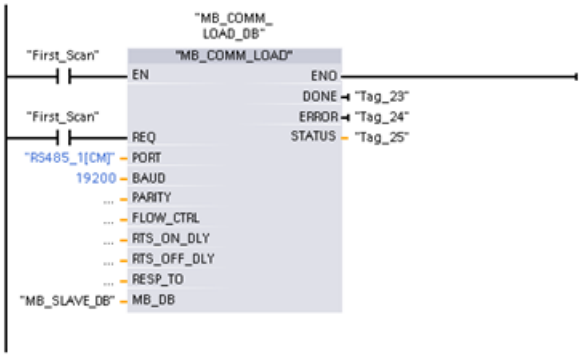


Table 11-86 Slave address with two bytes (byte 0 and byte 1)

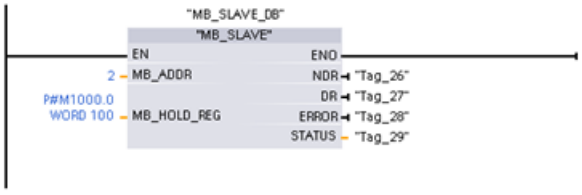
Function 1	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Request	Slave address		F code	Start address		Length of the coils	
Valid response	Slave address		F code	Length	Coil data		
Error response	Slave address		0x81	F code			



Sample program for a Modbus slave (S7-1200)

Networks (LAD)

Network 1: Initialize parameters of the RS-485 module only once during the first cycle.

Network 2: Check the requests of the Modbus master in every cycle. 100 words starting at MW1000 are configured for the Modbus holding register.

MODBUS (TCP) (S7-1200, S7-1500)

MODBUS (TCP) for the library versions V2.1 and V3.x of the S7-1200 CPUs (S7-1200)

MB_CLIENT: Communicating via PROFINET as a Modbus TCP client (S7-1200)

Description of MB_CLIENT (S7-1200)

Description

The "MB_CLIENT" instruction communicates as a Modbus TCP client via the PROFINET connection of the S7-1200 CPU. To use the instruction, you do not require any additional hardware module. With the "MB_CLIENT" instruction, you establish a connection between the client and the server, send requests and receive responses and control connection termination of the Modbus TCP server.

Parameters

The following table shows the parameters of the "MB_CLIENT" instruction:

Parameter	Declaration	Data type	Description
REQ (Page 4637)	Input	BOOL	Communication request with the Modbus TCP server The REQ parameter is level-controlled. This means that as long as the input is set (REQ=true), the instruction sends communication requests. • The instance DB for other clients is blocked with the communications request. • Changes to the input parameters will not become effective until the server has responded or an error message has been output. • If the parameter REQ is set again during an ongoing Modbus request, no additional transmission takes place afterwards.
DISCONNECT (Page 4637)	Input	BOOL	With this parameter, you control the establishment and termination of the connection to the Modbus server: • 0: Establish a communications connection to the specified IP address and port number. • 1: Disconnect the communication connection. No other function is executed during connection termination. The value 7003 is output at the STATUS parameter after successful connection termination. The request is sent immediately if the REQ parameter is set during connection establishment.
CONNECT_ID	Input	UINT	Unique ID to identify the connection. Each instance of the instructions "MB_CLIENT" and "MB_SERVER (Page 4643)" must be assigned a unique connection ID.
IP_OCTET_1	Input	USINT	1. Octet of the IP address* of the Modbus TCP server.
IP_OCTET_2	Input	USINT	2. Octet of the IP address* of the Modbus TCP server.

Parameter	Declaration	Data type	Description
IP_OCTET_3	Input	USINT	3. Octet of the IP address* of the Modbus TCP server.
IP_OCTET_4	Input	USINT	4. Octet of the IP address* of the Modbus TCP server.
IP_PORT	Input	UINT	IP port number of the server to which the client establishes the connection and communicates using the TCP/IP protocol (default value: 502).
MB_MODE (Page 4637)	Input	USINT	Selects the mode of the request (read, write or diagnostics).
MB_DATA_ADDR (Page 4637)	Input	UDINT	Start address of the data accessed by the "MB_CLIENT" instruction.
DATA_LEN	Input	UINT	Data length: Number of bits or words for the data access (see "MB_MODE and MB_DATA_ADDR parameters" - data length).
MB_DATA_PTR (Page 4638)	InOut	VARIANT	Pointer to the Modbus data register: The register is a buffer for the data received from the Modbus server or to be sent to the Modbus server. The pointer must reference a global data block with standard access. The number of bits addressed must be divisible by 8.
DONE	Out	BOOL	The bit at output parameter DONE is set to "1" as soon as the last job is completed without errors.
BUSY	Out	BOOL	• 0: No "MB_CLIENT " job in progress • 1: "MB_ CLIENT " job in progress
ERROR	Out	BOOL	• 0: No error • 1: Error occurred. The cause of error is indicated by the STATUS parameter.
STATUS (Page 4639)	Out	WORD	Error code of the instruction.
* 8-bit long component of the 32-bit IPv4 IP address of the Modbus TCP server.			

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Consistent input data during an "MB_CLIENT" call

When a Modbus client calls a Modbus instruction, the status of the input parameters is stored internally and then compared at the next call. The comparison is used to determine whether this particular call initialized the current request. Several "MB_CLIENT" calls can be executed if you use a common instance DB. The values of the input parameters must not be changed while an "MB_CLIENT" instance is being executed. If the input parameters are changed during execution, "MB_CLIENT" cannot be used to check whether or not the instance is currently being executed.

Multiple client connections

A Modbus TCP client can support several TCP connections and the maximum number of connections depends on the CPU being used. The total number of connections of one CPU, including those of the Modbus TCP clients and server must not exceed the maximum number of supported connections. Modbus TCP connections can also be shared by client and/or server connections.

With individual client connections, remember the following rules:

- Each "MB_CLIENT" connection must use a unique instance DB.
- For each "MB_CLIENT" connection, a unique server IP address must be specified.
- Each "MB_CLIENT" connection requires a unique connection ID.
  The relevant individual connection ID must be used for each individual instance DB of the instruction. The connection ID and instance DB belong together in pairs and must be unique for each connection.
- Unique numbers for the IP port may or may not be required depending on the server configuration.

Static tags of the instruction

The following table describes the editable static tags of the instance data block of the "MB_CLIENT" instruction.

Tag	Data type	Start value	Description
Blocked_Proc_Time-out	REAL	3.0	Wait time in seconds before the static tag ACTIVE is reset if there is a blocked Modbus instance. This can, for example, occur if a client request is output and the execution of the client function aborts before the request was fully executed. The maximum wait time is 55 seconds.
MB_Transaction_ID	WORD	1	Transaction ID of the Modbus TCP protocol. The start value of "1" should only be changed if the Modbus TCP server requires a different value.
MB_Unit_ID	BYTE	255	Modbus device detection: A Modbus TCP server is addressed using its IP address. For this reason, the MB_UNIT_ID parameter is not used in the case of Modbus TCP addressing. The MB_UNIT_ID parameter corresponds to the field of the slave address in the Modbus RTU protocol. If a Modbus TCP server is used as a gateway for a Modbus RTU protocol, the slave device in the serial network can be identified using MB_UNIT_ID. The MB_UNIT_ID parameter would in this case forward the request to the correct Modbus RTU slave address. Please note that some Modbus TCP devices may require the MB_UNIT_ID parameter for the initialization within a limited value range.
RCV_TIMEOUT	REAL	2.0	Time interval in seconds in which the "MB_CLIENT" instruction waits for a response from the server.
Connected	BOOL	0	Indicates whether the connection to the assigned client has been established or not: 1 = connected, 0 = not connected.

REQ and DISCONNECT parameters (S7-1200)

Description

If no instance of the "MB_CLIENT" instruction is executing and if the value of the DISCONNECT parameter is "0", a new job executes if REQ=1. If there is not yet a connection, this is established during execution.

If the same instance of the "MB_CLIENT" instruction executes again (DISCONNECT = 0 and REQ = 1), before the active job was executed, this is not executed on completion of the active job. A new job can only be started on completion of the active job (REQ = 1).

You can monitor the status of execution with the DONE parameter. You can use this to monitor the status of execution if the "MB_CLIENT" instruction is executed sequentially.

Description of MB_CLIENT (Page 4634)

MB_MODE, MB_DATA_ADDR and DATA_LEN parameters (S7-1200)

Description

The combination of the MB_MODE, MB_DATA_ADDR and DATA_LEN parameters defines the Modbus function code used in the current Modbus message for the values 0, 1 and 2 of MB_MODE:

- MB_MODE contains the information on whether to read or to write.
  MB_MODE=0: Read, MB_MODE=1 and 2: Writing
- MB_DATA_ADDR contains the information on what is to be read or written, as well as address information from which the "MB_CLIENT" instruction calculates the remote address.
- DATA_LEN contains the number of values to be read/written.

Examples:

- The combination MB_MODE=1, MB_DATA_ADDR=1, DATA_LEN=1 specifies the function code 05. 1 output bit is written starting from the remote address 0.
- The combination MB_MODE=1, MB_DATA_ADDR=1, DATA_LEN=2 specifies the function code 15. 2 output bits are written starting from the remote address 0.

The following table shows the relationship between the input parameters MB_MODE, MB_DATA_ADDR, DATA_LEN of the "MB_CLIENT" instruction and the associated Modbus function.

MB_MODE	MB_DATA_ADDR	DATA_LEN	Modbus function	Function and data type
0	1 to 9,999	1 to 2,000	01	Read 1 to 2,000 output bits on the remote address 0 to 9,998
0	10,001 to 19,999	1 to 2,000	02	Read 1 to 2,000 input bits on the remote address 0 to 9,998
0	40,001 to 49,999	1 to 125	03	Read 1 to 125 holding registers on the remote address 0 to 9,998
0	30,001 to 39,999	1 to 125	04	Read 1 to 125 input words on the remote address 0 to 9,998
1	1 to 9,999	1	05	Write 1 output bit on the remote address 0 to 9,998
1	40,001 to 49,999	1	06	Write 1 holding register on the remote address 0 to 9,998
1	1 to 9,999	2 to 1,968	15	Write 2 to 1,968 output bits on the remote address 0 to 9,998
1	40,001 to 49,999	2 to 123	16	Write 2 to 123 holding registers on the remote address 0 to 9,998
2	1 to 9,999	1 to 1,968	15	Write 1 to 1,968 output bits on the remote address 0 to 9,998
2	40,001 to 49,999	1 to 123	16	Write 1 to 123 holding registers on the remote address 0 to 9,998
11	The MB_DATA_ADDR and DATA_LEN parameters are not evaluated when this function is executed.		11	Read status word and event counter of the server: • The status word reflects the the processing status (0 - not processing, 0xFFFF - processing). • The event counter is incremented when the Modbus request was executed successfully. If an error occurred during execution of a Modbus function, a message is sent by the server but the event counter is not incremented.
80	-	1	08	Check the server status with the diagnostic code 0x0000 (return loop test - the server sends the request back): • 1 WORD per call
81	-	1	08	Reset the event counter of the server with the diagnostic code 0x000A: • 1 WORD per call
3 to 10, 12 to 79, 82 to 255				Reserved

Description of MB_CLIENT (Page 4634)

MB_DATA_PTR parameter (S7-1200)

Description

The MB_DATA_PTR parameter is a pointer to a data buffer for storing the data read from or written to the Modbus server. As the data buffer, you can use a global data block or a memory area (M).

For a buffer in the memory area (M), use a pointer in the ANY format as follows: "P#bit address" "data type" "length" (example: P#M1000.0 WORD 500).

The MB_DATA_PTR parameter uses a communications buffer:

- For the communication functions of the "MB_CLIENT" instruction:
  - Reading and writing of 1 bit of data of the Modbus server addresses 00001 to 09999 and 10001 to 19999.
  - Reading of 16-bit WORD data of the Modbus server addresses 30001 to 39999 and 40001 to 49999.
  - Writing 16-bit WORD data of the Modbus server addresses 40001 to 49999.
- During data transmission (length: bit or WORD) from or to the global DB or the memory area (M) that you assigned with the MB_DATA_PTR parameter.

If you use a data block for the buffer in the MB_DATA_PTR parameter, you will need to assign data types to the DB elements.

- Use the 1-bit data type BOOL for a Modbus bit address
- Use a 16-bit data type such as WORD, UINT, INT or REAL for a Modbus WORD address.
- Use a 32-bit data type (double word) such as DWORD, DINT or REAL for two Modbus WORD addresses.
- With MB_DATA_PTR, you can also access complex DB elements such as:
  - Standard arrays
  - Structures with unique element names
  - Complex structures with unique naming of the elements and data type lengths of 16 or 32 bits.
- The data areas for the MB_DATA_PTR parameter can also be in different global data blocks (or in different memory areas). You can, for example, use a data block for the the read jobs and another one for the write jobs or a separate data block for each "MB_CLIENT" station.

Parameter STATUS (S7-1200)

Parameter STATUS (general status information) (library version V2.1)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
7000	No call active (REQ=0).
7001	First call with REQ=1: Processing started; BUSY has the value 1.

STATUS* (W#16#)	Description
7002	Intermediate call (REQ irrelevant). Processing already active; BUSY has the value 1.
7003	Connection is being terminated.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (general status information) (library version V3.x)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
0001	Connection established.
0003	Connection terminated.
7000	No call active (REQ=0).
7001	First call with REQ=1: Processing started; BUSY has the value 1.
7002	Intermediate call (REQ irrelevant). Processing already active; BUSY has the value 1.
7003	Terminating connection.
7004	Connection established and monitored. No job processing active.
7005	Data was sent.
7006	Data was received.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (protocol error)

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
80C8	Local	-	No response of the server in the defined period. Check the connection to the Modbus server. This error is only reported on completion of the configured repeated attempts. If the "MB_CLIENT" instruction does not receive an answer with the originally transferred transaction ID (MB_TRANSACTION_ID tag) within the defined period, this error code is output.
8380	Local	-	Received Modbus frame has incorrect format or too few bytes were received.
8381	Remote	01	Function code is not supported.

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8382	Local	-	• The length of the Modbus frame in the frame header does not match the number of received bytes. • The number of bytes does not match the number of actually transmitted bytes (only functions 1-4). For example, this is the case when "MB_CLIENT" requests an odd number of words, but "MB_SERVER" always sends an even number of words. • The start address in the received frame does not match the saved start address (functions 5, 6, 15, 16). • The number of words does not match the number of actually transmitted words (functions 15 and 16).
	Remote	03	Invalid length specification in received Modbus frame. Check the server side.
8383	Local	-	Error reading or writing data or access outside the address area of MB_DATA_PTR (Page 4638).
	Remote	02	Error reading or writing data or access outside the address area of the server
8384	Local	-	• Invalid exception code received. • A different data value was received than was originally sent by the client (functions 5, 6 and 8). • Invalid status value received (function 11)
	Remote	03	Error in data value for function 5
8385	Local	-	• Diagnostics code not supported. • A different subfunction code was received than was originally sent by the client (function 8).
	Remote	03	Diagnostics code not supported
8386	Local	-	Received function code does not match the one sent originally.
8387	Local	-	• The assigned connection ID is different from that used for previous requests. Only one connection ID can be used for each instance DB of the "MB_CLIENT" instruction. • The error code is also output when the ID of the Modbus TCP protocol received by the server is not "0".
8388	Local	-	The Modbus server sent a different data length than was requested. This error occurs only when using the Modbus functions 15 or 16.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".			

Parameter STATUS (parameter error)

In addition to the errors listed in the following table, errors are also possible with the "MB_CLIENT" instruction caused by the communications instructions ("TCON", "TDISCON", "TSEND" and "TRCV").

STATUS* (W#16#)	Description
80BB	Invalid value at ACTIVE_EST parameter (identifier for the type of connection establishment, see T_CON_PARAM): • Only passive connection establishment permitted for server (ACTIVE_EST = FALSE). • Only active connection establishment permitted for client (ACTIVE_EST = TRUE).
8188	The MB_MODE parameter has an invalid value.
8189	Invalid addressing of data at the MB_DATA_ADDR parameter.
818A	Invalid data length at the MB_DATA_LEN parameter.
818B	The MB_DATA_PTR parameter has an invalid pointer. You should also check the values of the MB_DATA_ADDR (Page 4637) and MB_DATA_LEN parameters.
818C	• The MB_DATA_PTR (Page 4634) pointer references an an optimized data block. Either use a data block with standard access or a memory area. • Timeout at parameter BLOCKED_PROC_TIMEOUT (see static tags of instruction). The limit of 55 seconds has been exceeded.
8200	• A further Modbus request is currently being processed via the port. • Another instance of MB_CLIENT with the same connection parameters is processing an existing Modbus request.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Note

Error codes of internally used communications instructions.

With the "MB_CLIENT" instruction, in addition to the errors listed in the tables, errors caused by the communication instructions ("TCON", "TDISCON", "TSEND" and "TRCV") used by the instruction can occur.

The error codes are assigned via the instance data block of the "MB_CLIENT" instruction. The error codes are displayed for the respective instruction under STATUS in the Static section.

The meaning of the error codes is available in the documentation of the corresponding communications instruction.

MB_HOLD_REG parameter (Page 4646)

MB_SERVER: Communicating via PROFINET as a Modbus TCP server (S7-1200)

Description of MB_SERVER (S7-1200)

Description

The "MB_SERVER" instruction communicates as a Modbus TCP server via the PROFINET connection of the S7-1200 CPU. To use the instruction, you do not require any additional hardware module. The "MB_SERVER" instruction processes connection requests of a Modbus TCP client, receives requests from Modbus functions and sends responses.

NOTICE
Security information Note that each client of the network is given read and write access to the process image inputs and outputs and to the data block or bit memory area defined by the Modbus holding register. The option is available to restrict access to an IP address to prevent unauthorized read and write operations. Note, however, that the shared address can also be used for unauthorized access.

Parameters

The following table shows the parameters of the "MB_SERVER" instruction:

Parameter	Declaration	Data type	Description
DISCONNECT	Input	BOOL	The instruction "MB_SERVER" enters into a passive connection with a partner module, which means the server responds to a TCP connection request from each requesting IP address. You can use this parameter to control when a connection request is accepted: • 0: A passive connection is established when there is no communications connection. • 1: Initialization of the connection termination. If the input is set, no other operations are executed. The value 7003 is output at the STATUS parameter after successful connection termination.
CONNECT_ID	Input	UINT	The parameter uniquely identifies a connection within the CPU. Each individual instance of the instructions "MB_CLIENT (Page 4634)" and "MB_SERVER" must have a unique CONNECT_ID parameter.
IP_PORT	Input	UINT	Start value=502. The number of the IP port defines which IP port is monitored for connection requests of the Modbus client. The following TCP port numbers must not be used for the passive connection of the "MB_SERVER" instruction: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.
MB_HOLD_REG (Page 4646)	InOut	VARIANT	Pointer to the Modbus holding register of the "MB_SERVER" instruction: Use a global data block with standard access as holding register. The holding register contains the values that may be accessed by a Modbus client using the Modbus functions 3 (read), 6 (write) and 16 (read).

Parameter	Declaration	Data type	Description
NDR	Output	BOOL	"New Data Ready": • 0: No new data • 1: New data written by the Modbus client written
DR	Output	BOOL	"Data Read": • 0: No data read • 1: Data read by the Modbus client
ERROR	Output	BOOL	If an error occurs during the call of the "MB_SERVER" instruction, the output of the ERROR parameter is set to TRUE. Detailed information about the cause of the problem is indicated by the STATUS parameter.
STATUS (Page 4647)	Output	WORD	Error code of the instruction.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Mapping of Modbus addresses to the process image

The "MB_SERVER" instruction allows incoming Modbus functions (1, 2, 4, 5 and 15) direct read and write access to the process image input and output of the S7-1200 CPU (use of the data types BOOL and WORD).

For the data transfer of the function codes 3, 6 and 16, the holding register (MB_HOLD_REG parameter) must be defined longer than one byte. The following table shows the mapping of the Modbus addresses to the process image of the CPU.

Modbus function						S7-1200	
Code	Function	Data area	Address space			Data area	CPU address
01	Read: Bits	Output	0	to	8191	Process image output	Q0.0 to Q1023.7
02	Read: Bits	Input	0	to	8191	Process image input	I0.0 to I1023.7
04	Read: WORD	Input	0	to	1021	Process image input	IW0 to IW1022
05	Write: Bits	Output	0	to	8191	Process image output	Q0.0 to Q1023.7
15	Write: Bits	Output	0	to	8191	Process image output	Q0.0 to Q1023.7

Incoming Modbus alarms with the function codes 3, 6 and 16 write to or read from the Modbus holding registers (you specify the holding registers with the MB_HOLD_REG parameter).

Multiple server connections

You can create multiple Server connections. This allows a single CPU to establish connections to more than one Modbus TCP client at the same time.

A Modbus TCP server can support several TCP connections and the maximum number of connections depends on the CPU being used.

The total number of connections of one CPU, including those of the Modbus TCP clients and server must not exceed the maximum number of supported connections.

Modbus TCP connections can also be shared by client and/or server connections.

In the case of Server connections, remember the following rules:

- Each "MB_SERVER" connection must use a unique instance DB.
- Each "MB_SERVER" connection must be created with a unique IP port number. Only one connection is supported for each port.
- Each "MB_SERVER" connection must use a unique connection ID.
  The relevant individual connection ID must be used for each individual instance DB of the instruction. The connection ID and instance DB belong together in pairs and must be unique for each connection.
- For each connection, the "MB_SERVER" instruction must be called individually.

Modbus diagnostics functions

The table below contains a description of the Modbus diagnostics functions.

Code	Subfunction	Description
08	0x0000	Echo test: The "MB_SERVER" instruction receives a data word and returns this unchanged to the Modbus master.
08	0x000A	Reset event counter: The "MB_SERVER" instruction resets the event counter for communication that is used for Modbus function 11.
11	-	Fetch event counter of the communication: The "MB_SERVER" instruction uses an internal event counter for communication to record the number of successfully executed read and write requests sent to the Modbus server. The event counter is not incremented by the functions 8, 11 or broadcast requests. The same applies to requests that result in a communications error (for example parity errors or CRC errors). The broadcast function is not available for Modbus TCP because only one client/server connection can exist at any one time.

Static tags of the instruction

The following table describes the static tags of the instance data block of the "MB_SERVER" instruction used in the program. You can write the HR_Start_Offset tag. You can read the other tags to monitor the Modbus status.

Tag	Data type	Start value	Description
HR_Start_Offset	WORD	0	Assign the start address of the Modbus holding register.
Request_Count	WORD	0	Total number of requests received by the server.
Server_Message_Count	WORD	0	Total number of received alarms for the relevant server.
Xmt_Rcv_Count	WORD	0	Counter for detecting the number of transfers during which an error occurred. The counter is also incremented if an invalid Modbus alarm is received.
Exception_Count	WORD	0	Counter for detecting the number of errors specifically for Modbus cause an exception.
Success_Count	WORD	0	Counter for detecting the number of requests that contain no error in the transferred protocol.
Connected	BOOL	0	Indicates whether the connection to the assigned client has been established or not: 1 = connected, 0 = not connected.

Example: Addressing via static tag HR_Start_Offset

The addresses of the Modbus holding register start at 0 (from the perspective of the MB_CLIENT at 40.001). These addresses correspond to the address area of the CPU memory area for the holding register. You can also define the HR_Start_Offset tag so that the Modbus holding register has a start address other than 0.

Example: The holding register begins at MW100, and has a length of 100 WORD. An offset value in the HR_Start_Offset parameter means that the start address of the holding register is moved from 0 to 20. This causes an error whenever the holding register is addressed below the address 20 and above the address 119.

HR_Start_Offset	Address	Minimum	Maximum
0	Modbus address (WORD)	0	99
	CPU address	MW100	MW298
20	Modbus address (WORD)	20	119
	CPU address	MW100	MW298

Difference between synchronous and asynchronous instructions (Page 2571)

MB_HOLD_REG parameter (S7-1200)

Description

The MB_HOLD_REG parameter is a pointer to a data buffer for storing the data read from or written to the Modbus server. As the data buffer, you can use a global data block or a memory area (M).

- The high limit for the number of addresses in the data block (D) is determined by the maximum work memory of the CPU.
- The high limit for the number of bit memories (M) is determined by the size of the CPU memory area.

The following table shows examples of mapping Modbus addresses to the holding register for the Modbus functions 3 (read WORD), 6 (write WORD), 16 (write several WORD) and 23 (write and read several words).

Modbus addresses	MB_HOLD_REG parameter - examples		
0	MW100	DB10.DBW0	"Recipe".ingredient[1]
1	MW102	DB10.DBW2	"Recipe".ingredient[2]
2	MW104	DB10.DBW4	"Recipe".ingredient[3]
3	MW106	DB10.DBW6	"Recipe".ingredient[4]
4	MW108	DB10.DBW8	"Recipe".ingredient[5]

Parameter STATUS (S7-1200)

Parameter STATUS (general status information) (library version V2.1)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
7000	No call active (REQ=0).
7001	First call with REQ=1: Processing started; BUSY has the value 1.
7002	Intermediate call (REQ irrelevant). Processing already active; BUSY has the value 1.
7003	Connection is being terminated.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (general status information) (library version V3.x)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
0001	Connection established.
0003	Connection terminated.
7000	No call active (REQ=0).
7001	First call. Connection establishment triggered.
7002	Intermediate call. Establishing connection.
7003	Terminating connection.
7005	Data is being sent.
7006	Data is being received.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (protocol error)

STATUS* (W#16#)	Local and/ or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8380	Local	-	Received Modbus frame has incorrect format or too few bytes were received.
8381	Remote	01	Function code is not supported.
8382	Remote	03	Error in data length

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8383	Local	-	Error reading or writing data or access outside the address area of MB_HOLD_REG (Page 4646).
	Remote	02	Error reading or writing data or access outside the address area of the server
8384	Local	-	• Invalid exception code received. • A different data value was received than was originally sent by the server (functions 5, 6 and 8). • Invalid status value received (function 11)
	Remote	03	Error in data value for function 5
8385	Local	-	• Diagnostics code not supported. • A different subfunction code was received than was originally sent by the server (function 8).
	Remote	03	Diagnostics code not supported
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".			

Parameter STATUS (parameter error)

STATUS* (W#16#)	Description
80BB	Invalid value at ACTIVE_EST parameter (identifier for the type of connection establishment, see T_CON_PARAM): • Only passive connection establishment permitted for server (ACTIVE_EST = FALSE). • Only active connection establishment permitted for client (ACTIVE_EST = TRUE).
8187	The MB_HOLD_REG parameter has an invalid pointer. Data area is too small.
818C	• The pointer at parameter MB_HOLD_REG references an optimized data block. Either use a data block with standard access or a memory area. • Error due to timeout of execution (more than 55 seconds).
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Note

Error codes of internally used communications instructions.

With the "MB_SERVER" instruction, in addition to the errors listed in the tables, errors caused by the communication instructions ("TCON", "TDISCON", "TSEND" and "TRCV") used by the instruction can occur.

The error codes are assigned via the instance data block of the "MB_SERVER" instruction. The error codes are displayed for the respective instruction under STATUS in the Static section.

The meaning of the error codes is available in the documentation of the corresponding communications instruction.

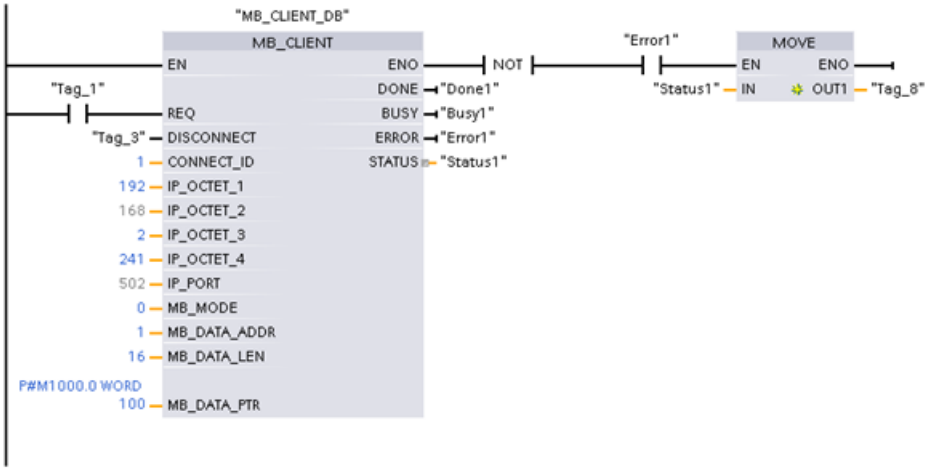
Description of MB_SERVER (Page 4643)

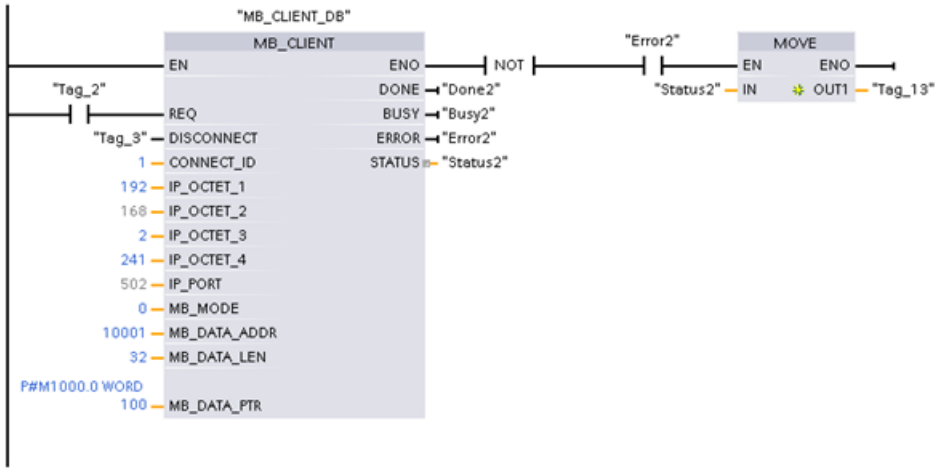
Examples (S7-1200)

MB_CLIENT example 1: Send several requests via a TCP connection (S7-1200)



Description

Several requests of the Modbus Client can be sent via a TCP connection. To do this, use the same instance DB, the same connection ID and the same port number.

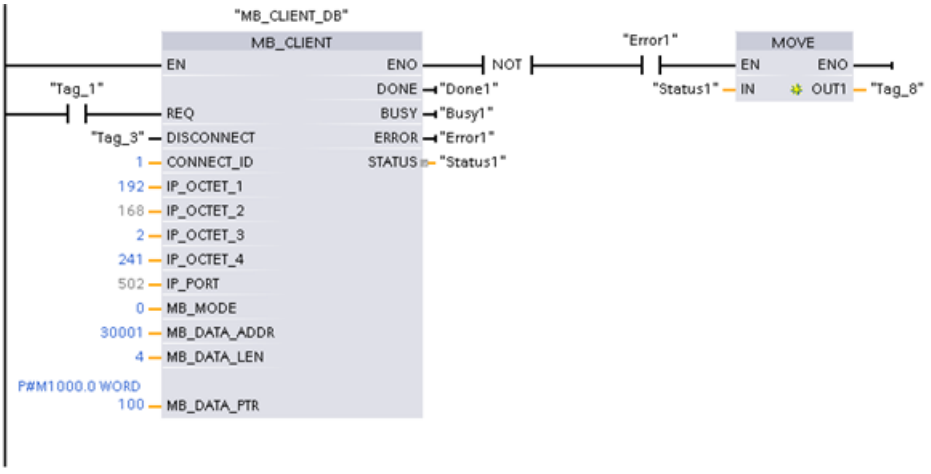


Only one client can be active at any one time. After processing of a client has been completed, the next client is processed. The order of execution must be defined in the program.

In the following sample program, the value of the STATUS output parameter is also copied.

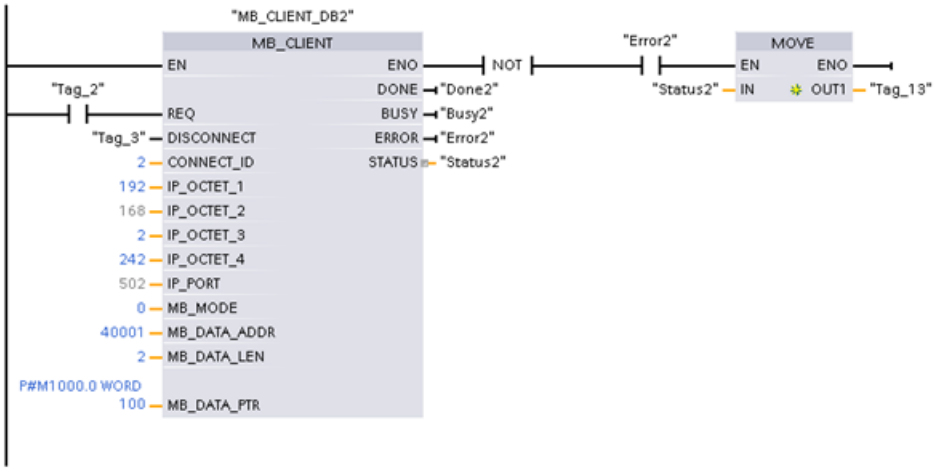
Network 1: Modbus function 1 - 16 read output bits

Network 2: Modbus function 2 - 32 read input bits



MB_CLIENT example 2: Send multiple requests via several TCP connections (S7-1200)

Description

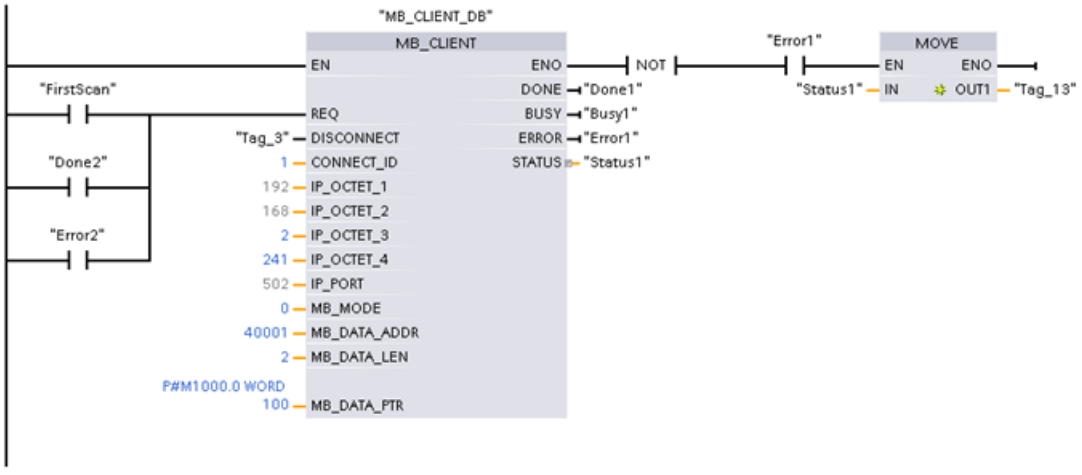


Requests from the Modbus client can be sent via different TCP connections. If you require this, use a different instance DB and a different connection ID.

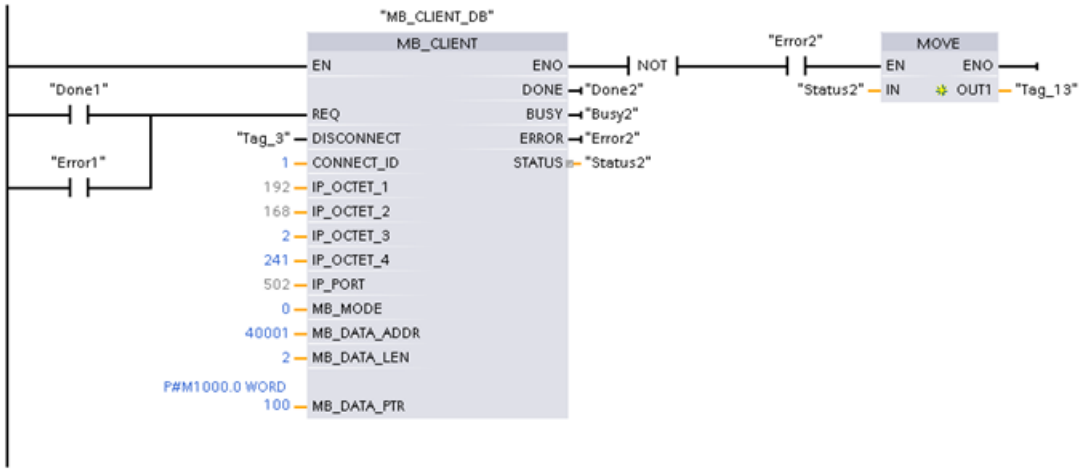
Use a different port number, if the connections are to the same Modbus server. If the connections are to different Modbus servers, you can freely assign the port number.

Network 1: Modbus function 4 - read input (WORD)

Network 2: Modbus function 3 - read holding register (WORD)



MB_CLIENT example 3: Coordinate several requests (S7-1200)



Description

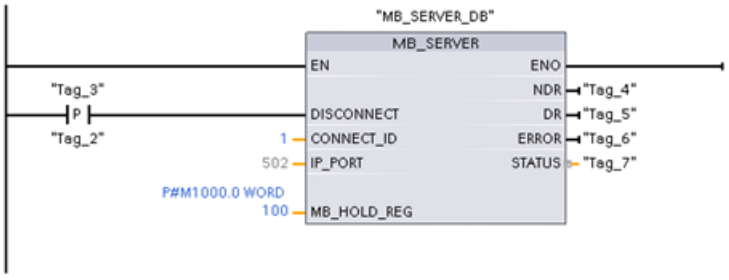
Make sure that the individual Modbus requests are executed. You control coordination of requests with the program. The following example demonstrates how the output parameters of the first and second client request can be used to coordinate execution of the instructions.

Network 1: Modbus function 3 - read holding register (WORD)

Network 2: Modbus function 3 - read holding register (WORD)

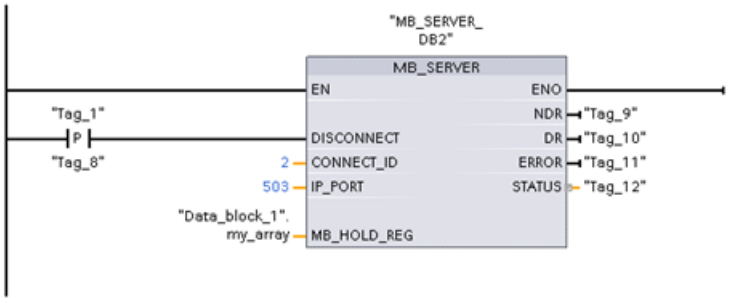
MB_SERVER example: Multiple TCP connections (S7-1200)

Description



You can use several Modbus TCP server connections. To do this, the "MB_SERVER" instruction must be called independently for each connection.

Every connection requires the following:



- An independent instance data block of the instruction
- A unique connection ID
- A separate IP port (on the S7-1200, only one connection is permitted per IP port)

To optimize the performance "MB_SERVER" should be executed once per program cycle for each connection.

Network 1: Connection #1 with associated IP port connection ID and instance DB

Network 2: Connection #1 with associated IP port connection ID and instance DB

MODBUS (TCP) for the library versions V4.0 and later of the S7-1200 CPUs and as of V3.x of the S7-1500 CPUs (S7-1200, S7-1500)

MB_CLIENT: Communicating via PROFINET as a Modbus TCP client (S7-1200, S7-1500)

Description of MB_CLIENT (S7-1200, S7-1500)

Description

The "MB_CLIENT" instruction communicates as a Modbus TCP client via the PROFINET connection. With the "MB_CLIENT" instruction, you establish a connection between the client and the server, send Modbus requests and receive responses and control connection termination of the Modbus TCP client.

For the S7-1200 with firmware version V4.0 you can use the "MB_CLIENT" instruction up to and including library version V3.1. With the S7-1200 as of firmware version V4.1 and the S7-1500, you can use the "MB_CLIENT" instruction of all library versions.

The connection can take place via the local interface of the CPU or CM/CP.

To use the instruction, you do not require an additional hardware module.

Multiple client connections

A Modbus TCP client can support several TCP connections and the maximum number of connections depends on the CPU being used. The total number of connections of one CPU, including those of the Modbus TCP clients and server must not exceed the maximum number of supported connections. Modbus TCP connections can also be shared by "MB_CLIENT" and/or "MB_SERVER" instances.

With individual client connections, remember the following rules:

- Each "MB_CLIENT" connection must use a unique instance DB.
- For each "MB_CLIENT" connection, a unique server IP address must be specified.

- Each "MB_CLIENT" connection requires a unique connection ID.
  The relevant individual connection ID must be used for each individual instance DB of the instruction. The connection ID and instance DB belong together in pairs and must be unique for each connection.
- Unique numbers for the IP port may or may not be required depending on the server configuration.

Parameters

The following table shows the parameters of the "MB_CLIENT" instruction:

Parameter	Declaration	Data type	Description
REQ (Page 4657)	Input	BOOL	Modbus query to the Modbus TCP server The REQ parameter is level-controlled. This means that as long as the input is set (REQ=true), the instruction sends communication requests. • After the Modbus query has started, the instance DB is locked for other clients. • Changes to the input parameters will not become effective until the server has responded or an error message has been output. • If the parameter REQ is set again during an ongoing Modbus request, no additional transmission takes place afterwards.
DISCONNECT (Page 4657)	Input	BOOL	With this parameter, you control the establishment and termination of the connection to the Modbus server: • 0: Establish communications connection to the connection partner configured at the CONNECT parameter (see CONNECT parameter). • 1: Disconnect the communication connection. No other function is executed during connection termination. The value 0003 is output at the STATUS parameter after successful connection termination. The Modbus request is sent immediately if the REQ parameter is set during connection establishment.
MB_MODE (Page 4658)	Input	USINT	Selects the mode of the Modbus request (read, write or diagnostics) or direct selection of a Modbus function
MB_DATA_ADDR (Page 4658)	Input	UDINT	depends on MB_MODE
MB_DATA_LEN	Input	UINT	Data length: Number of bits or words for the data access (see MB_MODE, MB_DATA_ADDR and MB_DATA_LEN parameters (Page 4658)).
MB_DATA_PTR (Page 4660)	InOut	VARIANT	Pointer to a data buffer for the data to be received from the Modbus server or to be sent to the Modbus server.

Parameter	Declaration	Data type	Description
CONNECT (Page 4661)	InOut	VARIANT	Pointer to the structure of the connection description The following structures (system data types) can be used: • TCON_IP_v4: Includes all address parameters that are required for establishing a programmed connection. When using TCON_IP_v4, the connection is established when calling the "MB_CLIENT" instruction. • TCON_Configured: Includes the address parameters of a configured connection. When using TCON_Configured, an existing connection is used that was created by the CPU after download of the hardware configuration.
DONE	Out	BOOL	The bit at output parameter DONE is set to "1" as soon as the last Modbus job is completed without errors.
BUSY	Out	BOOL	• 0: No Modbus request in progress • 1: Modbus request being processed The output parameter BUSY is not set during connection establishment and termination.
ERROR	Out	BOOL	• 0: No error • 1: Error occurred. The cause of error is indicated by the STATUS parameter.
STATUS (Page 4663)	Out	WORD	Detailed status information of the instruction.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Consistent input data during an "MB_CLIENT" call

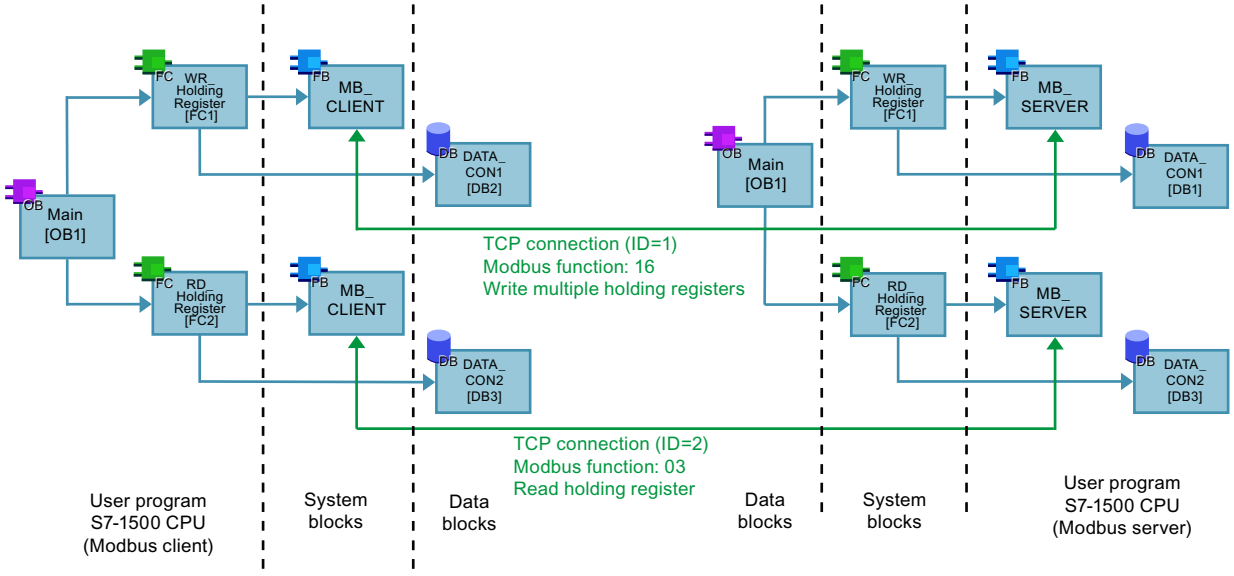
When a Modbus client instruction is called, the values of the input parameters are stored internally and then compared at the next call. The comparison is used to determine whether this particular call initialized the current request. Several "MB_CLIENT" calls can be executed if you use a common instance DB. The values of the input parameters must not be changed while an "MB_CLIENT" instance is being executed. If the input parameters are changed during execution, "MB_CLIENT" cannot be used to check whether or not the instance is currently being executed.

Static tags of the instruction

The following table describes the editable static tags of the instance data block of the "MB_CLIENT" instruction.

Tag	Data type	Start value	Description
Blocked_Proc_Time-out	REAL	3.0	Wait time in seconds before the static tag ACTIVE is reset if there is a blocked Modbus instance. This can, for example, occur if a client request is output and the execution of the client function aborts before the request was fully executed. The wait time must be between 0.5 s and 55 s.
MB_Transaction_ID	WORD	1	Transaction ID of the Modbus TCP protocol. The start value of "1" should only be changed if the Modbus TCP server requires a different value.
MB_Unit_ID	BYTE	255	Modbus device detection: A Modbus TCP server is addressed using its IP address. For this reason, the MB_UNIT_ID parameter is not used in the case of Modbus TCP addressing. The MB_UNIT_ID parameter corresponds to the field of the slave address in the Modbus RTU protocol. If a Modbus TCP server is used as a gateway for a Modbus RTU protocol, the slave device in the serial network can be identified using MB_UNIT_ID. The MB_UNIT_ID parameter would in this case forward the request to the correct Modbus RTU slave address. Please note that some Modbus TCP devices may require the MB_UNIT_ID parameter for the initialization within a limited value range. Use the following links to get more information on the MB_Unit_ID parameter: https://support.industry.siemens.com/cs/ww/en/view/102420337 (https://support.industry.siemens.com/cs/document/102420337/what-is-the-function-of-the-mb_unit_id-in-the-instance-data-block-of-the-modbus-block-mb_client?dti=0&dl=en&lc=de-WW) http://support.automation.siemens.com/WW/view/en/109736516 (https://support.industry.siemens.com/cs/document/109736516/how-do-you-clear-the-status-168382-in-the-case-of-a-modbus-tcp-connection-between-simatic-s7-1500-s7-1200-and-sentron-pac-devices?dti=0&dl=en&lc=de-WW)
RCV_TIMEOUT	REAL	2.0	Time interval in seconds in which the "MB_CLIENT" instruction waits for a response from the server. It must be between 0.5 s and 55 s.
Connected	BOOL	0	Indicates whether the connection to the assigned server has been established or not: 1 = connected, 0 = not connected.
RETRIES	WORD	0	Number of send attempts made by the "MB_CLIENT" instruction before it returns the error W#16#80C8.

