Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the USINT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
USINT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	USINT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	USINT_TO_BYTE
	WORD[1)]	X		USINT_TO_WORD
	DWORD[1)]	X		USINT_TO_DWORD
	SINT	X	The bit pattern of the source value is transferred unchanged to the target data type. If the sign is changed during the conversion, the enable output ENO is set to "0".	USINT_TO_SINT
	INT	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	USINT_TO_INT
	UINT	X		USINT_TO_UINT
	DINT	X		USINT_TO_DINT
	UDINT	X		USINT_TO_UDINT
	REAL	X	The value is converted into the format of the target data type (the value "1" will be converted into the value "1.0" with the "Convert value" (CONVERT) instruction.	USINT_TO_REAL, NORM_X
	LREAL	X		USINT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the target data type and interpreted as milliseconds.	USINT_TO_TIME
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	USINT_TO_TOD
	DATE	X		USINT_TO_DATE
	STRING	X	The value is converted to a character string. If the permitted length of the character string is violated, the enable output ENO is set to "0".	USINT_TO_STRING, S_CONV, VAL_STRG
	WSTRING	X		USINT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the target data type.	USINT_TO_CHAR
	WCHAR[1)]	X		USINT_TO_WCHAR

Source	Target	Conversion	Explanation	Mnemonics of the instruction
x: Conversion possible - : Conversion not possible [1] Bit strings (BYTE, WORD, DWORD) and data type CHAR are first extended to the necessary width (the non-existing sign is replaced with zeros) and then the bits are copied. The source type determines the interpretation.

Options for explicit conversion

The following table shows the options and instructions for explicit conversion of the INT data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
INT	BOOL	X	The following scenarios are possible: • If the source is "0", the target data type is also "0" and enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and enable output ENO is "1". • If bit is not equal to LSB in the source value, the target data type is set according to LSB and enable output ENO is "0".	INT_TO_BOOL
	BYTE[1)]	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	INT_TO_BYTE
	WORD[1)]	X		INT_TO_WORD
	DWORD[1)]	X		INT_TO_DWORD
	SINT	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	INT_TO_SINT
	USINT	X		INT_TO_USINT
	UINT	X		INT_TO_UINT
	DINT	X		INT_TO_DINT
	UDINT	X		INT_TO_UDINT
	REAL	X	The value is converted to the format of the target data type (the value "-1", for example, is converted with the instruction "Convert value" (CONVERT) to the value "-1.0").	INT_TO_REAL, NORM_X
	LREAL	X		INT_TO_LREAL, NORM_X
	TIME	X	The value is transferred to the target data type and interpreted as milliseconds.	INT_TO_TIME
	DTL	-	No explicit conversion	-
	TOD	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0". (interpretation in milliseconds since 0:0; check for 24h limit)	INT_TO_TOD
	DATE	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0". (interpretation	INT_TO_DATE

Source	Target	Conversion	Explanation	Mnemonics of the instruction
			in days since 1990-1-1; check for negative value)	
	STRING	X	The value is converted to a character string. • LAD/FBD: The first characters of the string are padded with spaces. The number of spaces depends on the length of the numerical value. Positive numeric values are output without a sign. • STL/SCL: No spaces are inserted. The character string is shown preceded by a sign. If the permitted length of the character string is violated, the enable output ENO is set to "0".	INT_TO_STRING, S_CONV, VAL_STRG[1)]
	WSTRING	X		INT_TO_WSTRING
	CHAR[1)]	X	The bit pattern of the source value is converted and transferred to the target data type. (The value "-1" (16#FF) becomes the value "-1" (16#FFFFFFFF)). If a negative value is converted to an unsigned target data type, the enable output ENO is set to "0".	INT_TO_CHAR
	WCHAR[1)]	X		INT_TO_WCHAR
	BCD16	X	The value to be converted has type INT and is accepted as an integer with a value between -999 and +999. The result is available after conversion as a BCD-coded number of the type WORD. A real conversion takes place. If the value is outside the target area, a synchronous error is not triggered, but rather only the status bit OV is set.	INT_TO_BCD16
	BCD16_WORD	X		INT_TO_BCD16_WORD

x: Conversion possible

x: Conversion possible

- : Conversion not possible

[1)] Bit strings (BYTE, WORD, DWORD) and data type CHAR are first extended to the necessary width and then the bits are copied. The source type determines the interpretation.

[2)] The data type DTL is initialized as follows: 1970-1-1-0:0:0. Conversion from DATE_TO_DTL only sets the corresponding part of the DTL. The rest of the DTL remains as it was initialized. This results in the following differences for the instructions "T_COMBINE" and "T_CONV":

- T_COMBINE(D#2015-24-12, LTOD#12:13:14) returns DTL#2015-24-12-12:13:14
- myDTL := T_CONV(D#2015-24-12); myDTL := T_CONV(LTOD#12:13:14) results in myDTL = DTL#1970-1-1-12:13:14

11.3.17 Data type conversion for S7-300, S7-400 (S7-300, S7-400)

11.3.17.1 Overview of data type conversions (S7-300, S7-400)

Introduction

If you combine several operands in an instruction, you must make sure that the data types are compatible. This also applies when you assign or supply block parameters. If the operands are not of the same data type, a conversion has to be carried out.

There are two options for conversion:

- Implicit conversion
  Implicit conversion is supported by the programming languages LAD, FBD, SCL and GRAPH. Implicit conversion is not possible in the STL programming language.
- Explicit conversion

Note

Converting bit strings to SCL

All bit strings (BYTE, WORD, and DWORD) are handled like the corresponding unsigned integers (USINT, UINT, and UDINT) in expressions. Therefore, implicit conversion from DWORD to REAL is carried out like a conversion from UDINT to REAL, for example.

Implicit conversion

Implicit conversion is executed automatically if the data types of the operands are compatible. This compatibility test can be carried out according to strict or less strict criteria:

- With IEC check
  The following rules apply in the LAD, FBD and GRAPH programming languages when the IEC check has been set:
  - The only data types for which implicit conversion is possible are BYTE and WORD.
  - The bit length of the source data type may not exceed the bit length of the target data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.

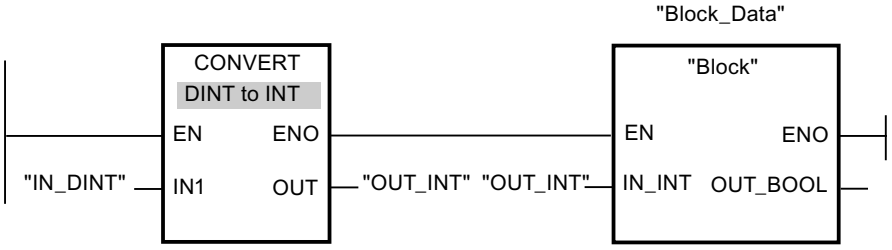
  The following rules apply in the SCL programming language when the IEC check has been set:
  - Implicit conversion of bit strings into other data types is not possible. A WORD data type operand, for example, cannot be specified at a parameter at which the INT data type is expected.
  - The bit length of the source data type may not exceed the bit length of the target data type. A WORD data type operand, for example, cannot be specified at a parameter at which the BYTE data type is expected.
- Without IEC check (default setting)
  The following rules apply in the LAD, FBD and GRAPH programming languages when the IEC check has not been set:
  - Implicit conversion of data types BYTE, WORD, DWORD, INT, DINT, TIME, S5TIME, TOD, DATE and CHAR is possible.
  - The bit length of the source data type may not exceed the bit length of the target data type. A DWORD data type operand, for example, cannot be specified at a parameter at which the WORD data type is expected.

  The following rules apply in the SCL programming language when the IEC check has not been set:
  - Bit strings can be implicitly converted into other data types. A WORD data type operand can, for example, be given at a parameter at which the WORD data type is expected.
  - Bit strings cannot be implicitly converted into floating-point numbers. A WORD data type operand, for example, cannot be specified at a parameter at which the REAL data type is expected.
  - Bit strings can only be implicitly converted into the data types TIME, TOD, DATE and CHAR if these have the same bit length. A DWORD data type operand, for example, cannot be specified at a parameter at which the DATE data type is expected.
  - The bit length of the source data type may not exceed the bit length of the target data type. A DINT data type operand, for example, cannot be specified at a parameter at which the INT data type is expected.
  - The bit length of an operand entered at in-out parameters must be the same as the programmed bit length for the parameter in question.

Explicit conversion

If the operands are not compatible and implicit conversion is therefore not possible, you can use an explicit conversion instruction. You can find the conversion instructions in the "Instructions" task card.

Any overflow will be displayed on the ENO enable output. An overflow occurs, for example, if the value of the source data type is greater than the value of the target data type.



Note

Shifting of bit patterns

If the explicit conversion involves shifting a bit pattern, the enable output ENO is not set.

You can find additional information on explicit conversion under "See also".

The following figure shows an example in which explicit data type conversion must be carried out:

The "Block" function block expects a tag of the INT data type at the "IN_INT" input parameter. The value of the "IN_DINT" tag has therefore to the converted first from DINT to INT. Conversion is performed if the value of the "IN_DINT" tag is within the admissible value range for the INT data type. Otherwise an overflow is reported. However, a conversion takes place even in the event of an overflow, but the values are truncated and the ENO enable output is set to "0".

Implicit conversions (Page 2533)

Explicit conversions (Page 2545)

11.3.17.2 Implicit conversions (S7-300, S7-400)

Setting and disabling the IEC check (S7-300, S7-400)

The data types of the tags used are checked for compatibility. This compatibility test can be carried out according to criteria that are more or less strict. If "IEC check" is activated, stricter criteria are applied.

You can set the IEC check centrally for all new blocks of the project or for individual blocks.

Setting IEC check for new blocks

To set the IEC check for all new blocks in the project, proceed as follows:

1. Select the "Settings" command in the "Options" menu.
   The "Settings" window is displayed in the work area.
2. Select the "PLC programming > General" group in the area navigation.
3. Select or clear the "IEC check" check box in the "Default settings for new blocks" group.
   The IEC check is enabled or disabled for all new blocks in the program.

Setting IEC check for a block

To set the IEC check for a block, proceed as follows:

1. Open the block.
2. Open the "Properties" tab in the inspector window.
3. Select the "Attributes" group in the area navigation.
4. Select or clear the "IEC check" check box.
   The IEC check is enabled or disabled for this block. The setting is stored together with the project.

Explicit conversion of BYTE (S7-300, S7-400)

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the BYTE data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
BYTE	BOOL	X	The following possibilities can occur: • If the source is "0", the target data type is also "0" and the enable output ENO "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the target data type is also "1" and the enable output ENO "1". • If bits are not equal to LSB in the source value, the target data type is set according to LSB and the enable output ENO is "0".	CONVERT
	WORD	X	The bit pattern of the source value is transferred unchanged right-justified to the target data type. The remaining bits are set to "0".	CONVERT
	DWORD	X		
	INT	X		
	DINT	X		
	REAL	-	No explicit conversion	-
	TIME	-		
	S5TIME	-		
	DT	-		
	TOD	-		
	DATE	-		
	STRING	-		
	CHAR	X	The bit pattern of the source value is transferred unchanged right-justified to the target data type. The remaining bits are set to "0".	CONVERT
x: Conversion possible - : Conversion not possible

Implicit conversion of BYTE (Page 2535)

Explicit conversion of WORD (S7-300, S7-400)

Options for explicit conversion

The following table shows the options and instructions for the explicit conversion of the WORD data type:

Source	Target	Conversion	Explanation	Mnemonics of the instruction
WORD	BOOL	X	The following possibilities can occur: • If the source is "0", the destination data type is also "0" and the enable output ENO is "1". • If only the LSB (Least Significant Bit) "1" is set in the source value, the destination data type is also "1" and the enable output ENO is "1". • If bit is not equal to LSB in the source value, the destination data type is set according to LSB and the enable output ENO is "0".	CONVERT
	BYTE	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If the permitted value range of the destination data type is violated, the enable output ENO is set to "0". The result of the conversion is invalid in such a case.	
	DWORD	X		
	INT	X		
	DINT	X		
	REAL	-	No explicit conversion	-
	TIME	-		
	S5TIME	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	MOVE
	DT	-	No explicit conversion	-
	TOD	-		
	DATE	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	MOVE
	STRING	-	No explicit conversion	-
	CHAR	X	The bit pattern of the source value is transferred unchanged, right-justified, to the target data type.	WORD_TO_CHAR
	BLOCK_DB	X	The bit pattern of WORD is interpreted as a data block number.	WORD_TO_BLOCK_DB

Source	Target	Conversion	Explanation	Mnemonics of the instruction
WORD_BCD[1) 2)]	INT	X	If the permitted value range of the destination data type is violated or if there is an invalid tetrad in the A - F range, the enable output ENO is set to "0". The result of the conversion is invalid in such a case.	WORD_BCD_TO_INT
BCD[1) 2)]	INT	X		BCD_TO_INT

x: Conversion possible

- : Conversion not possible

[1)] The value to be converted has data type WORD and is accepted as a BCD-coded value between -999 and +999. The result is available after conversion as an integer (in binary notation) of the type INT.

[2)] Valid for SCL: If the BCD code contains a pseudo tetrad, the CPU reports a programming error and opens the organization block "OB121". If the organization block OB121 is not present, the CPU changes to STOP mode.

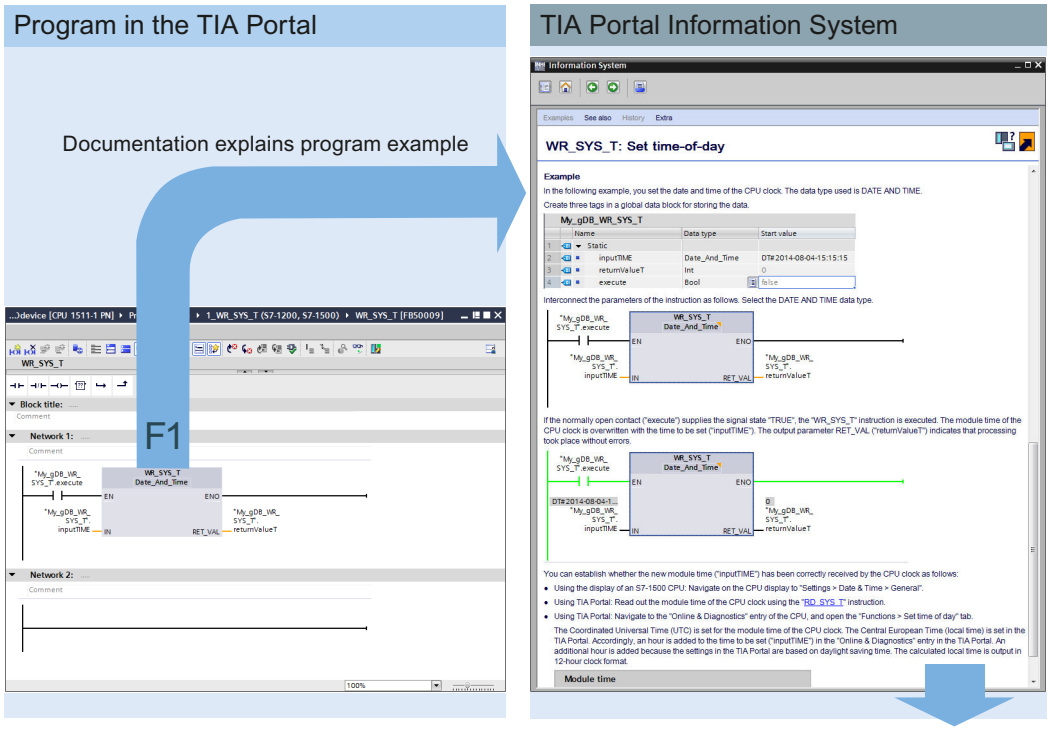
11.4 Instructions (S7-1200, S7-1500)

11.4.1 Example libraries (S7-1200, S7-1500)



11.4.1.1 Sample Library for Instructions (S7-1200, S7-1500)

The "Sample Library for Instructions" is the global library for the program examples using the instructions in STEP 7 (TIA Portal). This library offers you support during programming with its compact, easy to understand program examples in the programming language LAD. The precondition for using the library is at least one CPU from the SIMATIC S7-1200 / S7-1500 series.

Programming examples in the TIA Portal information system

Programming examples in the "Sample Library for Instructions" match the instructions used in the programming examples in the TIA Portal information system. This means that you can call the respective programming example documentation via the help (<F1>) in the TIA Portal.

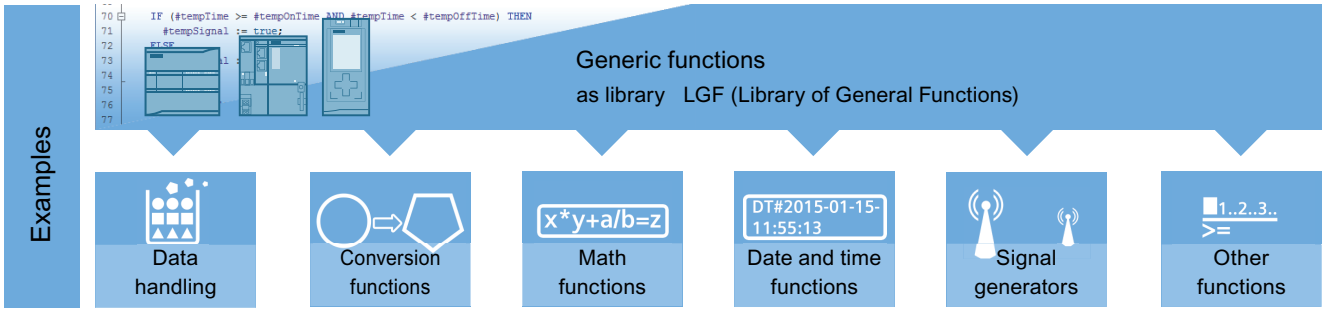
Library contains program example from the documentation

Downloading the library

The "Sample Library for Instructions" is available at the FAQ page (https://support.industry.siemens.com/cs/ww/en/view/109476781).

Note

Adding program examples to a project correctly



Due to the differing preconditions and functions, program examples may contain not only program blocks but also other components (e.g. PLC tags, PLC data types, watch tables or the like). There are also program examples that require special hardware (multiple CPUs, distributed I/O, input modules and the like).

Please observe the following rules:

- Never simply add all program examples or the entire "Sample Library for Instructions" folder to a CPU.
- Make sure that the corresponding program example does not consist of components for multiple CPUs.
- Always add the individual components of the program examples one at a time to the appropriate project folder. Also make sure that you select the appropriate CPU.

11.4.1.2 Library of General Functions (S7-1200, S7-1500)

The "Library of General Functions" is the global library for supplementary functions for the instructions in STEP 7 (TIA Portal). To expand the scope of instructions, this library offers blocks with useful basic functions that are often required in automation projects. All contents of the library can be used with a CPU of the series SIMATIC S7-1200(F) / S7-1500(F).

General functions

The general functions of the "Library of General Functions" are provided as blocks in the SCL programming language. The library includes the following functions: FIFO, search function, matrix calculations, astro clock. You can immediately use the functions by means of parameter assignment and implement them universally.

Downloading the library

The "Library of General Functions" is stored on the FAQ page (https://support.industry.siemens.com/cs/ww/en/view/109479728).

11.4.2 Asynchronous instructions (S7-1200, S7-1500)

11.4.2.1 Difference between synchronous and asynchronous instructions (S7-1200, S7-1500)

Asynchronous instructions

In program processing, a differentiation is made between synchronous and asynchronous instructions.

The "synchronous" and "asynchronous" properties relate to the temporal relationship between the call and execution of the instruction.

- The following applies to synchronous instructions: When the call of a synchronous instruction is ended, the execution is also ended.
- This is different in the case of asynchronous instructions: The execution of an asynchronous instruction can extend over multiple calls. The CPU processes asynchronous instructions in parallel with the cyclic user program. Asynchronous instructions occupy resources in the CPU while they are being processed.

Asynchronous instructions are usually instructions for transferring data (data records for modules, communication data, diagnostics data).

Additional information about asynchronous instructions can be found here: SIMATIC S7-1500 / ET 200MP Manual Collection (https://support.industry.siemens.com/cs/ww/en/view/86140384) in the system manual under Basics of program processing > Asynchronous instructions

Identification of the job

To execute an instruction over multiple calls, the CPU must be able to uniquely assign a subsequent call to a running job of the instruction. To assign a call to a job, the CPU uses one of the following two mechanisms, depending on the type of the instruction:

- The instance of the instruction (with type "SFB" system function block)
- The input parameter of the instruction identifying the job

If you use asynchronous instructions to trigger a process interrupt, output control commands to DP slaves, start a data transfer, or abort a non-configured connection and then call the instruction again before the current job is completed, the reaction of the instruction will depend on whether the second call involves the same job.

Passing parameters to program blocks that are to be executed asynchronously

Code blocks (FBs/FCs) and data blocks (DBs) can be created with different access types ("standard" and "optimized"). In code blocks, you can call any instructions. Some instructions (e.g. "WRIT_DBL" and "READ_DBL") are executed asynchronously. These blocks cannot be supplied with tags from TEMP because the data must not be changed during execution.

Ensure that you do not use these instructions in programs in which code blocks of different access types are called reciprocally. This could cause the following to occur:

- A structure from a standard data block is directly or indirectly passed to an optimized code block, which forwards this structure directly or indirectly to one of the blocks mentioned above.
- The reverse scenario, whereby a structure from an optimized code block is directly or indirectly passed to a standard data block, which forwards this structure directly or indirectly to one of the program blocks mentioned above.

Otherwise, a hidden copy of the passed data is created in TEMP, which leads to the asynchronous program blocks returning a negative acknowledgment.

Parameter REQ

The input parameter REQ (request) is used solely to start the job:

- Trigger the job by setting the input parameter REQ to "1" (case 1).
- If a particular job has been started and not yet completed and you call the instruction again to perform the same job (for example, in a cyclic interrupt OB), then REQ is not evaluated by the instruction (case 2).
- If the job is completed, but the input parameter REQ is still set to "1", the job is immediately started again.

Note

REQ bit = "1"

Please note that, when the REQ bit is set, the asynchronous instruction will be started again after the previous call is completed. This may not be desired. To make the project clearer and easier to maintain, it is therefore advisable to reset the REQ bit to "0" as early as possible.

Parameter RET_VAL and BUSY

The output parameters RET_VAL and BUSY indicate the status of the job.

Pay attention to the note in section: AUTOHOTSPOT

- In case 1 (first call with REQ = 1), code W#16#7001 will be entered in RET_VAL and BUSY will be set to "1" if system resources are available and the supply of the input parameters is correct.
  If the required system resources are currently being used or the input parameters contain an error, the corresponding error code is entered in RET_VAL and BUSY receives the value "0".

  Note

  Call with REQ = 0 when system resources are assigned

  If an asynchronous instruction with REQ = 0 is called for an S7-1500 CPU, all available resources are assigned at this time and this call not an intermediate call of a job that is already running, the error code W#16#80C3 (temporary resource error) is entered in RET_VAL.

  For an S7-300 CPU, the error code W#16#7000 (first call with REQ = 0) is entered in RET_VAL under these boundary conditions.

- In case 2 (intermediate call), the code W#16#7002 is entered in RET_VAL (this corresponds to the message that the call is currently still being processed) and BUSY is set to "1".
- The following applies to the last call for a job:
  - For instruction "DPNRM_DG (Page 3715)", the number of data in bytes will entered as integer in RET_VAL in case there are no errors in data transmission. BUSY has the value "0" in this case.
    If there is an error, then the error information will be entered in RET_VAL and you should not evaluate BUSY in this case.
  - For all other instructions, "0" will be entered in RET_VAL if the job was executed without errors and BUSY will receive the value "0". If there is an error, the error code will be entered in RET_VAL and BUSY will receive the value "0".

Note

If the first and last call coincide, the reaction for RET_VAL and BUSY is the same as for the last call.

Overview

The following table provides you with an overview of the relationships explained above. In particular, it shows the possible values of the output parameters if the execution of the job is not completed after an instruction call has been completed.

Note

Following every call, you must evaluate the relevant output parameters in your program.

Relationship between call, REQ, RET_VAL and BUSY during a "running" job.

Number of the call	Type of call	REQ	RET_VAL	BUSY	DONE	ERROR
1	First call	1	W#16#7001	1	0	0
			Error code	0	0	1
2 to (n - 1)	Intermediate call	irrelevant	W#16#7002	1	0	0
n	Last call	irrelevant	W#16#0000 (exceptions: RD_REC (Page 3694) and RD_DPARA (Page 3789): The successfully read data length is written to the parameter STATUS.)	0	1	0
			Error code if errors occurred	0	0	1

11.4.3 Basic instructions (S7-1200, S7-1500)

11.4.3.1 LAD (S7-1200, S7-1500)

Bit logic operations (S7-1200, S7-1500)

---| |---: Normally open contact (S7-1200, S7-1500)

Description

The activation of the normally open contact depends on the signal state of the associated operand. When the operand has signal state "1", the normally open contact closes and the signal state at the output is set to the signal state of the input.

When the operand has signal state "0", the normally open contact is not activated and the signal state at the output of the instruction is reset to "0".

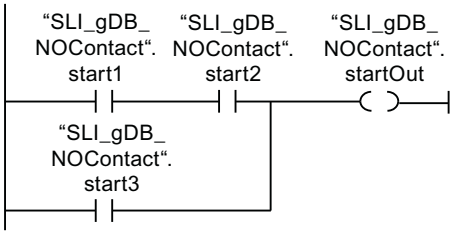
Two or more normally open contacts are linked bit-by-bit by AND when connected in series. With a series connection, power flows when all contacts are closed.

The normally open contacts are linked by OR when connected in parallel. With a parallel connection, power flows when one of the contacts is closed.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand whose signal state is queried.



Example

The following example shows how the instruction works.

Create a global data block with the following content for this purpose:

Name of the block: SLI_gDB_NOContact	
Name	**Data type**
start1	BOOL
start2	BOOL
start3	BOOL
startOut	BOOL

Write the following program code:

Operand "SLI_gDB_NOContact".startOut is set when one of the following conditions is fulfilled:

- The operands "SLI_gDB_NOContact".start1 and "SLI_gDB_NOContact".start2 have the signal state "1".
- The operand "SLI_gDB_NOContact".start3 has the signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

LAD programming examples (Page 4924)

Basic information on LAD (Page 4878)

---| / |---: Normally closed contact (S7-1200, S7-1500)

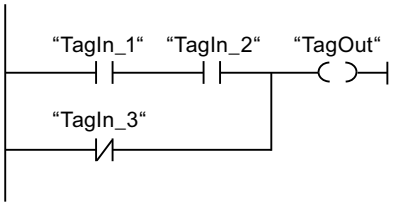
Description

The activation of the normally closed contact depends on the signal state of the associated operand. When the operand has signal state "1", the normally closed contact opens and the signal state at the output of the instruction is reset to "0".

When the operand has signal state "0", the normally closed contact is not enabled and the signal state of the input is transferred to the output.

Two or more normally closed contacts are linked bit-by-bit by AND when connected in series. With a series connection, power flows when all contacts are closed.

The normally closed contacts are linked by OR when connected in parallel. With a parallel connection, power flows when one of the contacts is closed.



Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand whose signal state is queried.

Example

The following example shows how the instruction works:

The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

--|NOT|--: Invert RLO (S7-1200, S7-1500)

Description

You use the "Invert RLO" instruction to invert the signal state of the result of logic operation (RLO). If the signal state is "1" at the input of the instruction, the output of the instruction has signal state "0". If the signal state is "0" at the input of the instruction, the output has the signal state "1".

Example

The following example shows how the instruction works:

Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The signal state of the operands "TagIn_2" and "TagIn_3" is "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

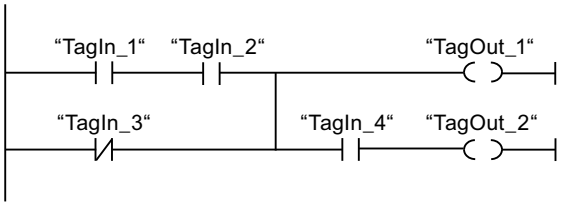
Basic information on LAD (Page 4878)

---( )---: Assignment (S7-1200, S7-1500)

Description

You can use the "Assignment" instruction to set the bit of a specified operand. If the result of logic operation (RLO) at the input of the coil has signal state "1", the specified operand is set to signal state "1". If the signal state is "0" at the input of the coil, the bit of the specified operand is reset to "0".

The instruction does not influence the RLO. The RLO at the input of the coil is sent directly to the output.



Parameter

The following table shows the parameters of the "Assignment" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:

The "TagOut_1" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

The "TagOut_2" operand is set when one of the following conditions is fulfilled:

- Operands "TagIn_1", "TagIn_2", and "TagIn_4" have signal state "1".
- The signal state of the "TagIn_3" operand is "0" and the signal state of the "TagIn_4" operand is "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

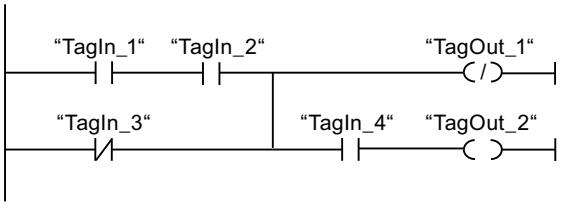
--(/)--: Negate assignment (S7-1200, S7-1500)

Description

The "Negate assignment" instruction inverts the result of logic operation (RLO) and assigns it to the specified operand. When the RLO at the input of the coil is "1", the operand is reset. When the RLO at the input of the coil is "0", the operand is set to signal state "1".



Parameter

The following table shows the parameters of the "Negate assignment" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:

Operand "TagOut_1" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

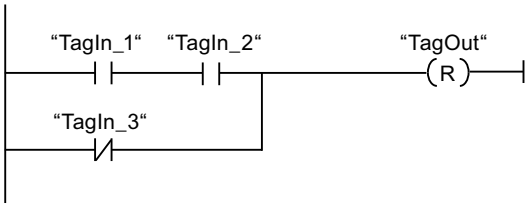
---(R)---: Reset output (S7-1200, S7-1500)

Description

You can use the "Reset output" instruction to reset the signal state of a specified operand to "0".

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If power flows to the coil (RLO = "1"), the specified operand is reset to "0". If the RLO at the input of the coil is "0" (no signal flow to the coil), the signal state of the specified operand remains unchanged.



Parameter

The following table shows the parameters of the "Reset output" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand that is reset when RLO = "1".

Example

The following example shows how the instruction works:

Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

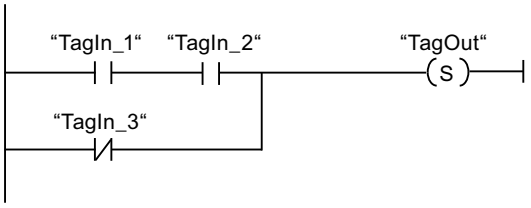
---(S)---: Set output (S7-1200, S7-1500)

Description

You can use the "Set output" instruction to set the signal state of a specified operand to "1".

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If power flows to the coil (RLO = "1"), the specified operand is set to "1". If the RLO at the input of the coil is "0" (no signal flow to the coil), the signal state of the specified operand remains unchanged.



Parameter

The following table shows the parameters of the "Set output" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand which is set with RLO = "1".

Example

The following example shows how the instruction works:

The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The signal state of the operand "TagIn_3" is "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SET_BF: Set bit field (S7-1200, S7-1500)

Description

You use the "Set bit field" instruction to set several bits starting from a certain address.

You determine the number of bits to be set using the value of <Operand1>. The address of the first bit to be set is defined by <Operand2>. If the value of <Operand1> may not be greater than the number of bits in a selected byte. If this value is greater, the instruction is not executed and the error message "Range violation for index <Operand1>" is displayed. The bits remain set until they are explicitly reset by another instruction.

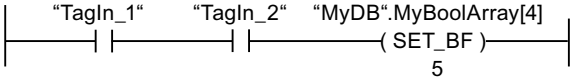
Specify <Operand1> at the operand placeholder below the instruction. Specify <Operand2> at the operand placeholder above the instruction.

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If the RLO at the input of the coil is "0", the instruction does not execute.

Bit fields of the type PLC data type, STRUCT or ARRAY

With structures of the type PLC data type, STRUCT or ARRAY, the number of bits contained in the structure represents the maximum number of bits that can be reset:

- If you specify the value "20" at <Operand1>, for example, and the structure only contains 10 bits, then only these 10 bits are set.
- If you specify the value "5" at <Operand1>, for example, and the structure contains 10 bits, then exactly 5 bits are set.



Parameter

The following table shows the parameters of the "Set bit field" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Input	UINT	Constant	Number of bits to be set
<Operand2>	Output	BOOL	I, Q, M In the case of a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be set.

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are set starting at the address of the operand "MyDB".MyBoolArray[4].

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

RESET_BF: Reset bit field (S7-1200, S7-1500)

Description

You use the "Reset bit field" instruction to reset several bits starting from a certain address.

You specify the number of bits to be reset using the value of <Operand1>. The address of the first bit to be reset is defined by <Operand2>. If the value of <Operand 1> may not be greater than the number of bits in a selected byte. If this value is greater, the instruction is not executed

and the error message "Range violation for index <Operand 1>" is displayed. The bits remain set until they are explicitly reset by another instruction.