Note



Tag MB_Transaction_ID

If the transaction ID in the answer of the Modbus TCP server does not match the transaction ID of the job from "MB_CLIENT", the "MB_CLIENT" instruction waits for the time period RCV_TIMEOUT * RETRIES for the answer of the Modbus TCP server with the correct transaction ID; once this time has expired, it returns the error W#16#80C8.

Example

An example project for the Modbus TCP communication between two S7-1500 CPUs can be found in the Service and Support Portal under Entry ID 94766380 (http://support.automation.siemens.com/WW/view/en/94766380).

Two Modbus functions are used in this example. For each Modbus function, a Modbus TCP connection is established using a Modbus block pair (MB_CLIENT and MB_SERVER).

See also

Difference between synchronous and asynchronous instructions (Page 2571)

REQ and DISCONNECT parameters (S7-1200, S7-1500)

Description

If no job is active and if the value of the DISCONNECT parameter is "0", a new job executes if REQ=1. If there is not yet a connection, this is established during execution.

If the same instance of the "MB_CLIENT" instruction executes again (DISCONNECT = 0 and REQ = 1), before the active job was executed, this is not executed on completion of the active job. A new job can only be started on completion of the active job (REQ = 1).

The status of the execution is output by the output parameters. You can use it to monitor the execution status when the "MB_CLIENT" instruction is executed sequentially.

MB_MODE, MB_DATA_ADDR and MB_DATA_LEN parameters (S7-1200, S7-1500)

Description

The combination of the MB_MODE, MB_DATA_ADDR and MB_DATA_LEN parameters defines the Modbus function code used in the current Modbus message for the values 0, 1 and 2 of MB_MODE:

- MB_MODE contains the information on whether to read or to write.
  MB_MODE=0: Read, MB_MODE=1 and 2: Write (Note: With MB_MODE=2, there is not distinction between Modbus functions 15 and 05 or between Modbus functions 16 and 06.)
- MB_DATA_ADDR contains the information on what is to be read or written, as well as address information from which the "MB_CLIENT" instruction calculates the remote address.
- MB_DATA_LEN contains the number of values to be read/written.

Examples:

- The combination MB_MODE=1, MB_DATA_ADDR=1, MB_DATA_LEN=1 specifies the function code 05. 1 output bit is written starting from the remote address 0.
- The combination MB_MODE=1, MB_DATA_ADDR=1, MB_DATA_LEN=2 specifies the function code 15. 2 output bits are written starting from the remote address 0.

The following applies to the values 101 to 106 and 115 to 116 from MB_MODE:

- MB_MODE defines the Modbus function code.
- MB_DATA_ADDR contains the remote address.
- MB_DATA_LEN contains the number of values to be read/written.

Example:

- MB_MODE=104, MB_DATA_ADDR=17,834, MB_DATA_LEN=125
  - MB_MODE=104 defines the function code 04 (read input words).
  - MB_DATA_ADDR=17,834 defines the remote address 17,834.
  - MB_DATA_LEN=125 defines that 125 values are read.

The following table shows the relationship between the input parameters MB_MODE, MB_DATA_ADDR, MB_DATA_LEN of the "MB_CLIENT" instruction and the associated Modbus function.

MB_MODE	MB_DATA_ADDR	MB_DATA_LEN	Modbus function	Function and data type
0	1 to 9,999	1 to 2,000	01	Read 1 to 2,000 output bits on the remote address 0 to 9,998
0	10,001 to 19,999	1 to 2,000	02	Read 1 to 2,000 input bits on the remote address 0 to 9,998

MB_MODE	MB_DATA_ADDR	MB_DATA_LEN	Modbus function	Function and data type
0	• 40,001 to 49,999 • 400,001 to 465,535	1 to 125	03	• Read 1 to 125 holding registers on the remote address 0 to 9,998 • Read 1 to 125 holding registers on the remote address 0 to 65,534
0	30,001 to 39,999	1 to 125	04	Read 1 to 125 input words on the remote address 0 to 9,998
1	1 to 9,999	1	05	Write 1 output bit on the remote address 0 to 9,998
1	• 40,001 to 49,999 • 400,001 to 465,535	1	06	• Write 1 holding register on the remote address 0 to 9,998 • Write 1 holding register on the remote address 0 to 65,534
1	1 to 9,999	2 to 1,968	15	Write 2 to 1,968 output bits on the remote address 0 to 9,998
1	• 40,001 to 49,999 • 400,001 to 465,535	2 to 123	16	• Write 2 to 123 holding registers on the remote address 0 to 9,998 • Write 2 to 123 holding registers on the remote address 0 to 65,534
2	1 to 9,999	1 to 1,968	15	Write 1 to 1,968 output bits on the remote address 0 to 9,998
2	• 40,001 to 49,999 • 400,001 to 465,535	1 to 123	16	• Write 1 to 123 holding registers on the remote address 0 to 9,998 • Write 1 to 123 holding registers on the remote address 0 to 65,534
11	The MB_DATA_ADDR and MB_DATA_LEN parameters are not evaluated when this function is executed.		11	Read status word and event counter of the server: • The status word reflects the the processing status (0 - not processing, 0xFFFF - processing). • The event counter is incremented when the Modbus request was executed successfully. If an error occurred during execution of a Modbus function, a message is sent by the server but the event counter is not incremented.
80	-	1	08	Check the server status with the diagnostic code 0x0000 (return loop test - the server sends the request back): • 1 WORD per call
81	-	1	08	Reset the event counter of the server with the diagnostic code 0x000A: • 1 WORD per call
101	0 to 65,535	1 to 2,000	01	Read 1 to 2,000 output bits on the remote address 0 to 65,535
102	0 to 65,535	1 to 2,000	02	Read 1 to 2,000 input bits on the remote address 0 to 65,535
103	0 to 65,535	1 to 125	03	Read 1 to 125 holding registers on the remote address 0 to 65,535
104	0 to 65,535	1 to 125	04	Read 1 to 125 input words on the remote address 0 to 65,535
105	0 to 65,535	1	05	Write 1 output bit on the remote address 0 to 65,535
106	0 to 65,535	1	06	Write 1 holding register on the remote address 0 to 65,535
115	0 to 65,535	1 to 1,968	15	Write 1 to 1,968 output bits on the remote address 0 to 65,535

MB_MODE	MB_DATA_ADDR	MB_DATA_LEN	Modbus function	Function and data type
116	0 to 65,535	1 to 123	16	Write 1 to 123 holding registers on the remote address 0 to 65,535
3 to 10, 12 to 79, 82 to 100, 107 to 114, 117 to 255				Reserved

MB_DATA_PTR parameter (S7-1200, S7-1500)

Description

The MB_DATA_PTR parameter is a pointer to a data buffer for the data to be received from the Modbus server or to be sent to the Modbus server. As the data buffer, you can use a global data block or a memory area (M).

For a buffer in the memory area (M), use a pointer in the ANY format as follows: "P#bit address" "data type" "length" (example: P#M1000.0 WORD 500).

Depending on the memory area in which the data buffer is located, MB_DATA_PTR can reference different data structures:

- When you use a global DB with optimized access, MB_DATA_PTR can reference a tag with elementary data type or an array of elementary data types. The following data types are supported:

Data type	Length in bits
Bool	1
Byte, SInt, USInt, Char	8
Word, Int, WChar, UInt	16
DWord, DInt, UDInt, Real	32

  In such cases, all supported data types can be used for all Modbus functions. For example, MB_CLIENT can also write a received bit in a tag of the byte type to a specified address without changing other bits in this byte. Therefore, it is not necessary to have an array of bits in order to execute bit-oriented functions.

- If you use a bit memory address area or a global DB with standard access as memory area, there is no longer any restriction to the elementary data types for MB_DATA_PTR; MB_DATA_PTR can then also reference complex data structures such as PLC data types (UDTs) and system data types (SDTs).

Note

Using a bit memory address area as data buffer

If you use a bit memory address area as data buffer for MB_DATA_PTR, you need to observe this variable. With S7-1500-CPUs it is 16 KB, with S7-1200-CPUs it is 8 KB.

CONNECT parameter (S7-1200, S7-1500)

Connection descriptions at CONNECT parameter

Two different connection descriptions can be used for the "MB_CLIENT" instruction:

- Programmed connections with the structure TCON_IP_v4
  The connection parameters are stored in the TCON_IP_v4 structure and the connection is set up with the call of the instruction "MB_CLIENT".
- Configured connections with the structure TCON_Configured
  The configured connection has already been established by the CPU. Use the structure TCON_Configured to specify which existing connection is to be used for the instruction.

Each instance of the instruction "MB_CLIENT" requires a unique connection. Create a separate structure TCON_IP_v4 or TCON_Configured for each instance of the instruction to describe the connection.

Connection description for programmed connections

Use the following structure for connection description to TCON_IP_v4 for programmed connections at the CONNECT parameter:

- Make sure that only connections of the type TCP are specified in the TCON_IP_v4 structure.
- The connection may not use the following TCP port numbers: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to this connection (value range: 1 to 4095). The parameter uniquely identifies a connection within the CPU. Each individual instance of the instruction "MB_CLIENT" must use a unique ID.
4	ConnectionType	BYTE	11	Connection type Select 11 (decimal) for TCP. Other connection types are not permitted. If another connection type (e.g. UDP) is used, a corresponding error message is output at the STATUS parameter of the instruction.
5	ActiveEstablished	BOOL	TRUE	ID for the manner in which the connection is established Select TRUE for active connection establishment.
6 … 9	RemoteAddress	ARRAY [1..4] of BYTE	-	IP address of the connection partner (Modbus server), for example, for 192.168.0.1: • addr[1] = 192 • addr[2] = 168 • addr[3] = 0 • addr[4] = 1

Byte	Parameter	Data type	Start value	Description
10 … 11	RemotePort	UINT	502	Port number of the remote connection partner (value range: 1 to 49151). Use the IP port number of the server to which the client establishes the connection and communicates using the TCP/IP protocol (default value: 502).
12 … 13	LocalPort	UINT	0	Port number of the local connection partner: • Port numbers: 1 to 49151 • Any port: "0"

Note

Migration of the instruction "MB_CLIENT" version 2.1

The parameters CONNECT_ID, IP_PORT and IP_OCTET_x are mapped in version 3.0 of the "MB_CLIENT" instruction in the TCON_IP_v4 structure:

- The parameter CONNECT_ID of the "MB_CLIENT" V2.1 instruction corresponds to the ID parameter of TCON_IP_v4.
- The parameter IP_PORT of the "MB_CLIENT" V2.1 instruction corresponds to the RemotePort parameter of TCON_IP_v4.
- The four parameters IP_OCTET_x of the "MB_CLIENT" V2.1 instruction correspond to the array of the RemoteAddress parameter of TCON_IP_v4.

Connection description for configured connections

For programmed connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured.

- Make sure that only connections of the type TCP are specified in the TCON_Configured structure.
- The connection may not use the following TCP port numbers: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceId	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to this connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	0	Connection type Select 254 (decimal) for a configured connection.

Parameter STATUS (S7-1200, S7-1500)

Parameter STATUS (general status information)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
0001	Connection established.
0003	Connection terminated.
7000	No job active and no connection established (REQ=0, DISCONNECT=1).
7001	Connection establishment triggered.
7002	Intermediate call. Connection is being established.
7003	Connection is being terminated.
7004	Connection established and monitored. No job processing active.
7005	Data is being sent.
7006	Data is being received.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (protocol error)

STATUS* (W#16#)	Local and/ or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
80C8	Local	-	No response of the server in the defined period. Check the connection to the Modbus server. This error is only reported on completion of the configured repeated attempts. If the "MB_CLIENT" instruction does not receive an answer with the originally transferred transaction ID (see static tag MB_TRANSACTION_ID) within the defined period, this error code is output.
8380	Local	-	Received Modbus frame has incorrect format or too few bytes were received.
8381	Remote	01	Function code is not supported.
8382	Local	-	• The length of the Modbus frame in the frame header does not match the number of received bytes. • The number of bytes does not match the number of actually transmitted bytes (only functions 1-4). For example, this is the case when "MB_CLIENT" requests an odd number of words, but "MB_SERVER" always sends an even number of words. • The start address in the received frame does not match the saved start address (functions 5, 6, 15, 16). • The number of words does not match the number of actually transmitted words (functions 15 and 16).
	Remote	03	Invalid length specification in received Modbus frame. Check the server side.

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8383	Local	-	Error reading or writing data or access outside the address area of MB_DATA_PTR (Page 4660).
	Remote	02	Error reading or writing data or access outside the address area of the server
8384	Local	-	• Invalid exception code received. • A different data value was received than was originally sent by the client (functions 5, 6 and 8). • Invalid status value received (function 11)
	Remote	03	Error in data value for function 5
8385	Local	-	• Diagnostics code not supported. • A different subfunction code was received than was originally sent by the client (function 8).
	Remote	03	Diagnostics code not supported
8386	Local	-	Received function code does not match the one sent originally.
8387	Local	-	The protocol ID of the Modbus TCP frame received by the server is not "0".
8388	Local	-	The Modbus server sent a different data length than was requested. This error occurs only when using the Modbus functions 5, 6, 15 or 16.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".			

Parameter STATUS (parameter error)

STATUS* (W#16#)	Description
80B6	Invalid connection type, only TCP connections are supported.
80BB	Invalid value at ActiveEstablished parameter (identifier for the type of connection establishment, see CONNECT parameter (Page 4661)): • Only passive connection establishment permitted for server (ActiveEstablished = FALSE). • Only active connection establishment permitted for client (ActiveEstablished = TRUE).
8188	The MB_MODE parameter has an invalid value.
8189	Invalid addressing of data at the MB_DATA_ADDR parameter.
818A	Invalid data length at the MB_DATA_LEN parameter.
818B	The MB_DATA_PTR parameter has an invalid pointer. You should also check the values of the MB_DATA_ADDR (Page 4660) and MB_DATA_LEN parameters.
818C	Timeout at parameter BLOCKED_PROC_TIMEOUT or RCV_TIMEOUT (see static tags of instruction). BLOCKED_PROC_TIMEOUT and RCV_TIMEOUT must be between 0.5 s and 55 s.
8200	• A different Modbus request is currently being processed via the port. • Another instance of MB_CLIENT with the same connection parameters is processing an existing Modbus request.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Note

Error codes of internally used communications instructions

With the "MB_CLIENT" instruction, in addition to the errors listed in the tables, errors caused by the communication instructions ("TCON", "TDISCON", "TSEND", "TRCV", "T_DIAG" and "TRESET") used by the instruction can occur.

The error codes are assigned via the instance data block of the "MB_CLIENT" instruction. The error codes are displayed for the respective instruction under STATUS in the "Static" section.

The meaning of the error codes is available in the documentation of the corresponding communications instruction.

Note

Communication error when sending or receiving data

If a communication error occurs when sending or receiving data (80C4 (Temporary communications error. The specified connection is temporarily down.), 80C5 (Remote partner closed connection actively.), 80A1 (The specified connection is disconnected or is not yet established.)), the existing connection is terminated.

This also means that you can see all STATUS values that are returned when the connection is terminated and that the STATUS code that caused the connection to be terminated is only output when the connection is terminated.

Example: If a temporary communication error occurs when data is received, the STATUS 7003 (ERROR=false) is output initially and then 80C4 (ERROR=true).

GET_ERR_ID: Get error ID locally (Page 2840)

MB_SERVER: Communicating via PROFINET as a Modbus TCP server (S7-1200, S7-1500)

Description of MB_SERVER (S7-1200, S7-1500)

Description

The "MB_SERVER" instruction communicates as Modbus TCP server via a PROFINET connection. The "MB_SERVER" instruction processes connection requests of a Modbus TCP client, receives and processes Modbus requests and sends responses.

For the S7-1200 with firmware version V4.0 you can use the "MB_SERVER" instruction up to and including library version V3.1. With the S7-1200 as of firmware version V4.1 and the S7-1500, you can use the "MB_SERVER" instruction of all library versions.

The connection can take place via the local interface of the CPU or CM/CP.

To use the instruction, you do not require an additional hardware module.

NOTICE
Security information Note that each client of the network is given read and write access to the process image inputs and outputs and to the data block or bit memory area defined by the Modbus holding register. The option is available to restrict access to an IP address to prevent unauthorized read and write operations. Note, however, that the shared address can also be used for unauthorized access.

Multiple server connections

You can create multiple Server connections. This allows a single CPU to accept connections from multiple Modbus TCP clients at the same time.

A Modbus TCP server can support several TCP connections and the maximum number of connections depends on the CPU being used.

The total number of connections of one CPU, including those of the Modbus TCP clients and server must not exceed the maximum number of supported connections.

Modbus TCP connections can also be shared by "MB_CLIENT" and/or "MB_SERVER" instances.

In the case of Server connections, remember the following rules:

- Each "MB_SERVER" connection must use a unique instance DB.
- Each "MB_SERVER" connection must use a unique connection ID.
  The relevant individual connection ID must be used for each individual instance DB of the instruction. The connection ID and instance DB belong together in pairs and must be unique for each connection.
- For each connection, the "MB_SERVER" instruction must be called individually.

Parameters

The following table shows the parameters of the "MB_SERVER" instruction:

Parameter	Declaration	Data type	Description
DISCONNECT	Input	BOOL	The "MB_SERVER" instruction is used to enter into a passive connection with a partner module. The server responds to a connection request from the IP address which is entered in the SDT "TCON_IP_v4" in the CONNECT parameter. You can use this parameter to control when a connection request is accepted: • 0: A passive connection is established when there is no communications connection. • 1: Initialization of the connection termination. If the input is set, no other operations are executed. The value 0003 is output at the STATUS parameter after successful connection termination.
MB_HOLD_REG (Page 4670)	InOut	VARIANT	Pointer to the Modbus holding register of the "MB_SERVER" instruction MB_HOLD_REG must always reference a memory area that is larger than two bytes. The holding register contains the values that may be accessed by a Modbus client using the Modbus functions 3 (read), 6 (write), 16 (multiple write) and 23 (reading and writing in one job). As the holding register, use either a global data block with optimized access or the memory area of the bit memories.
CONNECT (Page 4671)	InOut	VARIANT	Pointer to the structure of the connection description The following structures (SDTs) can be used: • TCON_IP_v4: Includes all address parameters that are required for establishing a programmed connection. The default address is 0.0.0.0 (any IP address), but you can enter a specific IP address so that the server only responds to requests from this address. When using TCON_IP_v4, the connection is established when calling the "MB_SERVER" instruction. • TCON_Configured: Includes the address parameters of a configured connection. When using TCON_Configured, the connection is established by the CPU after download of the hardware configuration.
NDR	Output	BOOL	"New Data Ready": • 0: No new data • 1: New data written by the Modbus client written
DR	Output	BOOL	"Data Read": • 0: No data read • 1: Data read by the Modbus client
ERROR	Output	BOOL	If an error occurs during the call of the "MB_SERVER" instruction, the output of the ERROR parameter is set to "1". Detailed information about the cause of the problem is indicated by the STATUS parameter.
STATUS (Page 4673)	Output	WORD	Detailed status information of the instruction.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Static tags of the instruction

The following table describes the static tags of the instance data block of the "MB_SERVER" instruction used in the program. You can write the HR_Start_Offset tag. You can read the other tags to monitor the Modbus status.

Tag	Data type	Start value	Description
HR_Start_Offset	WORD	0	Assign the start address of the Modbus holding register.
QB_Start	WORD	0	Start address of the permitted addressing range of the outputs that can be written (bytes 0 to 65535)
QB_Count	WORD	0xFFFF	Number of output bytes that can be written by the Modbus master. Example: QB_Start=0 and QB_Count=10: Output bytes 0 to 9 can be written. QB_Count=0: No output byte can be written.
Request_Count	WORD	0	Total number of requests received by the server.
Server_Message_Count	WORD	0	Total number of received alarms for the relevant server.
Xmt_Rcv_Count	WORD	0	Counter for detecting the number of transfers during which an error occurred. The counter is only incremented when an invalid Modbus request is received.
Exception_Count	WORD	0	Counters for detecting the number of errors specifically for Modbus which cause an error message to "MB_CLIENT".
Success_Count	WORD	0	Event counter for detecting the number of requests that were successfully executed by the server.
Connected	BOOL	0	Indicates whether the connection to the assigned client has been established or not: 1 = connected, 0 = not connected.

Mapping of Modbus addresses to the process image

The "MB_SERVER" instruction allows incoming Modbus functions (1, 2, 4, 5 and 15) direct read and write access to the process image inputs and outputs of the CPU (use of the data types BOOL and WORD).

For S7-1200-CPUs, the address space for the process image of the inputs and the process image of the outputs is 1 KB; it is 32 KB each for S7-1500-CPUs.

The following table shows the address space of the Modbus functions listed above.

Modbus function					
Function code	Function	Data area	Address space		
01	Read: Bits	Output	0	to	65.535
02	Read: Bits	Input	0	to	65.535
04	Read: WORD	Input	0	to	65.535
05	Write: Bit	Output	0	to	65.535
15	Write: Bits	Output	0	to	65.535

Incoming Modbus requests with the function codes 3, 6, 16 and 23 write to or read from the Modbus holding register (you specify the holding register with the MB_HOLD_REG parameter).

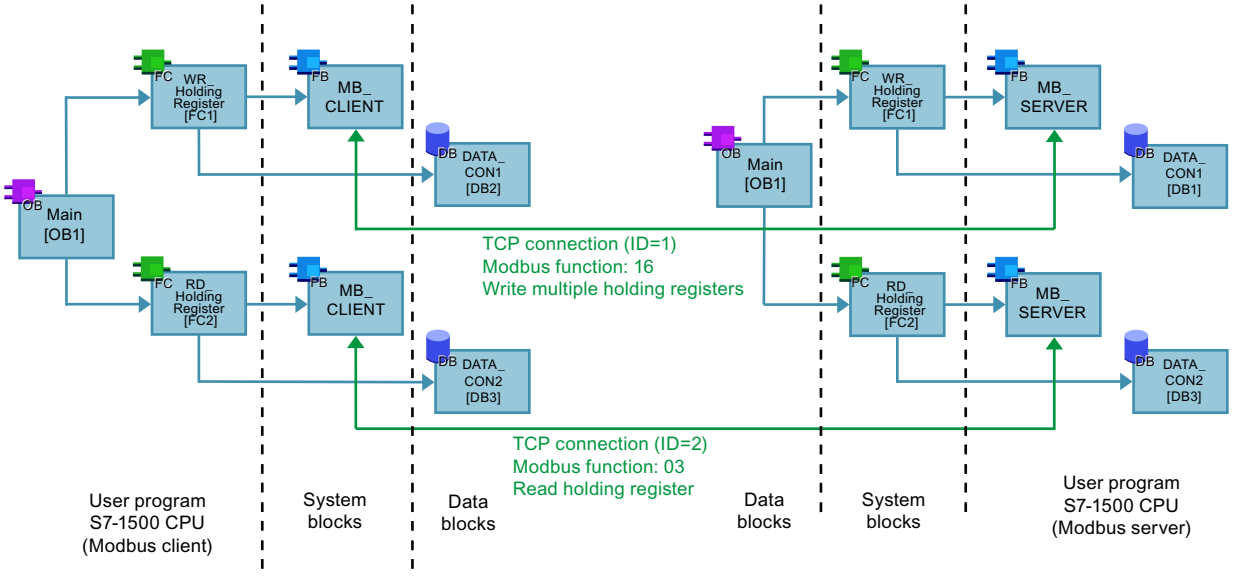
Example: Addressing via static tag HR_Start_Offset

The addresses of the Modbus holding register start at 0 (from the perspective of the MB_CLIENT at 40.001). These addresses correspond to the address area of the CPU memory area for the holding register. You can also define the HR_Start_Offset tag so that the Modbus holding register has a start address other than 0.

Example: The holding register begins at MW100, and has a length of 100 WORD. An offset value in the HR_Start_Offset parameter means that the start address of the holding register is moved from 0 to 20. This causes an error whenever the holding register is addressed below the address 20 and above the address 119.

HR_Start_Offset	Address	Minimum	Maximum
0	Modbus address (WORD)	0	99
	CPU address	MW100	MW298
20	Modbus address (WORD)	20	119
	CPU address	MW100	MW298

Modbus functions



The following table lists all the Modbus functions that are supported by the "MB_SERVER" instruction.

Function code	Description
01	Read output bits
02	Read input bits
03	Read a holding register
04	Read input words
05	Write an output bit
06	Write a holding register
08	Diagnostics function: • Echo test (subfunction 0x0000): The "MB_SERVER" instruction receives a data word and returns this unchanged to the Modbus client. • Reset event counter (subfunction 0x000A): The "MB_SERVER" instruction resets the following event counters: "Success_Count", "Xmt_Rcv_Count", "Exception_Count", "Server_Message_Count" and "Request_Count".
11	Diagnostics function: Fetch event counter of the communication The "MB_SERVER" instruction uses an internal event counter for communication to record the number of successfully executed read and write requests sent to the Modbus server. The event counter is not incremented with the functions 8 or 11. The same holds true for requests that cause a communications error, for example, if a protocol error has occurred (e.g., the function code in the received Modbus request is not supported).
15	Write output bits
16	Write a holding register
23	Write a holding register and read holding register with a request

Example

An example project for the Modbus TCP communication between two S7-1500 CPUs can be found in the Service and Support Portal under Entry ID 94766380 (http://support.automation.siemens.com/WW/view/en/94766380).

Two Modbus functions are used in this example. For each Modbus function, a Modbus TCP connection is established using a Modbus block pair (MB_CLIENT and MB_SERVER).

Difference between synchronous and asynchronous instructions (Page 2571)

MB_HOLD_REG parameter (S7-1200, S7-1500)

Description

The MB_HOLD_REG parameter is a pointer to a data buffer for storing the data read from or written to the Modbus server. You can use a global data block or a bit memory (M) as memory area.

- The high limit for the number of addresses in the data block (D) is determined by the maximum work memory of the CPU.
- The high limit for the number of bit memories (M) is determined by the size of the CPU memory area.

The following table shows examples of mapping Modbus addresses to the holding register for the Modbus functions 3 (read WORD), 6 (write WORD), 16 (write several WORD) and 23 (write and read several words).

Modbus addresses	MB_HOLD_REG parameter - examples		
0	MW100	DB10.DBW0	"Recipe".ingredient[1]
1	MW102	DB10.DBW2	"Recipe".ingredient[2]
2	MW104	DB10.DBW4	"Recipe".ingredient[3]
3	MW106	DB10.DBW6	"Recipe".ingredient[4]
4	MW108	DB10.DBW8	"Recipe".ingredient[5]

CONNECT parameter (S7-1200, S7-1500)

Connection descriptions at CONNECT parameter

Two different connection descriptions can be used for the "MB_SERVER" instruction:

- Programmed connections with the structure TCON_IP_v4
  The connection parameters are stored in the TCON_IP_v4 structure and the connection is set up with the call of the instruction "MB_SERVER".
- Configured connections with the structure TCON_Configured
  The configured connection has already been established by the CPU. Use the structure TCON_Configured to specify which existing connection is to be used for the instruction.

Each instance of the instruction "MB_SERVER" requires a unique connection. Create a separate structure TCON_IP_v4 or TCON_Configured for each instance of the instruction to describe the connection.

Connection description for programmed connections

For programmed connections at the CONNECT parameter, use the following structure for connection description to TCON_IP_v4.

- Make sure that only connections of the type TCP are specified in the TCON_IP_v4 structure.
- The connection may not use the following TCP port numbers: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to this connection (value range: 1 to 4095). The parameter uniquely identifies a connection within the CPU. Each individual instance of the instruction "MB_SERVER" must use a unique ID.

Byte	Parameter	Data type	Start value	Description
4	ConnectionType	BYTE	11	Connection type Select 11 (decimal) for TCP. Other connection types are not permitted. If another connection type (e.g. UDP) is used, a corresponding error message is output at the STATUS parameter of the instruction.
5	ActiveEstablished	BOOL	FALSE	ID for the manner in which the connection is established Select FALSE for passive connection establishment.
6 … 9	RemoteAddress	ARRAY [1..4] of BYTE	0.0.0.0	IP address of the connection partner, for example, for 192.168.0.1: • addr[1] = 192 • addr[2] = 168 • addr[3] = 0 • addr[4] = 1 If the instruction "MB_SERVER" is to accept connection requests from any connection partner, use "0.0.0.0" as IP address.
10 … 11	RemotePort	UINT	0	Port number of the remote connection partner (value range: 1 to 49151). If the instruction "MB_SERVER" is to accept connection requests from any remote partner, use "0" as port number.
12 … 13	LocalPort	UINT	502	Port number of the local connection partner (value range: 1 to 49151). The number of the IP port defines which IP port is monitored for connection requests of the Modbus client. The following TCP port numbers must not be used for the passive connection of the "MB_SERVER" instruction: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.

Note

Migration of the instruction "MB_SERVER" version 2.1

The parameters CONNECT_ID and IP_PORT are mapped in version 3.0 of the "MB_SERVER" instruction in the TCON_IP_v4 structure:

- The parameter CONNECT_ID of the "MB_SERVER" V2.1 instruction corresponds to the ID parameter of TCON_IP_v4.
- The parameter IP_PORT of the "MB_SERVER" V2.1 instruction corresponds to the LocalPort parameter of TCON_IP_v4.

Connection description for configured connections

For configured connections at the CONNECT parameter, use the following structure for connection description to TCON_Configured.

- Make sure that only connections of the type TCP are specified in the TCON_Configured structure.
- The connection may not use the following TCP port numbers: 20, 21, 25, 80, 102, 123, 5001, 34962, 34963 and 34964.

Byte	Parameter	Data type	Start value	Description
0 … 1	InterfaceID	HW_ANY	-	Hardware identifier of the local interface (value range: 0 to 65535).
2 … 3	ID	CONN_OUC	-	Reference to this connection (value range: 1 to 4095). Enter the connection ID of the existing connection.
4	ConnectionType	BYTE	-	Connection type Select 254 (decimal) for a configured connection.

Parameter STATUS (S7-1200, S7-1500)

Parameter STATUS (general status information)

STATUS* (W#16#)	Description
0000	Instruction executed without errors.
0001	Connection established.
0003	Connection terminated.
7000	No call active and no connection established (REQ=0, DISCONNECT=1).
7001	First call. Connection establishment triggered.
7002	Intermediate call. Connection is being established.
7003	Connection is being terminated.
7005	Data is being sent.
7006	Data is being received.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Parameter STATUS (protocol error)

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8380	Local	-	Received Modbus frame has incorrect format or too few bytes were received.
8381	Remote	01	Function code is not supported.
8382	Remote	03	Error in data length • Invalid length specification in received Modbus frame • The frame length entered in the header of the Modbus frame does not match the number of actually received bytes. • The number of bytes entered in the header of the Modbus frame does not match the number of actually received bytes (functions 15 and 16).

STATUS* (W#16#)	Local and/or remote errors	Error code in the answer from MB_SERVER (B#16#)	Description
8383	Local	-	Error reading or writing data or access outside the address area of MB_HOLD_REG.
	Remote	02	Error reading or writing data or access outside the address area of the server
8384	Local	-	• Invalid exception code received. • A different data value was received than was originally sent by the server (functions 5, 6 and 8). • Invalid status value received (function 11)
	Remote	03	Error in data value for function 5
8385	Local	-	• Diagnostics code not supported. • A different subfunction code was received than was originally sent by the server (function 8).
	Remote	03	Diagnostics code not supported
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".			

Parameter STATUS (parameter error)

STATUS* (W#16#)	Description
80BB	Invalid value at ActiveEstablished parameter (identifier for the type of connection establishment, see CONNECT parameter (Page 4671)): • Only passive connection establishment permitted for server (active_established = FALSE). • Only active connection establishment permitted for client (active_established = TRUE).
8187	The MB_HOLD_REG parameter has an invalid pointer. Data area is too small.
* The status codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Note

Error codes of internally used communications instructions

With the "MB_SERVER" instruction, in addition to the errors listed in the tables, errors caused by the communication instructions ("TCON", "TDISCON", "TSEND", "TRCV", "T_DIAG" and "T_RESET") used by the instruction can occur.

The error codes are assigned via the instance data block of the "MB_SERVER" instruction. The error codes are displayed for the respective instruction under STATUS in the "Static" section.

The meaning of the error codes is available in the documentation of the corresponding communications instruction.

Note

Communication error when sending or receiving data

If a communication error occurs when sending or receiving data (80C4 (Temporary communications error. The specified connection is temporarily down.), 80C5 (Remote partner closed connection actively.), 80A1 (The specified connection is disconnected or is not yet established.)), the existing connection is terminated.

This also means that you can see all STATUS values that are returned when the connection is terminated and that the STATUS code that caused the connection to be terminated is only output when the connection is terminated.

Example: If a temporary communication error occurs when data is received, the STATUS 7003 (ERROR=false) is output initially and then 80C4 (ERROR=true).

MB_HOLD_REG parameter (Page 4670)

Differences between the versions <= V3.x and >= V4.0 of the Modbus TCP library (S7-1200, S7-1500)

Differences between the versions <= V3.x and >= V4.0 of the Modbus instructions

The following differences between versions exist with the MB_SERVER/MB_CLIENT MODBUS instructions:

- Address parameter
  - In versions <= 3.x, the address data for the Modbus TCP server is specified via the input parameters "IP_x".
  - Versions >= 4.0 use TCON_IP_V4 and TCON_Configured system data types at the CONNECT input parameter for this purpose.
- If an error occurs during execution, as of version 4.0 of the Modbus instructions, there are more STATUS alarms available which can be evaluated accordingly.

You can find detailed information in the instruction descriptions for MB_CLIENT (Page 4653) and MB_SERVER (Page 4665).

Note

Changing the Modbus TCP library from a version <= V3.x to a version >= V4.0

When you replace the Modbus TCP library from a version <= V3.x to a version >= V4.0 you also need to replace the Open User Communication library. Afterwards check all the instructions relevant for your program.

11.4.6.5 TeleService (S7-1200)

TM_MAIL: Transfer email (S7-1200)

Description of TM_MAIL (S7-1200)

Description

The "TM_MAIL" instruction works asynchronously, in other words, its execution extends over multiple calls. You must specify an instance when you call the instruction "TM_MAIL". The attribute "retentive" may not be set in the instance. This attribute ensures that the instance is initialized when the CPU switches from STOP to RUN and that a new e-mail send job can be triggered afterwards.

You start the sending of an e-mail with an edge change from "0" to "1" for the REQ parameter. The job status is indicated by the output parameters BUSY, "DONE", "ERROR", "STATUS" and "SFC_STATUS". "SFC_STATUS" corresponds in this case to the "STATUS" output parameter of the called communication blocks.

The output parameters DONE, ERROR, STATUS, and SFC_STATUS are each displayed for only one cycle if the status of the BUSY output parameter changes from "1" to "0". The following table shows the relationship between BUSY, DONE, and ERROR. Using this table, you can determine the current status of the instruction "TM_MAILand when the sending of the e-mail is complete.

DONE	BUSY	ERROR	Description
0	1	0	The job is being processed.
1	0	0	Job successfully completed.
0	0	1	The job ended with an error. The cause of the error can be found in the STATUS and SFC_STATUS parameters.
0	0	0	The "TM_MAIL" instruction was not assigned a (new) job.

If the CPU changes to STOP mode while "TM_MAIL" is active, the communication connection to the mail server aborts. The communication connection to the mail server will also be lost if

communication problems occur on the Industrial Ethernet bus. In this case, the transfer of the e-mail will be interrupted and it will not reach its recipient.

NOTICE
Changing user programs You can change the parts of your user program that directly affect calls of "TM_MAIL" only: • when the CPU is in "STOP" mode or • when no mail is being sent (REQ = 0 and BUSY = 0). This relates, in particular, to deleting and replacing program blocks that contain "TM_MAIL" calls or calls for the instance of "TM_MAIL". Ignoring this restriction can tie up connection resources. The automation system can change to an undefined status for the TPC/IP communication functions via Industrial Ethernet. A warm or cold restart of the CPU is required after the changes are transferred.

Data consistency

The ADDR_MAIL_SERVER input parameter of the instruction is taken from the "TM_MAIL" instruction again each time the sending of an e-mail is triggered. If a change is made during operation, the "new" value only becomes effective once an e-mail is triggered again.

In contrast, the WATCH_DOG_TIME, TO_S, CC, FROM, SUBJECT, TEXT, ATTACHMENT, and, if applicable, USERNAME and PASSWORD parameters are taken from the "TM_MAIL" instruction while it is running, which means that they may only be changed after the job is complete (BUSY = 0)

Setting the parameters of the TS Adapter IE

On the TS Adapter IE, you need to specify parameters for outgoing calls in such a way as to enable the TS Adapter IE to establish a connection to the dial-up server of your service provider.

If you set "When required" for connection establishment, the connection will only be established when an e-mail needs to be sent.

Connection establishment can take longer (approx. one minute) for an analog modem connection. When you specify the WATCH_DOG_TIME parameter, remember to allow for the time required to establish the connection.

Parameter

The following table shows the parameters of the "TM_MAIL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Control parameter REQUEST: Activates the sending of an e-mail on a rising edge.
ID	Input	CONN_OUC (Word)	D, L or constant	Reference to the connection to be established. See ID parameter of the TCON (Page 4474), TDISCON (Page 4484), TSEND (Page 4490), and TRCV (Page 4493) instructions. A number that is not used for any additional instances of this instruction in the user program must be entered here.
TO_S (Page 4680)	Input	STRING	D	Input parameter for receiver addresses: STRING with a maximum length of 240 characters (see example call).
CC (Page 4680)	Input	STRING	D	Input parameter for CC recipient addresses (optional): STRING with a maximum length of 240 characters (see example call). If an empty string is assigned here, the e-mail is not sent to a CC recipient.
SUBJECT	Input	STRING	D	Input parameter for subject of the e-mail: STRING with a maximum length of 240 characters.
TEXT	Input	STRING	D	Input parameter for text of the e-mail (optional): Reference to a data string with a maximum length of 240 characters. If an empty string is assigned at this parameter, the e-mail is sent without text.
ATTACHMENT	Input	VARIANT	I, Q, M, D, L	Input parameter for e-mail attachment (optional): Reference to a byte/word/double word field with a maximum length of 65534 bytes. The specified attachment must be in the file format BIN. If no value is assigned, the e-mail is sent without an attachment.
DONE	Output	BOOL	I, Q, M, D, L	• DONE = 0: Job not yet started or still executing. • DONE = 1: Job executed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	• BUSY = 1: Sending of an e-mail is not yet complete. • BUSY = 0: Processing of "TM_MAIL" was terminated
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during processing. STATUS and SFC_STATUS supply detailed information about the type of error.
STATUS (Page 4681)	Output	WORD	I, Q, M, D, L	Output/status parameter STATUS: Return value or error information of the "TM_MAIL" instruction.

Parameter	Declaration	Data type	Memory area	Description
ADDR_MAIL_SERVER	Static*	DWORD	I, Q, M, D, L	IP address input parameter of the mail server: Specify as a data word in HEX format, for example: IP address = 192.168.0.200. ADDR_MAIL_SERVER = DW#16#C0A800C8, where: • 192 = 16#C0, • 168 =16#A8 • 0 = 16#00 and • 200 = 16#C8.
WATCH_DOG_TIME	Static*	TIME	I, Q, M, D, L	Input parameter for max. period of time: The "TM_MAIL" instruction should establish a connection within the period specified by WATCH_DOG_TIME. The block is exited with an error if this period is exceeded. The time before the block is exited and the error is output can exceed the WATCH_DOG_TIME because connection termination also takes a certain amount of time. To begin with, you should set a period of 2 minutes. If you have an ISDN telephone connection, a significantly shorter period can be selected.
USERNAME	Static*	STRING	D	Input parameter for user name: STRING with a maximum length of 180 characters. A user name is an absolute requirement for authentication.
PASSWORD	Static*	STRING	D	Input parameter for password: STRING with a maximum length of 180 characters. A password is an absolute requirement for authentication.
FROM (Page 4680)	Static*	STRING	D	Input parameter for sender address: STRING with a maximum length of 240 characters (see example call).
SFC_STATUS (Page 4681)	Static*	WORD	I, Q, M, D, L	Output/status parameter "SFC_STATUS": Error information of the called communication blocks.
*The values of the parameter are not modified at every call of the instruction "TM_MAIL". The values are in the static parameters of the instance and are only written once at the first call of the instruction.				

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Optional parameters

The optional parameters CC, TEXT, and ATTACHMENT are only sent with the e-mail if the corresponding parameters contain a string of length > 0.

Note

Parameter ATTACHMENT

The specified attachment must be in the file format BIN. If text is to be transferred, you have the following options:

- In Windows, you link the file format BIN with a text editor.
- You use the Windows functions "Send to" or "Open with".

SMTP authentication

Authentication refers here to a procedure for ensuring an identity, for example, by a password query.

The "TM_MAIL" instruction supports the SMTP authentication procedure AUTH-LOGIN that is requested by most mail servers. For information about the authentication procedure of your mail server, please refer to your mail server manual or the website of your Internet service provider.

To use the AUTH-LOGIN authentication procedure, the "TM_MAIL" instruction requires the user name with which it can log onto the mail server. This user name corresponds to the user name with which you set up a mail account on your mail server. It is made available to the "TM_MAIL" instruction in the USERNAME parameter.

To log on, the "TM_MAIL" instruction also requires the associated password. This password corresponds to the password you specified when you set up your mail account. It is made available to the "TM_MAIL" instruction in the PASSWORD parameter.

The user name and the password are each transferred to the mail server unencrypted (BASE64-coded).

If no user name is specified in the DB, the AUTH-LOGIN authentication procedure is not used. The e-mail is then sent without authentication.

Example

You can find a detailed application example in the Siemens Industry Online Support under the following FAQ ID: 67262019 (https://support.industry.siemens.com/cs/ww/en/view/67262019).

Parameters TO_S, CC, and FROM (S7-1200)

Description

The TO_S, CC, and FROM parameters are strings with, for example, the following content:

- TO: <wenna@mydomain.com>, <ruby@mydomain.com>,
- CC: <admin@mydomain.com>, <judy@mydomain.com>,
- FROM: <admin@mydomain.com>

Note the following rules when entering the parameters:

- The "TO:", "CC:", and "FROM:" characters must be entered.
- A space and an opening pointed bracket "<" must be entered before each address.
- A closing pointed bracket ">" must be entered after each address.
- A comma must be entered after each address in TO and CC.
- Only one e-mail may be entered in FROM, and there must not be a comma at the end of this address

Because of runtime and memory space, the "TM_MAIL" instruction does not perform any syntax check of the parameters TO_S, CC and FROM.

STATUS and SFB_STATUS parameters (S7-1200)

Description

The return values of the "TM_MAIL" instruction can be classified as follows:

- W#16#0000: "TM_MAIL" was completed successfully
- W#16#7xxx: Status of "TM_MAIL"
- W#16#8xxx: An error was reported during the internal call of a communication block or from the mail server.

The following table shows the return values of "TM_MAIL" except for error codes of the internally called communication blocks.

Return value STATUS* (W#16#...):	Return value SFB_STATUS (W#16#...):	Explanation	Notes
0000	-	The processing of "TM_MAIL" was completed without error.	A without error completion of "TM_MAIL" does not mean that the sent e-mail will necessarily arrive (see below - note on point 1)
7001		"TM_MAIL" is active (BUSY = 1).	Initial call; job has started
7002	7002	"TM_MAIL" is active (BUSY = 1).	Intermediate call; job already active
8xxx	xxxx	The processing of "TM_MAIL" was completed with an error code of the internally called communication instructions.	For detailed information on the evaluation of the SFB_STATUS parameter, refer to the descriptions of the STATUS parameter of the communication instructions.
8010	xxxx	Error during connection establishment.	For further information on the evaluation of the SFB_STATUS parameter, refer to the descriptions of the STATUS parameter of the "TCON (Page 4474)" instruction.
8011	xxxx	Error sending the data.	For further information on the evaluation of SFB_STATUS, refer to the descriptions of the STATUS parameter of the "TSEND (Page 4490)" instruction.

Return value STATUS* (W#16#...):	Return value SFB_STATUS (W#16#...):	Explanation	Notes
8012	xxxx	Error receiving the data.	For further information on the evaluation of SFB_STATUS, refer to the descriptions of the STATUS parameter of the "TRCV (Page 4493)" instruction.
8013	xxxx	Error during connection establishment.	For further information on the evaluation of SFB_STATUS, refer to the descriptions of the STATUS parameter of the "TCON (Page 4474)" and "TDISCON (Page 4484)" instructions.
8014	-	Establishment of a connection is not possible.	You have possibly entered an incorrect mail server IP address (ADDR_MAIL_SERVER) or a time span that is too short (WATCH_DOG_TIME) to establish the connection. It is also possible that the CPU has no connection to the network or that the CPU configuration is incorrect.
8016	-	Error copying the attachment	-
82xx, 84xx, or 85xx	-	The error message originates from the mail server and the last three digits correspond to the error number of the SMTP protocol. The following columns list several error codes that can occur:	See point 2 in the note.
8450	-	Action not executed: Mailbox not available/ not reachable.	Try again later.
8451	-	Action aborted: Local processing error	Try again later.
8500	-	Syntax error: Error not recognized. This also includes the error when a command string is too long. This can also be occur when the e-mail server does not support the LOGIN authentication procedure.	Check the parameters of "TM_MAIL". Try to send an e-mail without authentication. To do this, replace the USERNAME parameter with an empty string.
8501	-	Syntax error: Parameter or argument incorrect	You have possibly entered an incorrect address in TO_S or CC.
8502	-	Command unknown or not implemented.	Check your entries, in particular the FROM parameter. This is possibly incomplete and you have forgotten "@" or ".".
8535	-	SMTP authentication incomplete.	You have possibly entered an incorrect user name or incorrect password.
8550	-	Mail server cannot be reached, you have no access rights.	You have possibly entered an incorrect user name or password, or the mail server does not support your LOGIN. Another cause of error could be an incorrect entry of the domain name after the "@" in TO_S or CC.
8552	-	Action aborted: Assigned memory size has been exceeded	Try again later.

Return value STATUS* (W#16#...):	Return value SFB_STATUS (W#16#...):	Explanation	Notes
8554	-	Transmission failed.	Try again later.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For additional information on toggling display formats, refer to "See also".			