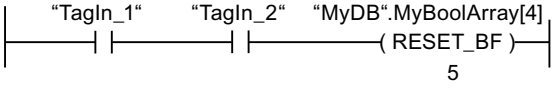
Specify <Operand1> at the operand placeholder below the instruction. Specify <Operand2> at the operand placeholder above the instruction.

The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If the RLO at the input of the coil is "0", the instruction does not execute.

Bit fields of the type PLC data type, STRUCT or ARRAY

With structures of the type PLC data type, STRUCT or ARRAY, the number of bits contained in the structure represents the maximum number of bits that can be set:

- If you specify the value "20" at <Operand1>, for example, and the structure only contains 10 bits, then only these 10 bits are reset.
- If you specify the value "5" at <Operand1>, for example, and the structure contains 10 bits, then exactly 5 bits are reset.



Parameter

The following table shows the parameters of the "Reset bit field" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Input	UINT	Constant	Number of bits to be reset
<Operand2>	Output	BOOL	I, Q, M With a DB or an instance DB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be reset.

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are reset starting at the address of the operand "MyDB".MyBoolArray[4]

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SR: Set/reset flip-flop (S7-1200, S7-1500)

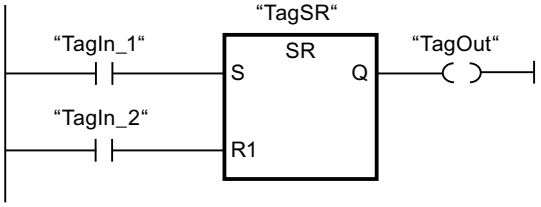
Description

Use the instruction "Set/reset flip-flop" to set or reset the bit of the specified operand, depending on the signal state of the inputs S and R1. If the signal state is "1" at input S and "0" at input R1, the specified operand is set to "1". If the signal state is "0" at input S and "1" at input R1, the specified operand will be reset to "0".

Input R1 takes priority over input S. When the signal state is "1" on both inputs S and R1, the signal state of the specified operand is reset to "0".

The instruction is not executed if the signal state at the two inputs S and R1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.



Parameter

The following table shows the parameters of the "Set/reset flip-flop" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
S	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable setting
R1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable resetting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is set or reset.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:

The operands "TagSR" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagSR" and "TagOut" are reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

RS: Reset/set flip-flop (S7-1200, S7-1500)

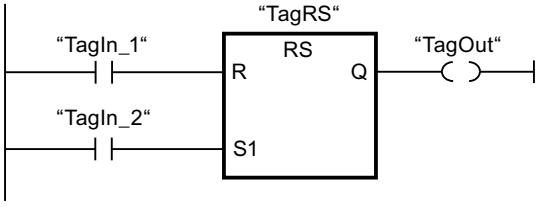
Description

You can use the "Reset/set flip-flop" instruction to reset or set the bit of a specified operand based on the signal state of the inputs R and S1. If the signal state is "1" at input R and "0" at input S1, the specified operand will be reset to "0". If the signal state is "0" at input R and "1" at input S1, the specified operand is set to "1".

Input S1 takes priority over input R. When the signal state is "1" at both inputs R and S1, the signal state of the specified operand is set to "1".

The instruction is not executed if the signal state at the two inputs R and S1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.



Parameter

The following table shows the parameters of the "Reset/set flip-flop" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
R	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable resetting
S1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is reset or set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:

The operands "TagRS" and "TagOut" are reset when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagRS" and "TagOut" are set when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

--|P|--: Scan operand for positive signal edge (S7-1200, S7-1500)

Description

You can use the "Scan operand for positive signal edge" instruction to determine if there is a "0" to "1" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan, which is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

The following figure shows the change in the signal state in case of a negative and a positive signal edge:

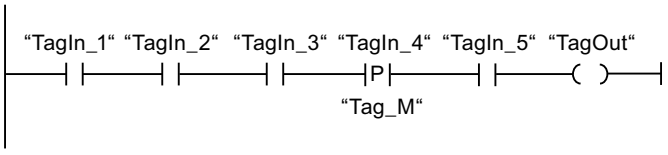
The positive signal edge is queried each time the instruction executes. When a positive signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the "Scan operand for positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous query is saved.

Example

The following example shows how the instruction works:

Operand "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1", "TagIn_2", and "TagIn_3" have signal state "1".
- There is a rising edge at operand "TagIn_4". The signal state of the previous scan is stored in the edge memory bit "Tag_M".
- The signal state of the operand "TagIn_5" is "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

--|N|--: Scan operand for negative signal edge (S7-1200, S7-1500)

Description

You can use the "Scan operand for negative signal edge" instruction to determine if there is a "1" to "0" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan that is saved in an edge memory bit <Operand2>. If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

The following figure shows the change in the signal state in case of a negative and a positive signal edge:

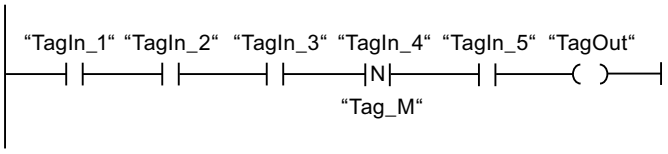
The negative signal edge is queried each time the instruction executes. When a negative signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the "Scan operand for negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous query is saved.

Example

The following example shows how the instruction works:

Operand "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1", "TagIn_2", and "TagIn_3" have signal state "1".
- There is a negative signal edge at operand "TagIn_4". The signal state of the previous scan is stored in the edge memory bit "Tag_M".
- The signal state of the operand "TagIn_5" is "1".

--(P)--: Set operand on positive signal edge (S7-1200, S7-1500)

Description

You can use the "Set operand on positive signal edge" instruction to set a specified operand (<Operand1>) when there is a "0" to "1" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

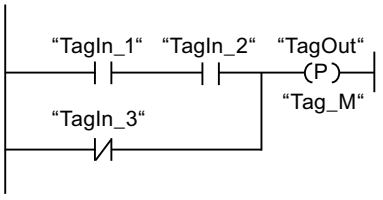
The positive signal edge is queried each time the instruction executes. When a positive signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand1>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the instruction "Set operand on positive signal edge":

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set by a positive edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:

Operand "TagOut" is set for one program cycle, when the signal state at the input of the coil switches from "0" to "1" (positive signal edge). In all other cases, the operand "TagOut" has the signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

--(N)--: Set operand on negative signal edge (S7-1200, S7-1500)

Description

You can use the "Set operand on negative signal edge" instruction to set a specified operand (<Operand1>) when there is a "1" to "0" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the RLO from "1" to "0", there is a negative signal edge.

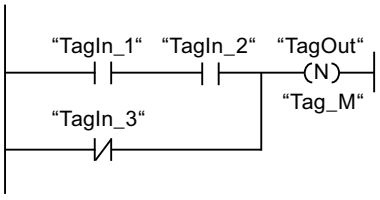
The negative signal edge is queried each time the instruction executes. When a negative signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand1>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the instruction "Set operand on negative signal edge":

Parameter	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set by a negative edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:

Operand "TagOut" is set for one program cycle, when the signal state at the input of the coil switches from "1" to "0" (negative signal edge). In all other cases, the operand "TagOut" has the signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

P_TRIG: Scan RLO for positive signal edge (S7-1200, S7-1500)

Description

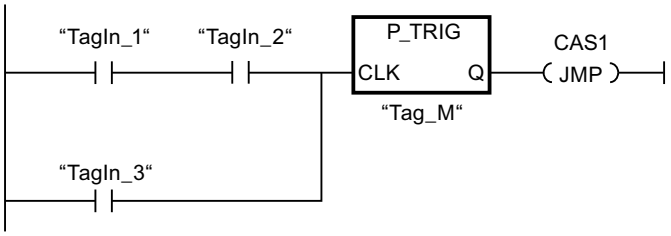
Use the "Scan RLO for positive signal edge" instruction to query a "0" to "1" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<operand>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

The positive signal edge is queried each time the instruction executes. As soon as a positive single edge is detected, the output Q of the instruction returns the signal state "1" for the length of a program cycle. In all other cases, the output returns the signal state "0".

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the instruction "Scan RLO for positive signal edge":

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The RLO of the previous query is saved in the edge memory bit "Tag_M". If a "0" to "1" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

N_TRIG: Scan RLO for negative signal edge (S7-1200, S7-1500)

Description

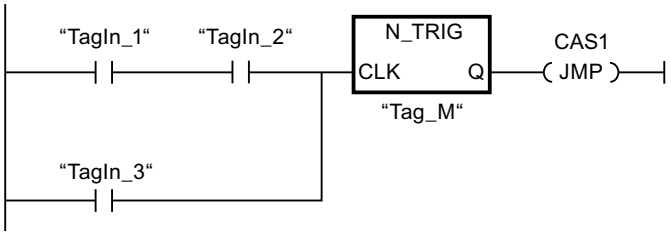
Use the "Scan RLO for negative signal edge" instruction to query a "1" to "0" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<operand>). If the instruction detects a change in the RLO from "1" to "0", there is a negative signal edge.

The negative signal edge is queried each time the instruction executes. As soon as a negative single edge is detected, the output Q of the instruction returns the signal state "1" for the length of a program cycle. In all other cases, the signal state at the output of the instruction is "0".

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This step influences the edge evaluation and the result is therefore no longer unique. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameter

The following table shows the parameters of the "Scan RLO for negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The RLO of the previous query is saved in the edge memory bit "Tag_M". If a "1" to "0" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

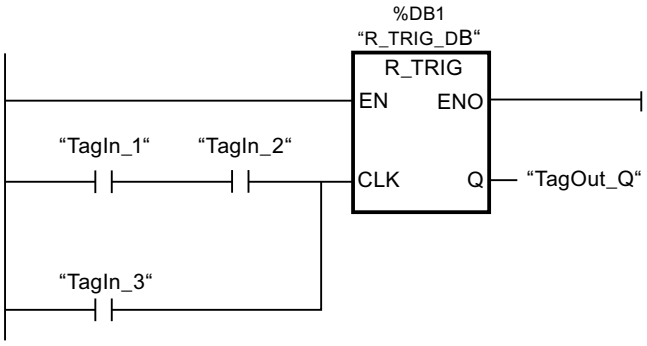
R_TRIG: Detect positive signal edge (S7-1200, S7-1500)

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".



Parameter

The following table shows the parameters of the "Detect positive signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change in the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

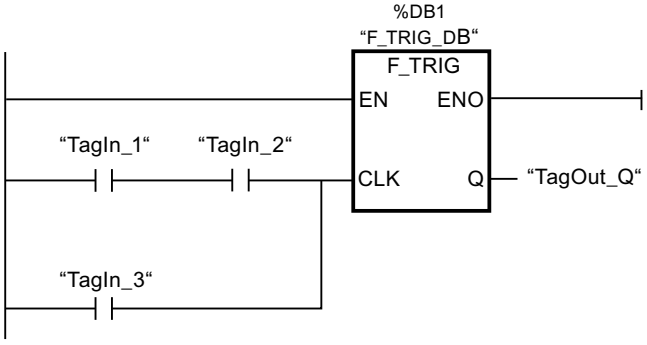
F_TRIG: Detect negative signal edge (S7-1200, S7-1500)

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".



Parameter

The following table shows the parameters of the "Detect negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Timer operations (S7-1200, S7-1500)

TP: Generate pulse (S7-1200, S7-1500)

Description

You can use the "Generate pulse" instruction to set the Q output for a programmed duration. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. Output Q is set for the duration PT, regardless of the subsequent course of the input signal. Even if a new positive signal edge is detected, the signal state at the output Q is not affected as long as the PT time duration is running.

You can scan the current time value at the ET output. The timer value starts at T#0s and ends when the value of the time duration PT is reached. When the time PT has elapsed and the signal state at input IN is "0", the ET output is reset.

Each call of the "Generate pulse" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

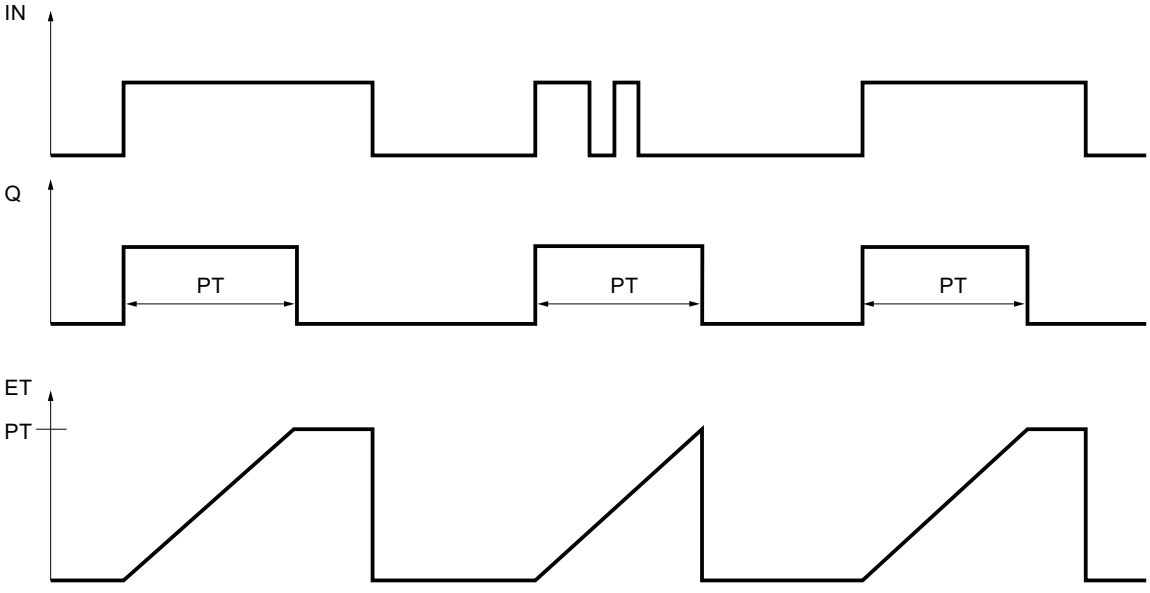
An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

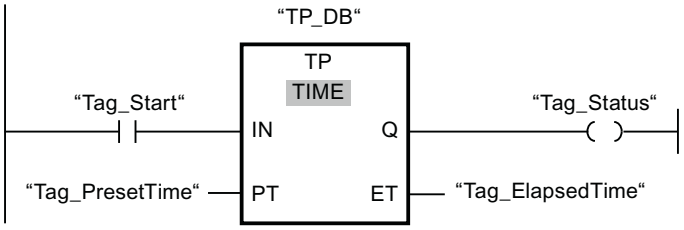
The execution of the "Generate pulse" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate pulse" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the pulse The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Pulse output
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	TRUE
ET	Tag_ElapsedTime	from T#0s => T#10s

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started and the "Tag_Status" operand is set to "1". The current time value is stored in the "Tag_ElapsedTime" operand. When the time expires, the "Tag_Status" operand is reset to signal state "0".

Basic information on LAD (Page 4878)

TON: Generate on-delay (S7-1200, S7-1500)

Description

You can use the "Generate on-delay" instruction to delay setting of the Q output by the programmed time PT. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the time PT has elapsed, the output Q has the signal state "1". Output Q remains set as long as the start input is still "1". When the signal state at the start input changes from "1" to "0", the Q output is reset. The timer function is started again when a new positive signal edge is detected at the start input.

The current time value can be queried at the ET output. The timer value starts at T#0s and ends when the value of the time duration PT is reached. The ET output is reset as soon as the signal state at the IN input changes to "0".