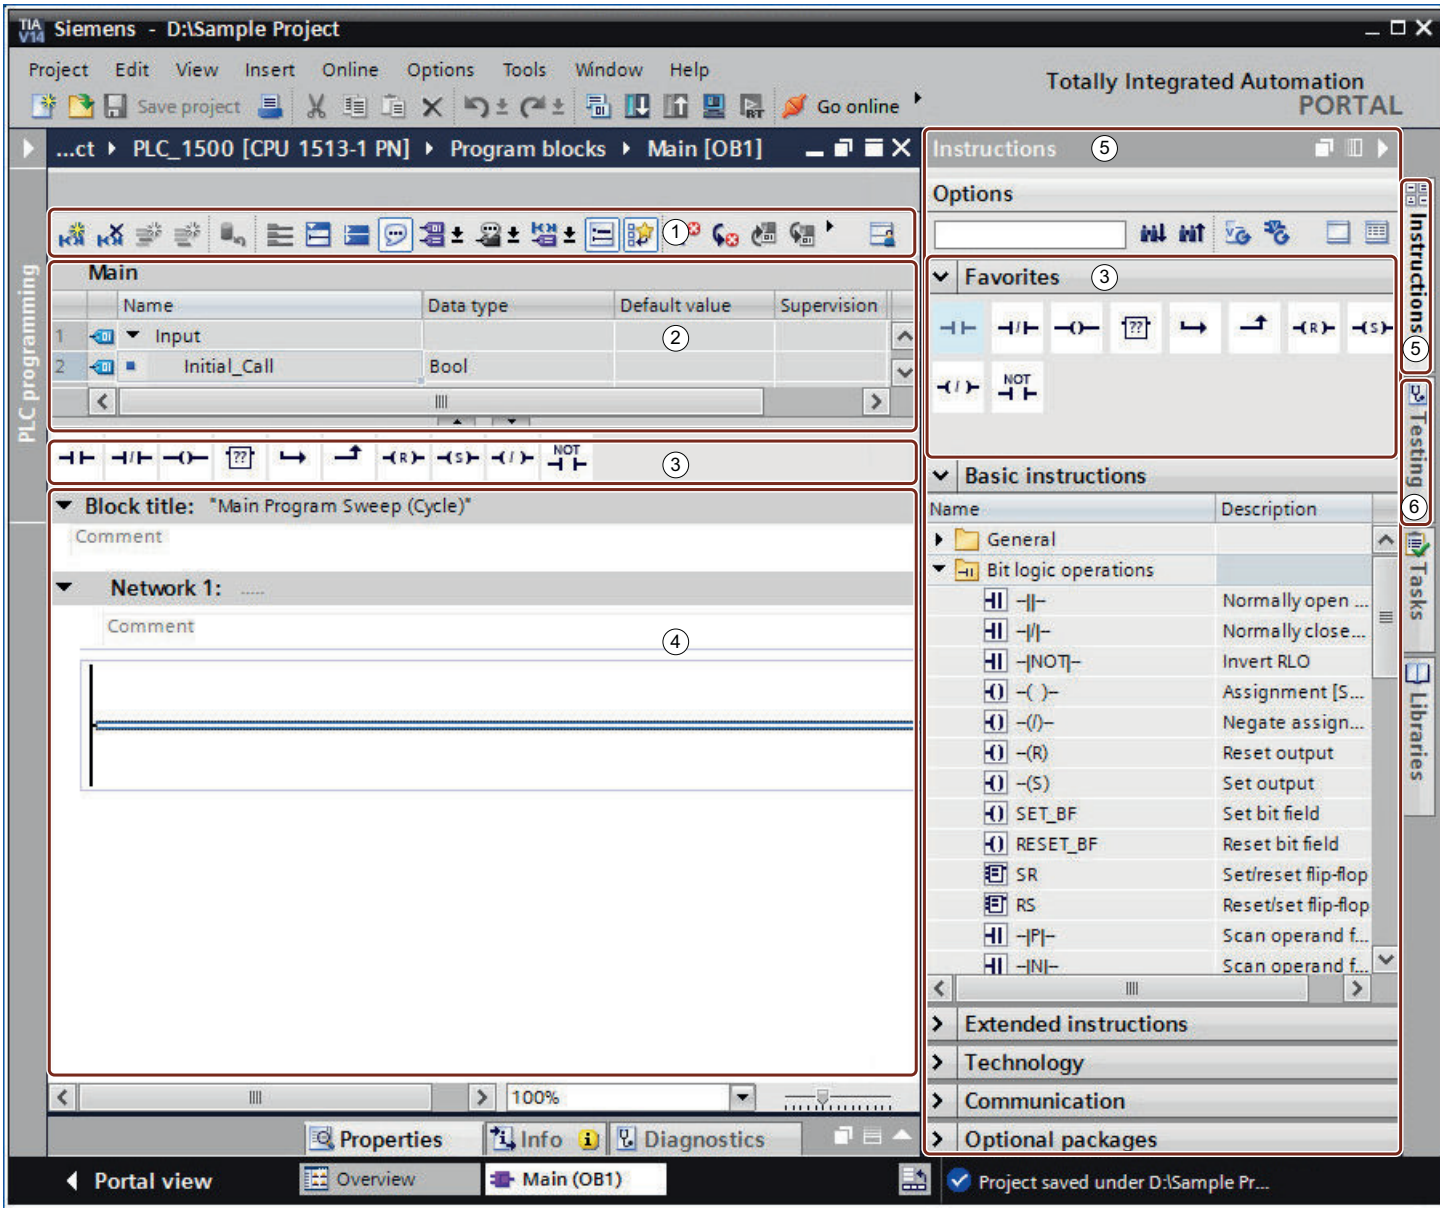
Note

Status error

1. An incorrect entry of the recipient addresses does not generate a status error of the "TM_MAIL" instruction. In this case, there is no guarantee that the e-mail will be sent to other recipients, even if these were entered correctly.
2. You can find more detailed information on the SMTP error code and other error codes in SMTP protocol on the Internet or in the error documentation of the mail server. You can also view the most recent message from the mail server in your instance DB in the BUFFER1 parameter. If you look under "Data", you will find the data most recently sent by the "TM_MAIL" instruction.

11.5 Program editor

11.5.1 Overview of the program editor



Function of the program editor

The program editor is the integrated development environment for programming functions, function blocks, and organization blocks. If offers comprehensive support for programming and troubleshooting.

The appearance and functionality of the program editor can vary depending on the CPU, programming language and block type used.

Structure of the program editor

Using LAD as an example, the following figure shows the components of the program editor:

① Toolbar
② Block interface
③ "Favorites" pane in the "Instructions" task card and favorites in the programming window
④ Programming window
⑤ "Instructions" task card
⑥ "Testing" task card

Toolbar

The toolbar allows you to access the principal functions of the program editor, such as:

- Show and hide absolute operands
- Showing and hiding favorites
- Skip to syntax errors
- Update block calls
- Show and hide program status

The functions available in the toolbar can vary depending on the programming language used.

Block interface

The block interface contains the declarations for local tags used solely within the block. The sections available depend on the block type.

Favorites

You can save frequently used instructions as favorites. These favorites are then displayed in the "Instructions" task card and the "Favorites" pane. You can also display favorites in the programming window using the program editor toolbar. This allows you to access your favorites even when the "Instructions" task card is not visible.

Programming window

The programming window is the work area of the program editor. You can enter the program code in this window. The appearance and functionality of the program window can vary depending on the programming language used.

"Instructions" task card

The "Instructions" task card offers you easy access to all instructions available for creating your program. The instructions are broken down by area into a number of different palettes. If an instruction profile is active, the offered instructions may vary. You receive a brief description for each instruction. If several versions of an instruction are available, the versions are listed in a drop-down list and the currently selected version is used in the program. If required, you can select a different instruction version. Read the information in the section "Basic information on instruction versions (Page 4697)".

With the task card toolbar, you can access the following functions:

- Search up or down for instructions
  You have the option of searching the panes for specific instructions.
- Upgrade project and instructions
  If you are still working with a project which was created with TIA Portal V14, only the instruction versions from V14 will be available. Using the "Upgrade project and instructions" button you can easily upgrade your project to TIA Portal V14 SP1. The "Instructions" task card then receives the new instruction versions of TIA Portal V14 SP1.

  Note

  Please note the following:
  - Your program is not changed by the upgrade, i.e. it still contains the old instruction versions from V14. To use the new instruction versions you must update your program.
  - The "project und operation upgrade" button is only active if you are still working with a TIA Portal V14 project. The button becomes inactive as soon as you upgrade your project to TIA Portal V14 SP1.
- Update program in the current PLC
  Updates the CPU program to the new instruction versions.
- Changing the pane mode
  You can choose between single and multi-pane mode.
  See also: Change pane mode (Page 259)
- Showing/hiding column headers
  You can show or hide column headers in the panes. You can modify the arrangement of columns by clicking a column header and moving the column to the new position by means of drag-and-drop.

"Testing" task card

You can set settings in the "Testing" task card for troubleshooting using the program status. The functions of the "Testing" task card are only available in online mode. It contains the following panes, which are displayed depending on the selected CPU and the configured programming language of the block:

- CPU operator panel
  The CPU operator panel allows you to switch the CPU operating mode.
- Breakpoints
  You can test blocks you created in the textual programming languages STL and SCL in single step mode. To do this, set breakpoints in the program code.
  In the "Breakpoints" pane, you can find all breakpoints that you have set and you can activate, delete, navigate to, or set the call environment for the individual breakpoints.
- PLC register
  This pane allows you to read off the values for the PLC registers and the accumulators.
- Sequence control
  In this pane you can set the operating mode for testing sequencers for GRAPH blocks.
- Test settings
  This pane allows you to specify the test settings for the GRAPH block.

- Call environment
  This pane allows you to specify the call environment for the block.
- Call hierarchy
  In this pane, you can trace the call hierarchy of the blocks. You only see the call hierarchy during block monitoring.

11.5.2 Using the keyboard in the program editor

Navigating in the editor

Function	Shortcut key
Open "Instructions" task card	<Ctrl+Shift+C>
Open "Testing" task card	<Ctrl+Shift+O>
Add new block	<Ctrl+N>
Open block/PLC data type	<F7>
Expand all networks	<Alt+F11>
Collapse all networks	<Alt+F12>
Navigate to the next point of use of the selected block or operand	<Ctrl+Shift+G>
Navigate to the previous point of use of the selected block or operand	<Ctrl+Shift+F>
Navigate to the next read/write access	<Alt+F8>
Navigate to the previous read/write access	<Alt+F9>
Navigate to the definition of the selected block or operand	<Ctrl+Shift+D>

Navigating in the program code (LAD/FBD)

Function	Selected object	Shortcut key
Navigating between objects in the network	Object in the network	Arrow keys
Navigate to the first element of the network	Object in the network	<Home>
Navigate to the last element of the network	Object in the network	<End>
Navigate to the next element of the network	Object in the network	<Tab>
Navigate to the previous element of the network	Object in the network	<Shift+Tab>
Insert network	Any	<Ctrl+R>

Navigating in the program code (STL/SCL)

Function	Position of the cursor	Shortcut key
Navigating in the program code	Line	Arrow keys
One word to the right/left	Line	<Ctrl+arrow keys>
Cursor to start of line	Line	<Home>
Cursor to end of line	Line	<End>
Cursor to start of code section	Line	<Ctrl+Home>
Cursor to end of code section	Line	<Ctrl+End>
To the next network (STL only)	Network title	<Down arrow>
To the next network (STL only)	Line	<Tab> Repeat the shortcut keys until the insertion point is in the next network.
To the previous network (STL only)	Network title	<Up arrow>
To the previous network (STL only)	Line	<Shift+Tab> Repeat the shortcut keys until the insertion point is in the previous network.
Insert network	Any	<Ctrl+R>

Inserting instructions (LAD)

Function	Selected object	Shortcut key
Insert normally open contact	Rung	<Shift+F2>
Insert normally closed contact	Rung	<Shift+F3>
Insert empty box	Rung	<Shift+F5>
Insert assignment	Rung	<Shift+F7>
Insert "Open branch"	Rung	<Shift+F8>
Insert "Close branch"	Rung	<Shift+F9>

Inserting instructions (FBD)

Function	Selected object	Shortcut key
Insert AND logic operation	Network, input or output	<Shift+F2>
Insert OR logic operation	Network, input or output	<Shift+F3>
Insert empty box	Network	<Shift+F5>
Insert assignment	Network, input or output	<Shift+F7>
Insert "Open branch"	Connection line between two boxes	<Shift+F8>

Function	Selected object	Shortcut key
Invert RLO	Network, input or output	<Ctrl+Shift+4>
Insert input	Network, input or output	<Ctrl+Shift+3>

Entering operands (LAD/FBD/GRAPH)

Function	Selected object	Shortcut key
Activate the input field for the first operand of the instruction	Instruction	<Return> Or <Any letters/numbers> An empty input field opens on <Return>, any letters or numbers will be entered in the input field.
Activate input field for the operand	Operand	<F2>
Delete operand	Operand	<Del>
Define tag	Operand	<Ctrl+Shift+I>
Rewire tag	Operand	<Ctrl+Shift+P>
Rename tag	Operand	<Ctrl+Shift+T>
Entering operands	Input field for operands	<Any letters/numbers>
Confirm entry of the operand	Input field for operands	<Return>
Open autocompletion	Input field for operands	<Ctrl+I>
Discard current change	Input field for operands	<Esc> The input field is deactivated and the previous contents restored.

Process instructions (STL/SCL)

Function	Selected object	Shortcut key
Indent line (SCL only)	Line	<Tab> or <Ctrl+R>
Outdent line (SCL only)	Line	<Shift+Tab> or <Ctrl+Shift+R>
Automatically formatting selected text (SCL only)		<Ctrl+Shift+W>
Open "Call options" dialog	Cursor after block call	<Return>
Define tag	Operand	<Ctrl+Shift+I>
Rewire tag	Operand	<CtrlShift+P>
Rename tag	Operand	<Ctrl+Shift+T>
Expand/collapse parameter list (SCL only)	Operand	<Ctrl+Shift+Space>

Function	Selected object	Shortcut key
Expand/collapse code section	Insertion mark within the code section	<Ctrl+Shift+Num+> <Ctrl+Shift+Num->
Expand/collapse all code sections	Any	<Ctrl+Shift+Num*> <Ctrl+Shift+Num/>
Open autocompletion	Any	<Ctrl+I> or <Ctrl+Spacebar>
Set/delete bookmarks		<Ctrl+Shift+M>
To the next bookmark		<Ctrl+Shift+6>
To the previous bookmark		<Ctrl+Shift+5>
Comment out selection	Line	<Ctrl+Shift+Y>
Remove comment	Line	<Ctrl+Shift+U>

Programming window of GRAPH

Function	Block	Shortcut key
Page Up/Down	Navigation view, single step view, sequence view, permanent instructions	<Page Up>/ <Page Down>
Navigate in the navigation view	Navigation view	<Up arrow> <Down arrow>
Expand/collapse object	Navigation view	<+> or <Right arrow> <-> or <Left arrow>
Switch between single step view and sequence view when a step or a transition is selected	Navigation view	<Return>
Switch between navigation view and work area	Navigation view, single step view, sequence view, permanent instructions	<ALT+F6>
Go to first element in a network	Single step view	<Home>
Go to last element in a network	Single step view	<End>
Switch to interlock	Single step view	<Ctrl+Home>
Switch to transition	Single step view	<Ctrl+End>
Navigate in the structure	Sequence view	Arrow keys
Go to first step	Sequence view	<Home> or <Ctrl+Home>
Go to last step	Sequence view	<End> or <Ctrl+End>
Open branch	Sequence view	<Shift+F8>
Close branch	Sequence view	<Shift+F9>
Insert sequence end	Sequence view	<Shift+F7>
Insert jump	Sequence view	<Shift+F12>
Insert step and transition	Sequence view	<Shift+F5>
Delete element	Sequence view	<Del>

Function	Block	Shortcut key
Go to first editable element	Permanent instructions	<Home>
Go to next editable element	Permanent instructions	<Tab>
Go to last editable element	Permanent instructions	<End>
Go to previous editable element	Permanent instructions	<Shift+Tab>
Jump to the start of the "Action" cell	Actions	<Home>
Jump to the end of the "Action" cell	Actions	<End>
Insert new action	Actions	<Return>

Programming window of SCL

Function	Block	Shortcut key
Expand block	Block overview, block in the programming window	<Ctrl+Shift+Num+>
Collapse block	Block overview, block in the programming window	<Ctrl+Shift+Num->
Expand all blocks	Block overview, programming window	<Ctrl+Shift+Num*>
Collapse all blocks	Block overview, programming window	<Ctrl+Shift+Num/>

Monitor program

Function	Shortcut key
Set/remove breakpoint (STL, SCL)	<Ctrl+Shift+F9>
Step over breakpoint (STL, SCL)	<Ctrl+Shift+F10>
Jump to lower-level block (STL, SCL)	<Ctrl+Shift+F11>
Return to calling block (STL, SCL)	<Ctrl+Shift+F12>
Run program up to marker (cursor position) (STL, SCL)	<Ctrl+F3>
Display program status (SCL, STL)	<Ctrl+T>
Enable all breakpoints (STL, SCL)	<Ctrl+Shift+F2>
Disable all breakpoints (STL, SCL)	<Ctrl+Shift+F3>
Modify to 0 (LAD, FBD)	<Ctrl+Shift+9>
Modify to 1 (LAD, FBD)	<Ctrl+Shift+1>
Modify operand (LAD, FBD)	<Ctrl+Shift+2>

11.5.3 Enlarging the programming window

Introduction

The programming window is relatively small when all components of the application are shown. If the program code is large, you may find you have to rearrange the work area constantly. To avoid this problem, you can hide or minimize the display of the following components of the application and of the program editor:

- Project tree
- Task cards
- Block interface
- Favorites
- Comments
- Networks

Note

You can also use the "Reduce automatically" option for the task cards, project tree, and Inspector window. These windows will then be minimized automatically when you do not need them.

See also: Maximizing and minimizing the work area

Hiding and showing the project tree

The project tree allows you to access all areas of the project. You can hide the project tree while you are creating a program so you have more space for the programming window.

To show and hide the project tree, follow these steps:

1. To hide the project tree, deselect the "Project tree" check box in the "View" menu, or click on "Collapse" on the project tree title bar.
2. To show the project tree, select the "Project tree" check box in the "View" menu or click on "Extend" on the project tree title bar.

Opening and closing task cards

The task cards are located at the right-hand edge of the programming window.

To open or close the task cards, follow these steps:

1. To close the task cards, deselect the "Task card" check box in the "View" menu or click "Collapse" on the task cards title bar.
2. To open the task cards, select the "Task card" check box in the "View" menu or click "Expand" on the task cards title bar.

Hiding and showing the block interface

The block interface is shown in the upper section of the program editor. During programming you can show and hide it as required.

To show and hide the block interface, follow these steps:

1. In the lower part of the interface within the window splitter, click on the Up arrow or Down arrow.

Showing and hiding favorites

To hide or show the favorites in the program editor, follow these steps:

1. Click the "Display favorites in the editor" button in the program editor toolbar.

Showing and hiding comments

Within a block you can enter a comment for the block or for each network. These two types of comments are shown and hidden differently.

To show or hide a block comment, follow these steps:

1. Click the the triangle at the start of the line with the block title.

To show or hide network comments, follow these steps:

1. Click "Network comments on/off" on the program editor toolbar.

Note

The comments available can vary depending on the programming language used.

Opening and closing networks

Some programming languages use networks. You can open or close these networks as required.

To open or close networks, follow these steps:

1. If you want to open a network, click the right arrow in front of the network title. If you want to close a network, click the down arrow in front of the network title.

To open and close all networks, follow these steps:

1. Click "Open all networks" or "Close all networks" in the program editor toolbar.

Note

Networks are not used in every programming language.

See also

Overview of the program editor (Page 4684)

Maximizing and minimizing the work area (Page 249)

11.5.4 Setting the mnemonics

You can program blocks using German or international mnemonics. When you open the TIA Portal for the first time, international mnemonics is set as default. You can change the mnemonics at any time.

Procedure

To set the mnemonics, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "General" group in the area navigation.
3. In the "General settings" group, select the mnemonics that you want to use.
   The mnemonics is changed in all blocks.

11.5.5 Displaying symbolic and absolute addresses

You have the following options for displaying operands in the program editor:

- Symbolic representation
  The symbolic operands are displayed in the program. The corresponding absolute addresses are shown in tooltips if you hold the mouse pointer over the operand.
- Absolute representation
  The absolute addresses are displayed in the program. The corresponding symbolic operands are displayed in tooltips.
- Symbolic and absolute representation
  Symbolic operands and absolute addresses are displayed in program. This setting only has an effect on blocks that were programmed with LAD, FBD, STL, and GRAPH.

Note

Note that absolute operands are not displayed for GRAPH blocks if you have disabled the option "Display absolute operands" in the "Action" column.

You can set the display of operands centrally for all new blocks of the project or for individual blocks.

Setting operand representation for new blocks

To set the operand representation for all new blocks in the project, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select the desired representation in the "Operand representation" drop-down list.
   The selected representation is enabled for all new blocks in the program.

Setting operand representation for an individual block

To change the representation of the operands, follow these steps:

1. Open the block in the program editor.
2. Click the "Absolute/symbolic operands" button in the program editor toolbar.
   Each time you click the button, the representation and the symbol on the button change.

Or:

1. Open the block in the program editor.
2. Click the small arrow next to the "Absolute/symbolic operands" button in the program editor toolbar.
   A drop-down list is displayed.
3. Select the required representation from the drop-down list.
   The symbol on the button changes.

11.5.6 Find instructions

You have the option of finding specific instructions in the "Instructions" task card and then inserting them in your program. Note the following rules when entering search terms:

- No distinction is made between upper and lower case text.
- The search function considers parts of a search term.
- You cannot use placeholders, such as "*" and "?".
- If an instruction name includes underscores, the instruction is found even if you do not enter the underscore.
- The text in the columns "Name" and "Description" are taken into consideration in the search.

Requirement

- A block is open.
- The "Instructions" task card is open.

Procedure

To search for a specific instruction in the "Instructions" task card, follow these steps:

1. Select a starting point for the search if you want to start the search at a specific point. If you do not select a starting point, the search starts either at the top or bottom in the task card, depending on the type of search you have selected.
2. Enter a search term in the text box of the task card toolbar.
3. Click "Search down" if you want to search the task card from top to bottom.
4. Click "Search up" if you want to search the task card from bottom to top.
   The first match with the search term found is displayed as the result. If you want to continue the search, click the "Search down" or "Search up" button again. If no matches are found, you will receive a corresponding message.

Overview of the program editor (Page 4684)

11.5.7 Use instruction versions

11.5.7.1 Basic information on instruction versions

Introduction

The instructions available to you for programming the user program are managed in system libraries. If a new version of a system library is installed by an update, the newer versions of the instructions of this system library may also be installed.

If there are several versions for an instruction, these are listed in a drop down list in the "Instructions" task card after the respective instruction. If the instruction versions are not shown, you can show them again using the shortcut menu of the column header. In the drop-down list, select the version of an instruction which is to be used in the program. If you do not select any versions, the most recent versions are used.

Note

Please note the following:

- You can only ever use the same version of an instruction within a device.
- If you use an instruction in a know-how-protected block with a version other than the version set in the project, you can compile the know-how-protected block without a password if the interfaces of the instruction versions are identical. The next time you open the know-how-protected block, you will need to update the call for the instruction. The corresponding call is marked in red. The call is updated automatically by the system by compiling the entire program.
- If you change the version of an instruction that other instructions depend on, the versions of the dependent instructions are also changed.
- If you select a version for an instruction that can not be run on the CPU used, the instruction is shaded out. This means that you cannot use this instruction in this version with your CPU.
- The system block in the project tree displays the block version number in its properties; it does not have to match the instruction version number of the associated instruction in the task card.
- If you change the version of an instruction in the task card, you must compile the associated system block in the project tree before you update its block version number.

Changes in the versions

New versions can be main versions or secondary versions. New versions, such as 2.0 or 3.0, have more substantial changes to them. New main versions may therefore result in changes to the block interface. New secondary versions, such as 1.3 or 1.4, contain lesser changes or remedies to errors.

Using instruction versions

You can decide within a device which version of an instruction you want to use. If you select another version for an instruction, the new version is specified for all locations of use of this instruction within your program. These instructions are identified in the program by a red frame. You must then download your program to the device to use the new instruction version.

If you open your project with a newer TIA Portal version, you can upgrade your project and the instructions to the new TIA Portal version within the "Instructions" task card. Newer versions for some instructions are then available. These do not, however, automatically replace the old versions in your program. To use the new instruction versions in your program, you must explicitly update your program.

See also

Upgrade project and instructions (Page 4699)

Update program in the current PLC (Page 4699)

11.5.7.2 Upgrade project and instructions

You can upgrade a project and the instruction versions to a newer TIA Portal version in one step. This will not change your program.

Note

No backward compatibility

Projects that are saved with the current version of the TIA Portal are not backward compatible with older versions due to their enhanced functionality. This means that after upgrade you will no longer be able to open your project with an older version of the TIA Portal.

Procedure

To upgrade a project and the instructions, follow these steps:

1. Open a code block.
2. Open the "Instructions" task card.
3. Click "Upgrade project and instructions" in the toolbar.
   The "Project compatibility" dialog opens.
4. Click "OK" to continue with the upgrade.

Result

The project and instructions are upgraded. The "Upgrade project and instructions" button becomes inactive and the function can no longer be executed.

As the next step, you can update your program so that the new instruction versions can be used.

See also

Basic information on instruction versions (Page 4697)

Update program in the current PLC (Page 4699)

11.5.7.3 Update program in the current PLC

If there are new instruction versions in your project, you can update the program in the PLC so that the new instruction versions are used. This may be the case, for example after upgrading your project to a new TIA Portal version. Please note that you have to compile your program after update.

Procedure

Proceed as follows to update the program in the current PLC:

1. Right-click on the PLC for which you would like to update the program in the project tree.
2. Select the "Update program" command in the shortcut menu.
   The "Update program in the current CPU" dialog opens.
3. Click "OK" to perform the update.
4. Compile your program to complete the upgrade.

Or:

1. Open a code block.
2. Open the "Instructions" task card.
3. Click on "Update program in the current PLC" in the toolbar.
   The "Update program in the current CPU" dialog opens.
4. Click "OK" to perform the update.
5. Compile your program to complete the upgrade.

See also

Basic information on instruction versions (Page 4697)

Upgrade project and instructions (Page 4699)

11.5.8 Using instruction profiles

11.5.8.1 Basics of instruction profiles

Introduction

The TIA Portal provides you with numerous instructions that you can use to program the user program. However, you may filter out specific instructions that you do not want to use. To this end you can create instruction profiles in which you can explicitly specify the instructions to be listed in the "Instructions" task card. However, although you may create several instruction profiles in a project, only one of these profiles may be active at any given time. You can exchange instruction profiles with other users by means of shared libraries.

Note

Please note the following:

- The use of instructions that are not allowed in the active profile in a block will trigger the output of a block compilation error. Such a situation may be triggered if you drag-and-drop a block from the library to your program.
- Instructions of a profile that are not supported by the currently installed products are deleted from the profile the next time it is edited. If you transfer this profile to an engineering system in which these instructions are supported by the installed products, the instructions are again present in the profile but they are disabled. You can enable these instructions as required at any time.
- If you want to make changes to the active profile, you must recompile the blocks in the project. This is also necessary when you disable or delete the active profile or when you enable a profile.

See also

Creating new instruction profiles (Page 4701)

Opening and editing instruction profiles (Page 4703)

Activating and deactivating instruction profiles (Page 4704)

Deleting instruction profiles (Page 4705)

11.5.8.2 Creating new instruction profiles

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Procedure

Proceed as follows to create a new instruction profile:

1. Double-click the "Add new profile" command.
   The Instruction Profile Editor opens and displays the new instruction profile. All instructions are activated for the new instruction profile.
2. Edit the new instruction profile to suit your requirements.

If necessary, you can rename the new instruction profile. To do this, follow these steps:

1. Right-click on the new instruction profile.
2. Select the "Rename" command in the shortcut menu.
3. Enter a name for the new instruction profile.

Note

The first instruction profile that you create will be used as active profile. In this case, compile all blocks in the project. If other instruction profiles are already available you must explicitly activate the new one in order to use it as active profile. You can identify the active profile by its icon in the project navigation.

See also

Basics of instruction profiles (Page 4701)

Opening and editing instruction profiles (Page 4703)

Activating and deactivating instruction profiles (Page 4704)

Deleting instruction profiles (Page 4705)

11.5.8.3 Opening and editing instruction profiles

Once you have opened an instruction profile, you can edit it as follows:

- Activating and deactivating instructions
  You can explicitly specify the instructions to be allowed in the instruction profile.

  Note

  Note that dependencies exist between some instructions. As a result, it is possible that several instructions may be activated or deactivated by an action. The check box icon indicates the folders in which instructions are deactivated.

- Activating and deactivating instruction versions
  Certain instructions are available with different versions. You can explicitly specify the instruction versions to be allowed in the instruction profile.
- Renumbering blocks
  An instruction representing an internal function block (FB) or function (FC) in the system is assigned a specific block number by the system. You can replace this block number with your own block number. Within a version, there are several implementations for certain instructions. The block numbers in such instructions can only be changed for the specific implementation.

  Note

  If an instruction from the instruction profile is used in the program and the specified block number is already in use by a different block, the specified block number of the instruction will be replaced by a free block number.

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Opening instruction profiles

Proceed as follows to open an instruction profile:

1. Double-click the instruction profile that you want to edit.
   The instruction profile opens in the Instruction Profile Editor.

Editing instruction profiles

Proceed as follows to edit an instruction profile in the Instruction Profile Editor:

1. Select the device that you want to edit from the "Device family" drop-down list box.
2. Select the programming language for which you want to edit the instruction profile from the "Language" drop-down list box.
3. Deactivate the instructions or instruction versions that you want to exclude from the instruction profile. You can deactivate a folder to deactivate all subordinate instructions.

4. Activate the instructions or instruction versions that you want to allow in the instruction profile.
5. You may assign your own block numbers.

Note

You can assign the number up to 65535 for CPUs of the S7-1200/1500 series. For CPUs of the S7300/400 series you find the restrictions of the number ranges in the respective CPU manual.

Note

A new compilation process is required for all blocks in the project when you change the active profile.

See also

Basics of instruction profiles (Page 4701)

Creating new instruction profiles (Page 4701)

Activating and deactivating instruction profiles (Page 4704)

Deleting instruction profiles (Page 4705)

Basic information on instruction versions (Page 4697)

11.5.8.4 Activating and deactivating instruction profiles

You first need to activate an instruction profile in order to include filtering of its instructions. You can always deactivate the instruction profile to reset the instructions task card to the default scope of instructions.

Note

A new compilation process is required for all blocks in the project.

Requirement

The "Common data > Instruction profiles" folder is open in the project navigation.

Activating instruction profiles

Proceed as follows to activate an instruction profile:

1. Right-click on the instruction profile that you want to activate.
2. Select the "Activate profile" command from the shortcut menu.
   The selected instruction profile is now active. Instructions can now only be used in accordance with the settings of this profile.

Deactivating instruction profiles

Proceed as follows to deactivate the instruction profile:

1. Right-click on the instruction profile that you want to deactivate.
2. Select the "Deactivate profile" command from the shortcut menu.
   No instruction profile is active and the "Instructions" task card once again shows all instructions that are available for use.

See also

Basics of instruction profiles (Page 4701)

Creating new instruction profiles (Page 4701)

Opening and editing instruction profiles (Page 4703)

Deleting instruction profiles (Page 4705)

11.5.8.5 Deleting instruction profiles

Requirement

The "Common data > Instruction profiles" folder is open in the project tree.

Procedure

Proceed as follows to delete an instruction profile:

1. Right-click on the instruction profile that you want to delete.
2. Select the "Delete" command in the shortcut menu.

Note

A new compilation process is required for all blocks in the project when you delete the active profile.

Result

The selected instruction profile is deleted. If you deleted the active instruction profile, no more active profiles are available and the "Instructions" task card once again shows all instructions that are available for use.

Opening and editing instruction profiles (Page 4703)

Activating and deactivating instruction profiles (Page 4704)

11.5.9 Using autocompletion

11.5.9.1 Basics of autocompletion

Function

You can use autocompletion in the program window of the program editor as an easy way to access available tags or instructions during programming. Autocompletion means a context-specific list appears in a dialog from which you can select the tags or instructions you need.

See also

Using autocompletion in graphic programming languages (Page 4706)

Using autocompletion in textual programming languages (Page 4707)

11.5.9.2 Using autocompletion in graphic programming languages

Inserting tags using autocompletion

To insert tags in graphic programming languages using autocompletion, follow these steps:

1. Select an operand of the instruction to which you wish to assign a tag.
   The input field for the operand opens. The autocompletion button will appear beside the input field.
2. Either click the autocompletion button or use the shortcut <Ctrl+l>.
   Autocompletion opens. It contains only the local and global tags, data blocks and multiple instances which are admissible for the operand in the given context. You can exit autocompletion at any time by pressing <Esc>.

3. Select the required tag from the list. If necessary, you can also filter the list:
   - For example, enter the first few letters of the name of the tag or instruction you wish to insert. Autocompletion will be filtered further with each letter entered. If there is no tag or instruction starting with the letters entered, autocompletion will remain at the last match.
   - Enter # to access the local tags from the block interface.
   - Enter " to access the global tags.
   - Enter % to access absolute addresses.

   If the tag is a structured tag, a data block or a multiple instance, then an arrow is displayed at the end of the row. Click on the arrow to display the lower-level elements. You can navigate to the very last level in this way. If a structure is allowed as a data type for the operand, you can choose "None" from the list. This assigns the entire structure to the operand as a tag. Use the <Backspace> key to return to the previous level.
4. Press the <Return> key to apply the tag.

See also

Basics of autocompletion (Page 4706)

Using autocompletion in textual programming languages (Page 4707)

11.5.9.3 Using autocompletion in textual programming languages

Inserting tags and instructions using autocompletion

To insert tags and instructions in textual programming languages using autocompletion, follow these steps:

1. Enter the first few letters of the name of the tag or instruction you wish to insert. If necessary, you can directly filter the kind of tags:
   - Enter # to access the local tags from the block interface.
   - Enter " to access the global tags.
   - Enter % to access absolute addresses.

   Autocompletion opens. It contains only the local and global tags, data blocks, multiple instances and instructions which are admissible at the current position. You can exit autocompletion at any time by pressing <Esc>.
2. Enter more letters of the name of the tag or instruction you wish to insert. You can use <Enter> or <Tab> to apply the tag or instruction and close autocompletion. Autocompletion will be filtered further with each letter entered. If there is no tag or instruction starting with the letters entered, autocompletion only contains the previous matches.

3. Select the tag or instruction required from the list.
   If a tag is a structured tag, a data block or a multiple instance, first select the tag, the data block or multiple instance from the autocompletion and apply the selection with <Enter>. To select the additional components of the structure, data block, or multiple instance, enter a period. Autocompletion then reopens and you can select the next component.
4. Press the <Return> key to apply the tag.

Basics of autocompletion (Page 4706)

Using autocompletion in graphic programming languages (Page 4706)

11.5.10 General settings for the PLC programming

11.5.10.1 Overview of the general settings

Overview

The following table shows the general settings that you can make:

Group	Setting	Description
View	Operand representation	Representation of the operand in the program editor. You can select between the following options: • Symbolic and absolute • Symbolic • Absolute (only for LAD, FBD, STL and GRAPH)
	Tag information	Additional information for the tags used is displayed in the program editor. When you select the option "Tag information with hierarchy", the comments of the higher structure levels are also displayed for structured tags.
	Location of tag information (LAD/FBD)	Specifies the position at which the tag information is to be displayed. You can display the tag information either collectively below a LAD/FBD network or directly at the respective operand.
	with network comments	Network comments are shown.
Compilation	Delete actual parameters on interface update	Actual parameters are deleted if the associated formal parameters were deleted in the called block, and you run the "Update block call" function or compile the block.

Group	Setting	Description
Default settings for new blocks	IEC check	The compatibility of operands in comparison operations and arithmetic operations are tested according to IEC rules. You have to explicitly convert non-compatible operands.
Additional settings	Set network title automatically	Sets the title of a network based on the comment of the output parameter of the first writing instruction in the network. See also: Inserting network title (Page 4887)
	Show autocompletion list	The autocompletion list is displayed.
	Mnemonics	German or international designation of operations and operands
Download without reinitialization	Memory reserve	Defines the size of reserve in volatile memory that can be used for interface extensions.

Group	Setting	Description
Block interface / data blocks	Set "Accessible from HMI/OPC UA" for new elements and ARRAY data blocks.	Enables the option "Accessible from HMI" for new tags in the block interface and in data blocks. The use of this option makes sense especially when working with large amounts of data in ARRAY data blocks. See also: Basic principles for programming of data blocks (Page 4795)
	Set data block elements with access type "Standard" to retentive.	When this check box is selected, the "Retain" attribute is set for newly created tags. The setting influences the following types of data blocks: • S7-1200/S7-1500: Instance data blocks without optimized access – the setting influences all data block tags. • S7-1200/S7-1500: Instance data blocks with optimized access – the setting influences all tags with the attribute "Retain: set in IDB". **Note** With other types of data blocks you cannot specify any default for the retentivity. • S7-300/S7-400: Tags in instance data blocks and global data blocks are retentive by default. If you change the retentivity setting, the change affects all tags in the block. • S7-1200/S7-1500: Tags in instance data blocks with optimized access are non-retentive by default. You can set the retentivity for each tab individually.

See also

Overview of the block interface (Page 4764)

Changing the settings (Page 4711)

Permissible addresses and data types of PLC tags (Page 4840)

Overview of the print settings (Page 233)

Setting and canceling the IEC check (Page 2467)

Using autocompletion (Page 4706)

11.5.10.2 Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

See also

Overview of the general settings (Page 4708)

11.5.11 Eliminating syntax errors in the program

11.5.11.1 Basic information on syntax errors

Syntax errors

Below are some examples of syntax errors:

- Missing separators or the use of too many separators
- Incorrect keyword spelling
- Incorrect jump label spelling/notation
- Notation which does not match the set mnemonics (for example, "I2.3" instead of "E2.3")
- The use of key words as operands

Identification of syntax errors

Syntax errors are underlined in red or appear in red type.

This identification allows you to recognise incorrect inputs at a glance and jump from error to error to eliminate them. Syntax errors are also listed in the "Info" tab of the inspector window with an error message.

See also

Finding syntax errors in the program (Page 4712)

11.5.11.2 Finding syntax errors in the program

Procedure

To find syntax errors in the program, follow these steps:

1. Select the position in the program in which you wish to look for errors.
2. Click "Go to next error" in the toolbar.
   The first error after the position you have selected will be marked.

You can use "Go to next error" and "Go to previous error" in the toolbar to find and correct all errors in the block.

Or:

1. Open the error list in the inspector window with "Info > Syntax".
   All syntax errors are listed in the table with a short description of the error.
2. If there are any errors, click on the blue question mark next to the error text to obtain information on eliminating the problem.
3. Double-click the error you want to correct.
   The corresponding error is highlighted.

See also

Basic information on syntax errors (Page 4711)

11.5.12 Changing the programming language

11.5.12.1 Rules for changing the programming language

Rules

Observe the following rules if you want to change the programming language for a block:

- All CPU series:
  - You can only change the programming language of entire blocks. The programming language cannot be changed for individual networks.
  - You cannot switch blocks programmed in the programming languages SCL or GRAPH. In GRAPH blocks, however, you can change between LAD and FBD as network languages.
- S7-300/400:
  - You can only change between the programming languages LAD, FBD and STL.
  - You can create networks within a block using another programming language and then copy them into the desired block.
  - If the language of individual networks of the block cannot be changed, these networks is displayed in their original language.
- S7-1200/1500:
  - You can change between the programming languages LAD and FBD.
- S7-1500:
  - You can create STL networks within the LAD and FBD blocks. However, you cannot copy between STL and LAD/FBD.

11.5.12.2 Change the programming language

Procedure

To change the programming language, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.
3. Select the "General" entry in the area navigation.
4. Select the new programming language in the "Language" drop-down list.
5. Confirm your selection with "OK".

See also

Rules for changing the programming language (Page 4713)

11.6 Creating and managing blocks

11.6.1 Creating blocks

11.6.1.1 Block folder

Function

You can find a "Program blocks" folder in the project tree, in which you can create and manage the following blocks:

- Organization blocks (OB)
- Function blocks (FB)
- Functions (FCs)
- Data blocks (DB)

A "System blocks" subfolder containing another subfolder, "Program resources", is also created in the "Program blocks" folder the first time you drag an instruction to your program which is an internal system function block. The instance data block of the internal system function block is also pasted to the "Program resources" folder. You can copy, rename or delete such instance data blocks in the "Program resources" folder. The "Program resources" folder is deleted together with the "System blocks" folder if contains no more blocks.

A program cycle OB is automatically generated for each device and inserted in the "Program blocks" folder.

Note

Moving blocks from the "Program resources" folder or to the "Program resources" folder

You can move blocks between the "Program resources" folder and other folders. When moving blocks from the "Program resources" folder or to the "Program resources" folder, note the following:

- Moving blocks from the "Program resources" folder into another folder: When the next time the user program is compiled, the shifted instance data blocks are moved back into the "Program resources" folder.
- Moving by any blocks to the "Program blocks" folder: Blocks in the "Program resources" folder that are not required to run the user program are removed during the next compilation. This may cause your moved block to be deleted.

See also

Creating functions and function blocks (Page 4716)

Creating data blocks (Page 4716)

Creating organization blocks (Page 4715)

Using blocks from libraries (Page 4718)

11.6.1.2 Creating organization blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create an organization block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Organization block (OB)" button.
3. Select the type of new organization block.
4. Enter a name for the new organization block.
5. Enter the properties of the new organization block.
6. To enter additional properties for the new organization block, click "Additional information".
   An area with further input fields is displayed.
7. Enter all the properties you require.
8. Activate the "Add new and open" check box if the organization block does not open as soon as it is created.
9. Confirm your entries with "OK".

Result

The new organization block is created. You can find the organization block in the project tree in the "Program blocks" folder. You can assign additional parameters to some organization blocks in the inspector window or device view after they have been created. The organization block description will state whether the newly created organization block has additional parameters.

Block folder (Page 4714)

Creating functions and function blocks (Page 4716)

Creating data blocks (Page 4716)

Using blocks from libraries (Page 4718)

Entering a block title (Page 4723)

Entering a block comment (Page 4724)

11.6.1.3 Creating functions and function blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a function (FC) or a function block (FB), follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Function block (FB)" or "Function (FC)" button.
3. Enter a name for the new block.
4. Enter the properties of the new block.
5. To enter additional properties for the new block, click "Additional information".
   An area with further input fields is displayed.
6. Enter all the properties you require.
7. Activate the "Add new and open" check box if the block does not open as soon as it is created.
8. Confirm your entries with "OK".

Result

The new block is created. You can find the block in the project tree in the "Program blocks" folder.

See also

Block folder (Page 4714)

Creating organization blocks (Page 4715)

Creating data blocks (Page 4716)

Using blocks from libraries (Page 4718)

Entering a block title (Page 4723)

Entering a block comment (Page 4724)

11.6.1.4 Creating data blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a data block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Select the type of the data block. You have the following options available to you:
   - To create a global data block, select the list entry "Global DB".
   - To create an ARRAY data block, select the "ARRAY DB" entry in the list.
   - To create an instance data block, select the function block to which you want to assign the instance data block from the list. The list contains only the function blocks that were previously created for the CPU.
   - To create a data block based on a PLC data type, select the PLC data type from the list. The list contains only the PLC data types that were previously created for the CPU.
   - To create a data block based on a system data type, select the system data type from the list. The list contains only those system data types that have already been inserted to program blocks in the CPU.
4. Enter a name for the data block.
5. Enter the properties of the new data block.
6. If you have selected an ARRAY DB as the data block type, enter the ARRAY data type and the high limit for the ARRAY.
   You can change the high limit for the ARRAY at any time in the property window of the created block. The ARRAY data type cannot be changed subsequently.
7. If you have selected a block that contains monitoring as the "Type", assign a ProDiag function block to the monitoring functions.
8. To enter additional properties of the new data block, click "Additional information".
   An area with further input fields is displayed.
9. Enter all the properties you require.
10. Activate the "Add new and open" check box if the block does not open as soon as it is created.
11. Confirm your entry with "OK".

Result

The new data block is created. You can find the data block in the project tree in the "Program blocks" folder.

Note

Retentivity of ARRAY data blocks

ARRAY data blocks and their components cannot be set retentively.

See also

Basic principles for programming of data blocks (Page 4795)

System data types (Page 2326)

Using blocks from libraries (Page 4718)

11.6.1.5 Using blocks from libraries

You can save blocks in the project library or in a global library, so that you can use them more than once within a user program. You can insert the blocks as master copies or as types.

See also: Library basics (Page 439)

Requirement

- The "Libraries" task card is displayed.
- No write protection is set for global libraries.

Adding blocks as master copies to the project library or to a global library

To add new blocks as master copies to the project library or to a global library, follow these steps:

1. Maximize the project library or the global library.
2. Use drag-and-drop to move the block you wish to add to the library to the "Master copies" folder or any one of the "Master copies" subfolders in the project library or a global library. Do not release the left mouse button until a small plus sign appears underneath the mouse pointer.

Or:

1. Copy the block you want to add as master copy.
2. Maximize the project library or the global library.
3. Right-click the "Master copies" folder or any of its subfolders.
4. Select "Paste" in the shortcut menu.

Adding blocks as types to the project library or to a global library

To add new blocks as types to the project library or to a global library, follow these steps:

1. Maximize the project library.
2. Drag-and-drop the block you want to add as a type into the "Types" folder or any subfolder of "Types" in the project library. Do not release the left mouse button until a small plus sign appears underneath the mouse pointer.
3. If necessary, drag the block from the "Types" folder of the project library into the "Types" folder of a global library. Or you can copy the block in the project library, and add it to a global library.

Or:

1. Copy the block you want to add as type.
2. Maximize the project library.
3. Right-click the "Types" folder or any of its subfolders.
4. Select "Paste" in the shortcut menu.
5. If necessary, drag the block from the "Types" folder of the project library into the "Types" folder of a global library. Or you can copy the block in the project library, and add it to a global library.

Using blocks of the project library or a global library

To use a block from the project library or a global library in your project, follow these steps:

1. Maximize the project library or the global library so that you can see the block you wish to use.
2. Use a drag-and-drop operation to move the block to the CPU block folder. If the selected insertion points is not allowed, the mouse pointer will appear as a circle with a slash.

Note

If you derive an instance from a type in a global library, the type is also inserted into the project library. The instance is then only linked to the type in the project library.

11.6.1.6 Copying and pasting blocks

Basics of copying and pasting blocks

Function

You can also create new blocks by copying existing blocks and pasting the copy. Note the following principles when copying to CPUs of the same device family:

- You can copy organization blocks (OBs), functions (FCs), function blocks (FBs), and global data blocks (DBs) without restriction.
- You can copy instance data blocks only for the same function block, since the assignment to the function block cannot be changed afterwards. However, the assignment is canceled if you copy the instance data block to a different CPU. If a function block with the same name exists there, the instance data block will be assigned to this function block. If you copy the instance data block together with the function block into the other CPU, the instance data block is assigned to the copy of the function block.

The various device families sometimes support different blocks, especially in the case of organization blocks. However, function blocks and functions can also be programmed on the

various devices with different access types. Therefore, not all blocks are supported on all devices. Note the following principles when copying to a different device family:

- Copying to an S7-1200 CPU:
  - Organization blocks with "Optimized" access type can be copied to an S7-1200. If the copied OB type is supported by the S7-1200 CPU, the copied OB retains the properties of its event. You must, however, compile it again.
  - Although organization blocks with the "Standard" access type can be copied to an S7-1200, they are not supported by the CPU.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Optimized" access type can be copied to an S7-1200. However, they must be recompiled after this.
  - Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.
- Copying to an S7-1500 CPU:
  - Organization blocks with "Optimized" access type can be copied to an S7-1500. If the copied OB type is supported by the S7-1500 CPU, the copied OB retains the properties of its event. You must, however, compile it again. OB types that are not supported receive a no parking symbol.
  - Organization blocks with "Standard" access type can be copied to an S7-1500. If the OB derives from an S7-300/400 CPU, it receives the standard event of the corresponding OB type. If the OB derives from an S7-1200/1500 CPU, it receives the properties of its event. However, it must be compiled again.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) with "Optimized" access type can be copied to an S7-1500. However, they must be recompiled after this.
  - Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.
- Copying to S7-300/400 CPUs:
  - Organization blocks can be copied as required between S7-300 and S7-400.
  - Although organization blocks from S7-1200/1500 CPUs can be copied to S7-300/400 CPUs, they are not supported by the target CPU.
  - Function blocks (FBs), functions (FCs) and global data blocks (DBs) can be copied as required between S7-300 and S7-400.
  - Although function blocks (FBs), functions (FCs) and global data blocks (DBs) can be copied from S7-1200/1500 CPUs to S7-300/400 CPUs, they are not supported by the target CPU.

- Instance data blocks: If there is a function block in the target CPU with the name that was assigned to the instance data block in the source CPU, the instance data block is assigned to the function block in the target CPU. If you copy the instance data block together with the function block to which it was assigned in the source CPU into the target CPU, the instance data block is assigned to the copy of the function block.
- You may be able to cop function blocks (FBs) and functions (FCs) that are programmed with LAD or FBD and contain SCL networks to S7-300/400 CPUs, but they are not supported by the target CPU.

In the project tree, blocks that are not supported are indicated by the no parking symbol. Blocks with a no parking symbol cannot be edited, but only used again as copy source.

Note

When blocks are copied between different device families, it is possible that the copied block needs to be recompiled. This applies also to the coping of blocks between CPUs and software controllers. If the block has know-how protection, re-compilation is only possible with the correct password.

Copying data

With paste, all the block data is copied and forwarded to the copy. This data includes:

- Block interface tags
- All networks
- Comments in all existing compilations
- Messages defined in the block
- The entire program code of the copied block including the call instructions contained in the block.
  However, the following objects are not copied:
  - Called blocks and associated instance data blocks
  - Global tags that are referenced in the copied block
  - The PLC data types used in the copied block for the declaration of the block parameters and local tags
  - The technology objects used in the copied block

Avoiding name conflicts during pasting

When pasting copied blocks with identical names to already existing blocks, the following mechanisms are used to avoid name conflicts:

- Pasting the copied block into the same CPU:
  The copy of the block gets a name that is extended by a number. For example, if block "A" is copied, a possible name for the copy is "A_1". Consecutive numbering is not used, but rather the smallest free number. The copy of block "A" can also get the name "A_25", if no lower number is available.
- Pasting the copied block into another CPU:
  A dialog box opens in which you can select whether the block with the same name will be replaced or the copied block will be pasted with a duplicate designation (Name_Number).

Note

Number conflicts

Number conflicts may occur, if the pasted block has the same block number as an existing block. The block number is not automatically changed during pasting. This double number may have an effect on block calls. When you copy blocks you should therefore check the block number carefully and correct duplicate block numbers manually or using the block properties. Duplicate block numbers lead to a compilation error.

Copying blocks (Page 4722)

Pasting blocks (Page 4723)

Copying blocks

Requirement

The "Program blocks" folder is opened in the project tree.

Procedure

To copy a block, follow these steps:

1. Right-click the block that you want to copy.
2. Select "Copy" in the shortcut menu.

Result

A copy of the block is now on the clipboard and can be pasted either into the same CPU or into another one.

See also

Basics of copying and pasting blocks (Page 4719)

Pasting blocks (Page 4723)

Pasting blocks

Requirement

You have copied a block.

Procedure

To paste a copied block and its data into a CPU, follow these steps:

1. In the project tree, open the folder structure for the CPU into which you want to paste the copied block.

   Note

   Please note that you can only paste the copied block into a CPU which supports the block programming language and type.

2. Right-click on the "Program blocks" folder.
3. Select "Paste" in the shortcut menu.
   - If you are pasting the block into the same CPU as the original block, "_<consecutive number>" will be appended to the name of the copy.
   - If you are pasting the block into a different CPU where a block of the same name already exists, the "Paste" dialog box opens. Select the required option and confirm with "OK".

11.6.1.7 Entering a block title

The block title is the title of the block. It is not the same thing as the block name, which was assigned when the block was created. The length of the block title is restricted to one row. You can enter the block title for open and closed blocks.

Requirement

A code block is available.

Enter block title for open block

To insert the block title in an open block, follow these steps:

1. Click on the title bar of the block in the program editor.
2. Enter the block title.

Enter block title for closed blocks

To insert the block title in a closed block, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.
3. Select the entry "Information" in the area navigation.
4. Enter the block title in the "Title" input field.
5. Confirm your entry with "OK".

See also

Creating organization blocks (Page 4715)

Creating functions and function blocks (Page 4716)

Entering a block comment (Page 4724)

11.6.1.8 Entering a block comment

You can use the block comment to document the entire code block. For example, you can indicate the purpose of the block or draw attention to special characteristics. You can enter the block comment for open and closed blocks.

Note

The block comment should not exceed 32,767 Unicode characters.

Requirement

A code block is available.

Enter block comment for open blocks

To insert a block comment in an open block, proceed as follows:

1. Click the small arrow in front of the block title.
   The right arrow becomes a down arrow, and the comment area is displayed.
2. Click "Comment" in the comment area.
   The "Comment" text passage is selected.
3. Enter the block comment.

Enter block comments for closed blocks

To insert the block comment in a closed block, follow these steps:

1. Right-click the block in the project tree.
2. Select the "Properties" command in the shortcut menu.
   The dialog with the properties of the block opens.
3. Select the entry "Information" in the area navigation.
4. Enter the block comment in the "Comment" input field.
5. Confirm your entry with "OK".

11.6.2 Specifying block properties

11.6.2.1 Basics of block properties

Block properties

Each block has certain properties, which you can display and edit. These properties are used amongst other things to:

- Identify the block
- Display the memory requirements and the compilation status of the block
- Display the time stamp
- Display the reference information
- Specify the access protection

See also

Overview of block properties (Page 4726)

Block time stamps (Page 4730)

Displaying and editing block properties (Page 4732)

Setting the mnemonics (Page 4695)

11.6.2.2 Overview of block properties

Overview

The properties of the blocks are block and CPU-specific. Not all properties are therefore available for all blocks or in all CPU families. The following table gives an overview of block properties:

Group	Property	Description
General	Name	Unique block name within the station
	Constant name	Name of the constant pasted for the OB in the PLC tag table
	Type	Block type (cannot be changed)
	Number	Block number
	Event class	Event class of an OB (cannot be changed)
	Language	Programming language of the block
	Language in networks	Language used to program conditions in GRAPH blocks.
	Version	Version of the GRAPH block
	Process image partition number	Display of the process image partitions that are assigned to the organization block (cannot be changed)
	ARRAY data type	Data type of an ARRAY data block (cannot be changed)
	ARRAY limit	High limit of an ARRAY data block The "Move operations" section of the "Instructions" task card offers options for addressing of ARRAY data blocks.
Information	Title	Block title
	Comment	Block comment
	Version	Version number of the block
	Family	Block family name
	Author	Name of the author, company name, department name, or other names
	User-defined ID	ID created by the user

Group	Property	Description
Time stamp	Block	Times of creation and time of change of the block (cannot be changed)
	Interface	Time of creation of the block interface (cannot be changed)
	Code	Code modification time (non-editable)
	Data	Data modification time (non-editable)
	Load-relevant	Time of the last load-relevant modification (cannot be changed)
Compilation	Status	Details of the last compilation run (cannot be changed)
	Lengths	Details of the block lengths (cannot be changed)
	Simulation	Indicates whether the block can be simulated with SIMATIC S7-PLCSIM Advanced for compiling. This requires the "Support simulation during block compilation" option to be selected in the project properties. See also: Displaying properties of the project
	Library compliance	Indicates whether the block in the library can be used with know-how protection.
Protection	Protection	Setting up know-how protection and copy protection for the block See also: Protecting blocks (Page 4746)

Group	Property	Description
Attributes	IEC check	The compatibility of the operands in comparison operations and arithmetic operations are tested according to IEC 61131. You have to explicitly convert non-compatible operands. See also: Overview of data type conversion (Page 2465)
	Local error handling within block	Troubleshooting inside the block with the GET_ERROR or GET_ERR_ID instruction (cannot be changed). See also: AUTOHOTSPOT
	Optimized block access	The tag declaration for blocks with optimized access contains only the symbolic names of the data elements. The system automatically optimizes and manages the addresses. The CPU performance increases and access errors, for example, from SIMATIC HMI, are prevented. See also: AUTOHOTSPOT
	Create extended status information	Allows you to monitor all tags in an SCL block. This option does, however, increase the program memory space required and the execution times.
	Check ARRAY limits	Checks whether array indexes are within the range declared for an ARRAY during the runtime of an SCL block. The block enable output ENO is set to "0" if an array index is outside of the permitted range.
	Set ENO automatically	Checks whether errors occur in the processing of certain instructions during the runtime of an SCL block. The block enable output ENO is set to "0" if a runtime error occurs.
	Create minimized DB	Creates instance data blocks for GRAPH blocks of the S7-300 and S7-400 in minimized format. This option reduces the GRAPH FB memory space required, however you will only receive limited program status information.
	Skip steps	If the transitions before and after a step become valid simultaneously in a GRAPH block, the step will not be activated and will be skipped.
	Acknowledge supervision alarms	Any supervision error which occurs during the operation of a GRAPH block must be acknowledged before the program can continue.
	Permanent processing of all interlocks in manual operation	Permanently monitors all interlock conditions in a GRAPH block in manual mode.
	Initial value acquisition (Can only be activated as of block version V4.0)	The signal state of operands and the results of comparisons from a step or a transition are stored in the static parameters "CRIT_LOC", "CRIT_LOC_ERR", "CRIT" and "CRIT_FLT" of the GRAPH block interface.
	Lock operating mode selection	Prevents a GRAPH block operating mode being selected.
	Data block write-protected in the device	Indicates whether the data block is read-only in the target system, and cannot be overwritten while the

Group	Property	Description
		program is running. The option is available only for data blocks.
	Only store in load memory	On activation the data block is stored only in the load memory, occupies no space in the work memory, and is not linked into the program. The Task Card "Instructions" in the "Extended Instructions > Data block functions" pane provide options for handling the data blocks. The option is available only for data blocks.
	Start information	Here you specify the structure of the start information of the OB for S7-1500 CPUs: either like for S7-300 and S7-400 CPUs or optimized start information.
	Priority	Shows the priority set for organization blocks. The CPU family used and the type of the organization block determine whether you can change the priority.
	Parameter input via registers	Enables parameter input by means of registers in an STL block of S7-1500. This feature allows you to use the "Conditional call of blocks" (CC) and "Unconditional call of blocks" (UC) instructions in the block.
	Enable readback	Enables you to mark individual parameters of the block for readback. The "Tag readback" function is relevant if the block is used in a CFC chart.
	Block representation	Specifies how the block is represented in a CFC chart.
Time-of-day interrupt	Time-of-day interrupt	Parameters of the time-of-day interrupt OB: active (yes or no), execution, start date and time, local time or system time
Cyclic interrupt	Cyclic interrupt	Cycle time and phase shift of the cyclic interrupt OB
Triggers	Triggers	Display of start events of the hardware interrupt OB
Isochronous mode	Isochronous mode	Parameters of the isochronous mode interrupt OB: application cycles, automatic setting (yes or no), delay time. Also indicated is the PROFINET IO system or DP master system whose IO devices or DP slaves are assigned to the isochronous mode interrupt OB.
Download without reinitialization	Reserve in volatile memory	Defines the reserve in volatile memory that can be used for interface extensions. The number of currently available bytes is displayed in parentheses. This information is updated with each compilation.
	Activate download without reinitialization for retentive tags	Enables definition of a reserve in retentive memory.
	Reserve in retentive memory	Defines the reserve in retentive memory that can be used for interface extensions. The number of currently available bytes is displayed in parentheses. This information is updated with each compilation.

11.6.2.3 Block time stamps

Introduction

Blocks receive a number of different time stamps which show you when the block was created and when it was last changed. These time stamps are also used for automatic consistency checks before compilation.

Code block time stamps

The following time stamps are generated for code blocks (OBs, FBs, FCs):

- Block: Created on, Modified on
- Interface: Modified on
- Code/data: Modified on
- Load-relevant: Modified on

A time stamp conflict is displayed during compilation if the time stamp for the block calling is older than that of the interface for the block called.

Time stamps for code blocks are updated as follows:

- Block: The time stamp for the last block modification is always the same as the time stamp either of the interface or of the code depending on which area was modified last.
- Interface: The interface time stamp is updated each time the interface is modified. Even if you manually undo a change to the interface, for example change the name back, that is also a change which updates the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Code/data: The code time stamp is updated each time the block code is changed. Even if you manually undo a change to the code, for example remove an instruction, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a code block is changed. These changes can affect the code, the data or the interface.

Global data block time stamps

The following time stamps are generated for global data blocks:

- Block: Created on, Modified on
- Interface: Modified on

- Data: Modified on
- Load-relevant: Modified on

Time stamp conflict is reported during compilation of a global data block based on a PLC data type if the time stamp of the global data block is older than the time stamp of the PLC data type used.

The time stamps for global data blocks are updated as follows:

- Block: The time stamp for the last change to a global data block is always the same as the time stamp for the interface and the data.
- Interface and data: The interface time stamps and the data are updated each time the global data block is changed. Even if you manually undo a change, for example remove a tag, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamps will be reset to the value they had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a global data block is changed. These changes can affect the data or the interface.

Instance data block time stamps

The following time stamps are generated for instance data blocks:

- Block: Created on, Modified on
- Interface: Modified on
- Data: Modified on
- Load-relevant: Modified on

A time stamp conflict will be reported during compilation of an instance data block if the interface time stamps of the instance data block are not identical to those of the function block.

The time stamps for instance data blocks are updated as follows:

- Block: The time stamp for the last change to an instance data block is always the same as the time stamp for the interface and the data.
- Interface and data: The interface time stamps and the data are updated each time the instance data block is changed. Even if you manually undo a change, for example cancel the tag retain setting, that is also a change which will update the time stamps. However, if you undo the change using the "Undo" function, the time stamps will be reset to the value they had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time an instance data block is changed. These changes can affect the data or the interface.

PLC data type time stamps

The following time stamps are generated for PLC data types:

- Block: Created on, Modified on
- Interface: Modified on
- Load-relevant: Modified on

The time stamps for PLC data types are updated as follows:

- Block: The time stamp for the last change to a PLC data type is always the same as the interface time stamp.
- Interface: The interface time stamp is updated each time the PLC data type is changed. Even if you manually undo a change, for example delete the content of a PLC data type, that is also a change which will update the time stamp. However, if you undo the change using the "Undo" function, the time stamp will be reset to the value it had before the undone change.
- Load-relevant: The time stamp for "Load-relevant" is updated each time a PLC data type is changed.

Overview of block properties (Page 4726)

Displaying and editing block properties (Page 4732)

11.6.2.4 Displaying and editing block properties

The properties of the blocks are block and CPU-specific. Not all properties are therefore available for all blocks or in all CPU families. Properties that can only be displayed are write-protected.

Displaying and editing properties of a closed block

To display and edit the properties of a closed block, follow these steps:

1. Open the "Program blocks" folder in the project tree.
2. Right-click the block whose properties you want to display or edit.
3. Select the "Properties" command in the shortcut menu.
   The properties dialog box of the block opens.
4. In the area navigation, click a group whose properties you want to display or edit.
5. Change the relevant property.
6. Confirm your entries with "OK".

Displaying and editing properties of an open block

To display or edit the properties of an open block, follow these steps:

1. Select the "Inspector window" check box in the "View" menu.
   The Inspector window opens.
2. Click the "Properties" tab.
   The properties of the block are shown in the "Properties" tab of the Inspector window.

3. In the area navigation, click a group whose properties you want to display or edit.
4. Change the relevant property.

Result

The properties of the block will be changed. The changes are not saved until the project is saved.

Block time stamps (Page 4730)

11.6.3 Managing blocks

11.6.3.1 Opening blocks

You can open both the blocks in the project (offline blocks) and also the blocks in the device (online blocks).

To open an offline block, you have the following options:

- Open offline block directly
  You can open a block directly if the corresponding block folder is open in the project tree or in the overview window.
- Find and open offline block
  You can search for blocks within a project, a device, the "Program blocks" folder and in the Program editor, and then open these blocks.

Note the following special features when opening online blocks:

- You cannot edit online blocks.
- It is possible that another user can carry out a loading process on the selected CPU through joint parallel working on a CPU. Consequently, it can happen that the online block that you have open is deleted by the loading process if the block only exists in the device. In this case, the online block is closed and a message is displayed in the Inspector window.

Open offline block directly

To open an offline block directly, you have the following options:

1. Open the folder with the block you wish to open in the project tree or in the overview window.
2. Double-click on the block you wish to open.
   The block will open in the program editor.

Find and open offline block

To find an offline block and then open it, follow these steps:

1. You can start the search process for the following three types:
   - In the shortcut menu of the project, a device or "Program block" folder, select the "Open block/PLC data type" command or press the <F7> key.
   - Press the <F7> key in the open program editor.

   The "Open block/PLC data type" dialog box opens.
2. Enter the name, the address or the type of block you are looking for.
   The block list is filtered further with each letter entered. The block list is closed if there is no block that matches the input. You can show the complete block list at any time by clicking the button to the right of the text box. Keep in mind that there is no filtering in this case. If you want to filter for your inputs again, click the button once again.
3. In the block list, click the block you wish to open.
   The block is opened in the program editor and displayed as selection in the project tree.

Open online block

To open an online block directly, you have the following options:

1. Open the "Online access" folder in the project tree.
2. Click on the arrow symbol to the left of the interface to show all the objects that are arranged below the interface.
3. Double-click on the "Update accessible devices" command below the interface.
   All devices that are accessible via this interface are displayed.
4. Open the folder of the device that contains the block you want to open.
5. Open the "Program blocks" folder.
   All the device's blocks are displayed.
6. Double-click on the block you wish to open.
   The block will open in the program editor.

Opening know-how protected blocks (Page 4759)

11.6.3.2 Saving blocks

Blocks are always saved together with the project. Faulty blocks can also be saved. This allows the error to be resolved at a convenient time.

Procedure

To save a block, follow these steps:

1. Select the "Save" or "Save as" command in the "Project" menu.
   See also: Saving projects

See also

Opening blocks (Page 4733)

Closing blocks (Page 4735)

Deleting blocks online (Page 4737)

11.6.3.3 Closing blocks

Procedure

To close a block, follow these steps:

1. Click the "Close" button in the title bar of the program editor.

Note

Note that the block will not be saved on closing.

See also

Opening blocks (Page 4733)

Saving blocks (Page 4734)

Renaming blocks (Page 4735)

Deleting blocks offline (Page 4736)

Deleting blocks online (Page 4737)

11.6.3.4 Renaming blocks

Requirement

The "Program blocks" folder is opened in the project tree.

Procedure

To change the name of a block, follow these steps:

1. Right-click the block that you want to rename.
2. Select the "Rename" command in the shortcut menu.
   The block name in the project tree changes to an input field.
3. Input the new name for the block.
4. Confirm your entry with the Enter key.

Result

The name of the block is now changed at all points of use in the program.

11.6.3.5 Deleting blocks offline

Requirement

The "Program blocks" folder opens in the project tree.

Procedure

To delete a block that exists offline, proceed as follows:

1. In the project tree in the "Program blocks" folder, right-click on the block that you want to delete.
2. Select the "Delete" command in the shortcut menu.
3. Confirm the safety prompt with "Yes".
   The block is deleted offline from the project.

Note

If you are deleting organization blocks, note that events may be assigned to these blocks. If you delete such organization block the program cannot respond to parameterized events.

Deleting blocks online (Page 4737)

11.6.3.6 Deleting blocks online (S7-300, S7-400)

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To delete a block that exists online, follow these steps:

1. In the "Program blocks" folder in the project tree, right-click on the block that you wish to delete from the device.
2. Select the "Delete" command from the shortcut menu.
   The "Delete" dialog opens.
3. Select the "Delete from device" check box.
4. Click "Yes".
   The block will be deleted from the device online.

Closing blocks (Page 4735)

Renaming blocks (Page 4735)

Deleting blocks offline (Page 4736)

11.6.3.7 Deleting CPU data blocks

You may delete CPU data blocks both in offline and online mode.

Deleting CPU data blocks in offline mode

Proceed as follows to delete a CPU data block from the offline project:

1. Right-click the CPU data blocks that you want to delete in the project navigation, "Program blocks" folder.
2. Select the "Delete" command from the shortcut menu.
3. Confirm the safety prompt with "Yes".
   The CPU data block is deleted from the offline project.

Deleting CPU data blocks in online mode

Proceed as follows to delete a CPU data block from the online project:

1. Establish an online connection to the device containing the CPU data block that you want to delete.
2. Right-click the CPU data block that you want to delete from the device in the project navigation, "Program blocks" folder.
3. Select the "Delete" command from the shortcut menu.
   The "Delete" dialog opens.
4. Select the "Delete from device" check box.
5. Click "Yes".
   The CPU data block is deleted from the online device.

11.6.4 Using external source files

11.6.4.1 Basics of using external source files

Function

The textual programming languages STL and SCL allow you to enter the program code in any ASCII editor and save it as an external source file. This enables you to perform a range of tasks, for example:

- Declaring tags
- Specify block properties
- Programming blocks

Note

For blocks to be generated from the external source file in the TIA Portal, the source file must be saved with one of the following character encodings:

- ANSI
- UTF-8 with BOM (Byte Order Mark)
- UTF-16 with BOM, little and big endian format
- UTF-32 with BOM, little and big endian format
- UCS2 in little and big endian format

You can import these source files to your project and use them to generate blocks. You can generate a number of different blocks from one source file. Observe the following special features when generating blocks from a source file:

- A block that exists under the same name in the project will be overwritten.
- If a block was programmed with its absolute block number instead of a symbolic name in the source file and this number is already assigned by a block in the project, the new generated block is initially assigned the next free symbolic name.
- If you have not explicitly defined the access mode for a block in the external source file, the block access mode is set depending on the CPU series used:
  - Blocks generated for a CPU of the S7-1200/1500 series are assigned "optimized" access mode by default.
  - Blocks generated for a CPU of the S7-300/400 product range are assigned "standard" access mode by default.

  Organization blocks are the exception in this case, as they are always assigned the "standard" access mode by default, regardless of the CPU series. You have the option of changing the block access mode manually.
- It is possible that not all comments from the source file will be applied in the block.
- If you use absolute addressing in the external source file, a symbolic tag is created for each absolute address during the generation of the block. The names of these tags are made up of "Tag_" and a time stamp. This may result in relatively long tag names, which you can change manually if required.
- If you are using instructions in a different version in the external source file than in the target device, this may result in compilation errors. Correct the respective instructions in this case and start the compilation process once again. You can also select a different version for the target device.
- CPUs of the S7-300/400 series accept organization blocks with any name during import. If you import an OB with a standard name (for example, CYCL_EXC or CYC_INT5), the correct OB class is automatically assigned. If you import an OB with an unknown name, an OB 0 is created. You can change this number after the import and hereby assign the desired OB class. To change the OB number, select "Properties" in the shortcut menu.

You also have the option of saving existing blocks as external source files. You can either write only the program code of the selected block to a source file or additionally the program code of the blocks and PLC data types dependent on the selected block. When saving several blocks

to a source file, all blocks must use the same programming language and none of the blocks may have know-how protection.

Inserting external source files (Page 4743)

Opening and editing external source files (Page 4743)

Generating blocks from external source files (Page 4744)

11.6.4.2 Rules for programming external source files

An external source file basically consists of continuous text. To compile the source into blocks, certain structures and syntax rules must however be adhered to.

Syntax rules

The syntax of the instructions in external source files is very similar to that in the creation of user programs in the program editor with STL or SCL. Note, however, the following additional syntax rules:

- Block call
  When calling a block, transfer the parameters in the defined order in the ASCII editor. If you do not, the comment assignments for these lines may not match.
  Enter the parameters in brackets. The individual parameters are separated by a comma.
- Upper or lower case
  The program editor generally disregards upper or lower case. Jump labels are an exception to this. Character string entries are also case-sensitive ("STRING" data type). Keywords are displayed in upper case. For compilation purposes, however, case is disregarded; you can therefore specify keywords in upper or lower case or a mixture of the two.
- Semicolon
  Mark the end of every instruction and every tag declaration with a semicolon. You can enter several instructions per line.
- Forward slashes
  Begin every comment with two forward slashes (//) and end the comment with the <Enter> key.
- Use of String constants
  To avoid compilation errors when using String constants, enter the text in the language of the target project. You can explicitly use the data type WSTRING for CPUs of the S7-1200/1500 series by using the prefix "WString#":
  `Operand := WString#'<String constant>';`

Generating blocks from external source files (Page 4744)

11.6.4.3 Saving blocks as external source files

You have the following options for saving STL and SCL blocks as external source files:

- Copying a block as text
  Note that with protected blocks only the information that you can also see without a password is copied to the source file.
- Generating external source file from blocks
  You can either write only the program code of the selected block to a source file or additionally the program code of all the blocks and PLC data types dependent on the selected block. All blocks must use the same programming language and none of the blocks may have know-how protection.

Copying a block as text

To copy a block as text and save it to an external source file, follow these steps:

1. In the project tree, right-click on the block that you want to save in an external source file.
2. Select the "Copy as text" command in the shortcut menu.
3. Open an external text editor.
4. Paste the copied text from the clipboard.
5. Save the file with one of the following file name extensions:
   – ".scl", if you want to generate a source file for an SCL block
   – ".stl", if you want to generate a source file for an STL block
   – ".DB" if you wish to generate a source file for a data block
   – ".UDT", if you want to generate a source file for a PLC data type

Generating external source file from blocks

To generate external source files from STL or SCL blocks, follow these steps:

1. In the project tree or in the overview window, select the STL or SCL blocks from which you want to generate an external source file.

   Note

   Select only blocks with the same programming language and without know-how protection.

2. Select the "Generate source from blocks > Selected blocks only" command from the shortcut menu to save only the selected block to an external source file. Or select the command "Generate source from blocks > Including dependent blocks" if you also want to save the program code of the dependent blocks and referenced PLC data types to the external source file.
   The "Save as" dialog opens.
3. Specify a path and a name for the external source file.
4. Click "OK".

You can also generate an opened STL or SCL block as external source file. To do this, follow these steps:

1. In the program editor, select the "Generate source from this block" command in the toolbar in the drop-down list "Generate source from block" to save only the open block in an external source file. Or select the command "Generate source from this block and all dependent blocks" if you also want to save the program code of the dependent blocks and referenced PLC data types to the external source file.
   The "Save as" dialog opens.
2. Specify a path and a name for the external source file.
3. Click "OK".

Result

Depending on the selected option, either only the block or the block together with the dependent blocks and PLC data types are saved as an external source file. You can include this source file in a project in the TIA Portal and use it to generate other blocks. However, please note that you can use STL source files only in S7-300/400/1500 CPUs.

Generating blocks from external source files (Page 4744)

11.6.4.4 Inserting external source files

Requirement

- An external source file is available and complies with the syntax and structure rules.
- The "External source files" folder is open in the project tree.

Procedure

Follow these steps to insert an external source file:

1. Double-click on the "Add new external file" command.
   The "Open" dialog box opens.
2. Navigate to and select existing external source files.
3. Confirm your selection with "Open".
   If there is already an external source file with this name in the project, the "Add external file" dialog opens. In this case, continue with step 4.
4. Select whether the new external source is to be renamed and inserted or whether the existing external source to be replaced.
5. Click "OK".

Result

The new source file will be added to the "External source files" folder.

Generating blocks from external source files (Page 4744)

11.6.4.5 Opening and editing external source files

By linking the files with the file name extensions "stl" and "scl" to an editor you will be able to open and edit external source files with these formats directly. Use Notepad as editor because other text editors may not let you open several sources at the same time.

This means you do not need to insert the external source files again after editing.

Linking files with the file name extensions "stl" and "scl" file types to an editor

Proceed as follows to link files with the file name extensions "stl" and "scl" to an editor:

1. Open Windows Explorer.
2. Right-click on an STL file.
3. Select "Properties" in the shortcut menu.
   The "Properties" dialog box opens.
4. Click "Change" in the "File type" area on the "General" tab.
   The "Open with" dialog box opens.
5. Select the text editor you want to link to the "stl" file type.
6. Confirm your selection with "OK".
7. Close the "Properties" dialog with "OK".
8. Repeat steps 2 to 7 with an SCL file.

Opening and editing an external source file

To open an external source file, follow these steps:

1. Open the "External source files" folder in the project tree.
2. Double-click on the external source file you want to open.
   The external source file will open in the linked editor and can be edited.

11.6.4.6 Generating blocks from external source files

Requirement

- The "External source files" folder is open in the project tree.
- An external source file is available.
- The external source file was saved with a permitted character encoding.

Procedure

To generate blocks from an external source file, follow these steps:

1. Open the external source file from which you wish to generate blocks.
2. Select the "Generate blocks from source" command in the "Edit" menu.
3. A prompt will appear telling you any existing blocks will be overwritten.
4. Confirm the safety prompt with "Yes".

Result

The external source file blocks will be generated and inserted in the "Program blocks" folder in the project tree. In the event of errors, information about the errors which have occurred will be displayed in the inspector window. This information, however, relates to the external source file and not to the block generated.

11.7 Protecting blocks

11.7.1 Protecting blocks

Introduction

You have the following options for protecting your blocks

- Know-how protection
  With the help of know-how protection you can use a password to protect blocks of the OB, FB, FC type and global data blocks from unauthorized access.
- Copy protection:
  For S7-1200/1500 CPUs, you can also set up copy protection for code blocks which binds execution of the block to the CPU or the memory card with the defined serial number. When using copy protection for a block it makes sense to also know-how-protect the block to ensure that copy protection can only be revoked with a password.
- Write protection:
  You can assign write protection for code blocks, which prevent unintentional changes to the block.

Note the following points for know-how protection:

- You can not manually protect instance data blocks; they depend on the know-how protection of the assigned FB. This means that when you create an instance data block for a know-how protected FB, the instance data block also receives this know-how protection. This is independent of whether you explicitly create the instance data block or if it is created by a block call.
- The know-how protection acts as write protection in global blocks and in instance data blocks.
- You cannot provide ARRAY data blocks with know-how protection.
- The load memory requirement can be higher for know-how-protected blocks.

If a block is know-how protected, only the following data is readable without the correct password:

- Interface parameters Input, Output, InOut, Return, Static
- Block title
- Block comment
- Block properties
- Tags of global data blocks without specification of the location of use

The following actions can be performed with a know-how protected block:

- Copying and deleting
- Calling in a program
- Online/offline comparison
- Downloading

The code of the block, on the other hand, is protected from unauthorized reading and modification.

Note

Please note the following:

- S7-1200 version 1.0 and S7-300/400 (only GRAPH and SCL blocks): If you download a know-how-protected block to a device, no restore information is loaded along with it. This means that you cannot open a know-how-protected block again even with the correct password if you upload it from the device.
- Only the non-protected data is compared in offline-online comparison of know-how protected blocks.
- You will no longer be able to access the block if you do not have the password.
- If you add a know-how-protected block to a library, the master copy created will also be know-how protected.
- You will find information on whether or not the block can be used as protected library item in the block properties under "Compilation > Library conformance". For this purpose, the block cannot use any tags from the operand areas Output (Q), Input (I), Bit memory (M), Timer function (T) or Count function (C), and cannot access data blocks.
- Cross references to used tags, bit memories, inputs and outputs in know-how protected blocks are not displayed even after the correct password is entered.
- Automatic renumbering and manual renumbering without password of know-how-protected blocks is only possible for CPUs of the series S7-1500 and S7-1200 (V4). The know-how protection must also be set with a TIA Portal version V13 SP1 or higher. If these requirements for a know-how-protected block are not met, the loadable binary component of the block is no longer up-to-date when you change the number. In this case, the block must be recompiled before downloading it to a device. For know-how-protected blocks, this is only possible with the correct password. Keep this in mind particularly if you want to copy a know-how-protected block to another device in which there is already a block with the same number.
- Always pass on a project that includes know-how-protected blocks as a project archive or library archive. In this way, you ensure that the know-how protection cannot be bypassed.
- You cannot change the know-how protection settings for an open, know-how protected block.

Using a password provider

You have the option of connecting the TIA Portal to an external password management system via a password provider. For this, a project product version V14 SP1 and higher is required.

If you are using a password provider, you can select the password from a list of passwords when setting know-how protection, copy or write protection. Only the names of the passwords are displayed in the list, the passwords themselves are not visible. When a block is opened, the TIA Portal connects to the password provider and retrieves the corresponding password. If the password provider is not available at this time, you can only open the block fully if manual input is defined as the fallback strategy and the corresponding password is known. The name of the password is not sufficient here. Depending on the selected security setting in the password provider, you can change the password for a know-how protected block or revoke protection again.

The use of a password provider increases security for your program code, as it is not necessary to pass on passwords for know-how protected blocks to other editors. Instead, all editors can connect the same password provider in order to obtain access to the blocks. If an editor leaves the project, there is no need to change the password.

In the event of problems with connected password providers, you can record the activities of password providers and forward the recording to Customer Support for analysis.

11.7.2 Connecting the password provider

As an alternative to manual password input, a password provider can be connected to the TIA Portal. When using a password provider, you can select a password from a list of available passwords. When a know-how protected block is opened, the TIA Portal connects to the password provider and retrieves the corresponding password.

To connect a password provider you have to install and activate it. A settings file in which the use of a password provider is defined is also required.

Requirement

The current project is a V14 SP1 project.

Installing and activating password providers

To install and activate a password provider, proceed as follows:

1. Install the desired password provider in accordance with the installation instructions of the password provider.
2. Open the TIA Portal.

3. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
4. In the area navigation, select the "Password provider > Available password providers" group.
   The newly installed password provider is displayed in the table of available password providers.
5. Select the check box in the "Status" column to use the password provider.
   The installed password provider is now active and can be used.
6. Set the preferred password input such that the password provider is used.
   See also: Define the preferred password assignment (Page 4753)

Create a settings file for using password providers

To create a settings file for the use of password providers, proceed as follows:

1. Create an XML file with the content specified below. Use the coding "UTF-8".
2. In the setting tag with the name "EnablePasswordPreference", define whether a user can switch between manual password assignment and password assignment via a password provider.
3. In the setting tag with the name "PasswordPreference", define which type of password assignment is to be used.
4. Save the XML file.
5. Save the file in the following directory on your computer:
   C:\ProgramData\Siemens\Automation\Portal V14\CorporateSettings\

Content of settings file

The settings file must have the following content:

XML

```
<?xml version="1.0" encoding="utf-8"?>
<--! Copyright (R) Siemens AG 2016. All rights reserved. -->
<Settingshttp://www.w3.org/2001/XML-Schema-instance>
 <SettingsNode name="General">
   <SettingNode name="Application">
     <Setting name="EnablePasswordPreference">
       <Bool>true</Bool>
     </Setting>
     <Setting name="PasswordPreference">
       <String>AdvancedWithManualFallback</String>
     </Setting>
   </SettingNode>
 </SettingNode>
</Settings>
```

The following values are possible as the setting for "EnablePasswordPreference":

- "true": In the TIA Portal the user can switch between manual password assignment and password assignment via password providers.
- "false": Switching between manual password assignment and password assignment via password providers is not possible in the TIA Portal.

The default setting is "false".

The following values are possible as the setting for "PasswordPreference" :

- "Manual": Assignment of passwords in the TIA Portal is done manually.
- "Advanced": Passwords are assigned in the TIA Portal via a password provider.
- "AdvancedWithManualFallback": Passwords are assigned in the TIA Portal via a password provider. If the password provider is not available, the protected block can be accessed via manual password input.

The default setting is "Manual".

11.7.3 Show available password provider

You can display the password providers which are available in the TIA Portal.

Requirement

- The current project is a V14 SP1 project.
- Password assignment via password provider was defined using a settings file.

Procedure

Proceed as follows to display the available password providers:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "Password provider > Available password providers" group.
   The available password providers are displayed in the overview table.

11.7.4 Recording activities of the password providers

In the event of problems in connection with connected password providers, you can record the activities of password providers. No passwords are recorded. You can then forward the recording to Customer Support for analysis.

Requirement

- The current project is a V14 SP1 project.
- A password provider is connected and activated.

Activate recording of the activities of the password providers

Proceed as follows to activate the recording:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "Password provider > Password provider analysis" group.

3. Select the "Record password provider activities" check box.
   The text field for the storage location of the recording file and the "Browse" button become active.
4. Enter a storage location for the recording file or select it using the "Browse" button.

Deactivate recording of the activities of password providers

Proceed as follows to deactivate recording:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "Password provider > Password provider analysis" group.
3. Deselect the "Record password provider activities" check box.
   The text field for the storage location of the recording file and the "Browse" button become inactive.

Printing know-how protected blocks (Page 4760)

Changing a password (Page 4761)

Removing block know-how protection (Page 4762)

11.7.5 Define the type of password assignment

The TIA Portal offers the following options for the type of password assignment for blocks for know-how protection, copy protection and write protection:

- "Manual password input"
  With manual password input, you enter the password directly in the dialog for the password request.
- "Selection via password provider"
  With password input via an external password provider, you can select the password using a name from the list of available passwords. If the password provider is not available, it is not possible to set protection. The block can only be accessed later if there is a connection to the password provider.
- "Selection via password provider with manual input as fallback strategy for access"
  Like password input via an external password provider. If the password provider is not available and you know the password, you can, however, open the block for editing by entering the password manually.

Manual password input is the default setting.

Requirement

The following requirements must be met in order that password assignment via an external password provider can be used

- The current project is a V14 SP1 project.
- Password assignment via password provider was defined using a settings file.
- The change of the type of password assignment was allowed in the settings file.
- A password provider is connected.

Procedure

Proceed as follows to define the type of password assignment:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "Password provider > Password provision" group.
3. Activate the desired type of password assignment.

Removing block know-how protection (Page 4762)

11.7.6 Setting up and removing block copy protection (S7-1200, S7-1500)

For S7-1200 /1500 CPUs, you can set up copy protection which binds execution of the block to a specific CPU or a specific memory card. The block can then only be executed if it is in the device with the set serial number. If you want to add the serial number automatically through a download process, you must specify a copy protection password. This password is queried during a download process of the block. You can change the password without having to remove the know-how protection of the block. When you change the copy protection settings or remove the copy protection, the password is retained until the next compilation process.

It is important that you also know-how-protect any block for which you have set up copy protection. If you do not, anyone can reset the copy protection.

Note

S7-1500 and S7-1200 V2.2 and higher: If you download a copy protected block to a device that does not match the specified serial number, the entire download operation will be rejected. This means that blocks without copy protection, too, will not be downloaded.

Setting up copy protection

To set up copy protection for a block, follow these steps:

1. Open the properties of the block for which you wish to set up copy protection.
2. Select the "Protection" entry in the area navigation in the block properties.
3. Select either "Bind to serial number of the CPU" or "Bind to serial number of the memory card" from the drop-down list in the "Copy protection" area.
4. Enter either the serial number directly or enable the option "Serial number inserted when downloading to a device or memory card" if the serial number is to be inserted automatically when you load.
   Continue with step 7 if you have entered the serial number directly. If the serial number is to be added automatically during the download process, you must also execute steps 5 and 6.
5. Click "Define password".
   The "Define protection" dialog opens.
6. If you are using manual password input, enter the password in the fields "New password" and "Confirm password".

7. If you are using a password provider, first select the password provider and then the password.
8. Confirm your entries with "OK".
   The status box provides the information that a copy protection password is defined.
9. You can now set up the know-how protection for the block in the "Know-how protection" area, if the block does not already have know-how protection.

Removing copy protection

To remove copy protection, follow these steps:

1. Open the properties of the block for which you wish to remove copy protection.

   Note

   If the block has know-how protection, you must open the block with the correct password in order to be able to change the copy protection settings.

2. Select the "Protection" entry in the area navigation in the block properties.
3. Select "No binding" in the drop-down list in the "Copy protection" area.

11.7.7 Setting up and removing block write protection

You can set up write protection for blocks of the type OB, FB, FC to prevent them from being changed unintentionally. Blocks with write protection can only be opened as "read only", the block properties can however still be edited.

Please note that write protection is not know-how protection, as you can remove write protection again at any time. If a block is write-protected, you cannot additionally set up know-how protection. Remove the write protection for the block if you want to set up know-how protection for it.

Setting up write protection

To set write protection for a block, follow these steps:

1. Open the properties of the block for which you wish to set up write protection.
2. Select the "Protection" entry in the area navigation in the block properties.
3. In the area "Write protection" select "Define password".
   The "Define protection" dialog opens.
4. If you are using manual password input, enter the password in the fields "New password" and "Confirm password".
5. If you are using a password provider, first select the password provider and then the password.
6. Confirm your entries with "OK".
   The status box provides the information that a write protection password is defined. The text of the button changes to "Change password".
7. Select the "Write protection" check box.
   The "Access protection" dialog will open.
8. Enter the correct password or select the correct password if you are using a password provider.
   Write protection is enabled and will be active the next time the block is opened.

Disabling write protection

Proceed as follows to disable write protection:

1. Open the properties of the block for which you wish to disable write protection.
2. Select the "Protection" entry in the area navigation in the block properties.
3. In the area "Write protection" select the "Write protection" check box.
   The "Access protection" dialog will open.
4. Enter the correct password or select the correct password if you are using a password provider.
   The write protection for the block is disabled the block can be edited again the next time the block is opened. The password is retained, so that you can enable write protection again at any time.

Enable write protection.

Proceed as follows to enable write protection:

1. Open the properties of the block for which you wish to enable write protection.
2. Select "Protection" in the area navigation in the inspector window.
3. In the area "Write protection" select the "Write protection" check box.
   The "Access protection" dialog will open.
4. Enter the correct password or select the correct password if you are using a password provider.
   The write protection for the block is reset and will be active the next time the block is opened.

Changing the write protection password

To change the write protection password, follow these steps:

1. Open the properties of the block for which you wish to change the write protection password.
2. Select the "Protection" entry in the area navigation in the block properties.
3. Click the "Change password" button.
   The "Change protection" dialog opens.
4. If you are using manual password input, enter the old password in the field "Old password" and the new password in the field "New password". Also enter the new password in the "Confirm password" box
5. If you are using a password provider, first select the password provider and then the new password.
6. Confirm your entries with "OK".
   The write protection password for the block is changed.

Note

It is always possible to change the write protection password for the block. This depends on whether write protection is active or not.

Removing write protection

To set write protection for a block, follow these steps:

1. Open the properties of the block for which you wish to remove write protection.
2. Select the "Protection" entry in the area navigation in the block properties.
3. Click the "Change password" button.
   The "Change protection" dialog opens.
4. If you are using manual password input, enter the current password in the field "Old password".
5. If you are using a password provider, first select the password provider and then the current password.
6. Click "Remove"
   The write protection for the block is removed. Unlike deactivation of write protection, the password is also deleted.

11.7.8 Setting up block know-how protection

You can set up know-how protection for blocks in the devices in your project.

Procedure

To set up block know-how protection, follow these steps:

1. Select the blocks with no know-how protection which you want to protect.
2. Select the command "Know-how protection" in the "Edit" menu.
   The "Define protection" dialog opens.
3. If you are using manual password input, enter the password in the fields "New password" and "Confirm password".
4. If you are using a password provider, first select the password provider and then the password.
5. Confirm your entries with "OK".
6. Close the "Define protection" dialog with "OK".

Result

The blocks selected will be know-how-protected. Know-how protected blocks are marked with a lock in the project tree. The password entered is valid for all blocks selected.

Changing a password (Page 4761)

Removing block know-how protection (Page 4762)

11.7.9 Opening know-how protected blocks

If the use of a password provider is set as the type of password assignment, the TIA Portal connects to the password provider when a protected block is opened. If the connection is successful, there is no need to enter a password. If the password provider is not available, you can only open the block fully if you had defined manual input as the fallback strategy and know the corresponding password. The name of the password is not sufficient here.

You can only open multiple know-how protected blocks at once if they are protected with the same password.

Requirement

- "Manual password input" is set as the type of password assignment.
- "Selection via password provider with manual input as fallback strategy for access" is set and there is no connection to the password provider.

Procedure

To open a know-how protected block, follow these steps:

1. Double-click on the block you wish to open.
   The "Access protection" dialog will open.
2. Enter the password for the know-how protected block.
3. Confirm your entry with "OK".

Result

The know-how protected block will open provided you have entered the correct password. However, the block will remain know-how protected. If you copy the block or add it to a library, for example, the copies will also be know-how protected.

Once you have opened the block, you can edit the program code and the block interface of the block for as long as the block or TIA Portal is open. The password must be entered again the next time the block is opened. If you close the "Access protection" dialog with "Cancel", the block will open but the block code will not be displayed and you will not be able to edit the block.

11.7.10 Printing know-how protected blocks

You can only print complete know-how protected blocks if they have been opened with the correct password. If you print a closed block or if the block was not opened with the correct password, only the non-protected block data will be printed.

Procedure

To print a know-how protected block in full, follow these steps:

1. Open the know-how protected block you wish to print.
   See also: Opening know-how protected blocks (Page 4759)
2. Select the "Print" command in the "Project" menu.
   The "Print" dialog will open.
3. Select the printer in the "Name" field.
4. Click "Advanced" to modify the Windows printer settings.
5. Select the documentation information set in the "Document information" drop-down list that you want to use for the frame layout.
6. Under "Print objects/area" select whether you want to print all objects or the complete area, or only a selection.
7. Under "Properties" select the print scope.
   - Select "All" to print the complete block.
   - Choose "Visible" to print all the information within the block that is visible on the screen.
   - Select "Compact" to print a shortened form of the block.

8. Click "Preview" to generate a print preview in advance.
   A print preview is created in the work area.
9. Click "Print" to start the printout.

11.7.11 Changing a password

If you are using a password provider, whether you are able to change the password for know-how protected blocks depends on the specifications of the password provider.

Procedure

To change the password, follow these steps:

1. Select the know-how protected blocks for which you want to change the password.

   Note

   You can only change the password for several blocks at once if all blocks selected have the same password.

2. Select the command "Know-how protection" in the "Edit" menu.
   The "Change protection" dialog opens.
3. If you are using manual password input, enter the old password in the field "Old password" and the new password in the field "New password". Also enter the new password in the "Confirm password" box
4. If you are using a password provider, first select the password provider and then the new password.
5. Close the "Change protection" dialog with "OK".