Each call of the "Generate on-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

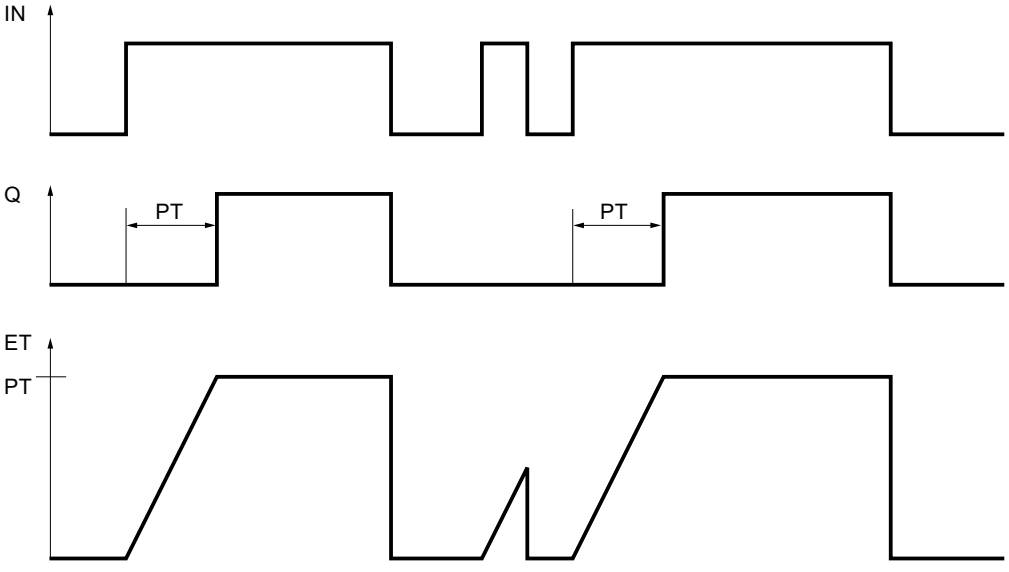
An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

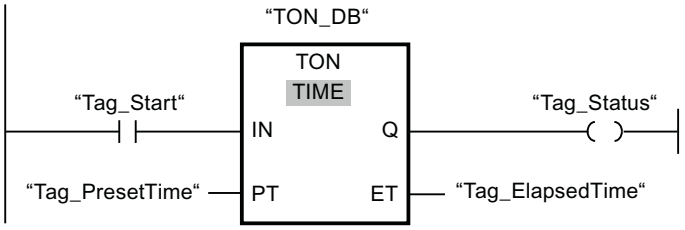
The execution of the "Generate on-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate on-delay" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the on-delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	FALSE; after 10 s => TRUE
ET	Tag_ElapsedTime	from T#0s => T#10s

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. When the time duration expires, the "Tag_Status" operand is set to the signal state "1". The Tag_Status operand remains set to "1" as long as the Tag_Start operand has signal state "1". The current time value is stored in the "Tag_ElapsedTime" operand. When the signal state at the operand "Tag_Start" changes from "1" to "0", the "Tag_Status" operand is reset.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

TOF: Generate off-delay (S7-1200, S7-1500)

Description

You can use the "Generate off-delay" instruction to delay resetting of the Q output by the programmed time PT. The Q output is set when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). When the signal state at input IN changes back to "0", the programmed time PT starts. Output Q remains set as long as the time duration PT is running. When the PT time duration expires, the Q output is reset. If the signal state at input IN changes to "1" before the PT time duration expires, the timer is reset. The signal state at the output Q continues to be "1".

The current time value can be queried at the ET output. The timer value starts at T#0s and ends when the value of the time duration PT is reached. When the PT time duration expires, the ET output remains set to the current value until input IN changes back to "1". If input IN switches to "1" before the duration PT has expired, the ET output is reset to the value T#0s.

Each call of the "Generate off-delay" instruction must be assigned to an IEC Timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

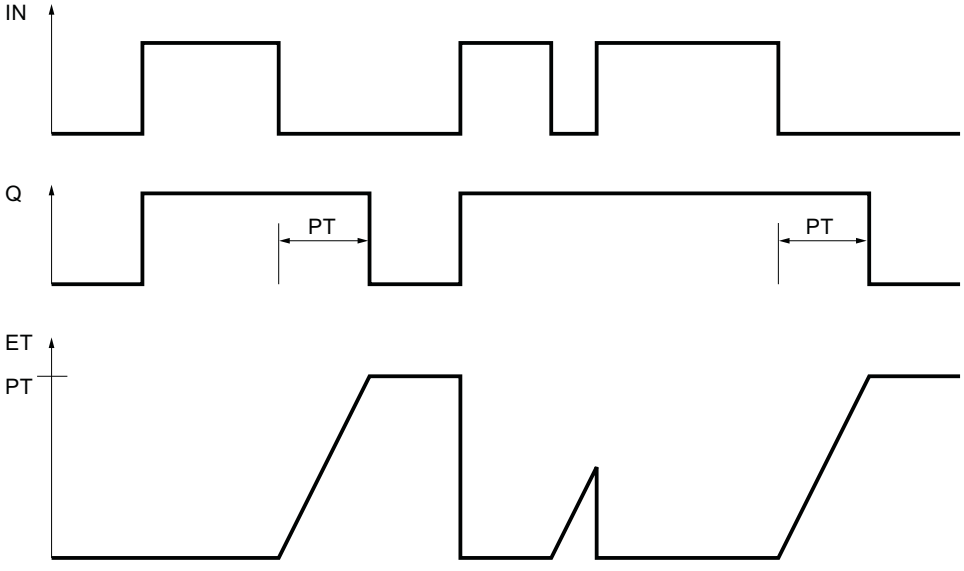
An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

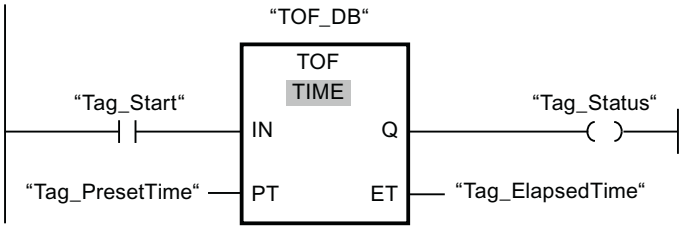
The execution of the "Generate off-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate off-delay" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the off delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is reset when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current time value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate off-delay" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"; signal transition "1" => "0"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	TRUE
ET	Tag_ElapsedTime	from T#10s => T#0s

When the signal state of the operand "Tag_Start" changes from "0" to "1", the "Tag_Status" operand is set to signal state "1". When the signal state of the "Tag_Start" operand changes from "1" to "0", the time programmed for the PT parameter is started. As long as the time is running, the "Tag_Status" operand remains set to TRUE. When the time has expired, the "Tag_Status" operand is reset to FALSE. The current time value is stored in the "Tag_ElapsedTime" operand.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

TONR: Time accumulator (S7-1200, S7-1500)

Description

The instruction "Time accumulator" is used to accumulate time values within a period set by the parameter PT. When the signal state at the IN input changes from "0" to "1" (positive signal edge), the instruction is executed and time PT starts. While the time PT is running, the time values are accumulated that are recorded when the IN input has signal state "1". The accumulated time is written to the ET output and can be queried there. When the duration PT expires, the output Q has signal state "1". The Q parameter remains set to "1", even when the signal state at the IN parameter changes from "1" to "0" (negative signal edge).

The R input resets the ET and Q outputs regardless of the signal state of the start input.

Each call of the "Time accumulator" instruction must be assigned an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

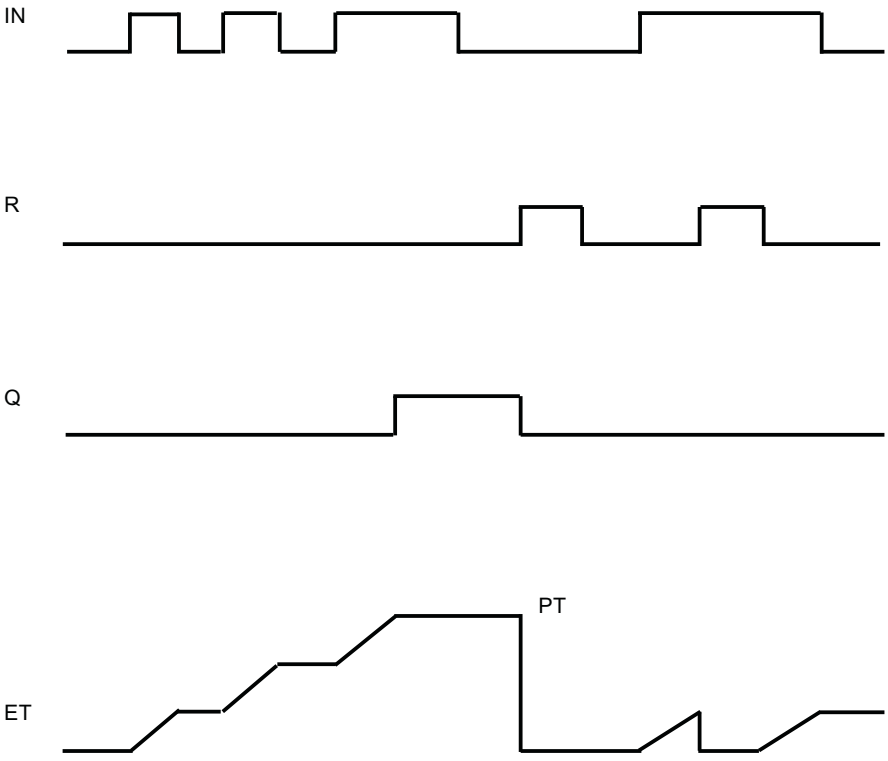
An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

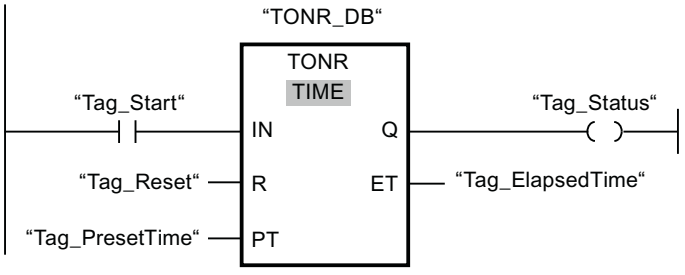
The execution of the Time accumulator" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Time accumulator" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Reset input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Maximum duration of time recording The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Accumulated time



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s

Parameters	Operand	Value
Q	Tag_Status	FALSE; after 10 s => TRUE
ET	Tag_ElapsedTime	Signal transition from "0" => "1" The time T#10s expires. After 5 s signal transition from "1" => "0": The time at the "Tag_Elapsed-Time" operand remains at T#5s. After approx. 2 s, renewed signal transition from "0" => "1": The time at the "Tag_Elapsed-Time" operand continues to run at T#5s.

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. The time continues to run as long as the "Tag_Start" operand has the signal state "1". When the signal state of the "Tag_Start" operand changes from "1" to "0", the time stops and the current time value at the Tag_ElapsedTime operand is recorded. When the signal state at the "Tag_Start" operand changes again from "0" to "1", the time continues to run starting at the time value that was recorded at the transition from "1" to "0". When the time value specified for the PT parameter is reached, the "Tag_Status" operand is set to the signal state "1". The current time value is stored in the "Tag_ElapsedTime" operand.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(TP)---: Start pulse timer (S7-1200, S7-1500)

Description

Use the "Start pulse timer" instruction to start an IEC timer with a specified duration as pulse. The IEC timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC timer runs for the specified time regardless of any subsequent changes in the RLO. The run of the IEC timer is also not affected by the detection of a new positive signal edge. As long as the IEC timer is running, the querying of the timer status for "1" returns the signal state "1". When the IEC timer has expired, the timer status returns the signal state "0".

Specify the duration of the pulse under the instruction at <Operand1> (duration) and specify the IEC time to be started above the instruction at <Operand2> (IEC time).

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER or TP_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_LTIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

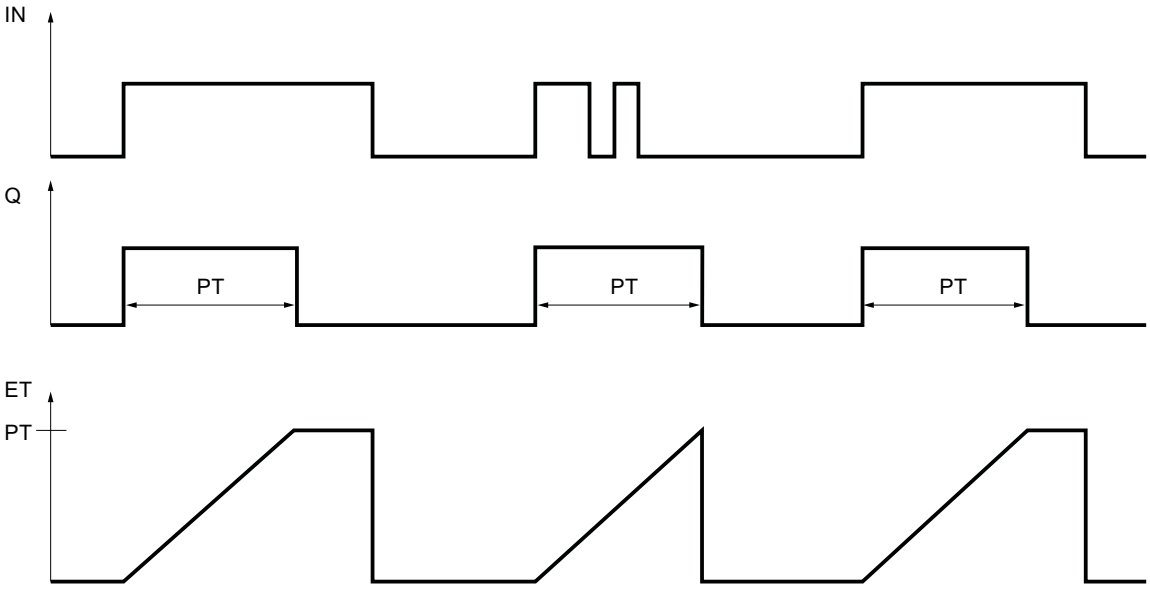
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is stored in the Q structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0".

The execution of the "Start pulse timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

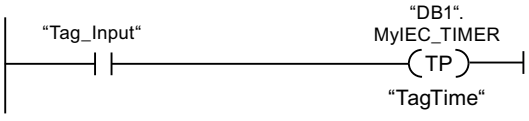
Parameters



The following table shows the parameters of the "Start pulse timer" instruction:

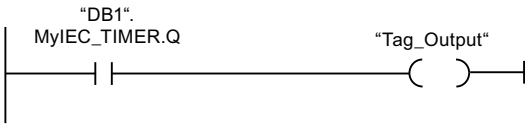
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TP_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME	D, L	IEC timer that is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Start pulse timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The timer "DB1".MyIEC_TIMER is started for the time stored in the operand "TagTime".

As long as the timer "DB1". MyIEC_TIMER is running, the timer status ("DB1".MyIEC_TIMER.Q) has signal state "1" and the operand "Tag_Output" is set. When the IEC timer has expired, the signal state of the time status changes back to "0" and the "Tag_Output" operand is reset.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(TON)---: Start on-delay timer (S7-1200, S7-1500)

Description

Use the "Start on-delay timer" instruction to start an IEC timer with a specified duration as on-delay. The IEC timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC timer runs for the specified time. The output returns the signal state "1" if the RLO at the input of the instruction has the signal state "1". If the RLO changes to "0" before the time expires, the IEC timer is reset. In this case, querying the timer status for "1" returns signal state "0". The IEC timer restarts when the next positive signal edge is detected at the input of the instruction.

Specify the duration of the ON delay under the instruction at <Operand1> (duration) and specify the IEC time to be started above the instruction at <Operand2> (IEC time).

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start on-delay timer" stores its data in a structure of the data type IEC_TIMER or TON_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start on-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

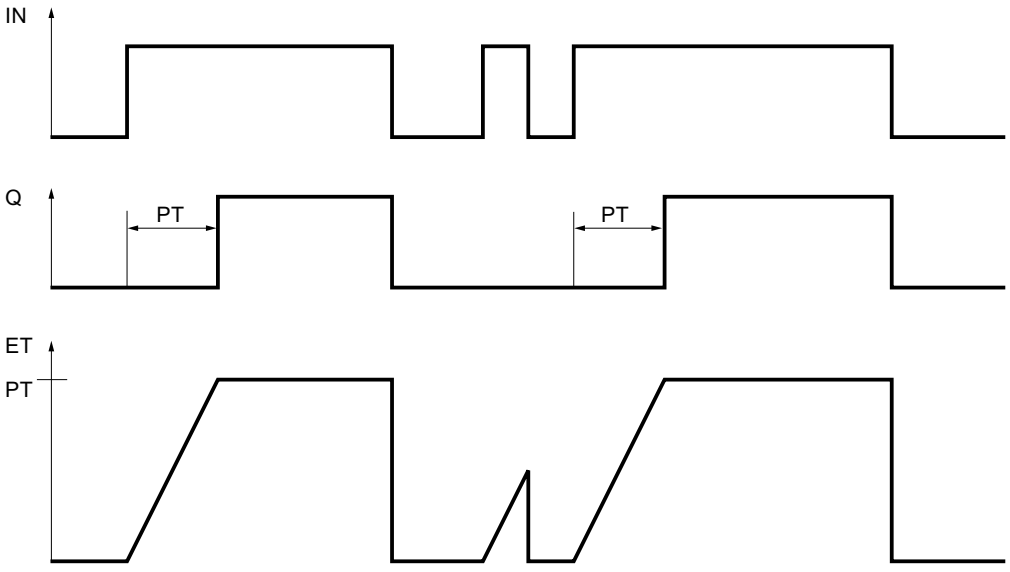
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0".

The execution of the "Start on-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

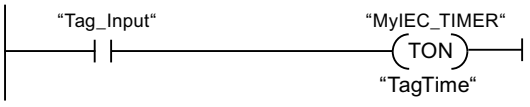
Parameters



The following table shows the parameters of the "Start on-delay timer" instruction:

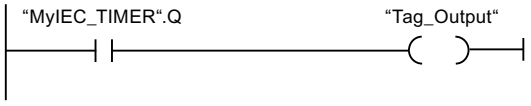
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TON_TIME	IEC_TIMER, IEC_LTIMER, TON_TIME, TON_LTIME	D, L	IEC timer that is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Start on-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The "MyIEC_TIMER timer is started for the time stored in the "TagTime" operand.

If the timer "MyIEC_TIMER" has expired and the operand "Tag_Input" has the signal state "1", querying the timer status ("MyIEC_TIMER).Q) returns signal state "1" and the "Tag_Output" operand is set. When the signal state of the operand "Tag_Input" changes to "0", the querying of the timer status returns the signal state "0" and the operand "Tag_Output" is reset.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(TOF)---: Start off-delay timer (S7-1200, S7-1500)

Description

Use the "Start off-delay timer" instruction to start an IEC timer with a specified duration as on-delay. The query of the timer status for "1" returns the signal state "0" if the result of logic operation (RLO) at the input of the instruction has the signal state "1". When the RLO changes from "1" to "0" (negative signal edge), the IEC timer starts with the specified time. The timer status remains at signal state "1" as long as the IEC timer is running. When the timer has run out and the RLO at the input of the instruction has the signal state "0", the timer status is set to the signal state "0". If the RLO changes to "1" before the time expires, the IEC timer is reset and the timer status remains at signal state "1".

Specify the duration of the OFF delay under the instruction at <Operand1> (duration) and specify the IEC time to be started above the instruction at <Operand2> (IEC time).

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start off-delay timer" stores its data in a structure of the data type IEC_TIMER or TOF_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start off-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

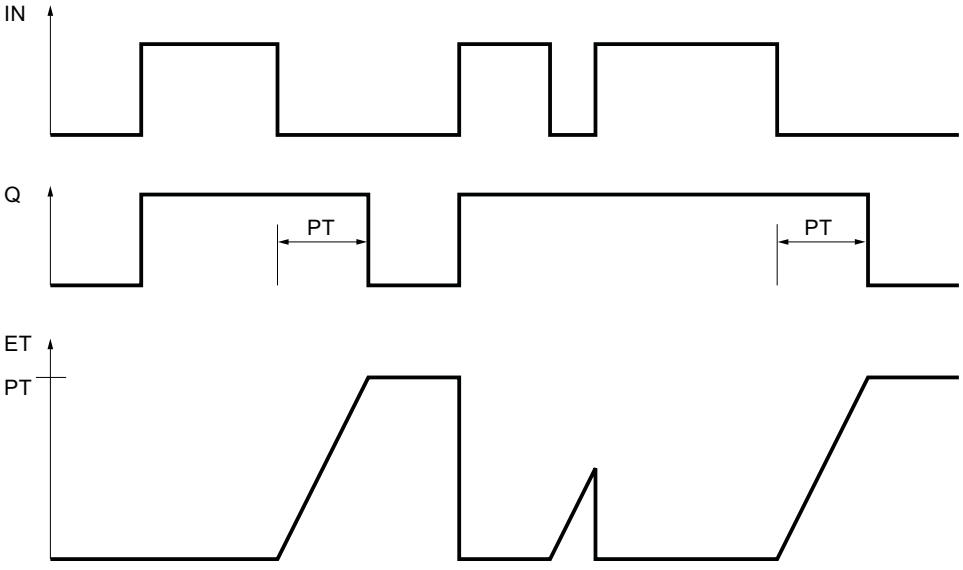
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0".

The execution of the "Start off-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

Parameters

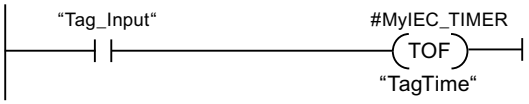


The following table shows the parameters of the "Start off-delay timer" instruction:

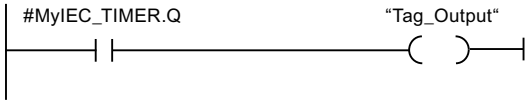
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TOF_TIME	IEC_TIMER, IEC_LTIMER, TOF_TIME, TOF_LTIME	D, L	IEC timer that is started.

You can find additional information on valid data types under "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the instruction:



Example

As long as timer #MyIEC_TIMER is running, the query of the time status (#MyIEC_TIMER.Q) returns the signal state "1" and operand "Tag_Output" is set. If the timer has expired and the operand "Tag_Input" has the signal state "0", the query of the timer status returns the signal state "0". If the signal state of the operand "Tag_Input" changes to "1" before timer #MyIEC_TIMER expires, the timer is reset. When the signal state of the operand "Tag_Input" is "1", the query of the timer status returns the signal state "1".

The following example shows how the instruction works:

The "Start off-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "1" to "0". The timer #MyIEC_TIMER is started for the time stored in the operand "TagTime".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(TONR)---: Time accumulator (S7-1200, S7-1500)

Description

You can use the "Time accumulator" instruction to record how long the signal is at the input of instruction "1". The instruction is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The time is recorded as long at the RLO is "1". If the RLO changes to "0", the instruction is halted. If the RLO changes back to "1", the time recording is continued. The query of the timer status for "1" returns the signal state "1" if the recorded time exceeds the value of the specified duration and the RLO at the input of coil is "1".

The timer status and the currently expired timer can be reset to "0" using the "Reset timer" instruction.

Specify the duration under the instruction at <Operand1> (duration) and specify the IEC time to be started above the instruction at <Operand2> (IEC time).

Note

You can start and query the IEC timer at various execution levels, as each querying of the outputs Q or ET updates the IEC_TIMER structure.

The execution of the "Time accumulator" instruction requires a preceding logic operation. It can be placed only at the end of the network.

For S7-1200 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER or TONR_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME. You can declare the structure as follows:

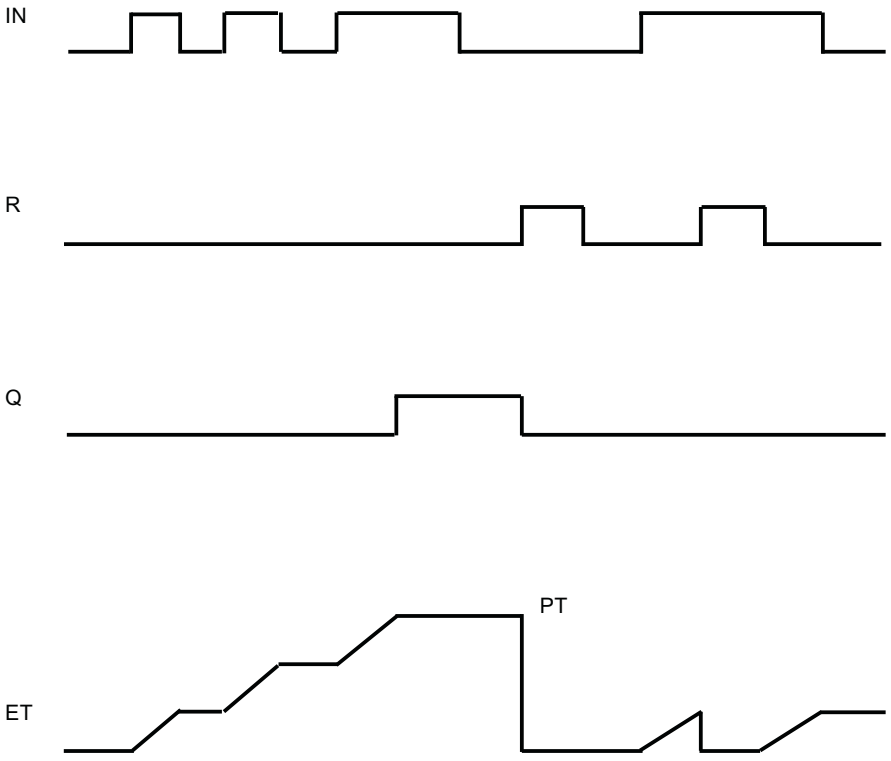
- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is stored in the ET structure component of the IEC timer. You can use a normally open contact to query timer status for "1" or a normally closed contact for "0".

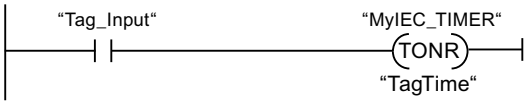
Parameters



The following table shows the parameters of the "Time accumulator" instruction:

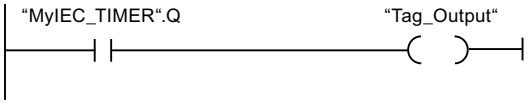
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	InOut	IEC_TIMER, TONR_TIME	IEC_TIMER, IEC_LTIMER, TONR_TIME, TONR_LTIME	D, L	IEC timer that is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Time accumulator" instruction executes on a positive signal edge in the RLO. The time is recorded as long as the operand "Tag_Input" has the signal state "1".

If the recorded time exceeds the value of the operand "TagTime", then the query of the timer status ("MyIEC_TIMER".Q) will return the signal state "1" and the operand "Tag_Output" will be set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(RT)---: Reset timer (S7-1200, S7-1500)

Description

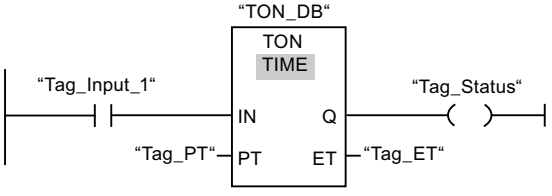
You can use the "Reset timer" instruction to reset an IEC timer to "0". The instruction is only executed if the result of logic operation (RLO) at the input of the coil is "1". If current is flowing to the coil (RLO is "1"), the structure components of the timer in the specified data block are reset to "0". If the RLO at the input of the instruction is "0", the timer remains unchanged.

The instruction does not influence the RLO. The RLO at the input of the coil is sent directly to the output of the coil.

You assign the "Reset timer" instruction an IEC timer that has been declared in the program.

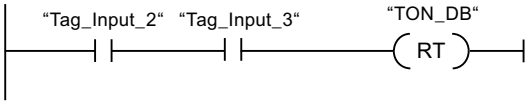
The instruction data is updated only when the instruction is called and not each time the assigned IEC timer is accessed. Querying the data is only identical from the call of the instruction to the next call of the instruction.

Parameters



The following table shows the parameters of the "Reset timer" instruction":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer that is reset.



You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The timer stored in the "TON_DB" instance data block starts running for the time duration specified by operand "Tag_PT".

If operands "Tag_Input_2" and "Tag_Input_3" have the signal state "1", the "Reset timer" instruction is executed and the timer stored in the "TON_DB" data block.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(PT)---: Load time duration (S7-1200, S7-1500)

Description

You can use the "Load time duration" instruction to set the time for an IEC timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time to the structure of the specified IEC timer.

Specify the duration that is loaded under the instruction at <Operand1> (duration) and specify the IEC time to be started above the instruction at <Operand2> (IEC time).

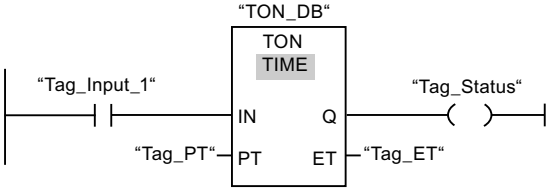
Note

If the specified IEC timer is running while the instruction executes, the instruction overwrites the current time of the specified IEC timer. This can change the timer status of the IEC timer.

You assign an IEC timer declared in the program to the "Load time duration" instruction.

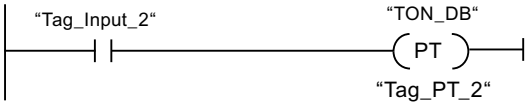
The instruction data is updated only when the instruction is called and each time the assigned IEC timer is accessed. The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Parameter



The following table shows the parameters of the "Load time duration" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC timer runs.
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer, the duration of which is set.



You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".

The "Load time duration" instruction is executed when the operand "Tag_Input_2" has the signal state "1". The instruction writes the time duration "Tag_PT_2" in the instance data block "TON_DB" and at the same time overwrites the value of the operand "Tag_PT" within the data block. The signal state of the timer status may therefore change at the next query or when "MyTimer".Q or "MyTimer".ET are accessed.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Legacy (S7-1500)

S_PULSE: Assign pulse timer parameters and start (S7-1500)

Description

The "Assign pulse timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as soon as the signal state at input S is "1". If the signal state at input S changes to "0" before the programmed duration expires, the timer is stopped. In this case, the signal state at output Q is "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign pulse timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

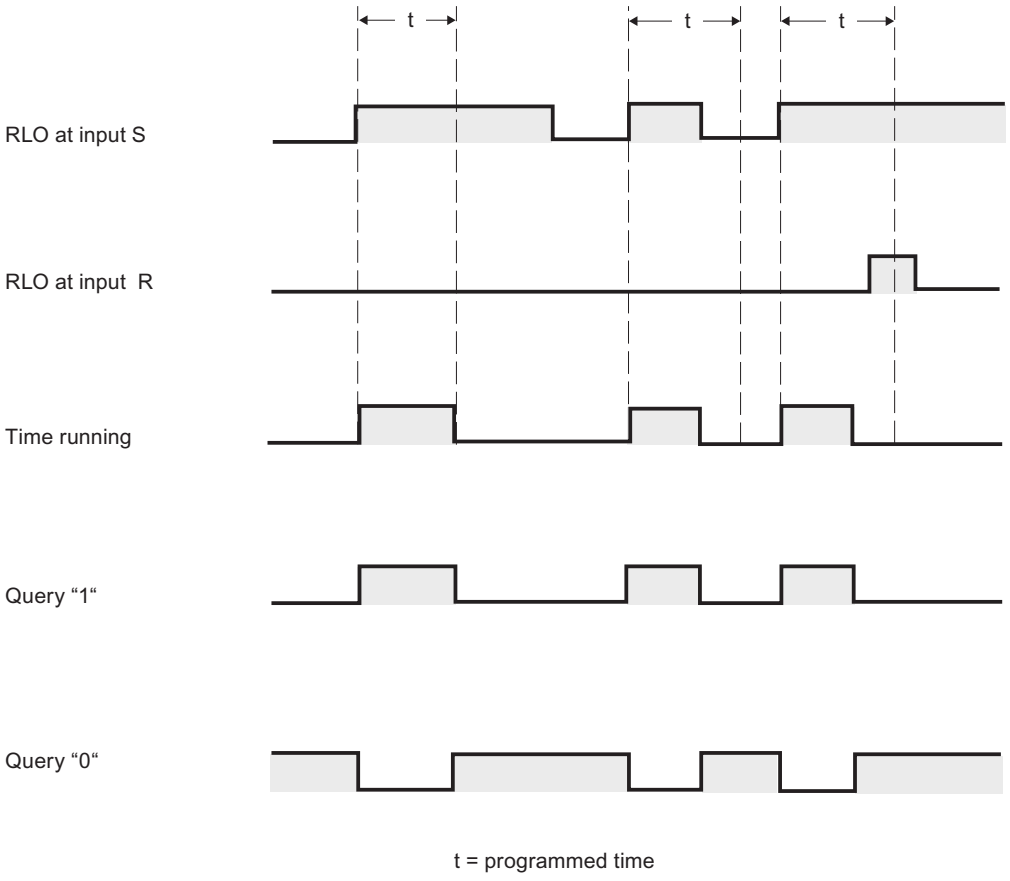
The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

Parameters

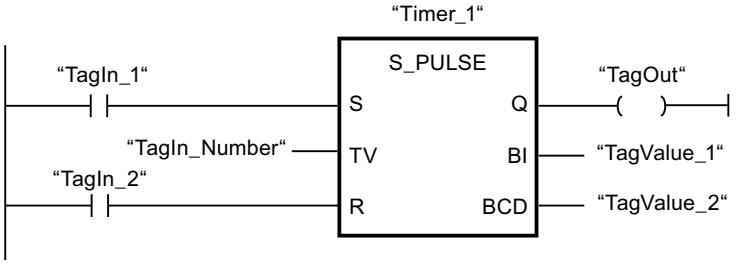


The following table shows the parameters of the instruction "Assign pulse timer parameters and start":

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

You can find additional information on valid data types under "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the instruction "Assign pulse timer parameters and start":

t = programmed time

Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" as long as the operand "TagIn_1" has the signal state "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer "Timer_1" is stopped. The operand "TagOut" is reset to "0" in this case.