11.7.12 Removing block know-how protection

If you are using a password provider, whether you are able to remove the know-how protection of a block depends on the specifications of the password provider.

Procedure

To remove block know-how protection, follow these steps:

1. Select the blocks for which you want to remove know-how protection.

   Note

   You can only remove know-how protection for several blocks at once if all blocks selected have the same password.

2. Select the command "Know-how protection" in the "Edit" menu.
   The "Change protection" dialog opens.
3. If you are using manual password input, enter the password for know-how protection of the block in the field "Old password". This is not required if you are using a password provider.
4. Click the "Remove" button.

Result

Know-how protection will be disabled for the blocks selected.

11.8 Declaring the block interface

11.8.1 Overview of the block interface

Introduction

The interface contains the declarations of local variables and constants that are used within the block. The variables are subdivided into two groups:

- Block parameters that form the block interface when it is called in the program.
- Local data that are used for storage of intermediate results.

You use the variable declaration to define the call interface of a block in the program and the names and data types of variables and constants that you want to use in the block.

The interface of function blocks also defines the structure of the instances that are assigned to the function block.

Block parameters

The following table shows the types of block parameters:

Type	Section	Function	Available in
Input parameters	Input	Parameters whose values are read by the block.	Functions, function blocks and some types of organization blocks
Output parameters	Output	Parameters whose values are written by the block.	Functions and function blocks
In/out parameters	InOut	Parameters whose values are read by the block when it is called, and whose values are written again by the block after execution.	Functions and function blocks
Return value	Return	Value that is returned to the calling block.	Functions

Depending on the type of block opened, additional sections may be displayed.

Local data

The following table shows the types of local data:

Type	Section	Function	Available in
Temporary local data	Temp	Tags that are used to store temporary intermediate results. Temporary local data are retained for only one cycle. If you use temporary local data, you have to make sure that the values are written within the cycle in which you want to read them. Otherwise the values will be random.	Functions, function blocks and organization blocks **Note**: Temporary local data is not shown in instance data blocks.
Static local data	Static	Tags that are used for storage of static intermediate results in the instance data block. Static data is retained until overwritten, which may be after several cycles. The names of the blocks, which are called in this code block as multiple instance, will also be stored in the static local data.	Function blocks
Constant	Constant	Constants with declared symbolic names that are used within the block.	Functions, function blocks and organization blocks **Note**: Local constants are not shown in instance data blocks.

11.8.2 Rules for declaring the block interface

11.8.2.1 General rules for declaring the block interface

Using block parameters

The following rules apply to the use of block parameters within the block:

- Input parameters may only be read.
- Output parameters may only be written.
- In/out parameters may be read and written.

Note

Maximum number of parameters per block

The maximum permitted number of formal parameters is sufficient for all usual application scenarios. The exact number depends on the selected data types, declaration subsections and other factors.

If the maximum number is exceeded, you receive a message during the compilation process. In this case, you can combine several parameters in a PLC data type (UDT) or in a global data block (DB) and transfer this as a block parameter.

Assigning default values to block parameters

You can assign default values to specific parameters in the function block interface. The possibility of the assignment depends on the declaration subsection and data type of the parameter.

The following table shows which parameters can be assigned a default value:

Parameter type	Section	Assignment of a default value is possible		
		Elementary data types	Structured data types	Parameter types
Input parameters	Input	X	X	-
Output parameters	Output	X	X	-
In/out parameters	InOut	X	- (1)	-
Static local data	Static	X	X	-
Temporary local data	Temp	-	-	-
Constants	Constant	X	-	-

(1) Exception: In blocks with optimized access, you have the option to use PLC data types as default values under certain conditions.

Note

You can find more information on permissible characters in tag names in the Siemens Industry Online Support in the following entries:

When should identifiers and operands be used in "quotation marks" in STEP 7 (TIA Portal)?

https://support.industry.siemens.com/cs/ww/en/view/109477857 (https://support.industry.siemens.com/cs/ww/en/view/109477857)

Declaring predefined actual parameters (Page 4783)

11.8.2.2 Valid data types in the block interface (S7-300, S7-400)

Valid data types in the block interface in S7-300/400

The following table shows which data types you can assign to the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING DT	Parameter types	VOID	POINTER	ANY
Organization block						
Temp	X	X	-	-	-	X
Constant	X	X (3)	-	-	-	-
Function block						
Input	X	X	X	-	X	X
Output	X	X	-	-	-	-
InOut	X	X (1)	-	-	X	X
Static	X	X	-	-	-	-
Temp	X	X	-	-	-	X
Constant	X	X (3)	-	-	-	-
Function						
Input	X	X (1)	X	-	X	X
Output	X	X (1)	-	-	X	X
InOut	X	X (1)	-	-	X	X
Temp	X	X	-	-	-	X
Return	X	X	-	X	X	X (2)
Constant	X	X (3)	-	-	-	-

(1) STRING can only be defined in the standard length of 254 characters.

(2) In SCL, ANY is not permitted as a function value.

(3) Constants with the ARRAY or STRUCT data type are not permitted.

11.8.2.3 Valid data types in the block interface (S7-1200, S7-1500)

Valid data types in the block interface in S7-1200

The following table shows which data types you can assign in the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	ARRAY [*]	VOID	VARIANT
Organization block					
Temp	X	X	-	-	X
Constant	X	X (1) (2)	-	-	-
Function block					
Input	X	X	-	-	X
Output	X	X	-	-	-
InOut	X	X (1)	X (4)	-	X
Static	X	X	-	-	-
Temp	X	X	-	-	X
Constant	X	X (1) (2)	-	-	-
Function					
Input	X	X (1)	X (4)	-	X
Output	X	X (1)	X (4)	-	X
InOut	X	X (1)	X (4)	-	X
Temp	X	X	-	-	X
Return	X	X (3)	-	X	-
Constant	X	X (1) (2)	-	-	-

(1) You cannot make length declarations for STRING and WSTRING in these sections. STRINGs always have the standard length 254; WSTRINGs the standard length 16832. A declaration in the format MyString[3] would not be permitted. WSTRING is only permitted in blocks with optimized access in these sections.

(2) Constants with the ARRAY or STRUCT data type are not permitted.

(3) Function values of the WSTRING data type must not be longer than 1022 characters.

(4) ARRAY[*] is available in blocks with optimized access as of firmware V4.2.

Valid data types in the block interface in S7-1500

The following table shows which data types you can assign in the parameters in the individual sections of the interface.

Section	Standard Data types	ARRAY STRUCT STRING / WSTRING DT	AR-RAY[*]	Parame-ter types	VOID	DB_ANY	POINT-ER	ANY	VAR-IANT
Organization block									
Temp	X	X	-	- (4)	-	X	-	X (3)	X
Constant	X	X (1) (5)	-	-	-	-	-	-	-
Function block									
Input	X	X	-	X	-	X	X	X	X
Output	X	X	-	-	-	X	-	-	-
InOut	X	X (1)	X(7)(8)	- (4)	-	X	X	X	X
Static	X	X	-	-	-	X	-	-	-
Temp	X	X	-	- (4)	-	X	-	X (3)	X
Constant	X	X (1) (5)	-	-	-	-	-	-	-
Function									
Input	X	X (1)	X (7)	X	-	X	X	X	X
Output	X	X (1)	X (7)	-	-	X	X	X	X
InOut	X	X (1)	X (7)	- (4)	-	X	X	X	X
Temp	X	X	-	- (4)	-	X	-	X (3)	X
Return	X	X (6)	-	-	X	X	X	x (2)	-
Constant	X	X (1) (5)	-	-	-	-	-	-	-

(1) You cannot make length declarations for STRING and WSTRING in these sections. STRINGs always have the standard length 254; WSTRINGs the standard length 16832. A declaration in the format MyString[3] would not be permitted. WSTRING is only permitted in blocks with optimized access in these sections.

(2) In SCL, ANY is not permitted as a function value.

(3) ANY can only be used in blocks with standard access in the "Temp" section.

(4) The "INSTANCE" parameter type is the only exception permissible in the "TEMP" and "InOut" sections.

(5) Constants with the ARRAY or STRUCT data type are not permitted.

(6) Function values of the WSTRING data type must not be longer than 1022 characters.

(7) ARRAY[*] is available in blocks with optimized access as of firmware V2.0.

(8) ARRAY[*] is only available when the "Set in IDB" attribute is not set.

11.8.2.4 Setting the retentivity of local tags

Introduction

Function blocks store their data in an instance. To prevent data loss in the event of power failure, you can mark the data as retentive. This data is stored in a retentive memory area. The option of setting the retentivity depends on the set access type of the function block.

Retentive behavior in blocks with standard access

In blocks with standard access you cannot set the retentive behavior of individual tags. You can only define them as retentive in the assigned instance. All tags contained in the block are then considered as retentive.

Retentivity for optimized block access

In data blocks with optimized access you can define the retentive behavior of individual tags.

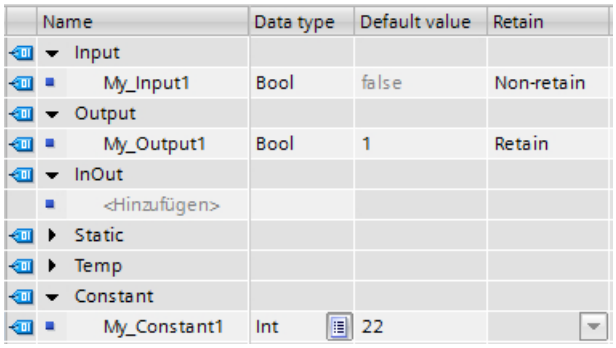
For structured data type tags, the retentivity setting always applies to the entire structure. You can make no individual retentivity setting for individual elements within the structure.

You cannot create retentive tags of the structured data type in the "InOut" section. In/out parameters with structured data type, for example ARRAY, STRUCT, or STRING, are always non-retentive.

The following settings are available:

- Retentive
  The values of the tags or the structure are available even after a power failure.
- Non-retentive
  The values of the tags or the structure are lost in the event of a power failure.
- Set in IDB
  The retentivity can be set in the instance data block. The setting that is made in the instance data block than applies, however, centrally to all tags that are selected with "Set in IDB".

See also



Properties of local tags and constants (Page 4784)

11.8.3 Declaring the block interface

11.8.3.1 Layout of the block interface

Layout of the block interface

The following figure shows the structure of the block interface. The number of columns and sections varies depending on the type of block.

Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series and the type of the open object.

Column	Explanation
	Symbol you can click on to drag-and-drop an element to a program for use as an operand.
Name	Name of the element.
Data type	Data type of the element.
Offset	Relative address of a tag within the block. The column is only visible in blocks with standard access. Note: Many instructions from the SIMATIC system libraries have the "optimized block access" property and therefore do not occupy any fixed memory addresses. No offset is displayed for these instructions, even if you use them as multi-instance in a block with standard access.

Column	Explanation
Default value	Value with which you can preassign specific tags in the interface of the code block, or the value of a local constant. Specification of the default value is optional for tags. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL. The default value of a tag is applied as the start value in the corresponding instance data block. You can replace these values with instance-specific start values in the instance data block. Constants always have the default value declared in the block interface. They are not shown in instance data blocks and cannot be assigned instance-specific values there.
Retain	Marks a tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This column is only visible in the interface of the function block with optimized access.
Visible in HMI engineering	Indicates whether a tag is visible by default in the HMI selection list.
Accessible from HMI/OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime.
Writable from HMI/OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.
Setpoint value	Marks a tag as a setpoint value Setpoint values are the values that will probably have to be fine tuned during commissioning. The column is only available in the interface of function blocks.
Supervision	Indicates whether Supervision has been created for process diagnostics for the tag.
Comment	Comments on documentation of the element.

Valid data types in the block interface (Page 4768)

Setting the retentivity of local tags (Page 4769)

Using setpoints during commissioning (Page 4831)

11.8.3.2 Declaring local tags and constants in the block interface

Requirement

The block interface is open.

Procedure

To declare a tag or constant of the elementary data type, follow these steps:

1. Select the desired declaration section in the block interface.
   You must declare a constant in the "Constant" section.
2. Enter a name for the element in the "Name" column.

3. Enter the required data type in the "Data type" column. You will be supported by Autocomplete during input.
4. For constants, enter a value in the "Default value" column.
5. Optional: Change the properties that are displayed in the other columns of the block interface.

Result

The element is created.

Syntax check

A syntax check is performed after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. However, you will not be able to compile the program if the tag declaration contains syntax errors.

Note

If you change the interface of a block, the calls of the block in the program will possibly become inconsistent. The call locations are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent blocks have to be updated manually.

See also:

Updating block calls in LAD (Page 4900)

Updating block calls in FBD (Page 4957)

See also

Rules for declaring the block interface (Page 4765)

Setting the retentivity of local tags (Page 4769)

Hiding parameters during the block call (Page 4782)

Declaring predefined actual parameters (Page 4783)

Properties of local tags and constants (Page 4784)

11.8.3.3 Declaring a local tag in the program editor

Requirement

The program editor is open.

Procedure

To declare a local tag, follow these steps:

1. Insert an instruction in your program.
   The "<???>", "<??.?>" or "..." strings represent operand placeholders.
2. Replace an operand placeholder with the name of the tag to be created.
3. Select the name of the element.
   If you want to declare multiple elements, select the names of all the elements to be declared.
4. Select the "Define tag" command in the shortcut menu.
   The "Define tag" dialog box opens. It displays a declaration table in which the name of the element is already entered.
5. To declare a local tag, select one of the following sections:
   - Local In
   - Local Out
   - Local InOut
   - Local Static
   - Local Temp
6. In the other columns, enter data type and comments.
7. Click the "Define" button to complete your entry.

Result

The declaration is written directly into the block interface and is valid within the entire block.

Note

If you change the interface of a block, the calls of the block in the program will possibly become inconsistent. The call locations are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent blocks have to be updated manually.

Properties of local tags and constants (Page 4784)

Setting the retentivity of local tags (Page 4769)

Edit table of the block interface (Page 4788)

Rules for declaring the block interface (Page 4765)

11.8.3.4 Declaring tags of the ARRAY data type

Requirement

The block interface is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter a tag name in the "Name" column.
3. In the "Data type" column, click the button for the data type selection.
   A list of the permissible data types is opened.
4. Select the "Array" data type.
   The "Array" dialog opens.
5. In the "Data type" text box, specify the data type of the array elements.
6. In the "ARRAY limits" input field, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `Array[0..3] of Bool`
   Example of a three-dimensional ARRAY:
   `Array[0..3, 0..15, 0..33]of Bool`
   Example of a one-dimensional ARRAY with variable limits:
   `Array[*]of Bool`
   Example of a three-dimensional ARRAY with variable limits:
   `Array[*, *, *]of Bool`
   Example of a one-dimensional ARRAY with local constants as ARRAY limits
   `Array[#My_local_const1..#My_local_const2]of Bool`
   Example of a one-dimensional ARRAY with global constants as ARRAY limits
   `Array["My_global_const1".."My_global_const1"]of Bool`
7. Confirm your entry.
8. Optional: Change the properties of the tags that are displayed in the other columns of the block interface.

The tag of ARRAY data type is created.

Note

Availability of ARRAY[*]

ARRAY[*] is available in optimized blocks for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. In functions (FC) you can use ARRAY[*] in all declaration subsections. In function blocks (FB) you can declare ARRAY[*] only as an in-out parameter in the "InOut" section.

Entering default values of ARRAY elements

To pre-assign default values to the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the desired values in the "Default value" column.

Adding comments for ARRAYs

To add a comment for the entire ARRAY, enter the comment in the top line of the ARRAY declaration. The comment is used as a preset comment for all lower-level ARRAY elements.

To provide specific comments for the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the desired values in the "Comment" column.

Note

Restriction when displaying ARRAY elements

Depending on the amount of work memory available on your computer, the following maximum limits apply when displaying ARRAYs:

- RAM < 8 GB: A maximum of 10,000 elements are displayed.
- RAM >= 8 GB: A maximum of 40,000 elements are displayed.

11.8.3.5 Declaring tags of STRUCT data type

Requirement

The block interface is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter a tag name in the "Name" column.
3. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
4. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
5. Select a data type for the structure element.
6. Optional: Change the properties of the structural element that is displayed in the other columns of the block interface.
7. Repeat the step 4 to 7 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
8. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

Note

S7-1500: A maximum of 252 structures in one data block

A maximum of 252 structures is permitted in one data block. If you need additional structures, you must restructure your program. You can, for example, create the structures in several global data blocks.

11.8.3.6 Declare variables of the STRING and WSTRING data types

Requirement

The block interface is open.

Procedure

To declare a variable the STRING or WSTRING data type, proceed as follows:

1. Select the appropriate declaration section in the interface.
2. Enter a variable name in the "Name" column.
3. Enter "STRING" or "WSTRING" in the "Data type" column. You will be supported by autocompletion during input.
4. Optional: Specify the maximum length of the string using square brackets after the keyword STRING or WSTRING. If you do not specify a maximum length, the string has a default length of 254 characters.
   Example of a WSTRING with the maximum length of 4:
   `WSTRING[4]`
   Example of a string whose maximum length is defined by a local constant:
   `STRING[#My_local_const1]`
   Example of a string whose maximum length is defined by a global constant:
   `STRING["My_global_const1"]`

Result

The variable of the STRING or WSTRING data type is applied.

11.8.3.7 Declaring tags based on a PLC data type

Requirement

A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a PLC data type, follow these steps:

1. Select the appropriate declaration section in the interface.
2. Enter the PLC data type in the "Data type" column. You will be supported by Autocomplete during input.
   The tag is created.
3. If you have already defined default values or comments for the tags within a PLC data type during declaration of the PLC data type, these are shown in gray. You can change these values in the block interface.
   The changed values are displayed in black and apply only to the specific point of use.

Note

If you change or delete PLC data types that are used in the block interface, the interface becomes inconsistent. To eliminate this inconsistency, you must recompile the program.

Editing tables (Page 278)

11.8.3.8 Declaring higher-level tags

Introduction

To access data areas within a declared tag, you can overlay the declared tags with an additional declaration. This provides you with the option of addressing an already declared tag with a different data type. You can, for example, address the individual bits of a tag of WORD data type with an ARRAY of BOOL.

Overlaying tags

To overlay a tag with a new data type, follow these steps:

1. Open the block interface.
2. In the interface, select the tag that you want to overlay with a new data type.
3. Click "Add row" in the toolbar.
   A row is inserted after the tag to be overlaid. The overlaying tag must be declared in the row directly after the tag that is to be overlaid.
4. Enter a tag name in the "Name" column.

5. Enter the "AT" entry in the "Data type" column. You will be supported by Autocomplete in this step.
   The following is added to the entry in the "Name" column.
   "AT<Name of the higher-level tag>"
6. Click the data type selection button again and select the data type for the new tag.
   The tag is created. It points to the same data as the higher-level tag, however interprets this data with the new data type.

Removing overlay

To remove the overlay of a tag, follow these steps:

1. Select the overlaid tag that you want to remove.
2. Select the "Delete" command in the shortcut menu.
3. The overlay is removed.

Editing tables (Page 278)

11.8.3.9 Declaring multi-instances

Requirement

- The function block to be called exists in project tree and is multi-instance capable.
- The block interface of the calling function block is open.

Declaring a multi-instance

To declare a function block to be called as a multi-instance, follow these steps:

1. In the "Name" column of the "Static" section, enter a designation for the block call.
2. In the "Data type" column, enter the symbolic name for the function block to be called.

Note

The program editor will declare the multi-instance automatically if you program a block call in a network and then specify in the "Call options" dialog that you want to call the block as a multiple instance.

Declaring multi-instances as ARRAY

To declare an ARRAY of multi-instances, follow these steps:

1. In the "Name" column of the "Static" section, enter a designation for the ARRAY.
2. Select the "Array" data type in the "Data type" column.
   The "Array" dialog opens.
3. In the "Data type" input field, enter the name of the function block for which an instance should be defined. The block name must be in quotation marks.
4. In the "ARRAY limits" input field, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:[0..3]
   Example of a three-dimensional ARRAY:[0..3, 0..15, 0..33]
5. Confirm your entry.

Updating the block interface (Page 4791)

11.8.3.10 Declaring parameter instances

Introduction

The following table shows the options for declaring and using parameter instances in the block interface:

Declaration	Block type	Application
InOut	FB FC	You can then call the instance that you transfer as actual parameter within the function block.
Input	FC	You have read access to the data of the instance that you transfer as actual parameter. However, you cannot call the instance from within the block.
Output	FC	You have write access to the data of the instance that you transfer as actual parameter. However, you cannot call the instance from within the block.

Requirement

- The block interface is open.

Procedure

To declare a parameter instance, follow these steps:

1. Open the required section of the block interface (see table).
2. In the "Name" column, enter a designation for the in/out parameter to which the instance is transferred.
3. In the "Data type" column, enter the name of the function block for which an instance should be defined. The block name must be in quotation marks.

Note

Declaring parameter instances automatically

The program editor will declare the parameter instance automatically if you program a block call in a network and then specify in the "Call options" dialog that you want to call the block as a parameter instance.

11.8.3.11 Hiding parameters during the block call

Introduction

You can hide the block parameters when calling the block in LAD or FBD. Hidden parameters are not visible initially, but can be displayed via a small arrow at the bottom edge of the call box.

Two options are available for hiding a parameter:

- Hide
  The parameter is always hidden.
- Hide, if no parameter is assigned
  The parameter is hidden as long as it has not yet been interconnected. If you assign an actual parameter, the parameter is displayed at the call box.

Procedure

Proceed as follows to define whether a block parameter is to be displayed or hidden during the call:

1. Open the block interface.
2. Select a parameter in the block interface.
3. Open the "Properties" tab in the Inspector window.
4. Select the "Attributes" group in the area navigation.
5. Select one of the following options under "Visibility at block calls in LAD / FBD":
   - "Show"
   - "Hide"
   - "Hide, if no parameter is assigned"

Result

The parameter is displayed or hidden at the block call in LAD or FBD depending on the setting.

If a syntax error is found during the block call, the parameter cannot be hidden.

See also

Wiring hidden parameters (Page 4914)

Declaring predefined actual parameters (Page 4783)

11.8.3.12 Declaring predefined actual parameters

Introduction

You can specify during the declaration of a block parameter which actual parameter is to be used during the block call.

This can be useful if you are using program blocks as library elements and want to store information about the actual parameters to be used along with the library element.

In addition you have the option in LAD and FBD to hide parameters that have a valid predefined actual parameter during the block call. Hidden parameters are not visible initially, but can be displayed via a small arrow at the bottom edge of the call box.

Two options are available for hiding a predefined parameter:

- The parameter is always hidden.
- The parameter is hidden as long as the predefined actual parameter is assigned. However, when a different parameter is assigned, the parameter becomes visible.

Requirement

- The parameter is located in the section "Input", "Output" or "InOut".

Procedure

Proceed as follows to predefine an actual parameter:

1. Open the block interface.
2. Select a parameter in the block interface.
3. Open the "Properties" tab in the Inspector window.
4. Select the "Attributes" group in the area navigation.
5. Enter the required actual parameter in the "Predefined actual parameter" input box.
   Optional:
6. Select the "Hide" option under "Visibility at block calls in LAD / FBD".
7. As an additional option, select "Show if parameter assigned on block call is not identical to the predefined actual parameter". This option is only available if the "Hide" option was activated beforehand.

Result

- An actual parameter is predefined. If you save the program block as a library element, it thus also contains information about the actual parameter to be used.
- If the library element is used in the program, a check is made to determine whether the actual parameter you have predefined can be addressed. If so, it is automatically used as the actual parameter.
- If the actual parameter If the actual parameter is not found in the program, a syntax error is signaled and you have to carry out the parameter assignment manually. Parameters with an invalid assignment are not hidden.

Hiding parameters during the block call (Page 4782)

11.8.3.13 Editing the properties of local tags and constants

Properties of local tags and constants

Properties

The table below provides an overview of the properties of local tags and constants:

Group	Property	Description
General	Name	Name of the element.
	Data type	Data type of the element.
	Default value	Value with which you can pre-assign specific tags in the interface of the code block, or the value of a local constant. Specification of the default value is optional for tags. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL. The default value of a tag is applied as the start value in the corresponding instance. You can then replace these adopted values with instance-specific start values.
	Comment	Comment for the element.

Group	Property	Description
Attributes	Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This attribute is only available in the interface of the function block with optimized access.
	Visible in HMI engineering	Shows whether the tag is visible by default in the HMI selection list.
	Writable from HMI/ OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.
	Accessible from HMI/OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime. Please note, however, that you cannot implement general access protection for the tag with the "Accessible from HMI/OPC UA" attribute. Read or write access from other applications is possible even if the attribute is not enabled.
	Visibility at block calls in LAD/FBD	Show: The parameter is always visible at block calls in LAD or FBD.
		Hide: The parameter is always hidden at block calls in LAD or FBD. The instruction box then has a small arrow on the lower edge. You can have the parameters displayed and interconnect them by clicking this arrow.
		Hide if no parameter is assigned: The parameter is always hidden at block calls in LAD or FBD as long as it has not yet been interconnected. If you assign an actual parameter, the parameter is displayed at the call box.
	Predefined actual parameter	Defines a parameter that is to be used as actual parameter during the block call.
	Show if the assigned actual parameter is not identical with the predefined actual parameter	The parameter is hidden at block calls in LAD or FBD as long as the predefined actual parameter has not yet been assigned. However, when a different parameter is assigned, the parameter becomes visible. This option is only active if you have selected the "Hide" parameter and have defined a predefined actual parameter.

Group	Property	Description
User-defined attributes	CFC_Configurable	Configurable Indicates whether a parameter is configurable in CFC.
	CFC_ForTest	For test Indicates whether a parameter is registered for the CFC test mode.
	CFC_Visible	Visible Indicates whether a parameter is visible in CFC.
	CFC_Interconnectable	Interconnectable Indicates whether a parameter is interconnectable in CFC.
	CFC_EnableTagReadback	Enable tag readback Indicates whether a parameter is relevant for the "Read back chart" function in CFC.
	CFC_EnumerationTexts	Enumeration texts Assigns a parameter to an enumeration in CFC.
	CFC_EngineeringUnit	Engineering unit Assigns a parameter to a unit in CFC.
	CFC_LowLimit	Low limit Defines the low limit for the parameter in CFC.
	CFC_HighLimit	High limit Defines the high limit for the parameter in CFC.

Changing properties of local tags and constants

Editing properties of an element in the block interface

To edit the properties of an element in the block interface, follow these steps:

1. Open the block interface.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the block interface

You can also simultaneously set or reset some properties for multiple selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the block interface.
2. Hold down the CTRL key.
3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag or constant, follow these steps:

1. Select an element in the table.
   The properties of the element are shown in the Inspector window.
2. Change the entries in the inspector window.

Renaming tags directly in the program editor

To rename one or more elements, follow these steps:

1. Select one or more elements in the program.
2. Select the "Rename tag" command in the shortcut menu.
   The "Rename tag" dialog opens. It displays a declaration table with the selected elements.
3. Change the entries in the "Name" column.
4. Confirm the input by clicking the "Change" button.

Editing the data type or comment in the program editor

Proceed as follows to edit the data type or tag comment in the program editor:

1. Select the name of the tag.
2. Select the "Rewire tag" command in the shortcut menu.
   The "Rewire tag" dialog will open. The dialog shows a declaration table.
3. Change the entry in the "Data type" or "Comment" columns.
4. Click the "Change" button to confirm the input.

Effect in the program

In case of a change of the name, data type or address of a tag or constant, each location of use of the tag is automatically updated in the program.

Note

If you change the interface of a block, the program may become inconsistent. The inconsistencies are automatically updated, if possible.

If an automatic updating is not possible, the inconsistent calls are marked in red. You than have to manually updated the inconsistencies.

Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

See also

Editing tables (Page 278)

Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

See also

Editing tables (Page 278)

Deleting tags

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

See also

Editing tables (Page 278)

Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

See also

Editing tables (Page 278)

Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

Editing tags with external editors

To edit individual tags in external table editors, such as Excel, you can export or import these tags using copy and paste.

Note

Restriction when displaying and copying ARRAY elements

Depending on the amount of work memory available on your computer, the following maximum limits apply when displaying and copying ARRAYs from the block interface in an Excel table:

- RAM < 8 GB: A maximum of 10,000 elements are displayed and copied.
- RAM >= 8 GB: A maximum of 40,000 elements are displayed and copied.

Requirements

The block interface and an external editor are opened.

Procedure

To export individual tags to an external editor and import them again, follow these steps:

1. Click the "Expanded mode" button to show all elements of structured data types.
2. Select one or more tags.
3. Select "Copy" in the shortcut menu.
4. Switch to the external editor and paste the copied tags.
5. Edit the tags as required.
6. Copy the tags in the external editor.
7. Select the tags in the external editor.
8. Switch back to the block interface.
9. Select "Paste" in the shortcut menu.

11.8.4 Updating the block interface

Introduction

If you change or delete PLC data types or multiple instances that are used in the block interface, the interface will become inconsistent. To remedy this inconsistency, the interface has to be updated.

You have two options for updating the block interface:

- Explicit updating of the block interface.
  The used PLC data types and multiple instances will be updated. The instance data blocks that belong to the block are not implicitly updated during this process.
- Implicit updating during compilation.
  All used PLC data types and multiple instances as well as the related instance data blocks will be updated.

Explicit updating of the block interface

To explicitly update the block interface, follow these steps:

1. Open the block interface.
2. Select the "Update" command in the shortcut menu.

Implicit Updating during Compilation

Proceed as follows to implicitly update all uses of PLC data types and multiple instances as well as the instance data blocks during compilation:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

11.8.5 Extending the block interface (S7-1200, S7-1500)

Description

In order to enable the editing of PLC programs that have already been commissioned and that are running without error on a system, CPUs of the S7-1500 series and most CPUs of the S7-1200 V4 and higher series support the option of extending the interfaces of function blocks during runtime.

You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

This is a simple means of implementing program changes. This load process (download without reinitialization) will not have a negative impact on the controlled process.

Principle of operation

Each function block is always assigned a default memory reserve. The memory reserve is not used initially. Activate the memory reserve if you decide on loading interface changes after having compiled and downloaded the block. All tags that you subsequently declare will be saved to the memory reserve. The subsequent download does not influence any tags that are already loaded or have a negative impact on runtime.

If you decide to review your program at a later time while the plant is not in operation, you are also provided an option of reworking the memory layout of individual or several blocks in a single pass. With this action, you move all tags from the reserve area to the regular area. The memory reserve is now cleared and made available for further interface extensions.

Requirements

This "Download without reinitialization" function is available if the following requirements are met:

- The project is in the "TIA Portal V12" format or a higher version.
- You are working with a CPU that supports "Download without reinitialization".
- The blocks were created in LAD, FBD, STL, or SCL.
- The blocks were created by the user, i.e. they are not included with the blocks delivered in your package.
- These blocks are assigned the optimized access attribute.

Basic steps

Perform the following steps if you want to extend the interface of a function block and then load the block without re-initialization.

1. All blocks have a default memory reserve of 100 bytes. You can adapt this memory reserve to suit your requirements.
2. Activate the memory reserve.
3. Extend the block interface.

4. Compile the block.
5. Download the block to the CPU as usual.

For more information on the various steps, refer to chapter "Loading blocks (S7-1200/1500) ".

Note

The full scope of the "Download without reinitialization" function is only available on CPUs of the S7-1500 and S7-1200 V4 series.

However, all CPU families support the option of extending the interface of function blocks and downloading newly declared tags without repercussion:

- You may add new tags in the "Temp" section and download these without influencing the process.
- You may create new tags of a structured data type in the "InOut" section and download these without influencing the process.

11.9 Programming data blocks

11.9.1 Basic principles for programming of data blocks

A data block (DB) is used to save the values that are written during execution of the program.

In contrast to the code block, the data block contains only tag declarations. It contains no networks or instructions. The tag declarations define the structure of the data block.

Types of data blocks

There are two types of data blocks:

- Global data blocks
  The global data block is not assigned to a code block. You can access the values of a global data block from any code block. A global data block contains only static tags.
  The structure of the global data block can be freely defined. In the declaration table for data blocks, you declare the data elements that are to contained in the global data block.
- Instance data blocks
  The instance data block is assigned directly to a function block (FB). The structure of an instance data block cannot be freely defined, but is instead determined by the interface declaration of the function block. The instance data block contains exactly those block parameters and tags that are declared there.
  However, you can define instance-specific values in the instance data block, for example, start values for the declared tags.

ARRAY data blocks (S7-1500)

ARRAY data blocks are global data blocks that consist of an ARRAY. This ARRAY can be based on any data type. For example, an ARRAY of a PLC data type (UDT) is possible. The DB contains no other elements besides the ARRAY. Because of their flat structure, ARRAY data blocks facilitate access to the ARRAY elements and their transfer to called blocks.

You use ARRAY data blocks to address ARRAYs indirectly: You can determine during runtime which ARRAY DB is read or written and how large it is.

The "Move operations" section of the "Instructions" task card offers options for addressing of ARRAY DBs.

Note

Retentivity of ARRAY data blocks

ARRAY data blocks and their components cannot be set retentively.

See also:

AUTOHOTSPOT

PLC data types as a template for global data blocks

PLC data types can be used as templates for the creation of global data blocks with identical data structures. You create the structure as PLC data type only once and then generate the required data blocks by assigning the PLC data type.

System data types as a template for global data blocks

System data types can also be used as templates for creating global data blocks with identical data structure. System data types already have a pre-defined structure. You insert the system data type in the program only once and then generate additional data blocks with an identical structure by assigning the system data type.

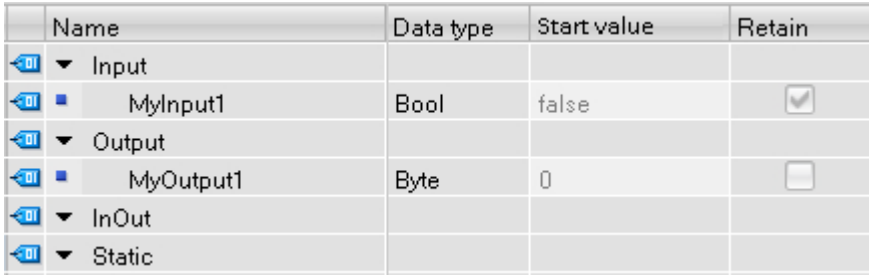
Access modes

There are two different modes of accessing data values in data blocks:

- Data blocks with optimized access (only S7-1200)
  Data blocks with optimized access have no fixed defined structure. In the declaration, the data elements are assigned only a symbolic name and no fixed address within the block. You access the data values in these block via symbolic names.
  The "Optimized block access" attribute is always enabled for ARRAY data blocks.
- Data blocks with standard access (all CPU families)
  Data blocks with standard access have a fixed structure. In the declaration, the data elements are assigned both a symbolic name and a fixed address within the block. You can access the data values in this block via the symbolic names or addresses.
  Data blocks with standard access are tailored to WORD limits. This means that they always occupy one WORD (16 bits) or a multiple thereof. If necessary, tags are automatically added to the data block during compilation so that the block fills the space to the next WORD.
  ARRAY data blocks with standard access are not possible.

Retentivity of data values

To prevent data loss in the event of power failure, you can store the data values in a retentive memory area.



See also

Creating data blocks (Page 4716)

11.9.2 Structure of the declaration table for data blocks

Structure of the declaration table for data blocks

The figure below shows the structure of the declaration table for data blocks. The display will vary depending on type of block and type of access.

Display of instance-specific values

In instance data blocks, you can apply the already defined values from the interface of the assigned function block or define instance-specific start values. Values that are applied from the function block cannot be edited. You can replace the grayed-out values with instance-specific values. Values that were already changed instance specific are not grayed out.

Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series.

Column	Explanation
	Symbol you can click to move or copy the tag. You can, for example, drag-and-drop the tag into a program and use it there as operand.
Name	Name of the tags.
Data type	Data type of the tags.
Offset	Relative address of the tags. The column is only visible in data blocks with standard access. Note: Many instructions from the SIMATIC system libraries have the "optimized block access" property and therefore do not occupy any fixed memory addresses. No offset is displayed for these instructions, even if you use them as multi-instance in a block with standard access.
Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.

Column	Explanation
Start value	Value that the tag should assume at startup. The default values defined in a code block are used as start values during the creation of the data block. You can then replace these adopted values with instance-specific start values. Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as standard for BOOL.
Monitor value	Current data value in the CPU. This column only appears if an online connection is available and you click "Monitor".
Snapshot	Shows values that were loaded from the device.
Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off.
Visible in HMI engineering	Shows whether the tag is visible by default in the HMI selection list.
Accessible from HMI/ OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime.
Writable from HMI/ OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.
Setpoint value	Setpoint values are the values that will probably have to be fine tuned during commissioning. After commissioning, the values of these tags can be transferred to the offline program as start values and stored there.
Supervision	Indicates whether Supervision has been created for process diagnostics for the tag.
Comment	Comment to document the tags.

11.9.3 Creating data blocks

Requirement

The "Program blocks" folder in the project tree is open.

Procedure

To create a data block, follow these steps:

1. Double-click the "Add new block" command.
   The "Add new block" dialog box opens.
2. Click the "Data block (DB)" button.
3. Select the type of the data block. You have the following options available to you:
   - To create a global data block, select the list entry "Global DB".
   - To create an ARRAY data block, select the "ARRAY DB" entry in the list.
   - To create an instance data block, select the function block to which you want to assign the instance data block from the list. The list contains only the function blocks that were previously created for the CPU.
   - To create a data block based on a PLC data type, select the PLC data type from the list. The list contains only the PLC data types that were previously created for the CPU.
   - To create a data block based on a system data type, select the system data type from the list. The list contains only those system data types that have already been inserted to program blocks in the CPU.
4. Enter a name for the data block.
5. Enter the properties of the new data block.
6. If you have selected an ARRAY DB as the data block type, enter the ARRAY data type and the high limit for the ARRAY.
   You can change the high limit for the ARRAY at any time in the property window of the created block. The ARRAY data type cannot be changed subsequently.
7. If you have selected a block that contains monitoring as the "Type", assign a ProDiag function block to the monitoring functions.
8. To enter additional properties of the new data block, click "Additional information".
   An area with further input fields is displayed.
9. Enter all the properties you require.
10. Activate the "Add new and open" check box if the block does not open as soon as it is created.
11. Confirm your entry with "OK".

Result

The new data block is created. You can find the data block in the project tree in the "Program blocks" folder.

Note

Retentivity of ARRAY data blocks

ARRAY data blocks and their components cannot be set retentively.

11.9.4 Updating data blocks

Introduction

Changes in the interface of a function block or a PLC data type can lead to the corresponding data blocks becoming inconsistent. These inconsistencies are marked in red in the declaration table and at the call point of the block. To remedy these inconsistencies, the data blocks must be updated.

You have three options to update block calls:

- Explicit updating in the declaration table for data blocks.
  The data block is updated. Changes from the interface of the assigned function block and changes to the used PLC data types are applied.
- Explicit updating in the program editor.
  The block calls in the open block will be updated. The associated instance data block is also adjusted in the process.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types and the corresponding instance data blocks are updated.

Explicit Updating in the Declaration Table for Data Blocks

To explicitly update an individual data block, follow these steps:

1. Open the data block.
2. Select "Update interface" in the shortcut menu.

Explicit Updating in the Program Editor

To update all block calls or a specific call within a block, follow these steps:

1. Open the block in the program editor.
2. Right-click on the instruction with the block call.
3. Select the "Update" command in the shortcut menu.
4. The "Interface update" dialog opens. This dialog shows the differences between the block interface in use and the changed interface of the called block.
5. If you want to update the block call, click "OK". To cancel the update, click "Cancel".

Implicit Updating during Compilation

To implicitly update all block calls and uses of PLC data types as well as the instance data blocks during the compiling, follow these steps:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

Changing the properties of tags in instance data blocks (Page 4814)

11.9.5 Extending data blocks (S7-1200, S7-1500)

Description

In order to enable the editing of PLC programs that have already been commissioned and that are running without error on a system, CPUs of the S7-1500 series and most CPUs of the S7-1200 V4 and higher series support the option of extending global data blocks during runtime.

You can download the modified blocks without setting the CPU to STOP and without affecting the values of already loaded tags.

This is a simple means of implementing program changes. This load process (download without reinitialization) will not have a negative impact on the controlled process.

Principle of operation

Each data block is always assigned a default memory reserve. The memory reserve is not used initially. Activate the memory reserve if you decide on loading interface changes after having compiled and downloaded the block. All tags that you subsequently declare will be saved to the memory reserve. A subsequent download has no impact on the values of tags that have already been loaded.

If you decide to review your program at a later time while the plant is not in operation, you are also provided an option of reworking the memory layout of individual or several blocks in a single pass. With this action, you move all tags from the reserve area to the regular area. The memory reserve is now cleared and made available for further interface extensions.

Requirements

This "Download without reinitialization" function is available if the following requirements are met:

- The project is in the "TIA Portal V12" format or a higher version.
- You are working with a CPU that supports "Download without reinitialization".
- The blocks were created in LAD, FBD, STL, or SCL.

- The blocks were created by the user, i.e. they are not included with the blocks delivered in your package.
- These blocks are assigned the optimized access attribute.

Basic steps

Perform the following steps if you want to extend the data block and then load the block without re-initialization.

1. All blocks have a default memory reserve of 100 bytes. You can adapt this memory reserve to suit your requirements.
2. Activate the memory reserve.
3. Extend the block interface.
4. Compile the block.
5. Download the block to the CPU as usual.

Reference

For more information on the various steps, refer to chapter "Loading blocks (S7-1200/1500) ".

11.9.6 Creating a data structure for global data blocks

11.9.6.1 Declaring tags of elementary data type

Requirement

A global data block is open.

Note

You cannot change the structure of instance data blocks and of data blocks based on a PLC data type directly, since the structures of these blocks are defined by the respective function block or the PLC data type.

The type of the data block is entered in the block properties.

Procedure

To declare a tag of the elementary data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. In the "Data type" column, click the button for the data type selection.
   A list of the permissible data types is opened.

3. Select the desired data type.
4. Optional: Change the properties of the tags that are displayed in the other columns.
5. Repeat steps 1 to 4 for all tags that are to be declared.

Defining start values (Page 4807)

Setting retentivity (Page 4809)

Online and diagnostic functions for data blocks (Page 4820)

11.9.6.2 Declaring tags of the ARRAY data type

Requirement

A global data block is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the "Array" data type in the "Data type" column. You will be supported by Autocomplete in this step.
   The "Array" dialog opens.
3. In the "Data type" text box, specify the data type of the array elements.
4. In the "ARRAY limits" input field, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `ARRAY [0..3] of Bool`
   Example of a three-dimensional ARRAY:
   `ARRAY[0..3, 0..15, 0..33] of Bool`
   Example of a one-dimensional ARRAY with local constants as ARRAY limits
   `ARRAY[#My_local_const1..#My_local_const2] of Bool`
   Example of a one-dimensional ARRAY with global constants as ARRAY limits
   `ARRAY["My_global_const1".."My_global_const1"] of Bool`
5. Confirm your entry.
6. Optional: Change the properties of the tags that are displayed in the other columns.

The tag is created but remains collapsed. To expand the ARRAY, click the triangle in front of the tag. Not that you cannot expand very large ARRAYs for reasons of clarity.

Note

Restriction when displaying ARRAY elements

Depending on the amount of work memory available on your computer, the following maximum limits apply when displaying ARRAYs:

- RAM < 8 GB: A maximum of 10,000 elements are displayed.
- RAM >= 8 GB: A maximum of 40,000 elements are displayed.

Entering start values of ARRAY elements

To set default start values for the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the required values in the "Start value" column.

Adding comments for ARRAYs

To add a comment for the entire ARRAY, enter the comment in the top line of the ARRAY declaration. The comment is used as a preset comment for all lower-level ARRAY elements.

To provide specific comments for the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the desired values in the "Comment" column.

Setting retentivity (Page 4809)

Editing the declaration table for data blocks (Page 4817)

ARRAY (Page 2286)

Using autocompletion (Page 4706)

11.9.6.3 Declaring tags of STRUCT data type

Requirement

A global data block is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
3. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
4. Select a data type for the structure element.
5. Optional: Change the properties of the structural element that is displayed in the other columns of the block interface.
6. Repeat the step 4 to 7 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
7. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

Enter start values of structure elements

To set default start values for the individual elements of a structure, follow these steps:

1. Click the triangle in front of the STRUCT data type tags.
   The structure opens and the individual structure elements are shown in separate rows.
   Note that, for reasons of clarity, you cannot expand very large structures.
2. Enter the required values in the "Start value" column.

Note

S7-1500: A maximum of 252 structures in one data block

A maximum of 252 structures is permitted in one data block. If you need additional structures, you must restructure your program. You can, for example, create the structures in several global data blocks.

Basic information on STRUCT (Page 2282)

Defining start values (Page 4807)

Setting retentivity (Page 4809)

Editing the declaration table for data blocks (Page 4817)

Using autocompletion (Page 4706)

11.9.6.4 Declaring tags of the STRING data type

Requirement

A global data block is open.

Procedure

To declare a tag of STRING data type, proceed as follows:

1. Select the appropriate declaration section in the interface.
2. Enter a tag name in the "Name" column.
3. Enter "STRING" in the "Data type" column. You will be supported by autocompletion during input.
4. Optional: Specify the maximum length of the string using square brackets after the keyword STRING. If you do not specify a maximum length, the string has a default length of 254 characters.
   Example of a STRING with the maximum length of 4:
   `STRING[4]`
   Example of a string whose maximum length is defined by a local constant:
   `STRING[#My_local_const1]`
   Example of a STRING whose maximum length is defined by a global constant:
   `STRING["My_global_const1"]`

Result

The tag of STRING data type is created.

11.9.6.5 Declaring tags based on a PLC data type

Requirement

- A global data block is open.
- A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a PLC data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the PLC data type in the "Data type" column. You will be supported by Autocomplete during input.

3. The tag is created.
4. Optional: Change the properties of the tags that are displayed in the other columns of the table.
   If you have already defined default values or comments for the tags within a PLC data type during declaration of the PLC data type, these are shown in gray. You can change these values in the block interface.
   The changed values are displayed in black and apply only to the specific point of use.

Note

If you change or delete PLC data types that are being used in the data block, the data block becomes inconsistent. To eliminate this inconsistency, you must recompile the program.

11.9.7 Defining start values

11.9.7.1 Basic information on start values

Definition of "Start value"

The start value of a tag is a value defined by you which the tag assumes after a CPU startup.

The retentive tags have a special status. Their values take the defined start value only after a "cold restart". After a "warm restart", they retain their values and are not reset to the start value.

Definition of "Default value"

The structure of the data blocks can be derived from higher-level elements.

- An instance data block is based, for example, on the interface of a higher-level code block.
- A global data block can be based on a predefined PLC data type.

In this case you can define a default value for each tag in the higher-level element. These default values are used as start values during the creation of the data block. You can then replace these values with instance-specific start values in the data block.

Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as standard for BOOL.

See also

Defining start values (Page 4808)

Structure of the declaration table for data blocks (Page 4797)

Declaring local tags and constants in the block interface (Page 4772)

Applying values from the online program as start values (Page 4834)

11.9.7.2 Defining start values

Defining start values

To define the start values for the tags of a data block, follow these steps:

1. Open the data block.
   The "Default value" column shows the default values that were defined for the tags in the interface of a higher-level code block or in a PLC data type.
2. Click the "Expanded mode" button to show all elements of structured data types.
3. Enter the desired start values in the "Start value" column. The value must match the data type of the tag and should not exceed the range of the data type.
   The start values are defined. The tag takes the defined value at startup, provided it was not declared as retentive.