The operand "TagOut" has the signal state "1" as long as the timer is running and the operand "TagIn_1" has the signal state "1". When the timer expires or is reset, the operand "TagOut" is reset to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

S_PEXT: Assign extended pulse timer parameters and start (S7-1500)

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". As long as the timer is running, the output Q has the signal state "1". When the timer expires, the output Q is reset to "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input TV.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign extended pulse timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

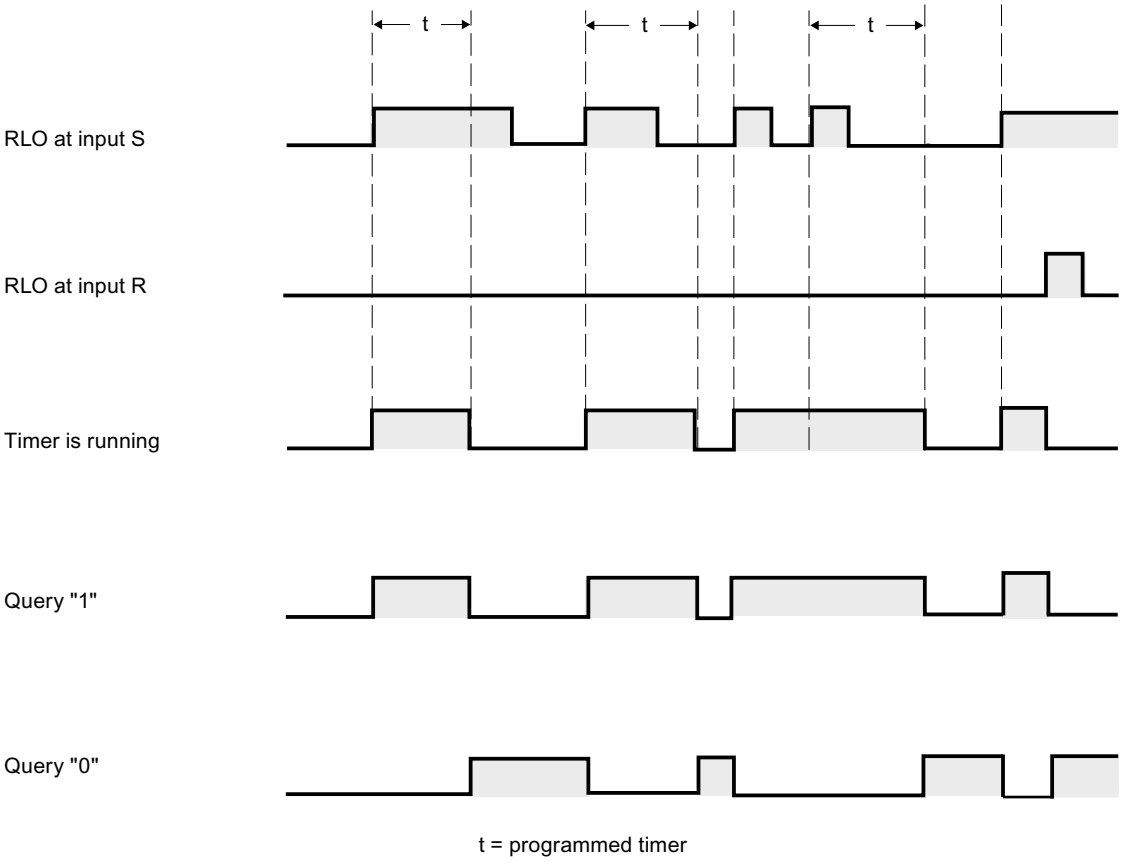
The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

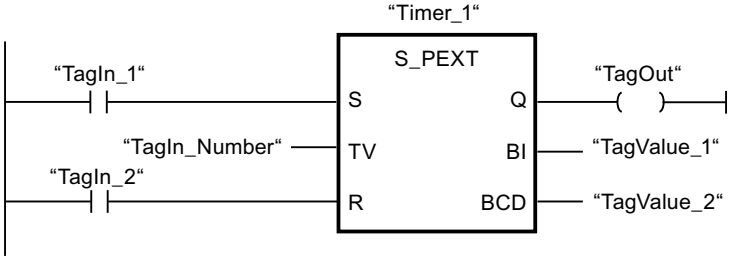
Parameters



The following table shows the parameters of the instruction "Assign extended pulse timer parameters and start":

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:

Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" without being affected by a negative edge at input S. If the signal state of the operand "TagIn_1" changes from "0" to "1" before the timer expires, the timer is restarted.

The operand "TagOut" has the signal state "1" as long as the timer is running. When the timer expires or is reset, the operand "TagOut" is reset to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

S_ODT: Assign on-delay timer parameters and start (S7-1500)

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as soon as the signal state at input S is "1". If the timer expires correctly and input S still has signal state "1" then output Q returns signal state "1". If the signal state at input S changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

If the time is running and the signal state at input R changes from "0" to "1" then the current time value and the time base are also set to zero. In this case, the signal state at output Q is "0". The timer is reset if the signal state is "1" at the R input even if the timer is not running and the RLO at input S is "1".

Specify the timer of the instruction in the placeholder above the box. The timer must be declared with the data type TIMER.

The "Assign on-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

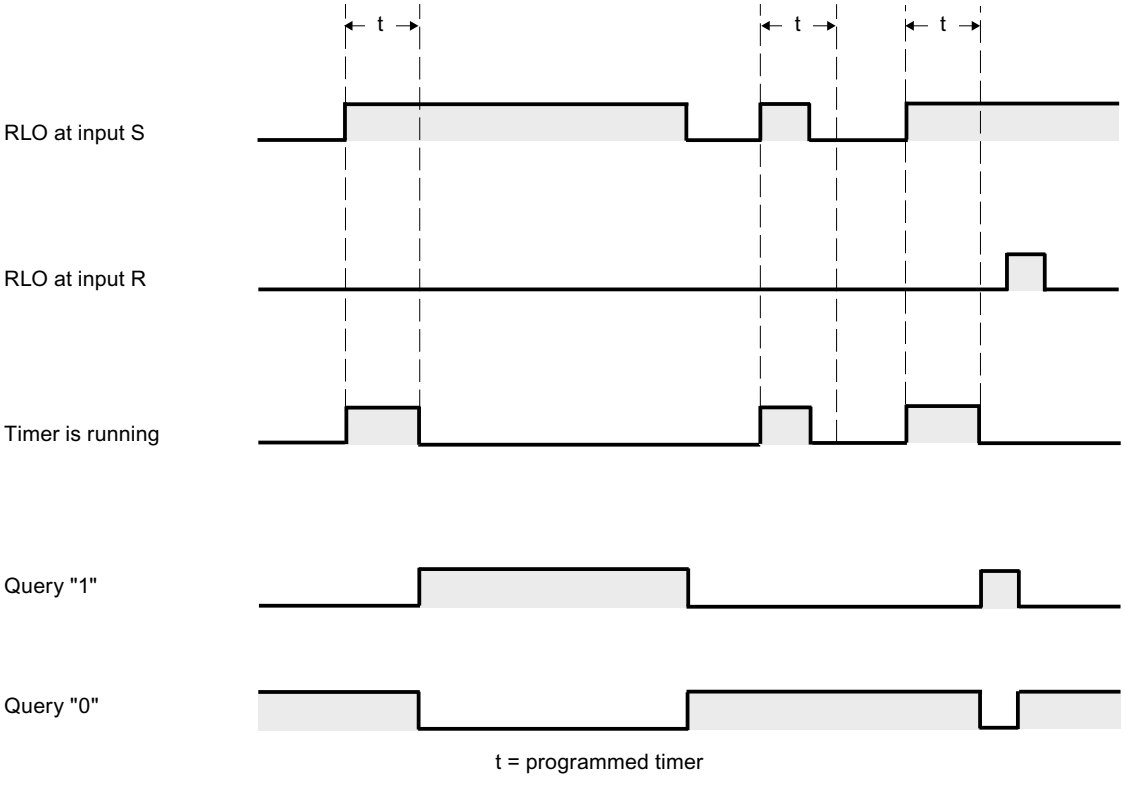
The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

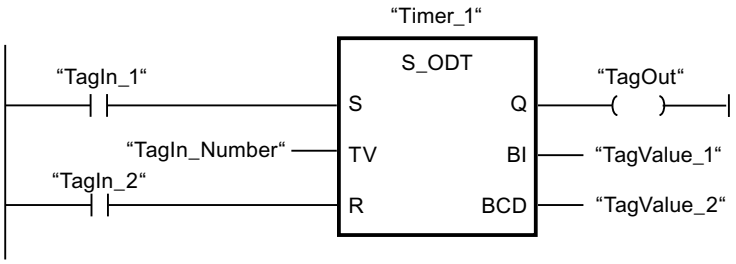
Parameters



The following table shows the parameters of the "Assign on-delay timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:

Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number". If the timer expires and the operand has the signal state "1", the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. The operand "TagOut" has the signal state "0" in this case.

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

S_ODTS: Assign retentive on-delay timer parameters and start (S7-1500)

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". If the timer expires, the "Q" output returns signal state "1" regardless of the signal state at input "S". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input (TV).

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0" regardless of the signal state at start input S. In this case, the signal state at output Q is "0".

The "Assign retentive on-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

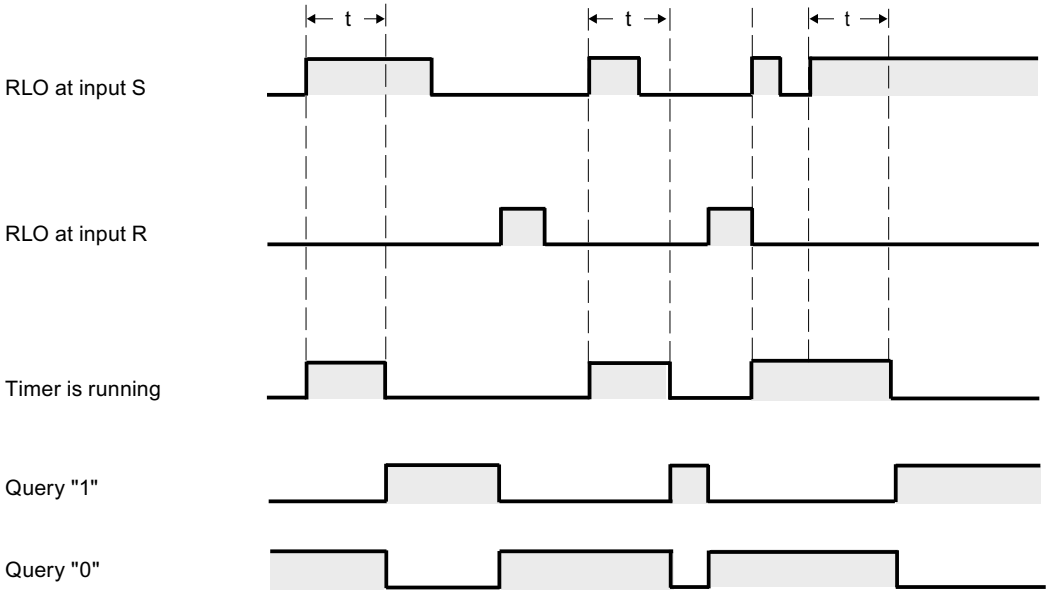
The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

Parameters

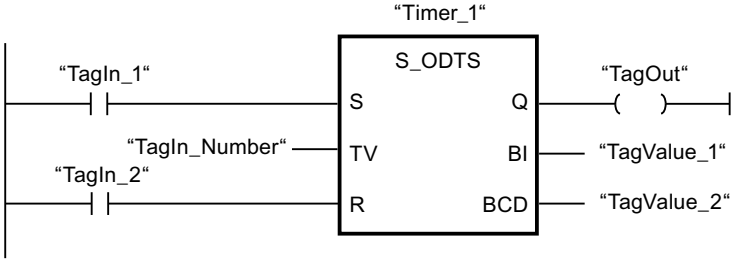


The following table shows the parameters of the "Assign retentive on-delay timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

You can find additional information on valid data types under "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:

t = programmed timer

Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number", even if the signal state of the operand "TagIn_1" changes to "0". When the timer expires, the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is restarted.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

S_OFFDT: Assign off-delay timer parameters and start (S7-1500)

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV). As long as the timer is running or input S returns signal state "1", then output Q has signal state "1". When the timer expires and the signal state at input S is "0", output Q is reset to the signal state "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at input S.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed. The current time value is output BI-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0". In this case, the signal state at output Q is "0".

The "Assign off-delay timer parameters and start" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

The instruction data is updated at every access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

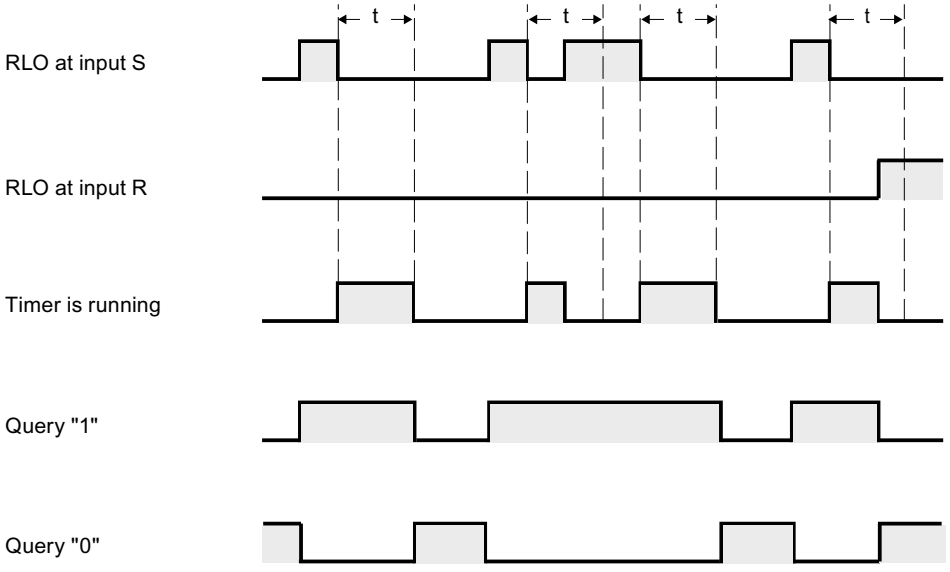
Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

Parameters

The following table shows the parameters of the "Assign off-delay timer parameters and start" instruction:

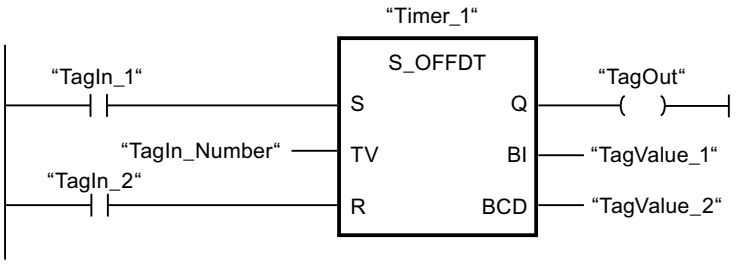


Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input

Parameters	Declaration	Data type	Memory area	Description
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Preset time value
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (BI-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the timer

You can find additional information on valid data types under "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:

t = programmed timer

Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "1" to "0". The timer expires with the time value of the operand "TagIn_Number". The operand "TagOut" is set to "1" when the timer is running and when the operand "TagIn_1" has the signal state "0". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is reset.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(SP): Start pulse timer (S7-1500)

Description

The "Start pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer runs with the specified duration as long as the RLO has the signal state "1". As long as the timer is running, the query of timer status "1" returns the signal state "1". If there is a change from "1" to "0" in the RLO before the time value has elapsed, the timer stops. In this case, the querying of the timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down to zero. The time base indicates the time period with which the time value is changed.

Specify the duration with which the time will run down at the operand placeholder <Operand1> (duration) and specify the time to be started above the instruction in <Operand2>.