Resetting a tag to the default value

To reset a tag for which you have defined a start value to the default value, follow these steps:

1. Select a modified value in the table.
2. Delete the value.
   The default value is entered. The default value is displayed.

Resetting all tags to the default value

To reset to the default value all tags for which you have defined an start value, follow these steps:

1. Select the "Reset start values" icon in the toolbar.
   The default values are transferred to the "Start value" column. Write-protected start values are not overwritten.

See also

Basic information on start values (Page 4807)

Applying values from the online program as start values (Page 4834)

Editing the declaration table for data blocks (Page 4817)

11.9.8 Setting retentivity

11.9.8.1 Retentivity of tags in data blocks

Retentive behavior

To prevent data loss in the event of power failure, you can mark the data as retentive. This data is stored in a retentive memory area. The options for setting the retentivity depend on the type of data block and the type of block access that is set.

See also

Setting retentivity in an instance data block (Page 4809)

Setting retentivity in a global data block (Page 4810)

11.9.8.2 Setting retentivity in an instance data block

Introduction

In an instance data block, the editability of the retentive behavior depends on the type of access of the higher-level function block:

- Function block with standard access
  You can define the instance data both as retentive or non-retentive. Individual retentivity settings are not possible for individual tags.
- Function block with optimized access
  In the instance data block, you can define the retentivity settings of the tags that are selected in the block interface with "Set in IDB". With these tags also, you cannot individually set the retentive behavior for each tag. The retentivity setting has an impact on all tags that are selected in the block interface with "Set in IDB".

Setting Retentivity for Standard Access

To centrally set the retentivity of all tags in the data block with standard access, follow these steps:

1. Open the instance data block.
2. Select the check box in the "Retain" column of a tag.
   All tags are defined as retentive.
3. To reset the retentivity setting for all tags, clear the check box in the "Retain" column of a tag.
   All tags will be defined as non-retentive.

Setting Retentivity for Optimized Access

To set the retentive behavior of the tags that are selected with "Set in IDB" in data blocks with optimized access, follow these steps:

1. Open the instance data block.
2. Select the check box in the "Retain" column of a tag.
   All tags selected with "Set in IDB" in the data block interface are defined as retentive.
3. To reset the retentivity setting for the tags, clear the check box in the "Retain" column of a tag.
   All tags selected with "Set in IDB" in the data block interface will be defined as non-retentive.

See also

Retentivity of tags in data blocks (Page 4809)

Editing the declaration table for data blocks (Page 4817)

11.9.8.3 Setting retentivity in a global data block

Introduction

In a global data block, the editability of the retentive behavior depends on the type of access:

- Global data block with standard access
  You can define the data both as retentive or non-retentive. Individual retentivity settings are not possible for individual tags.
- Global data block with optimized access
  You can individually define the retentivity settings of the tags. For tags with structured data types, retentivity settings are transferred for all tag elements.

Note

Retentivity of ARRAY data blocks

ARRAY data blocks and their components cannot be set retentively.

Setting Retentivity for Standard Access

To centrally set the retentivity of all tags in the data block with standard access, follow these steps:

1. Open the global data block.
2. Select the check box in the "Retain" column of a tag.
   All tags are defined as retentive.
3. To reset the retentivity setting for all tags, clear the check box in the "Retain" column of a tag.
   All tags are defined as non-retentive.

Setting Retentivity for Optimized Access

To individually set the retentivity of all tags in data blocks with optimized access, follow these steps:

1. Open the global data block.
2. In the "Retain" column, select the check box for the tags for which you want to set a retentive behavior.
   The selected tag is defined as retentive.
3. To reset the retentivity setting for the tags, clear the check box in the "Retain" column of a tag.
   All selected tags are defined as non-retentive.

See also

Retentivity of tags in data blocks (Page 4809)

Editing the declaration table for data blocks (Page 4817)

11.9.9 Editing the properties of tags in data blocks

11.9.9.1 Properties of the tags in data blocks

Properties

The properties of a tag are displayed in the Inspector window when you select the tag in the declaration table or at a point of use in the program editor.

Note

Properties of ARRAY elements

When you use ARRAY accesses with variable index in the form `#Program_Alarm_1[#myIndex]` in your program, the specific ARRAY element to be used during runtime is not yet known at the time of programming. For this reason, when you select this type of ARRAY access in the program editor, the properties of the first ARRAY element are always displayed.

The following table provides an overview of the properties of tags in data blocks:

Group	Property	Description
General	Name	Name of the tags.
	Data type	Data type of the tags.
	Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.
	Start value	Value that the tag should assume at CPU startup. The default values defined in a code block are used as start values during the creation of the data block. You can then replace these adopted values with instance-specific start values. Specification of an start value is optional. If you do not specify any value, the tag assumes the default value at startup. If a default is not defined either, the default value valid for the data type is used. For example, the value "FALSE" is specified as default value for BOOL.
	Comment	Comment on the tag.

Group	Property	Description
Attributes	Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off. This attribute is only available in the interface of the function block with optimized access.
	Visible in HMI engineering	Shows whether the tag is visible by default in the HMI selection list.
	Writable from HMI/OPC UA	Indicates whether or not the tag can be written from HMI/OPC UA during runtime.
	Accessible from HMI/OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime. Please note, however, that you cannot implement general access protection for the tag with the "Accessible from HMI/OPC UA" attribute. Read or write access from other applications is possible even if the attribute is not enabled.
	Visibility in block calls in LAD/FBD	Show: The parameter is always visible at block calls in LAD or FBD.
		Hide: The parameter is always hidden at block calls in LAD or FBD. The instruction box then has a small arrow on the lower edge. You can have the parameters displayed and interconnect them by clicking this arrow.
		Hide if no parameter is assigned: The parameter is always hidden at block calls in LAD or FBD as long as it has not yet been interconnected. If you assign an actual parameter, the parameter is displayed at the call box.
	Predefined actual parameter	Defines a parameter that is to be used as actual parameter during the block call.
	Show, if parameter assigned on block call is not identical to the predefined actual parameter	The parameter is hidden at block calls in LAD or FBD as long as the predefined actual parameter has not yet been assigned. However, when a different parameter is assigned, the parameter becomes visible. This option is only active if you have selected the "Hide" parameter and have defined a predefined actual parameter.

Group	Property	Description
User-defined attributes	CFC_Visible	Visible Indicates whether a parameter is visible in CFC.
	CFC_Configurable	Configurable Indicates whether a parameter is configurable in CFC.
	CFC_ForTest	For test Indicates whether a parameter is registered for the CFC test mode.
	CFC_Interconnectable	Interconnectable Indicates whether a parameter is interconnectable in CFC.
	CFC_EnableTagReadback	Enable tag readback Indicates whether a parameter is relevant for the "Read back chart" function in CFC.
	CFC_Enumeration-Texts	Enumeration texts Assigns a parameter to an enumeration in CFC.
	CFC_EngineeringUnit	Engineering unit Assigns a parameter to a unit in CFC.
	CFC_LowLimit	Low limit Defines the low limit for the parameter in CFC.
	CFC_HighLimit	High limit. Defines the high limit for the parameter in CFC.

Setting retentivity (Page 4809)

Defining start values (Page 4807)

11.9.9.2 Changing the properties of tags in instance data blocks

Instance-specific tag properties

Two options are available for defining the tag properties:

- The tag properties are applied from the interface of the assigned function block. Properties that are applied from the function block are displayed grayed out out in the columns of the declaration table. The "Name" and "Data type" properties are always applied.
- You define instance-specific properties.
  You can change some properties instance specific. Changeable values are, for example, "Comment" or "Visible in HMI". Properties that were changed instance specific are not grayed out in the columns of the declaration table. The instance-specific changes are retained, even if the interface of the higher-level function block is changed and the instance data blocks are subsequently updated.

Editing properties of an element in the declaration table

To edit the properties of an element, follow these steps:

1. Open the instance data block.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the declaration table

You can also simultaneously set or reset some properties for multiple selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the data block.
2. Hold down the CTRL key.
3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag, follow these steps:

1. Select a tag in the table.
2. Select the "Properties" command in the shortcut menu.
   The properties window opens. It shows the properties of the tag in the "General" and "Attributes" areas.
3. Select the required area in the area navigation.
4. Change the entries in the text boxes.

Reset individual properties to the default value.

To reset individual tag properties to the value that was defined as default in the function block, follow these steps:

1. Select an instance-specific, modified value in the table.
2. Delete the value.
   The instance-specific value will be deleted and the default value from the interface of the function block entered. The default value is displayed grayed out.

11.9.9.3 Changing the properties of tags in global data blocks

Introduction

Two options are available for defining the tag properties:

- The tag properties are applied from the PLC data type.
  Properties that are applied from the PLC data type are shown grayed out in the columns of the declaration table. The "Name" and "Data type" properties are always applied.
- You define specific properties.
  You can change some properties in the global data block. Changeable values are, for example, "Comment" or "Visible in HMI". Properties that were changed are not grayed out in the columns of the declaration table. The changes are retained, even if the PLC data type changes and the global data block is subsequently updated.

Editing properties of an element in the declaration table

To edit the properties of an element, follow these steps:

1. Open the global data block.
2. Select the required element in the table.
3. Change the entries in the columns.

Editing properties of several elements in the declaration table

You can also simultaneously set or reset some properties for multiple selected elements.

To change one of these properties for several elements, follow these steps:

1. Open the data block.
2. Hold down the CTRL key.
3. In the required column, select each of the table cells whose value you want to change.
4. Select the "Set <property>" or "Reset <property>" command in the shortcut menu.

Editing properties in the properties window

To edit the properties of an individual tag, follow these steps:

1. Select a tag in the table.
2. Select the "Properties" command in the shortcut menu.
   The properties window opens. It shows the properties of the tag in the "General" and "Attributes" areas.
3. Select the required area in the area navigation.
4. Change the entries in the text boxes.

Reset individual properties to the default value.

To reset individual tag properties to the value that was defined as default in the PLC data type, follow these steps:

1. Select a modified value in the table.
2. Delete the value.
   The default value from the PLC data type is entered. The default value is displayed grayed out.

11.9.10 Editing the declaration table for data blocks

11.9.10.1 Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

See also

Editing tables (Page 278)

11.9.10.2 Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

See also

Editing tables (Page 278)

11.9.10.3 Deleting tags

Requirements

A global data block is open.

Procedure

To delete a tag, follow these steps:

1. Select the row with the tag to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

Note

You cannot directly change the structure of instance data blocks and of global data blocks based on a PLC data type, since the structures of these blocks are defined in the higher-level object.

The type of the data block is entered in the block properties.

See also: Displaying and editing block properties (Page 4732)

See also

Editing tables (Page 278)

11.9.10.4 Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

11.9.10.5 Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

11.9.10.6 Editing tags with external editors

To edit individual tags in external table editors, such as Excel, you can export or import these tags using copy and paste.

Note

Restriction when displaying and copying ARRAY elements

Depending on the amount of work memory available on your computer, the following maximum limits apply when displaying and copying ARRAYs from the data block editor in an Excel table:

- RAM < 8 GB: A maximum of 10,000 elements are displayed and copied.
- RAM >= 8 GB: A maximum of 40,000 elements are displayed and copied.

Requirement

The data block and an external editor are opened.

Procedure

To export and re-import individual tags by drag-and-drop operation, follow these steps:

1. Click the "Expanded mode" button to show all elements of structured data types.
2. Select one or more tags.
3. Select "Copy" in the shortcut menu.
4. Switch to the external editor and paste the copied tags.
5. Edit the tags as required.
6. Copy the tags in the external editor.
7. Switch back to the declaration table.
8. Select "Paste" in the shortcut menu.

11.9.11 Online and diagnostic functions for data blocks

11.9.11.1 Editing data blocks in online mode

Introduction

When you load a data block to the CPU, there are two versions of the block:

- An offline version in the project on your programming device
- An online version on the CPU
  Data blocks can either be located only in the load memory, only in the work memory or in both memory areas.

Start values and actual values of tags

The values of the tags in the offline and online version of a data block are different because the tags in the online block can be changed by the user program during runtime.

When you declare a data block, you assign a start value to the tags. The start value is the value of the tag when the data block is called for the first time. This means the tag is "initialized" with the start value.

The start values of the tag are declared in the offline version of the block. When the data block is loaded to the CPU, it is transferred to the load memory with the start values. From there, the data block is loaded to the work memory of the CPU. When the block is loaded for the first time, the tags in the work memory are initialized with the declared start values. They can now be changed with the user program. The values of the tags in the work memory are referred to as "actual values".

Loading changed data blocks

When you make changes to a data block after initial loading, you are editing the offline version of the block. Depending on the existing conditions, subsequent loading of the data block has different effects on the actual values.

- Loading changes in "RUN":
  - If you have not made any changes to the structure of the data block, the actual values of all tags are retained. The program is processed further "bumplessly" Any changes to the start values in the offline data block are written to the load memory. They are not transferred to the CPU until the next transition from "STOP" to "RUN".
  - If you have changed the structure of the data block, all tags are reinitialized with their start values. Initializing the tags may have unwanted effects on the process because the process and the program may not be synchronous any longer.
    You can prevent this by using the memory reserve of the block. The memory reserve enables you to load data blocks in "RUN" without reinitialization. This means you can reload "bumplessly" even if you have changed the structure of the data block and have added new tags, for example.
    See also: AUTOHOTSPOT
- Loading changes in "STOP":
  - The start values of non-retentive tags are placed in the load memory of the CPU. The program runs with the new start values at the next transition from "STOP" to "RUN".
  - Retentive tags are not reinitialized. Your actual values are retained after loading in "STOP".
    To also reinitialize the retentive tags when loading in "STOP", select the blocks you want to load in the project tree and select the command "Compile > Software (rebuild all blocks)" in the shortcut menu. In the "Online" menu, select the command "Download and reset PLC program". The online blocks are deleted and overwritten by the new blocks. This reinitializes all tags, including the retentive tags.

Editing actual values with online and diagnostic functions

To manipulate actual values directly in online mode without having to reload data blocks, you can use the online and diagnostic functions of the TIA Portal.

See also: Overview of the online and diagnostic functions in data blocks (Page 4822)

Loading data blocks from a device

You can also load data blocks from a device again. This makes sense, for example, if the original offline project is not available during servicing. Please note that the two CPU families handle the values of tags differently when loading blocks from a device:

- S7-1200/1500
  CPUs of the S7-1200 and S7-1500 series store the start values with which a data block is loaded to the CPU in the load memory. If you load a data block from an S7-1200/1500 CPU, these start values are applied from the load memory to the offline data block again. Even if you have made value changes in the load memory during runtime by means of the "WRIT_DBL" instruction, the values originally loaded to the device are applied to the offline data block.
- S7-300/400
  CPUs of the S7-300/400 series also store the start values with which a data block is loaded to the CPU in the load memory. However, they cannot read the values back from the load memory. If you load a data block from a device, the current monitored values are loaded from the CPU and entered in the "Start values" column in the offline data block.

11.9.11.2 Overview of the online and diagnostic functions in data blocks

Overview of functions

The data block editor offers different options for editing data blocks in online mode. These functions directly access the actual values of the tags in the online program. Actual values are the values which the tags have at the current time during program execution in the CPU work memory.

The following table provides an overview of the online and diagnostic functions. Detailed descriptions of the individual functions can be found in the following chapters.

Button	Function	Description	S7-300/400	S7-1200/1500
	Monitor tags online (Page 4823)	Displays the actual values which the tags currently have in the CPU.	X	X
-	Modify individual actual values (Page 4824)	Modifies individual tags immediately and once only to specific values in the declaration table. The CPU then uses these values as actual values in the online program.	X	X
	Create a snapshot of the actual values (Page 4826)	Saves the actual values present at the current time as snapshot in the offline project. The snapshot always captures the actual values of all tags of the data block.	X	X
	Reinitialize actual values with a snapshot (Page 4828)	Loads the snapshot to the CPU as actual values. The CPU then uses these values as actual values in the online program.	-	S7-1200 V4.1 and higher S7-1500 V1.7 and higher

Button	Function	Description	S7-300/ 400	S7-1200/1500
	Apply snapshot values as start values (Page 4830)	Copies the snapshot to the start values in the offline program. The program runs with the new start values at the next transition from STOP to RUN. You can copy all start values or only the start values of the tags identified as "setpoint".	X	X
	Reinitialize actual values with start values (Page 4825)	Reinitializes the actual values of tags. The start values are written directly to the CPU work memory. You can copy all actual values or only the actual values of the tags identified as "setpoint".	X	X

Using setpoints during commissioning (Page 4831)

Defining start values (Page 4807)

11.9.11.3 Monitoring tags

You can monitor the actual values of the tags in the CPU directly in the declaration table.

Requirement

- An online connection is available.
- The data block has been loaded to the CPU.
- The program execution is active (CPU in "RUN").
- The data block is open.

Procedure

To monitor the tags, follow these steps:

1. Start monitoring by clicking the "Monitor all" button.
   The additional "Monitor value" column is displayed in the table. This shows the current data values.
   See also: Structure of the declaration table for data blocks (Page 4797)
2. End monitoring by clicking the "Monitor all" button again.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.4 Modifying tags

You can modify an individual tag in the data block to a specific value. The CPU then uses this value as the actual value in the online program.

DANGER

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors.

Make sure that no dangerous situations can arise before you modify the tags.

Requirement

- An online connection to the CPU is available.
- The data block whose tags you wish to modify is identical offline and online.
- The data block is open.

Procedure

To modify an individual tag in the data block, follow these steps:

1. Start monitoring by clicking the "Monitor all" button.
   The additional "Monitor value" column is displayed in the table. This shows the current data values.
2. Double-click the tag to be modified.
   The "Modify value" dialog opens.
   If there is a snapshot, the value is already entered as default.
3. Enter the desired value in the "Modify value" input field and confirm with "OK".

Result

The tag will have the specified value once when you execute the modify job. The job is executed immediately and is not tied to the next cycle control point.

See also

Introduction to modifying tags (Page 5216)

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.5 Loading start values as actual values

You can load the start values from the offline program to the CPU as actual values. The start values are loaded directly to the CPU work memory. The tags in the online block are reinitialized, and the CPU uses the new values as actual values in the online program. No distinction is made between retentive and non-retentive values. You can copy all actual values or only the actual values of the tags identified as "setpoint".

You can quickly bring the controlled process into a defined state this way.

You cannot reinitialize the following types of data blocks:

- Data blocks that are part of a reference project
- Fail-safe data blocks
- Data blocks generated by the CPU
- Data blocks with the attribute "Only store in load memory"
- Data blocks that only exist online

You can execute this function in "RUN" mode as well as "STOP" mode.

DANGER

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors.

If the volume of data to be transmitted is too large, the values may be transmitted in several cycles. If the program accesses tags before all values are completely transmitted, there is a risk that inconsistent value combinations may be created and processed.

Copying the values of elementary data types may also take several cycles. These values are potentially invalid until they have been completely transmitted. Dangerous states may occur if the program accesses these values before they have been completely transmitted.

To prevent dangerous states from occurring, please note the following:

- Make sure that the plant is in a safe state before you overwrite the actual values.
- Make sure that the program does not read or write the affected data during transmission.
- You may want to use the "Modify tag" function in the watch table or in the DB editor as an alternative.

Requirement

- You are using an S7-1200 V4.1 or higher or an S7-1500 V1.7 or higher.
- An online connection to the CPU is available.
- The data blocks whose actual values you want to reinitialize are identical offline and online.

Reinitializing actual values of an open block

To reinitialize all actual values or only the setpoints of a block with start values, follow these steps:

1. Open the data block.
2. Click the "Load start values as actual values > All values" button.

Or:

1. Open the data block.
2. Click the "Load start values as actual values > Only setpoints" button.

Reinitializing actual values of multiple blocks

To reinitialize all actual values of multiple blocks in one step, proceed as follows:

1. Select multiple blocks or the entire block folder in the project tree.
2. Select the "Load start values as actual values" command in the shortcut menu.

Result

The actual values in the online program are reinitialized with the start values.

The maximum number of tags that can be initialized is dependent on the CPU. If there are too many tags, an alarm informs you about this. In this case, you can insert the tags in a watch table and initialize them using the "Modify" function in the watch table.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.6 Creating a snapshot of the actual values

You can save the actual values of the tags of one or more data blocks as snapshot. Actual values are the values which the tags have at the current time during program execution in the CPU work memory.

A snapshot cannot be created for data blocks that are stored only in the load memory and are not integrated in the program.

You have the following options for creating a snapshot:

- Create a snapshot of an open data block
- Create a snapshot of several selected data blocks

A snapshot is also created automatically when you download a block or a program from the device.

CAUTION

Creating the snapshot

The values in the snapshot may originate in several cycles.

Requirement

- An online connection to the CPU is available.
- The data blocks for which you want to create a snapshot are identical offline and online.

Procedure

To create a snapshot of an open data block, follow these steps:

1. Open the data block.
2. Click "Snapshot".

To create a snapshot of several selected data blocks, follow these steps:

1. Select the blocks in the project tree.
   You can select the blocks individually or select devices, groups or folders in the project tree which include the data blocks.
2. In the shortcut menu, select "Snapshot of the current values" or select the menu command "Online > Snapshot of the current values".

Result

- The latest monitored values will be applied in the "Snapshot" column.
- An alarm is shown in the Inspector window after the operation is complete.
- The time stamp of the snapshot is displayed above the declaration table.

Note

If you subsequently change the structure of the data block, the display of the current values gets lost. The "Snapshot" column will then be empty.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.7 Loading snapshots as actual values

You can load the snapshots from the offline program to the CPU as actual values. The values from the snapshot are loaded directly to the CPU work memory. The tags in the online block are reinitialized, and the CPU uses the new values as actual values in the online program.

You can quickly bring the controlled process into a defined state this way.

You cannot reinitialize the following types of data blocks with snapshots:

- Data blocks that are part of a reference project
- Fail-safe data blocks
- Data blocks generated by the CPU
- Data blocks with the attribute "Only store in load memory"
- Data blocks that only exist online

⚠ DANGER

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors.

- Make sure that the plant is in a safe state before you overwrite the actual values.
- Make sure that the program does not read or write the affected data during transmission.
- You may want to use the "Modify tag" function in the watch table or in the DB editor as an alternative.

Dependencies on the CPU mode

You can execute this function in "RUN" mode as well as "STOP" mode. The table below shows the reactions of the CPU in the different modes:

Action	System reaction	Consequences for the online program
Overwrite actual values in "RUN" mode	The values of all DB tags are overwritten in the current program. No distinction is made between retentive and non-retentive values.	Changing the actual values can result in inconsistencies between the program and the actual process. If the volume of data to be transmitted is too large, the values may be transmitted in several cycles. If the program accesses tags before all values are completely transmitted, there is a risk that inconsistent value combinations may be created and processed. Copying the values of elementary data types may also take several cycles. These values are potentially invalid until they have been completely transmitted. Dangerous states may occur if the program accesses these values before they have been completely transmitted.
Overwrite actual values in "STOP" mode	Only the actual values of the retentive tags are overwritten by the snapshot. Non-retentive tags are initialized with their start values during the transition from "STOP" to "RUN". The values from the snapshot are not taken into consideration.	Because only the retentive data from the snapshot is transmitted, there is a risk that inconsistent value combinations may be created and processed.

Requirement

- You are using an S7-1200 V4.1 or higher or an S7-1500 V1.7 or higher.
- An online connection to the CPU is available.
- The data blocks whose actual values you want to reinitialize are identical offline and online.
- A snapshot of the data blocks has been created.

Reinitializing actual values of an open block

To reinitialize all actual values of a block with snapshots, follow these steps:

1. Open the data block.
2. Click "Load snapshots as actual values".

Reinitializing actual values of multiple blocks

To reinitialize the actual values of multiple blocks in one step, follow these steps:

1. Select multiple blocks or the entire block folder in the project tree.
2. Select the "Load snapshots as actual values" command in the shortcut menu.

Result

The actual values in the online program are reinitialized with the values from the snapshot.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.8 Copying the snapshot to the start values

You can copy the snapshot to the start values in the offline program. The program runs with the new start values at the next transition from "STOP" to "RUN".

You can copy all start values, the start values of the retentive tags or only the start values of the tags identified as "setpoint".

Note that the values from the snapshot are always copied. There is no check to determine whether all values originate from the same cycle.

Write-protected start values are not overwritten.

You have the following basic options for applying the values:

- Applying the values of an open data block
  You can apply all values or only the values of the tags marked as "setpoint" as start values in an open data block.
- Applying the values of multiple blocks in the project tree
  You can either apply all values, all setpoints or all retentive values as start values in the project tree.

Requirement

A snapshot has been created for the data block.

Procedure

To apply the snapshots as start values in a data block, follow these steps:

1. Open a data block.
2. In the toolbar, click "Copy snapshots to start values > All values".

Or:

1. Open a data block.
2. In the toolbar, click "Copy snapshots to start values > Only setpoints".

To apply the monitored values of multiple data blocks in the project tree, follow these steps:

1. Select the blocks in the project tree.
2. Then select one of the following commands in the shortcut menu:
   - "Copy snapshots to start values > All values"
   - "Copy snapshots to start values > Only setpoints"
   - "Copy snapshots to start values > Only retain values"

Result

The values from the "Snapshot" column are applied to the "Start value" column. The new start values are stored in the offline program.

Note

Applying values of individual tags

You can also apply the values of individual tags from the "Snapshot" column to the "Start values" column. Use the "Copy" and "Paste" commands from the shortcut menu to copy the values and insert them in the "Start value" column. Note that only the values that are currently located in the visible area of the table are copied.

Overview of the online and diagnostic functions in data blocks (Page 4822)

11.9.11.9 Using setpoints during commissioning

Basic information on adjusting setpoints during commissioning

Introduction

During commissioning of a plant, data values have to be frequently adjusted in order to optimally adapt the program to the general operating conditions on site. To this end, you can use the online and diagnostic functions of the declaration table for data blocks.

To use the functions, first define specific tags as "setpoints" in the program. Setpoints are the values that will probably have to be fine-tuned during commissioning.

The following table provides an overview of the functions for tuning values during commissioning. Detailed descriptions of the individual functions can be found in the following chapters.

In addition, there are also the general functions for monitoring and controlling the data block:

Overview of the online and diagnostic functions in data blocks (Page 4822)

Button	Function	Description
	Initialize setpoints in "RUN" mode (Page 4833)	This function enables you to change the values of individual tags online to quickly determine the optimum tag values.
 	Apply values from the online program as start values to the offline program (Page 4834)	When you have determined the optimum tag values, you can apply these as start values in the offline program. This allows you to ensure that the program starts with the optimized values the next time it is loaded.

See also

Marking data as values that can be set (Page 4832)

Marking data as values that can be set

You can mark specific tags in the program as "Setpoints". Setpoints are the values that will probably have to be fine-tuned during commissioning.

Rules

You can mark tags as "setpoints" in the following block types:

- In function blocks (FB), but only in the "Static" section
- in global data blocks (DB)
- in PLC data types (UDT)
  In the case of PLC data types, however, the setting is only effective if the UDT is used in the "Static" section of a function block or data block.

It is not possible to define setpoints in the following block types:

- In data blocks based on a PLC data type and in instance data blocks. These inherit the setting from the higher-level FB or UDT.
- You cannot mark tags as "setpoints" in ARRAY data blocks.
- You also cannot mark tags as "setpoints" at the call point of a multi-instance. You have to make the setting in the interface of the function block that is called as multiple instance.
- You cannot change the "setpoint" marking in know-how-protected blocks. To do so, you must first remove the know-how protection.

Requirement

A function block, a global data block or a PLC data type (UDT) is open.

Procedure

To mark a tag as "setpoint", follow these steps:

1. Select a tag from the "Static" section.
2. Select the check box in the "Setpoint" column.
   - You cannot define the higher-level element of a structure or a PLC data type as "setpoint". You have to make the setting for the lower-level elements individually.
   - In the case of ARRAYs, you can only mark the higher-level element as "setpoint". The lower-level elements inherit the setting.
   - For ARRAYs of STRUCT, you can only mark the elements below the first structure as setpoints. The elements of other structures inherit the setting.

Result

The tags are marked as setpoints. During commissioning, these tags can be initialized online. You do not need to set the CPU to "STOP" mode; it can remain in "RUN". In addition, the current tag values can be transferred as start values to the offline program and saved there.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

Online and diagnostic functions for data blocks (Page 4820)

Defining start values (Page 4807)

Initializing setpoint values in the online program

Basics on initializing setpoints

You can initialize all tags marked as "setpoints" with new values in the online program. At the same time, the start values will be loaded from the offline program to the online program. The CPU remains in "RUN" mode. All tags that are marked as setpoints are initialized once at the next cycle control point. This applies both to retentive and non-retentive tags. The program execution is then continued with the new tag values.

The maximum number of initializable tags is CPU-dependent: For S7-300/400 CPUs, you can initialize up to 35 setpoints. For S7-1200/1500 CPUs, the maximum amount is 200 setpoints. The maximum amount may be less, however, depending on the data types used.

If too many setpoints are selected, an alarm informs you of this. In this case, you can insert the tags in a watch table and initialize them using the "Modify" function in the watch table.

DANGER

Danger when changing tag values

Changing the tag values while the plant is operating can cause serious damage to property or injury to persons if there are functional disturbances or program errors.

Make sure that no dangerous situations can arise before you reinitialize the setpoints.

Requirement

- An online connection to the CPU exists.
- The structure of the data block is identical offline and online.
- One or more tags are marked as "setpoints".

Procedure

To initialize all setpoints of the data block, follow these steps:

1. Open a global data block or an instance data block.
2. Enter the required values in the "Start value" column. The start values must correspond to the indicated data type.
3. Click the "Load start values as actual values > Only setpoints" button.

Result

The setpoints in the online program are initialized with the start values from the offline program at the next cycle control point.

See also

Overview of the online and diagnostic functions in data blocks (Page 4822)

Applying values from the online program as start values

In order to apply tag values from the online program to the offline program as start values, first create a snapshot of the tag values from the online program. You can then apply them to the offline program. Note that the values from the snapshot are always copied. There is no check to determine whether all values originate from the same cycle.

Write-protected start values are not overwritten.

You have the following basic options for applying the values:

- Applying the setpoints of an open data block
- Applying the setpoints of multiple blocks in the project tree

Requirement

- An online connection to the CPU is available.
- As least one data block has been loaded to the CPU.

Procedure

To apply all setpoints as start values in a data block, follow these steps:

1. Open the data block.
2. Start monitoring by clicking the "Monitor all" button.
   The "Monitor value" column is displayed in the table. This shows the current data values.
3. In the toolbar, click "Snapshot".
   The actual values are applied in the "Snapshot" column.
4. In the toolbar, click "Copy snapshots to start values > Only setpoints".

The values from the "Snapshot" column are applied to the "Start values" column.

To apply the monitored values of multiple data blocks in the project tree, follow these steps:

1. Select the blocks in the project tree.
2. Select the "Snapshot" command in the shortcut menu.
   The actual values of all selected blocks are applied in the "Snapshot" column.
   An alarm is shown in the Inspector window after the operation is complete.
3. Next, select the command "Copy snapshot values as start values > Only setpoints" in the shortcut menu.

The values from the "Snapshot" column are applied to the "Start value" column.

Result

The new start values are stored in the offline program.

Note

Applying values of individual tags

You can also apply the values of individual tags that were not marked as setpoints beforehand from the "Snapshot" column to the "Start values" column. Use the "Copy" and "Paste" commands from the shortcut menu to copy the values and insert them in the "Start value" column. Note that only the values that are currently located in the visible area of the table are copied.

11.10 Declaring PLC tags

11.10.1 Overview of PLC tag tables

Introduction

PLC tag tables contain the definitions of the PLC tags and symbolic constants that are valid throughout the CPU. A PLC tag table is created automatically for each CPU used in the project. You can create additional tag tables and use these to sort and group tags and constants.

In the project tree there is a "PLC tags" folder for each CPU of the project. The following tables are included:

- "All tags" table
- Standard tag table
- Optional: Other user-defined tag tables

All tags

The "All tags" table gives an overview of all PLC tags, user constants and system constants of the CPU. This table cannot be deleted or moved.

Standard tag table

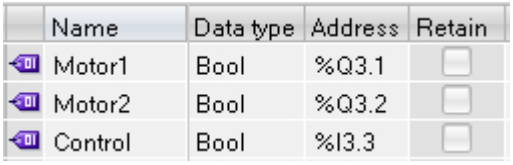
There is one standard tag table for each CPU of the project. It cannot be deleted, renamed or moved. The default tag table contains PLC tags, user constants and system constants. You can declare all PLC tags in the default tag table, or create additional user-defined tag tables as you want.

User-defined tag tables

You can create multiple user-defined tag tables for each CPU to group tags according to your requirements. You can rename, gather into groups, or delete user-defined tag tables. User-defined tag tables can contain PLC tags and user constants.

See also

Structure of the PLC tag tables (Page 4838)



11.10.2 Structure of the PLC tag tables

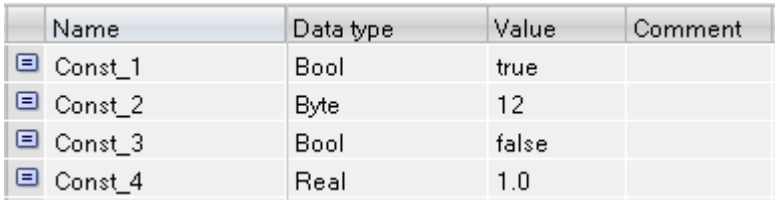
Introduction

Each PLC tag table contains a tab for tags and a tab for user constants. The default tag table and the "All tags" table also have a "System constants" tab.

Structure of the "PLC tags" tab

In the "Tags" tab you declare the global PLC tags that you require in the program. The following figure shows the tab structure. The number of columns shown may vary.

	Name	Data type	Address	Retain
	Motor1	Bool	%Q3.1	
	Motor2	Bool	%Q3.2	
	Control	Bool	%I3.3	



The following table shows the meaning of the individual columns. The number of columns shown may vary. You can show or hide the columns as required.

Column	Explanation
	Symbol you can click on to drag-and-drop a tag to a program for use as an operand.
Name	Unique name for the constants throughout the CPU.
Data type	Data type of the tags.
Address	Tag address.
Retain	Marks the tag as retentive. The values of retentive tags are retained even after the power supply is switched off.
Visible in HMI engineering	Shows whether the tag is visible by default in the operand selection of HMI.
Accessible from HMI/OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime.
Writable from HMI/OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.
Supervision	Indicates whether Supervision has been created for process diagnostics for the tag.
Monitor value	Current data value in the CPU. This column only appears if an online connection is established and you select the "Monitor all" button.
Tag table	Shows which tag table includes the tag declaration. This column is only available in the "All tags" table.
Comment	Comment to document the tags.

Structure of the "User constants" and "System constants" tabs

In the "User constants" you define symbolic constants that are valid throughout the CPU. The constants required by the system are shown in the "Systems constants" tab. System constants can be hardware IDs, for example, which can be used for identification of modules.

The following figure shows the structure of both tabs. The number of columns shown may vary.

	Name	Data type	Value	Comment
	Const_1	Bool	true	
	Const_2	Byte	12	
	Const_3	Bool	false	
	Const_4	Real	1.0	

The following table shows the meaning of the individual columns. You can show or hide the columns as required.

Column	Explanation
	Symbol you can click to move a tag into a network via a drag-and-drop operation for use as an operand.
Name	Unique name for the constants throughout the CPU.
Data type	Data type of the constants
Value	Value of the constants
Tag table	Shows which tag table includes the constant declaration. This column is only available in the "All tags" table.
Comment	Comments to document the tags.

11.10.3 Rules for PLC tags

11.10.3.1 Valid names of PLC tags

Permissible characters

The following rules apply to the use of names for PLC tags:

- Letters, numbers, special characters are permitted.
- The use of reserved keywords is not recommended.
- Quotation marks are not permitted as a component of the tag name.

Unique tag names

The names of the PLC tags must be unique throughout the CPU, even if the tags are located in different tag tables of a CPU. A name that is already used for a block, another PLC tag or a constant within the CPU, cannot be used for a new PLC tag. The uniqueness check does not differentiate between use of small and capital letters.

If you enter an already assigned name another time, a sequential number is automatically appended to the second name entered. For example, if you enter the name "Motor" a second time, the second entry is changed to "Motor(1)".

Unique table names

The names of the PLC tag tables must also be unique throughout the CPU. A unique name is automatically suggested when user-defined PLC tag tables are being created.

Note

You can find more information on permissible characters in tag names in the Siemens Industry Online Support in the following entries:

When should identifiers and operands be used in "quotation marks" in STEP 7 (TIA Portal)?

https://support.industry.siemens.com/cs/ww/en/view/109477857 (https://support.industry.siemens.com/cs/ww/en/view/109477857)

See also

Permissible addresses and data types of PLC tags (Page 4840)

Entering a PLC tag declaration (Page 4846)

11.10.3.2 Permissible addresses and data types of PLC tags

The addresses of PLC tags are made up of the particulars of the operand area and the address within this area.

The addresses must be unique throughout the CPU. If you enter an address that is already assigned to another tag, the address will be highlighted at both places in yellow and an error message will be issued.

Operand areas

The following table shows the possible operand areas. The available data types depend on the CPU you use:

Operand area		Explanation	Data type	Format	Address area:		
International mnemonics	German mnemonics				S7-1200	S7-300/400	S7-1500
I	E	Input bit	BOOL	I x.y E x.y	0.0..1023.7	0.0..65535.7	0.0..32767.7
I	E	Input (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL, PLC data type	I x.0 E x.0	-	-	0.0..32760.0
IB	EB	Input byte	BYTE, CHAR, SINT, USINT, PLC data type	IB x EB y	0..1023	0..65535	0..32767
IW	EW	Input word	WORD, INT, UINT, DATE, WCHAR, S5TIME, PLC data type	IW x EW y	0..1022	0..65534	0..32766
ID	ED	Input double word	DWORD, DINT, UDINT, REAL, TIME, TOD, PLC data type	ID x ED y	0..1020	0..65532	0..32764
Q	A	Output bit	BOOL	Q x.y A x.y	0.0..1023.7	0.0..65535.7	0.0..32767.7
Q	A	Output (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL, PLC data type	Q x.0 A x.0	-	-	0.0..32760.0
QB	AB	Output byte	BYTE, CHAR, SINT, USINT, PLC data type	QB x AB y	0..1023	0..65535	0..32767

Operand area		Explanation	Data type	Format	Address area:		
Interna-tional mnemon-ics	German mnemon-ics				S7-1200	S7-300/400	S7-1500
QW	AW	Output word	WORD, INT, UINT, DATE, WCHAR, S5TIME, PLC data type	QW x AW y	0..1022	0..65534	0..32766
QD	AD	Output dou-ble word	DWORD, DINT, UDINT, RE-AL, TIME, TOD, PLC da-ta type	QD x AD y	0..1020	0..65532	0..32764
M	M	Memory bit	BOOL	M x.y	0.0..8191.7	0.0..65535.7	0.0..16383.7
M	M	Bit memory (64-bit)	LREAL	M x.0	0.0..8184.0	-	0.0..16376.0
M	M	Bit memory (64-bit)	LWORD, LINT, ULINT, LTIME, LTOD, LDT	M x.0	-	-	0.0..16376.0
MB	MB	Memory byte	BYTE, CHAR, SINT, USINT	MB x	0..8191	0..65535	0..16383
MW	MW	Memory word	WORD, INT, UINT, DATE, WCHAR, S5TIME	MW x	0..8190	0..65534	0..16382
MD	MD	Memory dou-ble word	DWORD, DINT, UDINT, RE-AL, TIME, TOD	MD x	0..8188	0..65532	0..16380
T	T	Time function (for S7-300/400 only)	Timer	T n	-	0..65535	0..2047
C	Z	Counter func-tion (for S7-300/400 only)	Counter	Z n C n	-	0..65535	0..2047

Addresses

The following table shows the possible addresses of tags:

Data type	Address	Example
BOOL	Tags with BOOL data type are addressed with a byte number and a bit number. The numbering of the bytes begins at 0 for each operand range. The numbering of the bits is from 0 to 7.	A 1.0
BYTE, CHAR, SINT, USINT	Tags with BYTE, CHAR, SINT, and USINT data type are addressed with a byte number.	MB 1
WORD, INT, UINT, DATE, WCHAR, S5TIME	Tags with WORD, INT, UINT, DATE, S5TIME data type consist of two bytes. They are addressed with the number of the lowest byte.	IW 1
DWORD, DINT, UDINT, REAL, TIME, TOD	Tags with DWORD, DINT, UDINT, REAL, TIME, TOD data type consist of four bytes. They are addressed with the number of the lowest byte.	AD 1
LWORD, LINT, ULINT, LTIME, LTOD, LDT, LREAL	Tags of data type LWORD, LINT, ULINT, LTIME, LTOD, LDT, and LREAL consist of eight bytes. They are addressed with it number 0 and the number of the lower byte.	I 1.0

Mnemonics used

The addresses that you enter in the PLC tag table are automatically adapted to the set mnemonics.

11.10.4 Creating and managing PLC tag tables

11.10.4.1 Creating a PLC tag table

You can created multiple user-defined PLC tag tables in a CPU. Each tag table must have have a unique name throughout the CPU.

Requirement

The project view is open.

Procedure

To created a new PLC tag table, follow these steps:

1. Open the "PLC tags" folder under the CPU in the project tree.
2. Double-click the "Add new tag table" entry.
   A new PLC tag table with the default name "TagTable_x" is created.
3. Select the PLC tag table in the project tree.
4. Select the "Rename" command in the shortcut menu.
5. Type in a name that is unique throughout the CPU.

Result

A new PLC tag table is created. You can now declare tag and constants in this table.

See also

11.10.4.2 Grouping PLC tag tables

You can gather the user-defined tag tables of the CPU into groups. You cannot, however, move the standard tag table and the "All tags" table into a group.

Requirement

Multiple user-defined tag tables are contained in the "PLC tags" folder of the CPU.

Procedure

To gather multiple PLC tag tables into a group, follow these steps:

1. Select the "PLC tags" folder under the CPU in the project tree.
2. Select the "Insert > Group" menu command.
   A new group with the standard name "Group_x" is inserted.
3. Select the newly inserted group in the project tree.
4. Select the "Rename" command in the shortcut menu.

5. Assign the new group a unique name throughout the CPU.
6. Drag to the new group the tables you want to group together.

Result

The tag tables are gathered in the new group.

See also

Overview of PLC tag tables (Page 4837)

Structure of the PLC tag tables (Page 4838)

Declaring PLC tags (Page 4846)

Declaring global constants (Page 4852)

11.10.4.3 Opening the PLC tag table

Procedure

To open the PLC tag table in a CPU, proceed as follows:

1. Open the "PLC tags" folder under the CPU in the project tree.
2. Double-click the PLC tag table in the folder.
3. Select the desired tab in the upper corner.

Result

The PLC tag table associated with the CPU opens. You can declare the required tags and constants.

See also

11.10.5 Declaring PLC tags

11.10.5.1 Entering a PLC tag declaration

Declaring tags in the PLC tag table

Requirement

The "Tags" tab of the PLC tag table is open.

Procedure

To define PLC tags, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
   An address corresponding to the data type is automatically appended.
3. Optional: Click on the arrow key in the "Address" column and enter an operand identifier, an operand type, an address and a bit number in the dialog which then opens.
4. Optional: Enter a comment in the "Comments" column.
5. Repeat steps 1 to 4 for all the tags you require.
   See also: Permissible addresses and data types of PLC tags (Page 4840)

Syntax check

A syntax check is performed automatically after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. As long as the tag declaration contains syntax errors and the tag is used in the program, you will not be able to compile the program.

See also

Exporting and importing PLC tags (Page 4862)

Editing PLC tag tables (Page 4859)

Structure of the PLC tag tables (Page 4838)

Editing tables (Page 278)

Declaring PLC tags in the program editor

Requirement

- The program editor is open.

Procedure

To declare operands as global PLC tags, follow these steps:

1. Insert an instruction in your program.
   The "<???>", "<??.?>" or "..." strings represent operand placeholders.
2. Replace an operand placeholder with the name of the PLC tag to be created.
3. Select the tag name.
   If you want to declare multiple PLC tags, select the names of all the tags to be declared.
4. Select the "Define tag" command in the shortcut menu.
   The "Define tag" dialog box opens. This dialog displays a declaration table in which the name of the tag is already entered.
5. Click the arrow key in the "Section" column and select one of the following entries:
   - Global Memory
   - Global Input
   - Global Output
   - Global Timer
   - Global Counter
6. In the other columns, enter the address, data type, and comments.
   See also: Permissible addresses and data types of PLC tags (Page 4840)
7. If the CPU contains multiple PLC tag tables, you can use an entry in the "PLC tag table" column to indicate in which table the tag is to be inserted. If you make no entry in the column, the new tag will be inserted in the default tag table.
8. Click the "Define" button to complete your entry.

Result

The tag declaration is written to the PLC tag table and is valid for all blocks in the CPU.

See also

Valid names of PLC tags (Page 4840)

Declaring tags in the PLC tag table (Page 4846)

Using autocompletion (Page 4706)

11.10.5.2 Setting the retentivity of PLC tags

Retentive behavior of PLC tags

Retentive PLC tags

Each CPU has a memory area whose content remains available even after the supply voltage has been switched off. This area is referred to as retentive memory area.

To avoid data loss during power failure, you can save specific PLC tags to this memory area. You specify the retain setting of PLC tags in the PLC tag table.

Depending on the CPU family, the retentive memory area can accommodate various type of PLC tags. The following table provides an overview of the options of the various CPUs:

CPU type	Retentive bit memories	Retentive SIMATIC timers	Retentive SIMATIC counters
S7-300/400 series	✓	-	-
S7-1200 series	✓	-	-
S7-1500 series	✓	✓	✓

See also

Setting the retentive behavior of PLC tags (Page 4848)

Setting the retentive behavior of PLC tags

Introduction

In the PLC tag table you can specify the width of the retentive memory area for PLC tags. All tags with addresses in this memory area are then designated as retentive. You can recognize the retentivity setting of a tag by the check mark set in the "Retain" column of the PLC tag table.

Requirement

The "PLC tags" tab of the PLC tag table is open.

Procedure

To define the width of the retentive memory area for PLC tags, follow these steps:

1. On the toolbar, click the "Retain" button.
   The "Retain memory" dialog will open.
2. Specify the width of the retentive memory area by entering the number of retentive bytes, timers or counters in the input field.
3. Click the "OK" button.

Result

The width if the retentive memory area is defined. In the "Retain" column of the tag table a check mark is automatically set for all tags that are located within the retentive memory area.