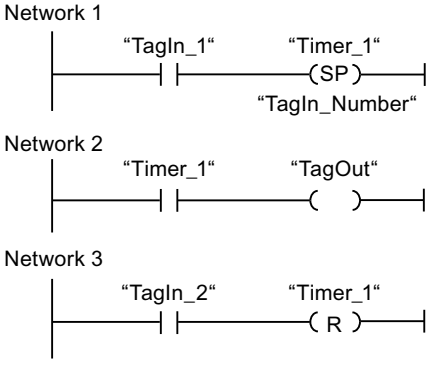
The "Start pulse timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

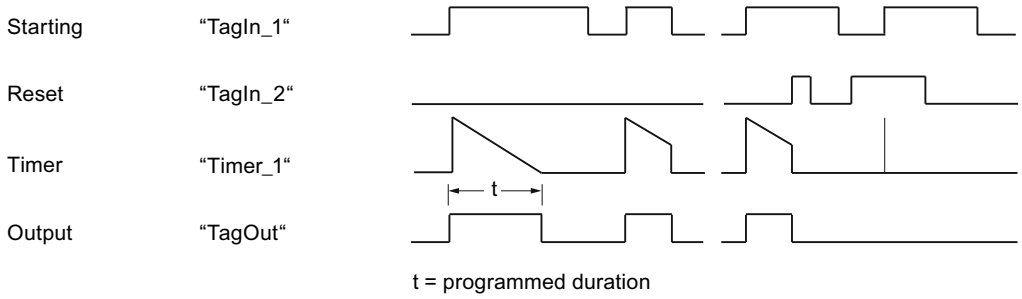
Parameters



The following table shows the parameters of the instruction "Start pulse timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Operand2>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand as long as the signal state of the "TagIn_1" operand is "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. As long as the timer is running, the "TagOut" operand returns signal state "1". A signal state change of the operand "TagIn_2" from "0" to "1" resets the timer, which stops the timer and sets the current time value to "0".

The figure below shows the timer diagram of the example:

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(SE): Start extended pulse timer (S7-1500)

Description

The "Start extended pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer runs for the specified time period even when the RLO changes to signal state "0". As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is restarted with the programmed time period. The querying of the timer status for "1" returns the signal state "0" when the timer expires.

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down to zero. The time base indicates the time period with which the time value is changed.

Specify the duration with which the time will run down at the operand placeholder <Operand1> (duration) and specify the time to be started above the instruction in <Operand2>.

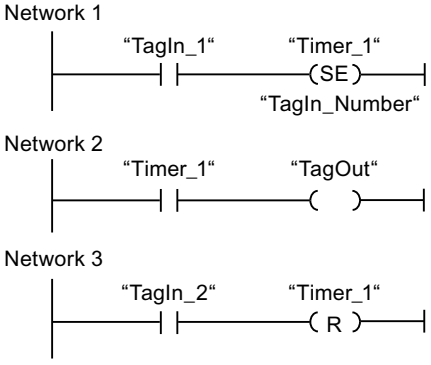
The "Start extended pulse timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

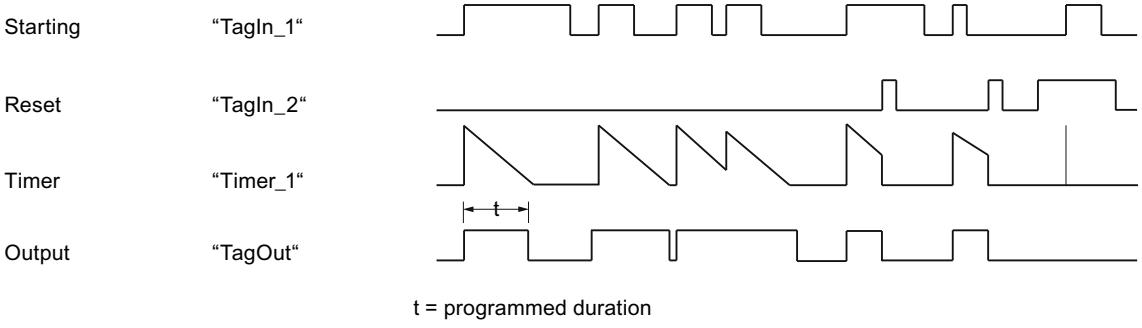
Parameters



The following table shows the parameters of the "Start extended pulse timer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Operand2>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" without being affected by a negative signal edge in the RLO. As long as the timer is running, the "TagOut" operand returns signal state "1". If the signal state of the operand "TagIn_1" changes again from "0" to "1" before the timer expires, the timer is restarted.

The figure below shows the timer diagram of the example:

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(SD): Start on-delay timer (S7-1500)

Description

The "Start on-delay timer" instruction starts a programmed timer when the signal state "1" is detected at the start input. As long as this signal state remains "1", the timer expires with the specified duration. When the timer expires and the signal state at the start input is still "1", the query for timer status also returns "1". If the signal at the start input is "0", the timer is reset. In this case, querying the timer status returns the signal state "0". As soon as the signal at the start input changes to "1" again, the timer starts running again.

The signal state of the timer output is identical to the signal state of the start input. The start input is directly interconnected to the output and is not linked to the timer.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero.

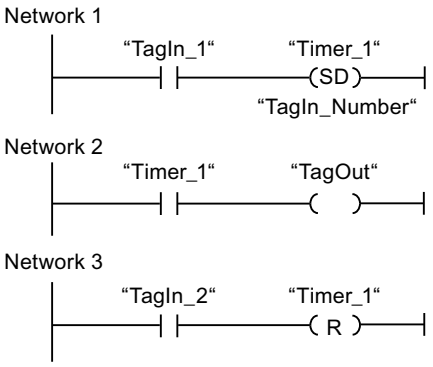
Specify the duration with which the time will run down at the operand placeholder <Operand1> (duration) and specify the time to be started above the instruction in <Operand2>.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

Parameters



The following table shows the parameters of the "Start on-delay timer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Operand2>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".

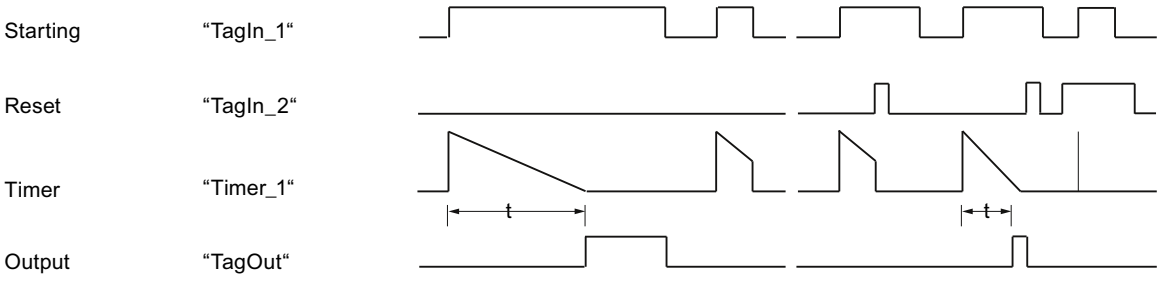
Example

The following example shows how the instruction works:

Network 1:

"#Timer_1" starts when the signal state of the "#TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "#TagIn_Number". If the signal state of the "#TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is reset.

Network 2:



When the timer has expired, the #TagIn_1 operand at the start input has signal state "1" and the timer was not reset, the #TagOut operand is "1".

Network 3:

When the signal state of the #TagIn_2 operand has signal state "1", the timer #Timer_1 and the output #TagOut are reset.

If you want to restart #Timer_1, the signal state at the #TagIn_2 operand must be "0" and the signal state at the start input #TagIn_1 must change from "0" to "1".

The figure below shows the timer diagram of the example:

t = programmed duration

---(SS): Start retentive on-delay timer (S7-1500)

Description

The "Start retentive on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO). The timer expires with the specified duration, even if the RLO changes to the signal state "0". When the timer expires, the querying of the timer status for "1" returns the signal state "1". After expiry of the timer, the timer can only be restarted if it is explicitly reset.

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

Specify the duration with which the time will run down at the operand placeholder <Operand1> (duration) and specify the time to be started above the instruction in <Operand2>.

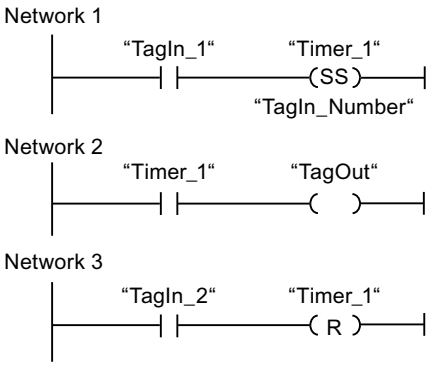
The "Start retentive on-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

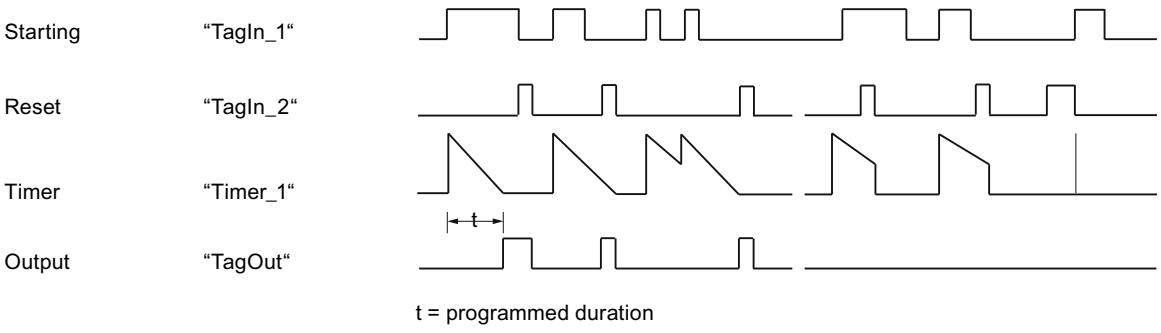
Parameters



The following table shows the parameters of the "Start retentive on-delay timer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Operand2>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

The timer "Timer_1" is started when the signal state of the operand "TagIn_1" changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number". When the timer expires, the operand "TagOut" is set to "1". If the signal state of the operand "TagIn_1" changes from "0" to "1" while the timer is running, the timer is restarted. If the signal state of the operand "TagIn_2" is "1", the timer "Timer_1" is reset, which stops the timer and sets the current time value to "0".

The figure below shows the timer diagram of the example:

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(SF): Start off-delay timer (S7-1500)

Description

The "Start off-delay timer" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO). The timer expires with the specified duration. As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is reset. The timer is always restarted when the RLO changes from "1" to "0".

The duration is made up internally of a time value and a time base. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The queries of the timer status for "1" return the query result "1" if the signal state of the result of logic operation is "1" at the execution of the instruction. If the RLO is "0", queries of the timer status for "1" return the query result "0".

Specify the duration with which the time will run down at the operand placeholder <Operand1> (duration) and specify the time to be started above the instruction in <Operand2>.

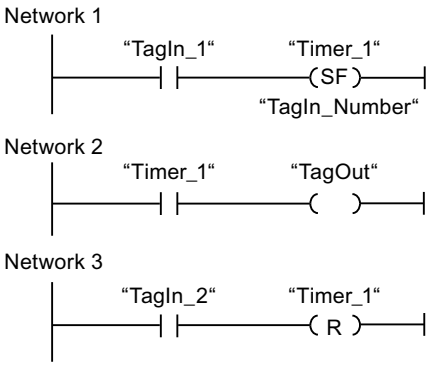
The "Start off-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

For an example of how a time cell can be structured, refer to See also "L: Load timer value".

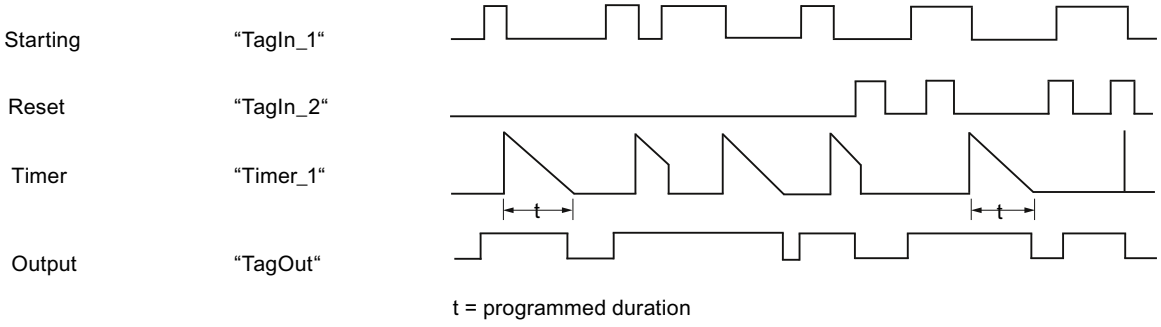
Parameters



The following table shows the parameters of the instruction "Start off-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	S5TIME, WORD	I, Q, M, D, L or constant	Duration with which the timer expires.
<Operand2>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "1" to "0". The timer expires with the time value of the operand "TagIn_Number". As long as the timer is running, the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" while the timer is running, the timer is restarted. If the signal state of the "TagIn_2" operand is "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

The figure below shows the timer diagram of the example:

t = programmed duration

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Counter operations (S7-1200, S7-1500)

CTU: Count up (S7-1200, S7-1500)

Description

You can use the "Count up" instruction to increment the value at output CV. When the signal state at the CU input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit for the data type specified at the output CV. When the high limit is reached, the signal state at the CU input no longer has an effect on the instruction.

You can query the counter status in the Q output. The signal state at the Q output is determined by the PV parameter. If the current counter value is greater than or equal to the value of the PV parameter, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0".

The value at the CV output is reset to zero when the signal state at input R changes to "1". As long as the R input has signal state "1", the signal state at the CU input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • CTU_LINT / CTU_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

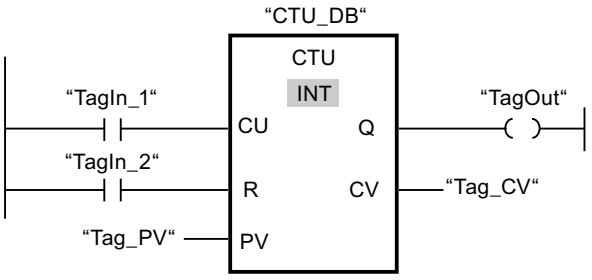
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTU_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count up" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
R	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Reset input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value at which the output Q is set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CV" operand is incremented by one. With each additional positive signal edge, the counter value is incremented until the high limit of the data type (INT = 32767) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PV" operand. In all other cases, the "TagOut" output has signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Setting the retentivity of local tags (Page 4769)

Setting retentivity in an instance data block (Page 4809)

Basic information on LAD (Page 4878)

CTD: Count down (S7-1200, S7-1500)

Description

You can use the "Count down" instruction to decrement the value at output CV. When the signal state at the CD input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state at the CD input no longer has an effect on the instruction.

You can query the counter status in the Q output. If the current counter value is less than or equal to zero, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0".

The value at the CV output is set to the value of the PV parameter when the signal state at the LD input changes to "1". As long as the LD input has signal state "1", the signal state at the CD input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • CTD_LINT / CTD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

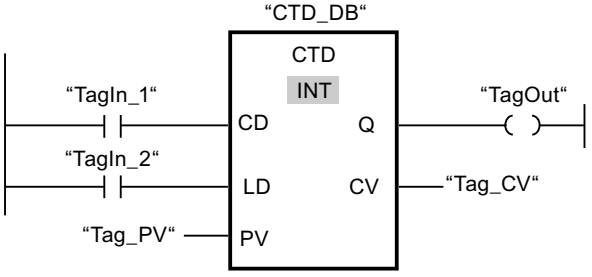
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count down" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
LD	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value to which the CV output is set with LD = 1.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1", the instruction is executed and the value at the "Tag_CV" output is decremented by one. With each additional positive signal edge, the counter value is decremented until the low limit of the specified data type (INT = -32768) is reached.

The "TagOut" output has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "TagOut" output has signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

CTUD: Count up and down (S7-1200, S7-1500)

Description

You can use the "Count up and down" instruction to increment and decrement the counter value at the CV output. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one and stored at the CV output. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value at the CV output is decremented by one. If there is a positive signal edge at the CU and CD inputs in one program cycle, the current counter value at the CV output remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV output. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state at the LD input changes to "1", the counter value at the CV output is set to the value of the PV parameter. As long as the LD input has signal state "1", the signal state at the CU and CD inputs has no effect on the instruction.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has signal state "1", a change in the signal state of the CU, CD and LD inputs has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU output. If the current counter value is greater than or equal to the value of the PV parameter, the QU output is set to signal state "1". In all other cases, the QU output has signal state "0".

You can query the status of the down counter at the QD output. If the current counter value is less than or equal to zero, the QD output is set to signal state "1". In all other cases, the QD output has signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • CTUD_LINT / CTUD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

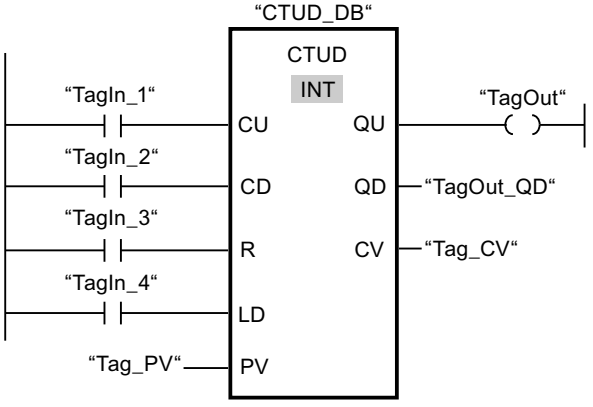
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTUD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up and down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count up and down" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count up input
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count down input
R	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Reset input
LD	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value at which the QU output is set / value to which the CV output is set when LD = 1.
QU	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status of the up counter
QD	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Status of the down counter
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

If the signal state at the "TagIn_1" or "TagIn_2" input changes from "0" to "1" (positive signal edge), the "Count up and down" instruction is executed. When there is a positive signal edge at the "TagIn_1" input, the current counter value is incremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the "TagIn_2" input, the counter value

is decremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the CU input, the counter value is incremented until it reaches the high limit of 32767. If input CD has a positive signal edge, the counter value is decremented until it reaches the low limit of INT = -32768.