Retentive behavior of PLC tags (Page 4848)

Editing tables (Page 278)

11.10.6 Grouping PLC tags for inputs and outputs in structures

11.10.6.1 Other useful information regarding structured PLC tags

Use of structured PLC tags (S7-1200 V4 and higher/S7-1500)

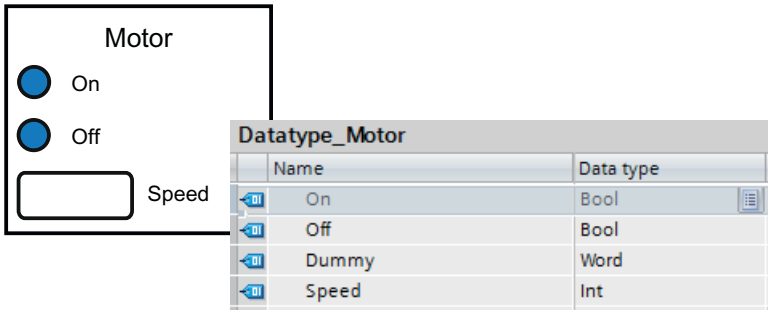
To make your program easier to view, you can group several input or output addresses in a higher-level PLC tag. The higher-level PLC tag represents a structure that contains several logically related inputs or outputs. When the block is called, you transfer the higher-level tag and thus need only an input or output parameter for all associated inputs or outputs.

Principle of operation

To create a structured PLC tag, you initially define a PLC data type (UDT). In it you declare the necessary data elements and specify their names and data types.

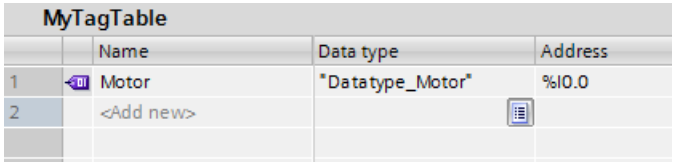
Then, you switch to the PLC tag table and specify the higher-level PLC tag there. As a data type for the tag, you select your PLC data types. The system now reserves a certain number of input or output addresses starting from the start address of the higher-level tag. The number of reserved addresses depends on the length of your PLC data type.

If you call a block that requires the reserved inputs or outputs for program execution, you transfer the higher-level tag as a block parameter.



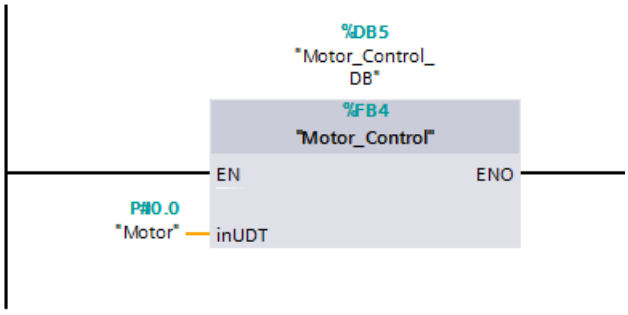
You can address the individual PLC tags like structure elements in the program code.

A detailed description of the individual handling steps can be found in the following chapters.



Application example

You can use structured PLC tags in order to group the inputs or outputs of a function module. The following figure shows the schematic representation of a motor: A component was created in the "Datatype_Motor" PLC data type for each of the three inputs.



The memory areas of the declared tags must not overlap. In the example, you see that the "Speed" component has the data type "Integer" and therefore must start at a word address. For this reason, the first input word has been filled with the "Dummy" fill tag. This means that "Speed" is located on the second input word.

The following figure shows the higher-level "Motor" PLC tag that is based on the "Data type_Motor" data type. With the declaration of "Motor", the addresses IW0 and IW1 are reserved on the input module.

The following figure shows the transfer of the "Motor" PLC tag as an input parameter of the "Motor_Control" block.

You can address the individual components of the tag in the "Motor_Control" block.

Addressing	Description
"Motor"	Addressing the higher-level PLC tag.
"Motor".On	Addressing a component of a structured PLC tag.
"Motor".On:P	Addressing an I/O input or output (PI or PQ).

Rules for use of structured PLC tags

Note the following rules when creating and using structured PLC tags.

- Structured PLC tags can be used in the "Inputs" and "Outputs" operand areas.
- Structured tags are not permitted in the bit memory address area.
- Structured PLC tags cannot be addressed from HMI.

Observe the following rules when creating the PLC data type that is to serve as the basis for a PLC tag:

- The memory areas of the individual elements must not overlap.
  See also: Permissible addresses and data types of PLC tags (Page 4840)
- Do not group inputs and outputs in one PLC data type but create different PLC data types for inputs and outputs.
- Do not group inputs or outputs from different modules in a PLC data type because it is not guaranteed that the process images of the modules are updated synchronously.
- In the lower-level PLC data types, all data types are permitted except for "STRING" and "WSTRING".

See also

Creating structured PLC tags (Page 4851)

11.10.6.2 Creating structured PLC tags

Rules

Note the following rules when creating structured PLC tags:

- Use separate PLC data types for the "Inputs" and "Outputs" operand areas.
- Structured tags are not permitted in the bit memory address area.
- Do not group inputs or outputs from different modules in a PLC data type because it is not guaranteed that the process images of the modules are updated synchronously.

Procedure

To create a structured PLC tag, follow these steps:

1. Double-click the "Add new data type" command in the "PLC data types" folder in the project tree.
   A new declaration table for creating a PLC data type will be created and opened.
2. Declare all the necessary components in the PLC type. All data types except for "STRING" and "WSTRING" are permitted.

3. Select the PLC data type in the project tree and select the "Compile > Software (only changes)" command from the shortcut menu.
   The PLC data type is compiled and can then be used in the PLC tag table.
   Even when you make changes to existing PLC data types, you must recompile the program. This updates all locations of use of the PLC data type.
4. Open a PLC tag table within the same CPU.
5. Declare a new tag or select an existing tag.
6. In the "Data type" column, select the PLC data type and assign it to the PLC tag.
   The PLC tag receives the structure of the PLC data type. A suitable address is assigned automatically. Structured PLC tags always start at word addresses.
   The highest structure element is displayed without its subelements in the table.

Note

Assignment rules and default values

- For the declaration of the PLC data type, note that the memory areas of the individual tags must not overlap. For example, tags of data type "Integer" must start at a word limit. If necessary, insert "fill tags" to prevent overlaps.
  See also: Permissible addresses and data types of PLC tags (Page 4840)
- It is not possible to assign default values for the individual components. Values that you enter in the "Default value" column are not evaluated. Tags of data types "DT" and "DTL" may therefore contain invalid values.

See also

Other useful information regarding structured PLC tags (Page 4849)

Declaring PLC tags (Page 4846)

11.10.7 Declaring global constants

11.10.7.1 Rules for global user constants

Permitted characters

Names of global constants may consist of the following characters:

- Letters, numbers, special characters are permitted.
- Quotation marks are not permitted.

Unique constant names

The names of global constants must be unique throughout the CPU, even if the constants are located in different tag tables of a CPU. A name that is already used for a block, a PLC tag or another constant within the CPU, cannot be used for new constant. The uniqueness check does not differentiate between use of small and capital letters.

If you enter an already assigned name another time, a sequential number is automatically appended to the second name entered. For example, if you enter the name "Motor" a second time, the second entry is changed to "Motor(1)".

Permitted data types

For constants, all data types supported by the CPU are permitted, with the exception of structured data types.

Permitted values

You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

See also: AUTOHOTSPOT

See also

Declaring global constants (Page 4854)

11.10.7.2 Rules for global system constants

Definition

System constants are global constants, unique throughout the CPU, that are required and automatically created by the system. System constants can, for example, be used to address and identify hardware objects.

Rules

System constants are assigned automatically when components are inserted in the device or network view, and entered in the default tag table ("System constants" tab). A system constant is created for each module, but also for each submodule. An integrated counter, for example, therefore receives a system constant as well. System constants consist of a symbolic name and a numeric HW identifier and cannot be changed.

Names of system constants

The names of the system constants are structured hierarchically. They consist of a maximum of four hierarchical levels, each of which is separated by a tilde "~". Based on the name, you can therefore recognize the "path" to the relevant hardware module.

Example

A system constant with the name "`Local~PROFINET_interface_1~Port_1`" designates Port 1 of the PROFINET interface 1 of the local CPU.

See also

Instructions for address conversion (Page 4073)

11.10.7.3 Declaring global constants

Introduction

You declare constants in the "User constants" tab of a PLC tag table. During declaration you have to to enter a symbolic name, a data type and a fixed value for each constant. You can select any value from the value range of the specified data type as constant value. For information on the value ranges, refer to the "Data types" chapter.

See also: AUTOHOTSPOT

Procedure

To declare constants, follow these steps:

1. Open a PLC tag table.
2. Open the "User constants" tab.
   The constants table opens.
3. Enter a constant name in the "Name" column.
4. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
5. Enter a constant value in the "Value" column; this constant value must be valid for the selected data type.
6. If you want, enter comments on the constants in the "Comments" column. The entry of a comment is optional.
7. If you want to declare additional constants, place the cursor in the next row and repeat steps 3 to 6.

Syntax check

A syntax check is performed automatically after each entry, and any errors found are displayed in red. You do not have to correct these errors immediately - you can continue editing and make any corrections later. As long as the tag declaration contains syntax errors and the constant is used in the program, you will not be able to compile the program.

11.10.8 Editing properties

11.10.8.1 Editing the properties of PLC tags

Properties of PLC tags

Overview

The following table provides an overview of the properties of PLC tags. The display of properties may vary depending on the CPU type.

Group	Property	Description
General	Name	A unique name within the CPU.
	Data type	Data type of the tags.
	Address	Tag address.
	Retain	Shows whether the tag is in the retentive memory area.
	Comment	Comment on the tag.
History	Date created	Time when the tag was created (cannot be changed).
	Last modified	Time when the tag was last changed (cannot be changed).
Application	Visible in HMI engineering	Shows whether the tag is visible by default in the HMI selection list.
	Accessible from HMI/ OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime.
	Writable from HMI/OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.

Editing the properties of PLC tags (Page 4856)

Editing the properties of PLC tags

Editing properties in a PLC tag table

To edit the properties of one or more tags, follow these steps:

1. In the project tree, double-click the PLC tag table that contains the tags.
   The PLC tag table opens.
2. Change the entries in the columns.

Editing addresses in the program editor

To edit the address of a tag in the program editor, follow these steps:

1. Select the tag name.
2. Select the "Rewire tag" command in the shortcut menu.
   The "Rewire tag" dialog will open. The dialog shows a declaration table.
3. Enter the new address in the "Address" column.
4. Click the "Change" button to confirm the input.

Editing names in the program editor

To edit the name of a tag in the program editor, follow these steps:

1. Select the tag name.
2. Select the "Rename tag" command in the shortcut menu.
   The "Rename tag" dialog opens. The dialog shows a declaration table.
3. Enter the new name in the "Name" column.
4. Click the "Change" button to confirm the input.

Effect in the program

In the case of a change of the tag's name, data type or address, each location of use of the tag is automatically updated in the program.

11.10.8.2 Editing properties of global constants

Properties of global constants

Overview

The following table gives an overview of the properties of constants:

Group	Property	Description
General	Name	A unique name within the table
	Data type	Data type of the constants
	Value	Value that you defined for the constants. This value must be compatible with the declared data type. See also: AUTOHOTSPOT
	Comment	Comment on the constants
History	Date created	Time when the constant was created (cannot be changed)
	Last modified	Time when the constant was last changed (cannot be changed)

Editing properties of global constants

Editing properties in a PLC tag table

To edit the properties of one or more constants, follow these steps:

1. In the project tree, double-click the PLC tag table that contains the constants.
   The PLC tag table opens.
2. Open the "User constants" tab.
3. Change the entries in the "Name", "Data type", "Value", or "Comments" column.

Effect in the program

In the case of a change of a constant's name, data type or value, each location of use of the constant is automatically updated in the program.

See also

Editing tables (Page 278)

11.10.9 Monitoring of PLC tags

11.10.9.1 Monitoring of PLC tags

You can monitor the current data values of the tags on the CPU directly in the PLC tag table.

Requirement

An online connection to the CPU exists or is possible.

Procedure

To monitor the data values, proceed as follows:

1. Open a PLC tag table.
2. Start monitoring by clicking the "Monitor all" button.
   - If no online connection to the CPU exists, this is established.
   - Monitoring is started with the trigger setting "Permanent".
   - The additional "Monitor value" column is displayed in the table. This shows the current data values.
   - The symbol for the forcing of tags is displayed if a tag is currently being forced.
3. End the monitoring by clicking the "Monitor all" button again.

Note

Editing PLC tags during the monitoring of tags

If the editing of tags is started and the PLC tag table is edited, for example by adding new tags, the monitoring is re-started after editing is complete.

Note

You also have the option of copying PLC tags to a monitor or force table so that you can monitor, control or force them in the table.

See also

Structure of the PLC tag tables (Page 4838)

Introduction to testing with the watch table (Page 5196)

Copying entries in the PLC tag table (Page 4859)

11.10.10 Editing PLC tag tables

11.10.10.1 Inserting a table row in the PLC tag table

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

See also

Editing tables (Page 278)

11.10.10.2 Copying entries in the PLC tag table

You can copy PLC tags within a table or to other tables.

Procedure

To copy a tag, follow these steps:

1. Select the tags you want to copy.
   You can also select several tags by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last tag.
2. Select "Copy" in the shortcut menu.
3. Position the insertion pointer at the location where you want to insert the tags.
4. Select "Paste" in the shortcut menu.

Or

1. Select the tag.
2. Hold down the left mouse button.
3. At the same time, press <Ctrl>.
4. Drag the tag to the destination.

Result

- The tag is copied to the destination.
- If there is a name conflict, a number is automatically appended to the tag name. For example, "Tag" becomes "Tag(1)".
- All other properties of the tag remain unchanged.

Editing tables (Page 278)

11.10.10.3 Deleting entries in the PLC tag table

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

See also

Editing tables (Page 278)

11.10.10.4 Sorting rows in the PLC tag tables

You can sort the rows in the tables alphanumerically by name, data type, or address.

Procedure

To sort the table rows, follow these steps:

1. Select the column by which you want to sort.
2. Click the column header.
   The column will be sorted in order of increasing values.
   An up arrow shows the sort sequence.
3. In order to change the sort sequence, click the arrow.
   The column will be sorted in order of decreasing values. A down arrow shows the sort sequence.
4. To restore the original sequence, click a third time on the column header.

Editing tables (Page 278)

11.10.10.5 Automatically filling in cells in the PLC tag table

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

If you fill the cells in the column "Address" automatically, the addresses will be increased depending on the indicated data type.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically. If entries are already present in the cells that are to be automatically updated, a dialog appears in which you can indicate whether you want to overwrite the existing entries or whether you want to insert new rows for the new tags.

See also

Editing tables (Page 278)

11.10.10.6 Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

Editing tables (Page 278)

11.10.10.7 Exporting and importing PLC tags

Basics for exporting and importing PLC tags

Introduction

You can export PLC tag tables to edit them further with external applications. Similarly, you can import PLC tag tables edited externally to the TIA Portal.

The following formats are supported for import and export:

- XLSX (Excel)
  For the export to Excel you can specify which elements you want to export:
  - Tags and/or constants
  - All elements or just the elements that are actually being used in the program on the current CPU.
- XML
- SDF

Overwriting existing PLC tags and constants during import

Existing entries of the same name will be overwritten during import if they have the same name as the entries that will be imported.

Link to existing objects

References to PLC tags or constants that already exist in the project are updated automatically during import. The update is executed based on the name of the PLC tags and constants.

See also

Format of the export file (*.xlsx) (Page 4862)

Exporting PLC tags (Page 4864)

Importing PLC tags (Page 4865)

Format of the export file (*.xlsx)

Introduction

During the export of PLC tag tables, a standardized XSLX format will be generated that you can edit with external table editors.

This format is also expected during the import of tables.

Format of the export file

The sheet is always named "PLCTags". This sheet can contain the displayed columns. The sorting order of columns can vary. The sheet does not necessarily have to include all columns. During import, the following values will be identified by a <no value> entry.

The names of the column headers are also clearly defined and are always expected in English.

The following table specifies the contents expected for the individual columns:

Element	Description
Name	Name of the tags
Path	Group and name of the PLC tag table
Data Type	The notation of the data type corresponds to the notation used in the PLC tag table.
Logical Address	The address can be specified with German or international mnemonics.
Comment	Free-form comments
Hmi Visible	The value TRUE or FALSE is expected.
Hmi Accessible	The value TRUE or FALSE is expected.
Hmi Writeable	The value TRUE or FALSE is expected.

See also

Basics for exporting and importing PLC tags (Page 4862)

Exporting PLC tags (Page 4864)

Importing PLC tags (Page 4865)

Format of the export file (*.xml)

Introduction

During the export of PLC tag tables, a standardized xml format will be generated. This format is also expected during the import of xml files.

Example of an xml export file

The following example shows a PLC tag table which was exported to the *.xml format:

```
<?xml version='1.0' encoding='utf-8'?>
<Tagtable name='Default tag table'>
  <!-- exported by 'Totally Integrated Automation Portal' version 14.0.1.0   © 2004-2016 Siemens A
  <Tag type='Bool' hmiVisible='True' hmiWriteable='True' hmiAccessible='True' retain='False' remark
  <Constant type='Bool' remark='comment' value='TRUE'>xxxx</Constant>
</Tagtable>
```

Format of the export file (*.sdf)

Introduction

During the export of PLC tag tables, a standardized sdf format will be generated. This format is also expected during the import of sdf files.

Example of an sdf export file

The following example shows a PLC tag table which was exported to the *.sdf format:

```
"Tag_1","%I0.0","Bool","True","True","False","Comment","","True"
"Tag_2","%I0.1","Bool","True","True","False","","","True"
"Const_1","CONSTANT","Bool","","","","Comment1","TRUE",""
"Const_2","CONSTANT","Bool","","","","","TRUE",""
```

Exporting PLC tags

Requirement

A PLC tag table is open.

Procedure

To export PLC tags and constants, follow these steps:

1. In the PLC tag table, click the "Export" button.
   The "Export" dialog box opens.
2. Click the selection button under "Path of export file".
   The "Save as" dialog opens.
3. Enter the name of the export file and select the file in which it is to be stored.
4. Select *.xlsx, *.sdf or *.xml as the file type.
5. Click the "Save" button.
6. If you have selected the "*.xlsx" format, select the export options:
   - Select whether to export tags and/or constants.
   - Select whether you want to export all elements of the table or just the elements that are actually being used in the program on the current CPU.
7. Click the "OK" button.

Result

The export file will be generated. Errors and warnings generated during export are indicated in the "Info" tab of the Inspector window.

See also

Basics for exporting and importing PLC tags (Page 4862)

Format of the export file (*.xlsx) (Page 4862)

Importing PLC tags (Page 4865)

Importing PLC tags

Requirement

A PLC tag table is open.

Procedure

To import PLC tags, follow these steps:

1. Click the "Import" button.
   The "Import" dialog box opens.
2. Select the file you want to import.
3. If you have selected a file in the format "XLSX", select whether you want to import tags and/or constants.
4. Click the "OK" button.

Result

Errors and warnings generated during import are indicated in the import log.

If the PLC tag table "All tags" is opened in the TIA Portal, a new user-defined PLC tag table for the imported tags is created. If the standard tag table or a user-defined tag table is opened, the imported tags are integrated in the open PLC tag table. Existing entries of the same name will be overwritten if they have the same name as the entries that will be imported.

References to PLC tags or constants that already exist in the project are updated automatically during import. The update is executed based on the name of the PLC tags and constants.

See also

Basics for exporting and importing PLC tags (Page 4862)

Format of the export file (*.xlsx) (Page 4862)

Exporting PLC tags (Page 4864)

Editing individual PLC tags with external editors

To edit individual PLC tags in external editors outside the TIA portal, you can export or import these tags using copy and paste. However, you cannot copy structured tags to an editor.

Requirement

A PLC tag table and an external editor are opened.

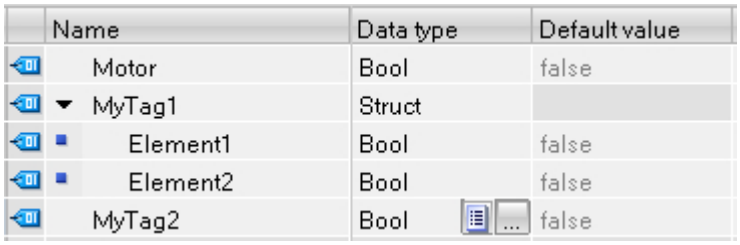
Procedure

To export and import individual PLC tags, follow these steps:

1. Select one or more PLC tags.
2. Select "Copy" in the shortcut menu.
3. Switch to the external editor and paste the copied tags.
4. Edit the tags as required.
5. Copy the tags in the external editor.
6. Switch back to the PLC tag table.
7. Select "Paste" in the shortcut menu.

Note

You also have the option of export or importing PLC tags as mass data.



See also: Exporting and importing PLC tags (Page 4862)

11.11 Declaring PLC data types (UDT)

11.11.1 Structure of the declaration table for PLC data types

Structure of the declaration table for PLC data types

The figure below shows the structure of the declaration table for PLC data types.

	Name	Data type	Default value
	Motor	Bool	false
	MyTag1	Struct	
	Element1	Bool	false
	Element2	Bool	false
	MyTag2	Bool	false

Meaning of the columns

The following table shows the meaning of the individual columns. You can show or hide the columns as required. The number of columns displayed varies depending on the CPU series.

Column	Explanation
	Symbol you can click to move or copy the tag.
Name	Name of the tags.
Data type	Data type of the tags.
Default value	Value with which you predefine the tag in the declaration of the PLC data type. Specification of the default value is optional. If you do not specify any value the predefined value for the indicated data type is used. For example, the value "false" is predefined for BOOL.
Visible in HMI engineering	Shows whether the tag is visible by default in the HMI selection list.
Accessible from HMI/OPC UA	Indicates whether HMI/OPC UA can access this tag during runtime.
Writable from HMI/OPC UA	Indicates whether the tag from HMI/OPC UA can be written during runtime.
Setpoint value	Setpoint values are the values that will probably have to be fine tuned during commissioning. After commissioning, the values of these tags can be transferred to the offline program as start values and stored there.
Comment	Comment to document the tags.

Basics of PLC data types (UDT) (Page 2277)

Using setpoints during commissioning (Page 4831)

11.11.2 Creating PLC data types

Requirement

The "PLC data types" folder opens in the project tree.

Procedure

To create a PLC data type, proceed as follows:

1. In the "PLC data types" folder, click the "Add new data type" command.
   A new declaration table for creating a PLC data type will be created and opened.
2. Select the PLC data type and select the "Rename" command in the shortcut menu.
3. Enter the name of the PLC data type.

The new PLC data type is created. You can find the PLC data type in the project tree in the "PLC data types" folder.

Adding comments for a PLC data type

To enter a comment for a PLC data type, follow these steps:

1. Right-click the PLC data type in the project tree.
2. Select the "Properties" command in the shortcut menu.
   A dialog containing the properties of the PLC data type opens.
3. Select the "Information" entry in the area navigation.
4. Enter the comment in the "Comment" input field.
5. Confirm your entry with "OK".

See also

Structure of the declaration table for PLC data types (Page 4867)

Basics of PLC data types (UDT) (Page 2277)

11.11.3 Delete PLC data types

Requirement

The PLC data type you want to delete is not open.

Procedure

To delete a PLC data type, follow these steps:

1. In the project tree, open the "PLC data types" folder.
2. Select the PLC data type to be deleted. You can also select several PLC data types by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last data type.
3. Select the "Delete" command in the shortcut menu.

Note

If you delete a PLC data type, the blocks that use the data type will become inconsistent. These inconsistencies are marked in red in the block used. To remedy these inconsistencies, the data blocks have to be updated.

See also

Updating the block interface (Page 4791)

Updating data blocks (Page 4800)

Basics of PLC data types (UDT) (Page 2277)

11.11.4 Renumbering PLC data types

For performance reasons, PLC data types are processed internally with numbers. If there are number conflicts, these are resolved automatically. But this is not possible for a PLC data type which is used by a know-how protected block. The block must be recompiled when you change the number of the PLC data type which results in a password prompt for the know-how protected block. You can bypass this step by setting up a separate numbering scheme for your PLC data types. Use numbers greater than 5000.

Procedure

To change the default number of a PLC data type, follow these steps:

1. Open the project library in the "Libraries" task card.
2. Drag the compilable PLC data type to the "Types" folder.
   The "Add type" dialog opens.
3. Enter the properties of the new type.

4. Click "OK" to confirm.
5. Right-click the PLC data type in the project library and select the "Edit type" command from the shortcut menu.
6. Click "OK" to confirm your selection of the instance.
   The library view opens.
7. Close the library view.
   The extension "in test" is now added to the name of the PLC data type.
8. Right-click the PLC data type and select the "Properties" command from the shortcut menu.
9. Select the "General" group in the area navigation.
   You can now edit the number of the PLC data type.
10. Change the number of the PLC data type.
11. Click "OK" to confirm.
12. Right-click the PLC data type in the project library and select the "Release version" command from the shortcut menu.
    The PLC data type has a new number. The assigned number is retained even if the type of the PLC data type is revoked.

11.11.5 Programming the structure of PLC data types

11.11.5.1 Declaring tags of elementary data type

Requirement

A PLC data type is open.

Procedure

To declare a tag, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the required data type in the "Data type" column. You will be supported by autocompletion during input.
3. Optional: Change the properties of the tags that are displayed in the other columns.
4. Repeat steps 1 to 3 for all tags that are to be declared.

See also

Editing tables (Page 278)

Editing the declaration table for PLC data types (Page 4875)

11.11.5.2 Declaring tags of the ARRAY data type

Requirement

A PLC data type is open.

Procedure

To declare a tag of the ARRAY data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the "Array" data type in the "Data type" column. You will be supported by Autocomplete in this step.
   The "Array" dialog opens.
3. In the "Data type" text box, specify the data type of the array elements.
4. In the "ARRAY limits" input field, specify the high and low limit for each dimension.
   Example of a one-dimensional ARRAY:
   `[0..3]`
   Example of a three-dimensional ARRAY:
   `[0..3, 0..15, 0..33]`
5. Confirm your entry.
6. Optional: Change the properties of the tags that are displayed in the other columns.

Entering default values of ARRAY elements

To pre-assign default values to the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the desired values in the "Default value" column.

Adding comments for ARRAYs

To add a comment for the entire ARRAY, enter the comment in the top line of the ARRAY declaration. The comment is used as a preset comment for all lower-level ARRAY elements.

To provide specific comments for the individual elements of an ARRAY, follow these steps:

1. Click the triangle in front of the ARRAY data type tags.
   The ARRAY is expanded and the individual ARRAY elements are shown in separate lines.
2. Enter the desired values in the "Comment" column.

Note

Restriction when displaying ARRAY elements

Depending on the amount of work memory available on your computer, the following maximum limits apply when displaying ARRAYs:

- RAM < 8 GB: A maximum of 10,000 elements are displayed.
- RAM >= 8 GB: A maximum of 40,000 elements are displayed.

See also

Structure of the declaration table for PLC data types (Page 4867)

ARRAY (Page 2286)

Using autocompletion (Page 4706)

11.11.5.3 Declaring tags of STRUCT data type

Requirements

A PLC data type is open.

Procedure

To declare a tag of the STRUCT data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter "Struct" in the "Data type" column. You will be supported by autocompletion during input.
   An empty, indented row is inserted after the new tag.
3. Insert the first structural element in the first empty row.
   An additional empty row is inserted after the element.
4. Select a data type for the structure element.
5. Optional: Change the properties of the structural element that is displayed in the other columns.
6. Repeat steps 3 to 5 for all additional structure elements.
   It is not necessary to end the structure explicitly. The structure ends with the last element that is entered.
7. To insert a new tag after the structure, leave a blank row after the end of the structure and then start the new tag in the second empty row.

Result

The tag of STRUCT data type is created.

See also

Basic information on STRUCT (Page 2282)

Structure of the declaration table for PLC data types (Page 4867)

Using autocompletion (Page 4706)

11.11.5.4 Declaring tags based on a different PLC data type

Requirement

- A global data block is open.
- A PLC data type is declared in the current CPU.

Procedure

To declare a tag based on a different PLC data type, follow these steps:

1. Enter a tag name in the "Name" column.
2. Enter the PLC data type in the "Data type" column. You will be supported by Autocomplete during input.
   The tag is created.
3. Optional: change the properties of the tags that are displayed in the other columns of the table.
   If you have already defined default values or comments for the tags within a PLC data type during declaration of the PLC data type, these are shown in gray. You can change these values here.
   The changed values are displayed in black and apply only to the specific point of use.

Note

If you change or delete PLC data types that are being used in the data block, the data block becomes inconsistent. To eliminate this inconsistency, you must recompile the program.

Using autocompletion (Page 4706)

11.11.6 Editing tag properties in PLC data types

11.11.6.1 Properties of tags in PLC data types

Properties

The following table gives an overview of tag properties in PLC data types:

Group	Property	Description
General	Name	Name of the tags.
	Data type	Data type of the tags.
	Default value	Default value of the tag in the interface of a higher-level code block or in a PLC data type. The values contained in the "Default value" column can only be changed in the higher-level code block or PLC data type. The values are only displayed in the data block.
	Start value	Not relevant in PLC data types
	Comment	Comment on the tag.
Attributes	Retain	Not relevant in PLC data types
User-defined attributes	CFC_Visible	Visible Indicates whether a parameter is visible in CFC.
	CFC_Configurable	Configurable Indicates whether a parameter is configurable in CFC.
	CFC_ForTest	For test Indicates whether a parameter is registered for the CFC test mode.
	CFC_Interconnectable	Interconnectable Indicates whether a parameter is interconnectable in CFC.
	CFC_EnableTagReadback	Enable tag readback Indicates whether a parameter is relevant for the "Read back chart" function in CFC.
	CFC_EnumerationTexts	Enumeration texts Assigns a parameter to an enumeration in CFC.
	CFC_EngineeringUnit	Engineering unit Assigns a parameter to a unit in CFC.
	CFC_LowLimit	Low limit Defines the low limit for the parameter in CFC.
	CFC_HighLimit	High limit Defines the high limit for the parameter in CFC.

Changing the properties of tags in PLC data types (Page 4875)

Structure of the declaration table for PLC data types (Page 4867)

11.11.6.2 Changing the properties of tags in PLC data types

Editing general properties in the declaration table

To edit the general properties of one or more tags, follow these steps:

1. Open the PLC data type.
2. Change the entries in the columns.

Editing detailed properties in the properties window

To edit the detailed properties of an individual tag, follow these steps:

1. Select a tag in the table.
2. Select the "Properties" command in the shortcut menu.
   The inspector window shows the properties of the tag in the "General" and "Attributes" areas.
3. Select the required area in the area navigation.
4. Change the entries in the text boxes.

See also

Updating the block interface (Page 4791)

Updating data blocks (Page 4800)

11.11.7 Editing the declaration table for PLC data types

11.11.7.1 Inserting table rows

Procedure

Proceed as follows to insert a row above the selected row:

1. Select the row in front of which you want to insert a new row.
2. Click the "Insert row" button on the toolbar of the table.

Result

A new row is inserted above the selected row.

11.11.7.2 Inserting table rows

Procedure

Proceed as follows to insert a row below the selected row:

1. Select the row below which you want to insert a new row.
2. Click the "Add row" button on the table toolbar.

Result

A new empty row will be inserted below the selected row.

11.11.7.3 Deleting tags

Procedure

Follow the steps below to delete elements:

1. Select the row with the element to be deleted. You can also select several rows by clicking on them one after the other while holding down the <Ctrl> key or by pressing and holding down <Shift> and clicking on the first and last row.
2. Select the "Delete" command in the shortcut menu.

See also

Updating the block interface (Page 4791)

Updating data blocks (Page 4800)

11.11.7.4 Automatically filling in successive cells

You can load the contents of one or several table cells into the cells below, automatically filling in the successive cells.

If you automatically fill in cells in the "Name" column, a consecutive number will be appended to each name. For example, "Motor" will become "Motor_1".

You can define individual or more cells as well as entire rows as source area.

If less rows exist in the open table than you want to fill, then you will first have to insert additional empty rows.

Requirement

- The table is open.
- Sufficient declaration rows are available.

Procedure

To automatically fill in successive cells, follow these steps:

1. Select the cells to be loaded.
2. Click the "Fill" symbol in the bottom right corner of the cell.
   The mouse pointer is transformed into a crosshair.
3. Keep the mouse button pressed and drag the mouse pointer downwards over the cells that you want to fill in automatically.
4. Release the mouse button.
   The cells are filled in automatically.
5. If entries are already present in the cells that are to be automatically filled in, a dialog appears. In this dialog you can indicate whether you want to overwrite the existing entries or insert new rows for the new tags.

11.11.7.5 Show and hide table columns

You can show or hide the columns in a table as needed.

Procedure

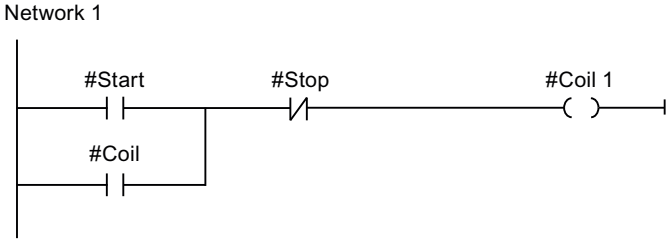
To show or hide table columns, follow these steps:

1. Click a column header.
2. Select the "Show/Hide" command in the shortcut menu.
   The selection of available columns is displayed.
3. To show a column, select the column's check box.
4. To hide a column, clear the column's check box.
5. To hide or show several columns, click "More" and activate or deactivate the check box of the corresponding columns in the "Show/Hide" dialog.

11.12 Creating LAD programs

11.12.1 Basic information on LAD

11.12.1.1 LAD programming language



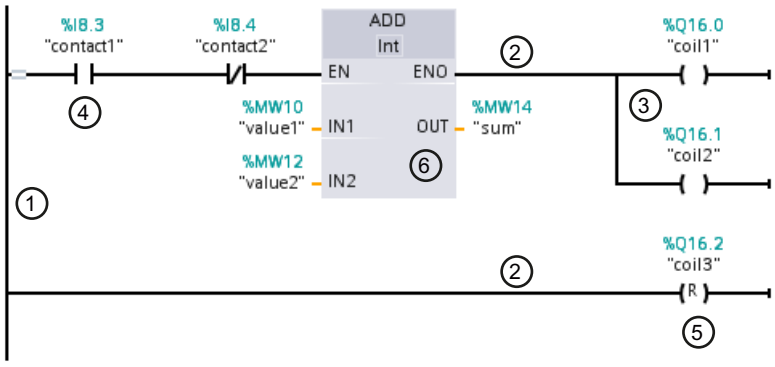
Overview of the Ladder Logic (LAD) programming language

LAD is a graphical programming language. The representation is based on circuit diagrams.

The program is mapped in one or more networks. A network contains a power rail on the left where the rungs originate. The binary signal scans are arranged in the form of contacts on the rungs. The serial arrangement of the elements on a rung creates a series connection; arrangement on simultaneous branches creates a parallel connection. Complex functions are represented by boxes.

Example of networks in LAD

The following figure shows a LAD network with two normally open contacts, one normally closed contact and one coil:



11.12.1.2 Overview of the LAD elements

LAD elements

A LAD program consists of separate elements that you can arrange in series or parallel on the power rail of a network. Most program elements must be supplied with tags.

There is at least one rung from the power rail. Network programming starts at the left edge of the rung. You can expand the power rail by several rungs and branches.

For example, the following figure shows elements of a LAD network:

1) Power rail

2) Rung

3) Branch

4) Contact

5) Coil

6) Box

Power rail

Each LAD network consists of a power rail that contains at least one rung. A network can be extended by adding additional rungs. You can use branches to program parallel connections in the specific rungs.

Contacts

You can use contacts to create or interrupt a current-carrying connection between two elements. The current is relayed from left to right. You can use contacts to query the signal state or the value of an operand and control it depending on the result of the current flow.

The following types of contact are available to you in a LAD program:

- Normally open contact:
  Normally open contacts forward the current if the signal state of a specified binary operand is "1".
- Normally closed contacts:
  Normally closed contacts forward the current if the signal state of a specified binary operand is "0".
- Contact with additional function:
  Contacts with additional function forward the current if a specific condition is met. With these contacts you can also execute an additional function, such as an RLO edge detection and a comparison.

Coils

You can use coils to control binary operands. Coils can set or reset a binary operand depending on the signal state of the result of logic operation.

The following types of coils are available to you in a LAD program:

- Standard coils:
  Standard coils set a binary operand if current flows in the coil. The "Assignment" instruction is an example of a standard coil.
- Coils with additional function:
  These coils have additional functions in addition to the evaluation of the logic operation result. Coils for RLO edge detection and program control are examples of coils with additional function.

Boxes

Boxes are LAD elements with complex functions. The empty box is an exception. You can use the empty box as a placeholder in which you can select the required instruction.

The following types of boxes are available to you in a LAD program:

- Boxes without EN/ENO mechanism:
  A box is executed depending on the signal state at the box inputs. The error status of the processing cannot be queried.
- Boxes with EN/ENO mechanism:
  A box is only executed if the enable input "EN" carries the signal state "1". If the box is processed correctly, the "ENO" enable output has signal state "1". If an error occurs during the processing, the "ENO" enable output is reset.

Calls of code block are also shown in the network as boxes with EN/ENO mechanism.

Rules for the use of LAD elements (Page 4890)

11.12.2 Settings for LAD

11.12.2.1 Overview of the settings for LAD

Overview

The following table shows the settings that you can make:

Group	Setting	Description
Font	Font size	Font size in program editor
View	Layout	Compact or wide Changes the vertical spacing between operands and other objects (such as operand and contact). The change becomes visible once the block is reopened.
	With absolute information	Additional display of the absolute addresses
Operand field	Maximum width	Maximum number of characters that can be entered horizontally in the operand field. This setting recalculates the layout of the networks.
	Maximum height	Maximum number of characters that can be entered vertically in the operand field. This setting recalculates the layout of the networks.

See also

Changing the settings (Page 4881)

11.12.2.2 Changing the settings

Procedure

To change the settings, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Change the settings.

Result

The change will be loaded directly, there is no need to save it explicitly.

Overview of the settings for LAD (Page 4881)

11.12.3 Working with networks

11.12.3.1 Using networks

Function

The user program is created in the block within networks. For a code block to be programmed, it must contain at least one network. To achieve a better overview of the user program, you can also subdivide your program into several networks.

You have the option to insert networks for the textual programming languages SCL and STL in LAD and FBD blocks, and then use instructions in these programming languages. Depending on the CPU you are using, you can insert networks for the following programming languages:

- S7-300/400: STL networks
- S7-1200: SCL networks
- S7-1500: STL and SCL networks

The programming editor always adapts to the network that currently has the focus. This means that you have access to the SCL instructions as well as the SCL functions when programming an SCL network.

Note

You cannot access the blocks that contain SCL networks via the Openness interface.

EN/ENO mechanism in blocks with different network languages

You can also use the EN/ENO mechanism in blocks with different network languages. Each programming language displays the error status differently:

- SCL has an "ENO" tag that stores the error status and can be queried. Direct access to this tag is only possible with SCL.
- LAD/FBD/STL have no special tag for "ENO". However, you can read the error status for STL from the BR bit, and query it via the RET coil for LAD/FBD.

The following rules apply to reading out the error status for the entire block:

- The last network in the block is a LAD/FBD network:
  If you do not use RET coils, the error status is "TRUE" by default.
- The last network in the block is an STL network:
  The BR bit determines the error status. The BR bit can be edited in STL networks using the BR tab.
- The last network in the block is an SCL network:
  The "ENO" tag determines the error status of the block.

Entering a network comment (Page 4888)

Navigating networks (Page 4889)

11.12.3.2 Inserting networks

You can either insert a network of the same programming language or a network for a textual programming language in an LAD or FBD block. Keep in mind, however, that not all CPU types support all textual languages.

Requirement

An LAD or FBD block is open.

Insert LAD or FBD network

To insert a new network, follow these steps:

1. Select the network after which you want to insert a new network.
2. Select the "Insert network" command in the shortcut menu.

Insert STL or SCL network

To insert a new network, follow these steps:

1. Select the network after which you want to insert a new network.
2. Select the "Insert STL network" or "Insert SCL network" command in the shortcut menu.

Result

A new, empty network is inserted in the block in the corresponding programming language.

11.12.3.3 Selecting networks

Requirements

A network is available.

Selecting a network

To select a network, follow these steps:

1. Click the title bar of the network that you want to select.

Selecting several networks

Proceed as follows to select several individual networks:

1. Press and hold down the <Ctrl> key.
2. Click all the networks that you want to select.

To select several successive networks, follow these steps:

1. Press and hold down the <Shift> key.
2. Click the first network that you want to select.
3. Click the last network that you want to select.
   The first and last networks and all those in between are selected.

11.12.3.4 Copying and pasting networks

Copied networks can be pasted within the block or in another block. Networks that were created in LAD or FBD can also be inserted in blocks of the respective other programming language.

Requirement

A network is available.

Procedure

To copy and paste a network, follow these steps:

1. Select the network or networks to be copied.
2. Select "Copy" in the shortcut menu.
3. Select the network after which you want to paste in the copied network.
4. Select "Paste" in the shortcut menu.

11.12.3.5 Deleting networks

Requirement

A network is available.

Procedure

To delete a network, follow these steps:

1. Select the network that you want to delete.
2. Select the "Delete" command in the shortcut menu.

Entering a network comment (Page 4888)
Navigating networks (Page 4889)

11.12.3.6 Expanding and collapsing networks

Requirements

A network is available.

Opening and closing a network

To open a network, follow these steps:

1. Click on the right arrow in the network title bar.

To close a network, follow these steps:

1. Click on the down arrow in the network title bar.

Opening and closing all networks

To open and close all networks, follow these steps:

1. In the toolbar, click "Open all networks" or "Close all networks".

Deleting networks (Page 4885)

Inserting network title (Page 4887)

Entering a network comment (Page 4888)

Navigating networks (Page 4889)

11.12.3.7 Inserting network title

The network title is the header of a network. The length of the network title is limited to one line. You can enter the title manually or set it automatically. When you set it automatically, you can do this for individual networks or use the settings to specify that the network title is always set automatically.

For automatic insertion of the network title, the comment of the operand in one of the following instructions in the network is evaluated:

- Assignment
- Set output
- Reset output

The instruction that is listed first in the network is used.

The network title is only inserted automatically when the following conditions are fulfilled:

- The network does not have a title yet.
- The operand of the instruction used for the comment has a comment.

Note

Note the following restrictions for automatic insertion of the network title:

- The network title is not adapted if you change the comment of the operand at a later time.
- The network title is not adapted if you change the operand of the instruction.
- The network title is only set by the writing instructions listed above.
- If the operand is of the data type array, the comment of the array is used and not the comments of the array elements.
- Comments of invalid operands are not taken into consideration.

Entering the network title manually

To enter a network title, follow these steps:

1. Click on the title bar of the network.
2. Enter the network title.

Setting the network title automatically

To specify that the network titles are always set automatically, follow these steps:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.
3. Select the "Set network title automatically" check box in the "Additional settings" group.
   The network titles are set automatically as of this time if the conditions listed above are fulfilled.

To set an individual network title automatically, follow these steps:

1. Right-click "Network <Number of the network>" in the title bar of a network.
2. Select the "Set network title automatically" command in the shortcut menu.
   The title of the selected network is set based on the comment of the operand if the conditions listed above are fulfilled.

11.12.3.8 Entering a network comment

You can use network comments to provide comments on the program contents of individual networks. For example, you can indicate the function of the network or draw attention to special characteristics.

Requirement

A network is available.

Procedure

To enter a network comment, follow these steps:

1. Click on the right arrow before the network title.
2. If the comment area is not visible, click "Network comments on/off" in the toolbar.
   The comment area is displayed.

3. Click "Comment" in the comment area.
   The "Comment" text passage is selected.
4. Enter the network comment.

Navigating networks (Page 4889)

11.12.3.9 Navigating networks

You can navigate straight to a specific position within a block.

Procedure

To navigate to a specific position within a block, follow these steps:

1. Right-click in the code area of the programming window.
2. Select the "Go to > Network/line" command in the shortcut menu.
   The "Go to" dialog will open.
3. Enter the network to which you want to navigate.
4. Enter the line number of the network to which you want to navigate.
5. Confirm your entry with "OK".

Result

The relevant line will be displayed if this is possible. If the network or line requested does not exist, the last existing network or the last existing line in the network requested will be displayed.

11.12.4 Inserting LAD elements

11.12.4.1 Rules for the use of LAD elements

Rules

Note the following rules when inserting LAD elements:

- Every LAD network must terminate with a coil or a box. However, the following LAD elements must not be used to terminate a network:
  - Comparator boxes
  - Instructions for positive and negative RLO edge detection
- The starting point of the branch for a box connection must always be the power rail. Logic operations or other boxes can be present in the branch before the box.
- Only contacts can be inserted into simultaneous branches with preceding logic operations. The contact for negating the result of logic operation (-|NOT|-) is an exception here. The contact for negating the result of logic operation, as well as coils and boxes, can be used in simultaneous branches if they originate directly from the power rail.
- Constants (e.g. TRUE or FALSE) cannot be assigned to normally closed or normally open contacts. Instead, use operands of the BOOL data type.
- Only one jump instruction can be inserted in each network.
- Only one jump label can be inserted in each network.
- Instructions with positive or negative edge detection may not be arranged directly at the left margin of the rung as they requires a prior logic operation.

Placement rules for S7-1200/1500 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	Name	
SET_BF	Set bit field	No
RESET_BF	Reset bit field	No
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes

Instruction		Preceding logic operation required
Mnemonics	Name	
JMP_LIST	Define jump list	No
SWITCH	Jump distributor	No
RET	Return	No

Placement rules for S7-300/400 CPUs

The following table sets out the instructions that can only be positioned at the end of the network:

Instruction		Preceding logic operation required
Mnemonics	Name	
S	Set output	Yes
R	Reset output	Yes
SP	Start pulse timer	Yes
SE	Start extended pulse timer	Yes
SD	Start on-delay timer	Yes
SS	Start retentive on-delay timer	Yes
SF	Start off-delay timer	Yes
SC	Set counter value	Yes
CU	Count up	Yes
CD	Count down	Yes
JMP	Jump if RLO = 1	No
JMPN	Jump if RLO = 0	Yes
RET	Return	No
OPN	Open global data block	No
OPNI	Open instance data block	No
CALL	Call block	No
SAVE	Save RLO in BR bit	No
MCRA	Enable MCR range	No
MCRD	Disable MCR range	No
MCR<	Open MCR ranges	No
MCR>	Close MCR ranges	No

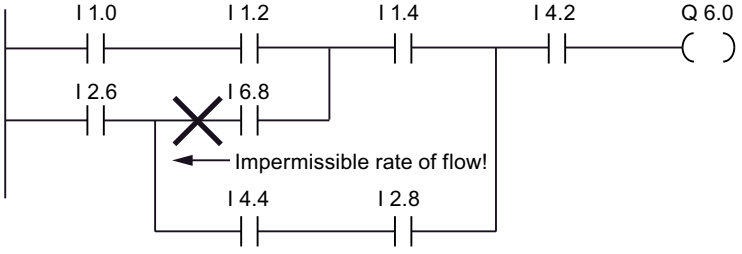
Note

Calling blocks with binary inputs in S7-300/400 CPUs

The following FAQ describes the special features when calling blocks with binary inputs:

FAQ 13988019: What should you watch out for when programming nested FB/FC calls with binary inputs in FBD? (Page 4892)

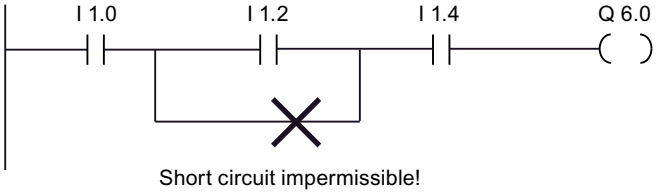
See also



Overview of the LAD elements (Page 4878)

FAQ 13988019 (https://support.industry.siemens.com/cs/de/de/view/13988019)

11.12.4.2 Prohibited interconnections in LAD



Power flow from right to left

No branches can be programmed that could result in a power flow in the reverse direction.

Short-circuit

No branches may be programmed that would cause a short-circuit.

Logic operations

The following rules apply to logic operations:

- Only Boolean inputs can be combined with preceding logic operations.
- Only the first Boolean output can be combined with a further logic operation.
- Only one complete logical path can exist per network. Paths that are not connected can be linked.

See also

Rules for the use of LAD elements (Page 4890)

11.12.4.3 Inserting LAD elements using the "Instructions" task card

Requirement

A network is available.

Procedure

To insert a LAD element into a network using the "Instructions" task card, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to the LAD element that you want to insert.
3. Use drag-and-drop to move the element to the desired place in the network.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog, you can determine if the data of the inserted element is to be stored in a single, multi or parameter instance. If you select "Single instance", you can find the new instance data block once it is created in the "Program resources" folder of the project tree under "Program blocks > System blocks". You can find multi-instances in the block interface in the "Static" section and parameter instances in the "InOut" section.

Or:

1. Select the point in the network at which you want to insert the element.
2. Open the "Instructions" task card.
3. Double-click on the element you want to insert.
   If the element is an internal system function block (FB), the "Call options" dialog opens. In this dialog, you can determine if the data of the inserted element is to be stored in a single, multi or parameter instance. If you select "Single instance", you can find the new instance data block once it is created in the "Program resources" folder of the project tree under "Program blocks > System blocks". You can find multi-instances in the block interface in the "Static" section and parameter instances in the "InOut" section.

Result

The selected LAD element is inserted with placeholders for the parameters.

11.12.4.4 Inserting LAD elements using an empty box

Requirement

A network is available.

Procedure

To insert an LAD element into a network using an empty box, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Empty box" in the "Basic instructions" palette.

3. Use a drag-and-drop operation to move the "Empty box" element to the desired place in the network.
4. Position the cursor over the triangle in the top right-hand corner of the empty box.
   A drop-down list is displayed.
5. Select the required LAD element from the drop-down list.
   If the element is an internal system function block (FB), the "Call option" dialog opens. In this dialog, you can determine if the data of the inserted element is to be stored in a single, multi or parameter instance. If you select "Single instance", you can find the new instance data block once it is created in the "Program resources" folder of the project tree under "Program blocks > System blocks". You can find multi-instances in the block interface in the "Static" section and parameter instances in the "InOut" section.

Result

The empty box is changed to the respective LAD element. Placeholders are inserted for the parameters.

11.12.4.5 Selecting the data type of a LAD element

Selecting a data type

Introduction

Some instructions can be executed with several different data types. If you use one of these instructions in the program, you have to specify a valid data type for the instruction at the specific point in the program. For some instructions, you have to select the data types for the inputs and outputs separately.

Note

The valid data type (BOOL) for the tags on the enable input EN and the enable output ENO is predefined by the system and cannot be changed.

The valid data types for an instruction are listed in the instruction drop-down list. You specify the data type of the instruction by selecting an entry from the drop-down list. If the data type of an operand differs from the data type of the instruction and cannot be converted implicitly, the operand is displayed in red and a rollout with the corresponding error message appears.

Data type selection of mathematical instructions

Some mathematical instructions provide you with the option of having the data type automatically set corresponding to the data types of the operand. In the drop-down list for data type selection, these instructions have the entry "Auto" in addition to the actual data types. If you select this entry and then allocate the first operand, the data type of the operand is selected as data type for the instruction. The entry in the drop-down list changes to "Auto (<Data type>)", e.g. "Auto (Real)". If you allocate additional operands, the automatically set data type of the instruction is adjusted according to the following criteria:

- You supply all other operands with tags of the same data type:
  The data type of the instruction is not changed.
- You supply all other operands with tags whose data type is smaller than the data type of the instruction:
  The data type of the instruction is not changed. For the operand with the smaller data type, an implicit conversion is conducted if necessary.
- You supply an additional operand with a tag whose data type is greater than the data type of the instruction:
  The data type of the instruction is changed to the larger data type. An implicit conversion is performed, if necessary, for operands that deviate from the newly set data type of the instruction.

Each change in the data type of an operand can result in a change of the data type of the instruction. Other operands may possibly be implicitly converted as a result. Operands for which an implicit conversion is performed are marked with a gray square.

Note

Please also observe the information on data type conversion for your device and, in particular, the notes on the IEC check.

See also: Data type conversion (Page 2465)

See also

Defining the data type of an instruction (Page 4895)

Defining the data type of an instruction

Introduction

Some instructions can be executed with several different data types. When you insert such instructions into your program, you must specify the data type for these instructions at the actual point in the program.

Specifying the data type by means of the drop-down list

To define the data type of an instruction using the drop-down list, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Click the triangle in the upper corner of the drop-down list.
   The drop-down list will open to display the data types valid for the instruction.
3. Select a data type from the drop-down list.
   The selected data type is displayed.
4. If the instruction has two drop-down lists, select the data type for the instruction inputs in the left-hand drop-down list and the data type for the instruction outputs in the right-hand drop-down list.

Specifying data type by assigning tags

To define the data type of an instruction by assigning tags, follow these steps:

1. Insert the instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. At an input or output, specify a valid tag, the data type of which is to be applied as the instruction data type.
   The data type of the tag is displayed in the drop-down list.
3. Enter a valid tag at an input and a valid tag at an output if data types need to be defined for both the inputs and outputs of the instruction. The tag specified at the input determines the data type of the inputs; the tag specified at the output determines the data type of the outputs of the instruction.

Automatically specifying the data type of mathematical instructions

To automatically specify the data type for mathematical instructions, follow these steps:

1. Insert the mathematical instruction at the required point in the program using drag-and-drop.
   The entry "???" (undefined) is displayed in the drop-down list of the inserted instruction.
2. Select the "Auto" entry from the drop-down list.
3. Enter a valid tag at an input or output.
   The data type of the tag is applied as data type of the instruction. The entry in the drop-down list changes to "Auto (<Data type>)".

11.12.4.6 Using favorites in LAD

Adding LAD elements to Favorites

Requirement

- A block is open.
- The multipane mode is set for the "Instructions" task card or the Favorites are also displayed in the editor.

Procedure

To add SCL instructions to the Favorites, follow these steps:

1. Open the "Instructions" task card.
2. Maximize the "Basic instructions" pane.
3. Navigate in the "Basic instructions" pane to the instruction that you want to add to the Favorites.
4. Drag-and-drop the instruction into the "Favorites" pane or into the Favorites area in the program editor.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

Removing LAD elements from Favorites (Page 4898)

Overview of the program editor (Page 4684)

Inserting LAD elements using favorites

Requirement

- A block is open.
- Favorites are available.

Procedure

To insert an instruction into a program using Favorites, follow these steps:

1. Drag-and-drop the desired instruction from Favorites to the desired position.

Or:

1. Select the position in the program where you want to insert the instruction.
2. In the Favorites, click on the instruction you want to insert.

Note

To additionally display the Favorites in the program editor, click the "Display favorites in the editor" button in the program editor toolbar.

11.12.4.7 Insert block calls in LAD

Inserting block calls using a drag-and-drop operation

You can insert calls for existing functions (FC) and function blocks (FB) using a drag-and-drop operation from the project tree. If you call function blocks from other function blocks, you can either call them as a single instance, multi-instance or parameter instance.

See also: AUTOHOTSPOT

Requirement

- A network is available.
- The block that is to be called is available.

Inserting a call of a function (FC)

To insert a call of a function (FC) into a network using a drag-and-drop operation, follow these steps:

1. Drag the function from the project tree to the required network.

Inserting a call for a function block (FB)

To insert a call for a function block (FB), follow these steps:

1. Drag the function block from the project tree to the required network.
   The "Call options" dialog opens.
2. In the dialog, enter whether you want to call the block as a single, multi or parameter instance.
   - If you click on the "Single instance" button, you will have to enter a name in the "Name" text box for the data block that you want to assign to the function block.
     If you call a block that contains monitoring, assign a ProDiag function block to the monitoring functions in the "ProDiag FB" text box.
   - If you click on the "Multi-instance" button, you will have to enter the name of the tag in the "Name in the interface" text box; this is the name that you use to enter the called function block as a static tag in the interface of the calling block.
   - If you click on the "Parameter instance" button, enter the name of the in/out (InOut) parameter to which the instance should be passed during runtime in the "Name in the interface" text box.
3. If you call a block that contains monitoring, assign a ProDiag function block to the monitoring functions.
4. Confirm your entries with "OK".

Result

The function or the function block is inserted with its parameters. You can then assign the parameters.

See also: AUTOHOTSPOT

Note

If when calling a function block you specify an instance data block that does not exist, it will be created.

See also

Updating block calls in LAD (Page 4900)

Changing the instance type (Page 4902)

Updating block calls in LAD

If interface parameters of a called block are changed, the block call can no longer be executed correctly. You can avoid such inconsistent block calls by updating the block calls.

You have the following options for updating the block calls:

- Explicit updating of all inconsistent block calls in the program editor.
  The inconsistent block calls within the open block are updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Explicit updating of a block call in the program editor.
  The "Interface update" dialog is displayed. In this dialog, you have the option of changing the connection of the operands of the new interface. The inconsistent call of this block is then updated. The following actions are carried out in the process:
  - New parameters are added.
  - Deleted parameters are removed if they are not connected.
  - Renamed parameters get the new parameter names.
- Implicit updating during compilation.
  All block calls in the program as well as the used PLC data types will be updated. Note that when you call functions (FCs) before the next compilation process, all new formal parameters must be supplied with actual parameters.

Updating all inconsistent block calls in the program editor

To open all block calls in a block, follow these steps:

1. Open the calling block in the program editor.
2. Click "Update inconsistent block calls" in the toolbar.

Updating a specific block call in the program editor

To update a specific block call in the program editor, follow these steps:

1. Open the calling block in the program editor.
2. Right-click on the block call that you want to update.
3. Select the "Update" command in the shortcut menu.
   The "Interface update" dialog opens. This dialog shows the differences between the block interface in use and the changed interface of the called block.
4. If necessary, change the connection of the operands. To do this, you have the following options:
   - You can use either a drag-and-drop operation or a cut/copy-and-paste operation to move the operand from the old interface to the new interface.
   - You can delete an operand.
   - You can rename an operand.
   - You can specify a new operand via autocompletion.
5. Click "OK" to update the block call. If you want to cancel the update, click "Cancel".

Note

Note that the "Update block call" command is only available provided you did not previously update all block calls in the editor with the "Update inconsistent block calls" command.

Update block calls during compilation

Follow these steps to update all block calls and uses of PLC data types during compilation implicitly:

1. Open the project tree.
2. Select the "Program blocks" folder.
3. Select the command "Compile > Software (rebuild all blocks)" in the shortcut menu.

See also

Inserting block calls using a drag-and-drop operation (Page 4899)

Changing the instance type (Page 4902)

Changing the block call

You have the option of changing the called block for a block call. But keep in mind that no new instance data blocks are created, for example, when changing from a function (FC) to a function block (FB).

Procedure

To change the called block of a block call, follow these steps:

1. Click on the name of the called block within the block call and press the <F2> key. Or double-click the name of the called block.
   A text box opens, and the name of the currently called block is selected.
2. Enter the name of the block you want to call or select a block in the autocompletion.
3. If you want to call an FB, create a new instance data block, if necessary, and specify it as operand.

Changing the instance type

Instance type

There are two ways of calling function blocks:

- As a single instance
- As a multiple instance
- As parameter instance

See also: AUTOHOTSPOT

You can modify a defined instance type at any time.

Requirement

The user program contains a block call.

Procedure

To change the instance type of a function block, follow these steps:

1. Open the code block and select the block call.
2. Select the "Change instance" command in the shortcut menu.
   The "Call options" dialog opens.
3. Click on the button "Single instance", "Multi-instance" or "Parameter instance".
   - If you select the "Single instance" instance type, enter a name for the data block that is to be assigned to the function block.
   - If you select "Multiple instance" as the instance type, enter in the "Name in the interface" text field the name of the tag with which the called function block is to be entered as a static tag in the interface of the calling block.
   - If you select "Parameter instance" as the instance type, enter the name of the in/out (InOut) parameter to which the instance should be passed during runtime in the "Name in the interface" text box.
4. Confirm your entries with "OK".

Note

The previous instances are not deleted automatically.

11.12.4.8 Inserting complex LAD instructions

Using the "Calculate" instruction (S7-1200, S7-1500)

Requirement

A network is available.

Procedure

Proceed as follows to use the "Calculate" instruction:

1. Open the "Instructions" task card.
2. Navigate to "Math functions > CALCULATE" in the "Basic instructions" pane.
3. Use drag-and-drop to move the element to the desired place in the network.
   The instruction "Calculate" will be inserted for the data type with a placeholder expression and question mark.
4. Enter the data type for the calculation.
5. Enter the operands for the calculation.

   Note

   The calculation is run with the inputs of the "Calculate" instruction. If you want to use constants you must also insert appropriate inputs for them.

6. Click on the "Edit 'Calculate' instruction" button to replace the placeholder expression with the correct expression.
   The "Edit 'Calculate' instruction" dialog will open.

7. Enter the required expression in the "OUT:= " text box.

   Note

   In the "Example" area you can find an example of a valid expression and possible instructions that you can use.

   To determine a value with the help of Pythagoras' theorem, for example, enter "OUT := SQRT (SQR (IN1) + SQR (IN2))".

8. Confirm your entry with "OK".

11.12.4.9 Using free-form comments

Basic information on using free-form comments in LAD

Introduction

Free-form comments allow you to add comments to the source code for graphic programming languages similar to line comments for textual languages.

Free-form comments can be used for the following elements:

- Boxes
- Coils

Commenting out program code

To deactivate individual instructions or entire program sections in the LAD and FBD programming languages, you must set a bit parallel to the instruction or in series to an instruction block. Commenting out, as in STL and SCL, is not possible in LAD and FBD.

Examples of commenting out program code in all programming languages are available in the Siemens Industry Online under the following FAQ ID: 109482004 (https://support.industry.siemens.com/cs/hu/en/view/109482004)

Deleting free-form comments (Page 4906)

Inserting free-form comments

Requirement

A network with instructions is available.

Procedure

To insert a free comment on an instruction, proceed as follows:

1. If necessary, activate the "Free-form comments on/off" button in the toolbar.
2. Right-click on the instruction for which you want to insert a free-form comment.
3. Select the "Insert comment" command in the shortcut menu.
   A comment box with a standard comment opens. The comment box is connected by an arrow to the corresponding instruction.
4. Enter the required comment in the comment box.

See also

Basic information on using free-form comments in LAD (Page 4904)

Editing free-form comments (Page 4905)

Deleting free-form comments (Page 4906)

Editing free-form comments

Introduction

Free-form comments can be edited as follows:

- Changing the comment text
- Changing the position and size of the comment box
- Attaching a comment to another element
- Showing and hiding free comments

Changing the comment text

To change the text of free-form comments, follow these steps:

1. Click on the comment box.
2. Enter the desired text.

Changing the position of the comment box

To change the positioning of the comment box, follow the steps below:

1. Left-click the comment box and keep the mouse button pressed.
2. Drag the comment box to the desired location.

Changing the size of the comment box

To change the size of the comment box, follow the steps below:

1. Click on the comment box.
2. Drag the comment box on the move handle in the lower right corner to the desired size.

Attaching a comment to another element

To attach a free-form comment to another element, follow these steps:

1. Left-click the point of the arrow that links the comment box with the instruction and keep the mouse button pressed.
2. Drag the arrow to the element to which you want to attach the comment. Possible insertion points are marked with a green square.
3. Release the mouse button.

Showing and hiding free comments

To show or hide a free-form comments, follow these steps:

1. Click the "Free-form comment on/off" button in the toolbar.

See also

Editing free-form comments (Page 4905)

11.12.5 Editing LAD elements

11.12.5.1 Selecting LAD elements

You can select several individual elements or all elements in a network.

Requirement

LAD elements are available

Selecting several individual LAD elements

To select several individual LAD elements, follow these steps:

1. Press and hold down the <Ctrl> key.
2. Click on all the LAD elements you wish to select.
3. Now release the <Ctrl> key.

Selecting all LAD elements in a network

To select all LAD elements in a network, follow these steps:

1. Go to the network whose elements you wish to select.
2. Select the "Select all" command in the "Edit" menu or press <Ctrl A>.

See also

Copying LAD elements (Page 4908)

Removing inputs and outputs (Page 4911)

Deleting LAD elements (Page 4912)

11.12.5.2 Copying LAD elements

Requirement

An LAD element is available.

Procedure

To copy a LAD element, follow these steps:

1. Right-click the LAD element that you want to copy.
2. Select "Copy" in the shortcut menu.

Result

The LAD element will be copied and saved to the clipboard.

See also

Selecting LAD elements (Page 4907)
Cutting LAD elements (Page 4908)

Removing inputs and outputs (Page 4911)
Deleting LAD elements (Page 4912)

11.12.5.3 Cutting LAD elements

Requirement

An LAD element is available.

Cutting

To cut a LAD element, follow these steps:

1. Right-click the LAD element that you want to cut.
2. Select "Cut" in the shortcut menu.

Result

The LAD element will be cut and saved to the clipboard.

See also

Selecting LAD elements (Page 4907)

Removing inputs and outputs (Page 4911)
Deleting LAD elements (Page 4912)

11.12.5.4 Pasting an LAD element from the clipboard

Requirement

An LAD element is available.

Procedure

To paste an LAD element from the clipboard, follow these steps:

1. Copy a LAD element or cut a LAD element.
2. Right-click the point in the network where you want to paste the element.
3. Select "Paste" in the shortcut menu.

See also

Selecting LAD elements (Page 4907)

Removing inputs and outputs (Page 4911)
Deleting LAD elements (Page 4912)

11.12.5.5 Replacing LAD elements

You can easily exchange LAD elements with other LAD elements of the same type. This has the advantage that the parameters are retained and need not be entered again. For example, you can exchange normally open contacts and normally closed contacts or RS FlipFlop and SR FlipFlop.

Requirements

A network with at least one LAD element is present.

Procedure

To replace an LAD element with another LAD element, follow these steps:

1. Select the LAD element that you want to replace.
2. Position the cursor over the triangle in the top right-hand corner of the LAD element.
   A drop-down list is displayed.
3. From the drop-down list, select the LAD element that you want to use to replace the existing LAD element.

Removing inputs and outputs (Page 4911)

Deleting LAD elements (Page 4912)

11.12.5.6 Inserting additional inputs and outputs in LAD elements (S7-1200, S7-1500)

Introduction

You can expand LAD elements which execute commutative arithmetic instructions by adding additional inputs. Such elements are, for example, the instructions "Add" (ADD) and "Multiply" (MUL). You can expand the MOVE and DEMUX instruction boxes by adding additional outputs.

Requirement

An LAD element is available that permits the insertion of additional inputs and outputs.

Inserting an additional input

To add an additional input to the box of a LAD element, follow these steps:

1. Right-click on an existing input of the LAD element.
2. Select "Insert input" in the shortcut menu.
   An additional input is added to the box of the LAD element.

Or:

1. Click on the yellow star symbol beside the last input in the instruction box.
   An additional input is added to the box of the LAD element.

Inserting an additional output

To add an additional output to the box of a LAD element, follow these steps:

1. Right-click on an existing output of the LAD element.
2. Select "Insert output" from the shortcut menu.
   An additional output is added to the box of the LAD element.

Or:

1. Click on the yellow star symbol beside the last input in the instruction box.
   An additional output is added to the box of the LAD element.

Deleting LAD elements (Page 4912)

11.12.5.7 Removing inputs and outputs (S7-1200, S7-1500)

Introduction

Inputs and outputs which you have added to an instruction can be removed.

Requirement

An LAD element is available to which you have added additional inputs and outputs.

Remove input

To remove an input, follow these steps:

1. Select the input that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The input of the LAD element is removed.

Remove output

To remove an output, follow these steps:

1. Select the output that you want to remove.
2. Select the "Delete" command in the shortcut menu.
   The output of the LAD element will be removed.

Removing inputs and outputs (Page 4911)

11.12.6 Inserting operands into LAD instructions

11.12.6.1 Inserting operands

The character strings "<???>", "<??.?>" and "..." are inserted as placeholders for the parameters when an LAD element is inserted. The "<???>" and "<??.?>" strings displayed in red indicate parameters that need to be connected. The "..." string displayed in black indicates parameters that may be connected. "<??.?>" stands for Boolean placeholders. In addition, LAD elements can have the following different I/Os for the parameters:

- Orange I/Os: Only tags or constants can be interconnected at this I/O.
- Black I/Os: Boolean input or output to which other elements can be connected upstream or downstream.

Note

If you position the cursor over the placeholder, the expected data type will be displayed.

Requirement

An LAD element is available.

Procedure

To connect the parameters of a LAD element, follow these steps:

1. Double-click the placeholder of the parameter.
   An entry field opens, and the placeholder is selected.
2. Enter the appropriate parameter.

   Note

   If you enter the absolute address of a parameter that has already been defined, this absolute address will be changed to the symbolic name of the parameter as soon as the input is confirmed. If you have not yet defined the parameter, a new tag with this absolute address and the default name "Tag_<n>" will be entered in the PLC tag table. When you confirm your input, the absolute address will be replaced with the symbolic name "Tag_<n>".

3. Confirm the parameter with the Enter key.
4. If you have not yet defined the parameter, you can define it directly in the program editor using the shortcut menu.
   See also:
   Declaring PLC tags in the program editor (Page 4847)
   Declaring local tags in the program editor (Page 4773)

Or drag from it the PLC tag table:

1. In the project tree, select the "PLC tags" folder or open the PLC tag table.
2. If you have opened the PLC tag table, drag the symbol from the first column of the desired tag to the appropriate place in your program. If you have not opened the PLC tag table yet, open the detail view now. Drag the desired tag from the detail view to the appropriate place in your program.

Or drag from it the block interface:

1. Open the block interface.
2. Drag the required operand from the block interface to the instruction window.

Result

- If the syntax is error-free, the displayed parameter is black. The editor then jumps to the next placeholder.
- If there is an error in the syntax, the cursor stays in the entry field and a corresponding error message is displayed in the status line. If you press the Enter key again, the entry field is closed and the faulty entry is displayed in red italics.

See also

Using autocompletion (Page 4706)

11.12.6.2 Wiring hidden parameters

Introduction

If an instruction contains hidden parameters, the instruction box has a small arrow on the lower edge. You can recognize hidden parameters by their white font.

You can show and wire the hidden parameters at any time.

Showing or hiding hidden parameters

To show or hide hidden parameters, follow these steps:

1. Click on the down arrow at the bottom edge of the instruction box to show hidden parameters.
2. Click on the up arrow at the bottom edge of the instruction box to hide hidden parameters.

Wiring hidden parameters

To wire parameters, follow these steps:

1. Wire the hidden parameters like normally visible parameters.
   Its visibility may change due to the interconnection of the parameter:
   - The parameter is visible if you have selected the "Hide, if no parameter is assigned" option in the properties.
   - The parameter remains hidden if you have selected the "Hide" option in the properties.

See also

Hiding parameters during the block call (Page 4782)

11.12.6.3 Displaying or hiding tag information

Introduction

You can display the following information about the tags to be used in the Program editor:

- Name of the tag
- Tag addresses
- Simple or hierarchical comments to document the tags

The information is taken from the block interface for local tags and DB tags and from the PLC tag table for tags that are valid CPU-wide.

You can display the tag information either for all the blocks or for individually opened blocks. If you display the tag information for all the blocks, the tag information for all the blocks currently opened and opened in future is shown. You can hide the tag information at any time again. If you have hidden the tag information for all blocks, you can display it again for individual blocks that are open.

When you select the display of tag information with hierarchical comments, the comments of the higher structure levels are also displayed for structured tags. The comments are shown in brackets after the tag comment; the comments of the individual levels are separated by a dot. If there is no comment for a tag on a structure level, it is not displayed. This is indicated by two successive dots.

You can display the tag information either collectively below a LAD/FBD network or directly at the respective operand. As with showing and hiding tag information, you can set this via the settings for all block or change specifically for an opened block.

Displaying or hiding tag information for all the blocks

Proceed as follows to display or hide the tag information for all the blocks:

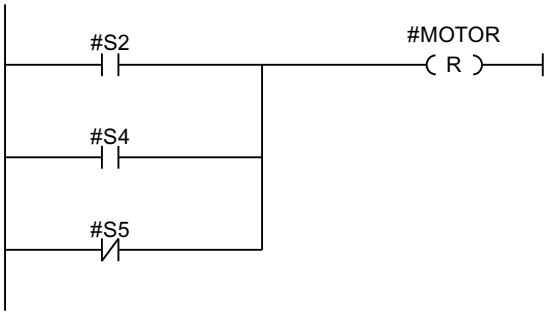
1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. In the area navigation, select the "PLC programming" group.

3. If you want to display the tag information, select the "Show" option or the "Tag information with hierarchical comments" option in the drop-down list, depending on whether you want to display simple or hierarchical comments.
4. Use the "Position of the tag information (LAD/FBD)" drop-down list to specify whether the tag information is to be displayed below the LAD/FBD network or on the operand.
   For all open blocks, the tag information is shown and displayed at the selected position. If you open additional blocks the tag information for these blocks is also shown.
5. If you want to hide the tag information, select the option "Hide" in the "Tag information" drop-down list.
   The tag information is hidden for all open blocks. If you open additional blocks the tag information for these blocks is also hidden.

Displaying or hiding tag information for an opened block

Proceed as follows to display or hide the tag information for an opened block:

1. If you want to display the tag information, select the "Show tag information" option or the "Tag information with hierarchical comments" option in the "Shows the tag information" drop-down list, depending on whether you want to display simple or hierarchical comments.
2. To define the position of the tag information, click the "Position of the tag information (LAD/FBD)" button in the program editor toolbar. The position changes with each click on the button. Alternatively, you can click the small arrow beside the "Position of the tag information (LAD/FBD)" button to open the drop-down list. Than select the position from the drop-down list.
   The tag information is shown and displayed at the selected position.
3. If you want to hide the tag information, select the option "Hide tag information" in the "Shows the tag information" drop-down list.
   The tag information is hidden.



11.12.7 Branches in LAD

11.12.7.1 Basic information on branches in LAD

Definition

You use branches to program parallel circuits with the Ladder Logic (LAD) programming language. Branches are inserted in the main rung. You can insert several contacts into the branch and thus achieve a parallel circuit of series connections. This allows you to program complex ladder logic.

The figure below shows an example of the use of branches:

MOTOR carries signal 1, if one of the following conditions is fulfilled:

- Signal 1 is pending on S2 or S4
- Signal 0 is pending on S5.

See also

Rules for branches in LAD (Page 4917)

Inserting branches into the LAD network (Page 4918)

Closing branches in the LAD network (Page 4918)

Deleting branches in LAD networks (Page 4919)

11.12.7.2 Rules for branches in LAD

Rules

The following rules apply to simultaneous branches:

- A simultaneous branch can only be inserted if the main branch already contains an LAD element.
- Simultaneous branches are opened downwards or are connected directly to the power rail. They are terminated upwards.
- Simultaneous branches are opened after the selected LAD element.
- Simultaneous branches are terminated after the selected LAD element.
- To delete a simultaneous branch, you must delete all LAD elements of this branch. When the last LAD element is removed from the branch, the rest of the branch is also removed.
- You can only insert a coil in a parallel connection when the parallel connection starts directly at the power rail.

See also

Basic information on branches in LAD (Page 4916)

Inserting branches into the LAD network (Page 4918)

Deleting branches in LAD networks (Page 4919)

Closing branches in the LAD network (Page 4918)

11.12.7.3 Inserting branches into the LAD network

You can create several branches in a network.

Requirement

- A network is available.
- The network contains elements.

Procedure

To insert a new branch in a network, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Open branches" in the "Simple instructions" palette.
3. Use drag-and-drop to move the element to the desired place in the network.
   If you want to connect the new branch directly to the power rail, drag the element to the power rail.

See also

Basic information on branches in LAD (Page 4916)

Rules for branches in LAD (Page 4917)

Deleting branches in LAD networks (Page 4919)

11.12.7.4 Closing branches in the LAD network

Branches must be closed again at suitable places. If necessary, branches will be arranged so that they do not cross each other.

Requirement

A branch is available.

Procedure

To close an open branch, follow these steps:

1. Select the open branch.
2. Press and hold down the left mouse button.
   A dashed line will appear as soon as the cursor is moved.

3. Drag the dashed line to a suitable place on the network. Permissible connections are indicated by green lines.
4. Release the left mouse button.

See also

Basic information on branches in LAD (Page 4916)

Rules for branches in LAD (Page 4917)

11.12.7.5 Deleting branches in LAD networks

Requirement

A branch is available.

Procedure

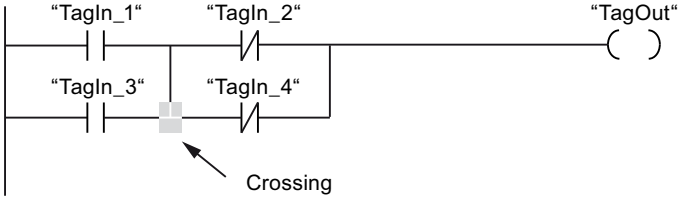
To delete a branch, follow these steps:

1. Select the connection line that links the branch to the main branch.
2. Select the "Delete" command in the shortcut menu.

See also

Basic information on branches in LAD (Page 4916)

Rules for branches in LAD (Page 4917)



Inserting branches into the LAD network (Page 4918)

11.12.8 Crossings in LAD

11.12.8.1 Basic information on crossings in LAD

Definition

A crossing is a place in a LAD network where one branch is closed and at the same time another branch is opened.

"TagOut" receives signal 1, if the following two conditions are met:

- "TagIn_1" or "TagIn_3" has signal 1
- "TagIn_2" or "TagIn_4" has signal 0

11.12.8.2 Inserting crossings

You can insert crossings in a LAD network by creating connections between the main branch and an additional branch or between different branches.

Requirements

A branch is available.

Procedure

To insert a new crossing in an LAD network, follow these steps:

1. Open the "Instructions" task card.
2. Navigate to "General > Open branches" in the "Simple instructions" palette.
3. Drag the element behind the existing branch.
4. Insert any element into the open branch.
5. Click the arrow of the open branch after the inserted element.
6. Hold down the left mouse button and drag the dashed connecting line to the main branch.
7. Release the left mouse button.

See also

Rearranging crossings (Page 4920)

Deleting crossings (Page 4921)

Inserting branches into the LAD network (Page 4918)

11.12.8.3 Rearranging crossings

Requirement

A crossing is available.

Procedure

To rearrange a connection, follow these steps:

1. Select the connection line that defines the crossings in the respective branches.
2. Select the "Delete" command in the shortcut menu.
3. Open the "Instructions" task card.
4. Navigate to "General > Open branches" in the "Simple instructions" palette.
5. Use a drag-and-drop operation to move the element to the place in the network where you want to insert the new crossing.
6. Click on the arrow for the open branch.
7. Hold down the left mouse button and drag the dashed connecting line to the subsidiary branch in which you wish to insert the new crossing.
8. Release the left mouse button.

11.12.8.4 Deleting crossings

Requirement

A crossing is available.

Procedure

To delete a crossing, follow these steps:

1. Select the connection line that defines the crossings in the respective branches.
2. Select the "Delete" command in the shortcut menu.

11.12.9 Rungs in LAD

11.12.9.1 Basic information on rungs in LAD

Using rungs

The program is mapped in one or more networks. A network contains a power rail on the left where one or more rungs originate. The binary signal scans are arranged in the form of contacts on the rungs. The serial arrangement of the elements on a rung creates a series connection; arrangement on simultaneous branches creates a parallel connection. A rung is closed by a coil or a box in which the result of logic operation will be written.

The figure below shows an example of the use of several rungs within a network:

Rules

Remember the following rules when using several rungs:

- Connections are not permitted between rungs.
- Only one jump instruction is permissible per network. The positioning rules for jump instructions remain valid.

Running rungs

Rungs and networks are executed from top to bottom and from left to right. This means that the first instruction in the first rung of the first network is processed first. All instructions of this rung are then processed. After this come all other rungs of the first network. The next network is processed only after all rungs have first been run.

Differences between branches and rungs

The difference between branches and rungs is that the rungs are independent branches that can also stand in a different network. Branches, on the other hand, permit the programming of a parallel connection.

Insert rung (Page 4923)

Deleting a rung (Page 4923)

11.12.9.2 Insert rung

Requirement

- A block is open.
- A network is available.

Procedure

To insert a new rung in a network, proceed as follows:

1. Insert any coil on the power rail.
   A new rung will be inserted and the coil positioned at the end of the rung.
2. Insert additional instructions in the new rung.

Deleting a rung (Page 4923)

11.12.9.3 Deleting a rung

Requirement

A rung is available.

Procedure

To delete a rung, proceed as follows:

1. Hold down the left mouse button and draw a frame around the rung. At the same time, make sure that you select all instructions. Alternatively, you can hold down the <Shift> key and select the first the last instruction of the rung.
2. Right-click on one of the instructions in the rung.
3. Select the "Delete" command in the shortcut menu.

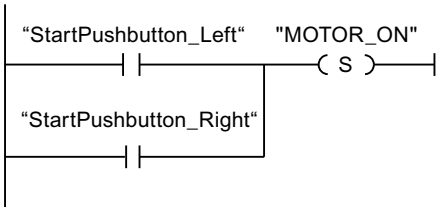
11.12.10 LAD programming examples

11.12.10.1 Example of controlling a conveyor belt

Controlling a conveyor belt

The following figure shows a conveyor belt that can be activated electrically. There are two pushbuttons at the beginning of the conveyor belt: S1 for START and S2 for STOP. There are also two pushbuttons at the end of the conveyor belt: S3 for START and S4 for STOP. It is possible to start and stop the conveyor belt from either end.

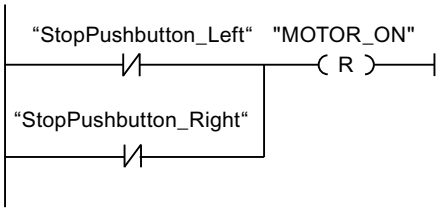
Implementation



The following table shows the definition of the tags used:

Name	Declaration	Data type	Description
StartPushbutton_Left (S1)	Input	BOOL	Start pushbutton on the left side of the conveyor belt
StopPushbutton_Left (S2)	Input	BOOL	Stop pushbutton on the left side of the conveyor belt
StartPushbutton_Right (S3)	Input	BOOL	Start pushbutton on the right side of the convey-or belt
StopPushbutton_Right (S4)	Input	BOOL	Stop pushbutton on the right side of the convey-or belt
MOTOR_ON	Output	BOOL	Turn on the conveyor belt motor

The following networks show the LAD programming for solving this task:



Network 1:

The conveyor belt motor is switched on when start pushbutton "S1" or "S3" is pressed.

Network 2:

The conveyor belt motor is switched off when stop pushbutton "S2" or "S4" is pressed.

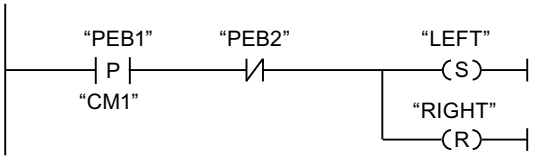
11.12.10.2 Example of detecting the direction of a conveyor belt

Detecting the direction of a conveyor belt

The detected running direction of the belt is indicated by a RIGHT arrow or a LEFT arrow. If additional conveyed material is approaching PEB1 from the right or PEB2 from the left, the displayed arrow is initially switched off until, after both photoelectric barriers are passed, the running direction can be detected again and the corresponding arrow displayed. For the solution of the task, 2 edge memory bits are needed that detect the signal change from "0" to "1" at the two photoelectric barriers.

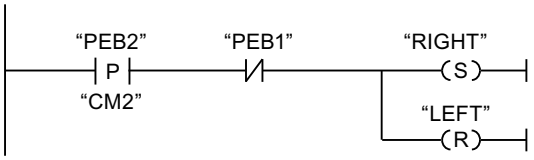
Implementation



The following table shows the definition of the tags used:

Name	Declaration	Data type	Description
PEB1	Input	BOOL	Photoelectric barrier 1
PEB2	Input	BOOL	Photoelectric barrier 2
RIGHT	Output	BOOL	Display during movement to right
LEFT	Output	BOOL	Display during movement to left
CM1	Input	BOOL	Edge bit memory 1
CM2	Input	BOOL	Edge bit memory 2

The following networks show the LAD programming for solving this task:



Network 1:

If the signal state changes from "0" to "1" (positive edge) at photoelectric barrier "PEB1" and, at the same time, the signal state at "PEB2" is "0", the object on the belt is moving to the left.

Network 2:

If the signal changes from "0" to "1" (positive edge) at photoelectric barrier "PEB2" and, at the same time, the signal state at "PEB1" is "0", the object on the belt is moving to the right.

11.12.10.3 Example of detecting the fill level of a storage area

Detecting the fill level of a storage area

The following figure shows a system with two conveyor belts and a temporary storage area between them. Conveyor belt 1 delivers packages to the storage area. A photoelectric barrier at the end of conveyor belt 1 near the storage area detects how many packages are delivered to the storage area. Conveyor belt 2 transports packages from the temporary storage area to a loading dock where they are loaded onto trucks. A photoelectric barrier at the storage area exit detects how many packages leave the storage area to be transported to the loading dock. Five display lamps indicate the capacity of the temporary storage area.

Implementation

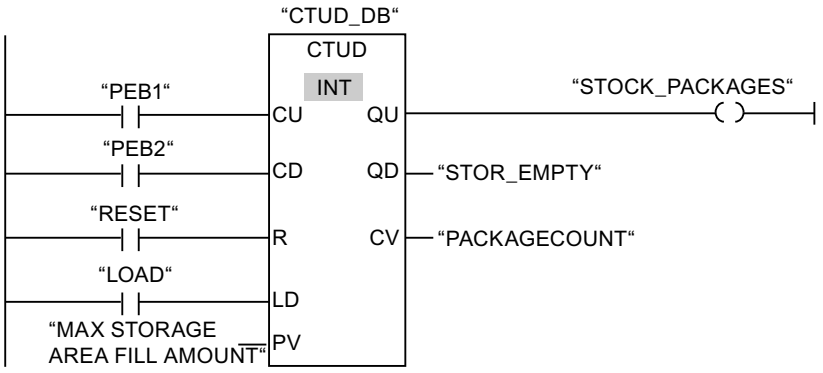
The following table shows the definition of the tags used:

Name	Declaration	Data type	Description
PEB1	Input	BOOL	Photoelectric barrier 1
PEB2	Input	BOOL	Photoelectric barrier 2
RESET	Input	BOOL	Reset counter
LOAD	Input	BOOL	Adjust the current counter value to the value of the PV parameter.
MAX STORAGE AREA FILL AMOUNT	Input	INT	Maximum possible number of packages in the storage area
PACKAGECOUNT	Output	INT	Number of packages in the storage area (current count value)

Name	Declaration	Data type	Description
STOCK_PACKAGES	Output	BOOL	Is set when the current count value is greater than or equal to the value of the "MAX STORAGE AREA FILL AMOUNT" tag.
STOR_EMPTY	Output	BOOL	Display lamp: Storage area empty
STOR_NOT_EMPTY	Output	BOOL	Display lamp: Storage area not empty
STOR_50%_FULL	Output	BOOL	Display lamp: Storage area 50 % full
STOR_90%_FULL	Output	BOOL	Display lamp: Storage area 90 % full
STOR_FULL	Output	BOOL	Display lamp: Storage area full
VOLUME_50	Input	INT	Comparison value: 50 packages
VOLUME_90	Input	INT	Comparison value: 90 packages
VOLUME_100	Input	INT	Comparison value: 100 packages

The following networks show the LAD programming for activating the lamps:

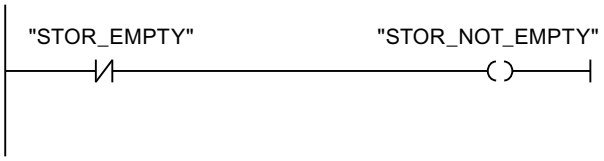
Network 1:



When a package is delivered to the storage area, the signal state at "PEB1" switches from "0" to "1" (positive signal edge). On a positive signal edge at "PEB1", the "Up" counter is enabled, and the current count value of "PACKAGECOUNT" is increased by one.

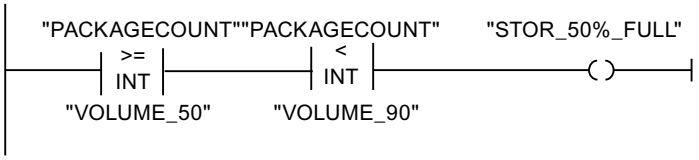
When a package is delivered from the storage area to the loading dock, the signal state at "PEB2" switches from "0" to "1" (positive signal edge). On a positive signal edge at "PEB2", the "Down" counter is enabled, and the current count value of "PACKAGECOUNT" is decreased by one.

If there are no packages in the storage area ("PACKAGECOUNT" = "0"), the "STOR_EMPTY" tag is set to signal state "1", and the "Storage area empty" lamp is switched on.



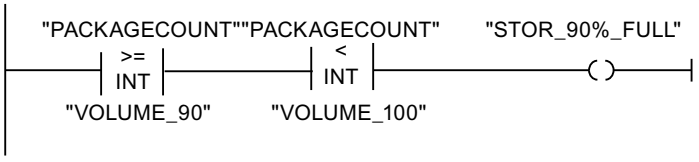
The current count value can be reset to "0" if the "RESET" tag is set to signal state "1".

If the "LOAD" tag is set to signal state "1", the current count value is set to the value of the "MAX STORAGE AREA FILL AMOUNT" tag. As long as the current count value is greater than or equal to the value of the "MAX STORAGE AREA FILL AMOUNT" tag, the "STOCK_PACKAGES" tag supplies the signal state "1".



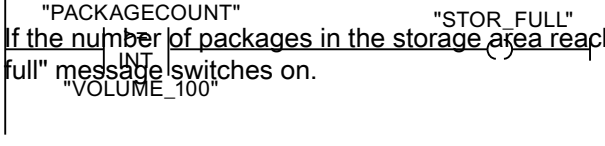
Network 2:

As long as there are packages in the storage area, the "STOR_NOT_EMPTY" tag is set to signal state "1", and the "Storage area not empty" lamp is switched on.



Network 3:

If the number of packages in the storage area is greater than or equal to 50, the "Storage area 50 % full" lamp switches on.



Network 4:

If the number of packages in the storage area is greater than or equal to 90, the "Storage area 90% full" lamp switches on.

Network 5:

If the number of packages in the storage area reaches 100, the lamp for the "Storage area full" message switches on.

11.12.10.4 Example of calculating an equation

Calculating an equation

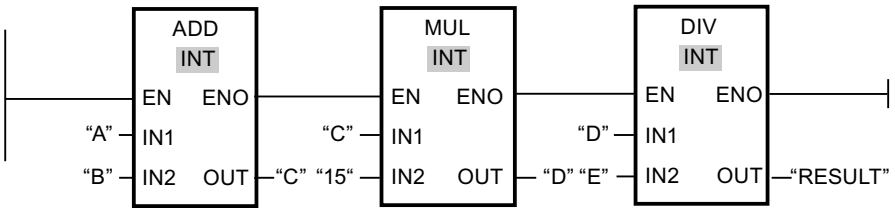
The following program example shows you how to solve equations of the following type with the LAD programming language:

X= ((A + B) x C) / D

You can always solve this equation with mathematical operations. To do so, you can use the instructions "ADD", "MUL" and "DIV". If you are using a CPU of the S7-1200 or S7-1500 series, you can also use the instruction "CALCULATE". Depending on the data type you choose, different mathematical operations are available for this instruction which can be combined with one another.

Implementation with the instructions "ADD", "MUL" and "DIV"

You want to calculate the following equation:



RESULT = ((A + B) x 15) / E

The following table shows the definition of the tags used:

Name	Data type	Comment
A	INT	First value for addition
B	INT	Second value for addition
C	INT	First intermediate result
15	INT	Multiplier
D	INT	Second intermediate result

Name	Data type	Comment
E	INT	Divisor
RESULT	INT	End result

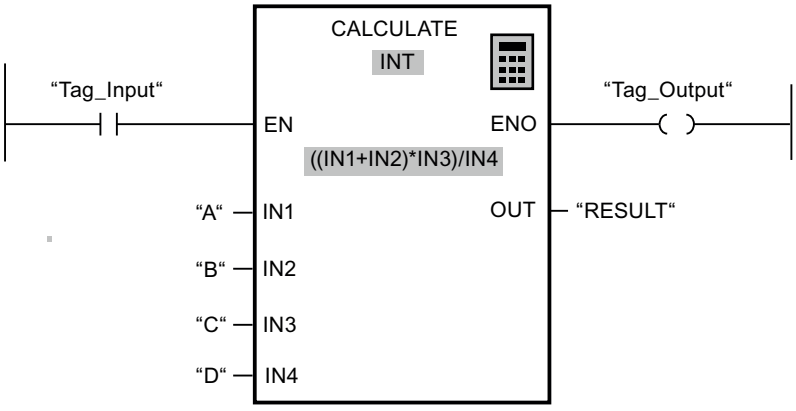
The following network shows the LAD programming for calculating the equation:

The value of operand "A" is added to the value of operand "B". The sum is stored in operand "C". The value of operand "C" is multiplied by "15". The multiplication result is stored in operand "D". The value stored in operand "D" is then divided by the value of operand "E". The end result is saved in the "RESULT" operand.

Implementation with the instruction "CALCULATE" (S7-1200/1500 only)

You want to calculate the following equation:

RESULT = ((5 + 10) x 4) / 6



The following table shows the definition of the tags used:

Name	Declaration	Data type	Comment	Value
A	Input	INT	First value for addition	5
B	Input	INT	Second value for addition	10
C	Input	INT	Multiplier	4
D	Input	INT	Divisor	6
RESULT	Output	INT	End result	10

To program the equation with the instruction "CALCULATE", follow these steps:

1. Drag the instruction "CALCULATE" from the "Instructions" task card to an LAD network.
2. You can select the data type INT for the instruction from the "<???>" drop-down list.
3. Interconnect the tags declared in the block interface with the inputs and outputs of the instruction box.
4. Click the "Calculator" icon on the top right corner of the instruction box to enter the equation to be calculated.
   The dialog "Edit 'Calculate' instruction" opens.
5. Enter the following expression in the "OUT:=" field:
   ((IN1 + IN2) * IN4) / IN3
   The equation is displayed in the instruction box.

The following network shows the result in the LAD programming language:

If the "Tag_Input" has signal state "1", the instruction is executed. The value of operand "A" is added to the value of operand "B". The subtotal is multiplied by "C" and then divided by the value of the "D" operand. The end result is saved in the "RESULT" operand.