The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value at the "Tag_PV" input. In all other cases, the "TagOut" output has signal state "0".

The "TagOut_QD" output has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "TagOut_QD" output has signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Legacy (S7-1500)

S_CU: Assign parameters and count up (S7-1500)

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The counter value can be incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CU is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU and S inputs has no effect on the counter value.

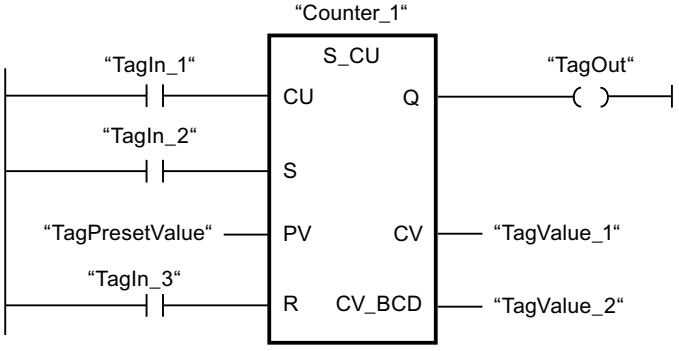
The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Assign parameters and count up" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
BI	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. When the signal state at input "TagIn_2" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

S_CD: Assign parameters and count down (S7-1500)

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The counter value is decremented until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CD is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CD and S inputs has no effect on the counter value.

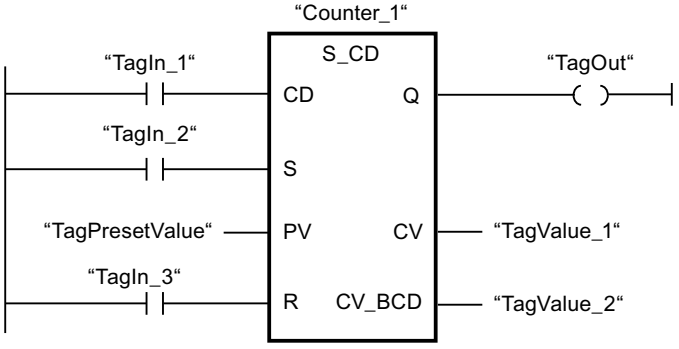
The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count down" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Assign parameters and count down" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
BI	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decremented by one. When the signal state at input "TagIn_2" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

S_CUD: Assign parameters and count up / down (S7-1500)

Description

You can use the "Assign parameters and count up / down" instruction to increment or decrement the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. If there is a positive signal edge at the CU and CD inputs in one program cycle, the counter value remains unchanged.

The counter value can be incremented until the high limit of "999" is reached. When the high limit value is reached, the counter value is no longer incremented on a positive signal edge. When the low limit "0" is reached, the counter value is not decremented any further.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO is "1" at the inputs CU and CD, the counter counts accordingly in the next scan cycle, even if no change in the signal edge was detected.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU, CD and S inputs has no effect on the counter value.

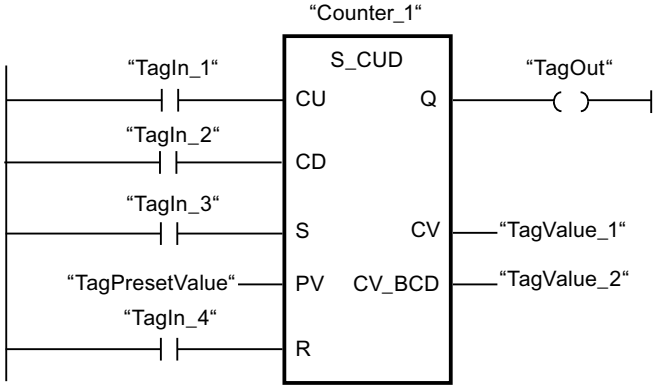
The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up / down" instruction requires a preceding logic operation for edge evaluation and can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Assign parameters and count up / down" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L, T, C or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
BI	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the signal state at the "TagIn_1"" or "TagIn_2" input changes from "0" to "1" (positive signal edge), the "Assign parameters and count up / down" instruction is executed. When there is a positive signal edge at the "TagIn_1" input and the current counter value is less than "999", the counter value is incremented by one. When there is a positive signal edge at the "TagIn_2" input and the current counter value is greater than "0", the counter value is decremented by one.

When the signal state at input "TagIn_3" changes from "0" to "1", the counter value is set to the value of the operand "TagPresetValue". The counter value is reset to "0" when the "TagIn_4" operand has signal state "1".

The current counter value is saved as a hexadecimal value in the operand "TagValue_1" and BCD-coded in the operand "TagValue_2".

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(SC): Set counter value (S7-1500)

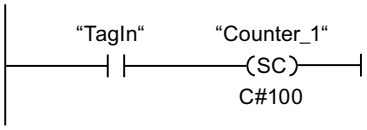
Description

You can use the "Set counter value" instruction to set the value of a counter. The instruction is executed when the result of logic operation (RLO) at the input changes from "0" to "1". When the instruction is executed, the counter is set to the specified counter value.

At the operand placeholder <Operand1> below the instruction, specify the duration with which counter is preset and specify the counter above the instruction in <Operand2>.

The "Set counter value" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameters



The following table lists the parameters of the "Set counter value" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	WORD	I, Q, M, D, L or constant	Value with which the counter is preset in the BCD format. (C#0 to C#999)
<Operand2>	InOut/Input	COUNTER	C	Counter that is preset.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

the counter "Counter_1" starts with the value "100" when the signal state of the "TagIn" operand changes from "0" to "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

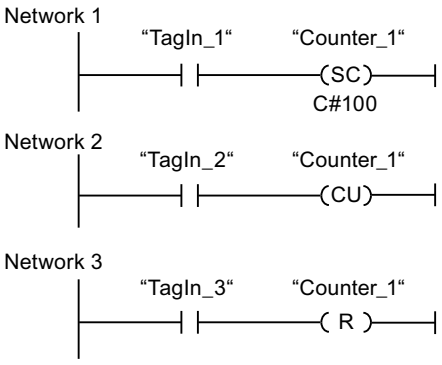
---(CU): Count up (S7-1500)

Description

With the "Count up" instruction you can increment the value of the specified counter by one if there is a positive signal edge in the result of logic operation (RLO). The counter value can be incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

The "Count up" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Parameters



The following table shows the parameters of the "Count up" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter whose value is incremented.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of the counter "Counter_1" is incremented by one when the signal state of the operand "TagIn_2" changes from "0" to "1".

When the operand "TagIn_3" has the signal state "1", the value of the counter "Counter_1" is reset to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

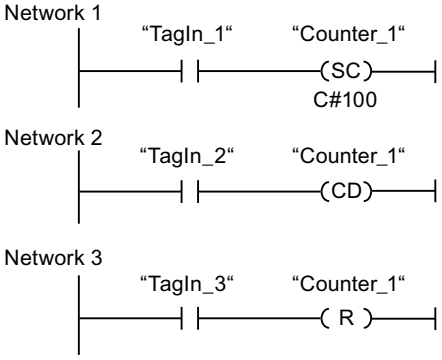
---(CD): Count down (S7-1500)

Description

With the "Count down" instruction you can increment the value of the specified counter by one if there is a positive signal edge in the result of logic operation (RLO). The counter value can be decremented until the limit of "0" is reached. When the limit is reached, the counter value is no longer changed on a positive signal edge.

The "Count down" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Parameters



The following table shows the parameters of the "Count down" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Counter>	InOut/Input	COUNTER	C	Counter whose value is decremented.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of the counter "Counter_1" is decremented by one when the signal state of the operand "TagIn_2" changes from "0" to "1".

When the operand "TagIn_3" has the signal state "1", the value of the counter "Counter_1" is reset to "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Comparator operations (S7-1200, S7-1500)

CMP ==: Equal (S7-1200, S7-1500)

Description

You can use the "Equal" instruction to determine if a first comparison value (<Operand1>) is equal to a second comparison value (<Operand2>).

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width of the operands must be the same.

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, then instead of the instruction "CMP ==: Equal" we recommend using the instruction "IN_RANGE: Value within range".

When floating-point numbers are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check.

The special bit patterns of invalid floating-point numbers (NaN) that are the outcome of undefined results (e.g. root of -1) are not comparable. This means that if one of the operands has the value NaN, the instruction "CMP ==: Equal" has the result FALSE.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'AA'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'aa'	'aaa'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

Bit patterns of invalid timers, date and times, e.g. DT#2015-13-33-25:62:99.999_999_999, cannot be compared. This means that if one of the operands has an invalid value, the instruction "CMP ==: Equal" has the result FALSE.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Comparison of hardware data types

To be able to compare the operands of the PORT data type, you need to select the WORD data type from the drop-down list in the instruction box.

If you want to compare the two hardware data types HW_IO and HW_DEVICE, you must first create a tag of data type HW_ANY in the section "Temp" of the block interface and then copy the LADDR (of data type HW_DEVICE) to the tag. It is then possible to compare HW_ANY and HW_IO.

Comparison of structures

Note

Availability of comparison of structures

The option to compare structures is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

You can compare the values of two structured operands when both tags are of the same structure data type. When structures are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check. An exception is comparisons in which one of the two operands is a VARIANT or an ANY. If the data type is not yet known when the program is created, you can use the VARIANT data type. In this case you can also compare the operand with a structured tag of any data type. You can also compare two tags of the data type VARIANT or ANY with each other.

You can select the data type VARIANT for the comparison of structures from the drop-down list in the instruction box. The following data types are possible:

- PLC data type
- STRUCT (the structure of the data type STRUCT must be contained in a PLC data type (UDT) or the two structures to be compared are two elements of an ARRAY of STRUCT. Anonymous structures are not permitted.)
- Tag to which ANY is pointing
- Tag to which VARIANT is pointing

The following requirements must be met to compare two tags of the data type ARRAY with VARIANT selected:

- The elements must each have the same data type.
- The two ARRAYs must have the same dimension.
- All dimensions must have the same number of elements. The exact ARRAY limits do not have to match.

Note

ARRAY of BOOL

When you compare two operands of the data type ARRAY of BOOL with each other, you have selected the data type VARIANT from the drop-down list, and the number of elements cannot be divided by 8, the fill bits are compared as well. This may affect the comparison result.

If an element within the structures that you want to compare is an invalid STRING/WSTRING, an invalid time or date or an invalid floating-point number, the comparison result in the RLO (result of logic operation) will return the signal state "0".

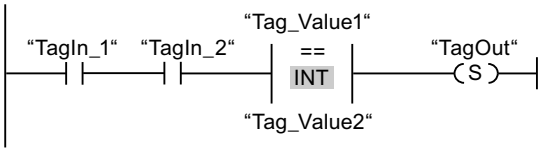
The table below shows an example of a comparison of structures:

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	Tag of data type A <PLC data type>		Tag value	1
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	Tag of data type B <PLC data type>		Tag value	0
	BOOL	FALSE		BOOL	TRUE	
	INT	2		INT	3	

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	VARIANT (supplied with tag of data type A)		Tag value	1
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

Parameters



The following table shows the parameters of the instruction "Equal":

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	Second value to compare
As detailed above, the data types ARRAY, STRUCT (in a PLC data type), VARIANT, ANY and PLC data type (UDT) are only available as of firmware version 2.0 or 4.2.				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" = "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

CMP <>: Not equal (S7-1200, S7-1500)

Description

You can use the "Not equal" instruction to determine if a first comparison value (<Operand1>) is not equal to a second comparison value (<Operand2>).

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width of the operands must be the same.

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, then instead of the instruction "CMP <>: Not equal" we recommend using the instruction "OUT_RANGE: Value outside range".

If floating-point numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

The special bit patterns of invalid floating-point numbers (NaN) that are the outcome of undefined results (e.g. root of -1) are not comparable. This means that if one of the operands has the value NaN, the instruction "CMP <>: Not equal" has the result FALSE.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'Hello World'	'HelloWorld'	1
'AA'	'AA'	0
'aa'	'aaa'	1

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

Bit patterns of invalid timers, date and times, e.g. DT#2015-13-33-25:62:99.999_999_999, cannot be compared. This means that if one of the operands has an invalid value, the instruction "CMP <>: Not equal" has the result FALSE.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Comparison of hardware data types

To be able to compare the operands of the PORT data type, you need to select the WORD data type from the drop-down list in the instruction box.

If you want to compare the two hardware data types HW_IO and HW_DEVICE, you must first create a tag of data type HW_ANY in the section "Temp" of the block interface and then copy the LADDR (of data type HW_DEVICE) to the tag. It is then possible to compare HW_ANY and HW_IO.

Comparison of structures

Note

Availability of comparison of structures

The option to compare structures is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

You can compare the values of two structured operands when both tags are of the same structure data type. When structures are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check. An exception is comparisons in which one of the two operands is a VARIANT or an ANY. If the data type is not yet known when the program is created, you can use the VARIANT data type. In this case you can also

compare the operand with a structured tag of any data type. You can also compare two tags of the data type VARIANT or ANY with each other.

You can select the data type VARIANT for the comparison of structures from the drop-down list in the instruction box. The following data types are possible:

- PLC data type
- STRUCT (the structure of the data type STRUCT must be contained in a PLC data type (UDT) or the two structures to be compared are two elements of an ARRAY of STRUCT. Anonymous structures are not permitted.)
- Tag to which ANY is pointing
- Tag to which VARIANT is pointing

The following requirements must be met to compare two tags of the data type ARRAY with VARIANT selected:

- The elements must each have the same data type.
- The two ARRAYs must have the same dimension.
- All dimensions must have the same number of elements. The exact ARRAY limits do not have to match.

Note

ARRAY of BOOL

When you compare two operands of the data type ARRAY of BOOL with each other, you have selected the data type VARIANT from the drop-down list, and the number of elements cannot be divided by 8, the fill bits are compared as well. This may affect the comparison result.

If an element within the structures that you want to compare is an invalid STRING/WSTRING, an invalid time or date or an invalid floating-point number, the comparison result in the RLO (result of logic operation) will return the signal state "0".

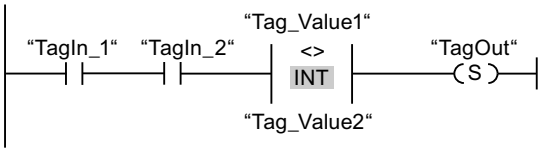
The table below shows an example of a comparison of structures:

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	Tag of data type A <PLC data type>		Tag value	0
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	Tag of data type B <PLC data type>		Tag value	1
	BOOL	FALSE		BOOL	TRUE	
	INT	2		INT	3	

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	VARIANT (supplied with tag of data type A)		Tag value	0
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

Parameters



The following table shows the parameters of the "Not equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	Second value to compare
As detailed above, the data types ARRAY, STRUCT (in a PLC data type), VARIANT, ANY and PLC data type (UDT) are only available as of firmware version 2.0 or 4.2.				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <> "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

CMP >=: Greater or equal (S7-1200, S7-1500)

Description

You can use the "Greater or equal" instruction to determine if a first comparison value (<Operand1>) is greater than or equal to a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'Hello World'	'Hello World'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'AAA'	'a'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is greater (more recent) than or equal to the point of time at <Operand2>.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

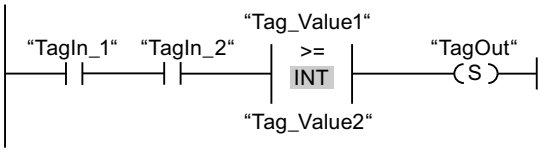
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Greater or equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" >= "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Example of detecting the fill level of a storage area (Page 4928)

Basic information on LAD (Page 4878)

CMP <=: Less or equal (S7-1200, S7-1500)

Description

You can use the "Less or equal" instruction to determine if a first comparison value (<Operand1>) is less than or equal to a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'Hello World'	'Hello World'	1
'HelloWorld'	'Hello World'	0
'BB'	'AA'	0
'AAA'	'AA'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is less (less recent) than or equal to the point of time at <Operand2>.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

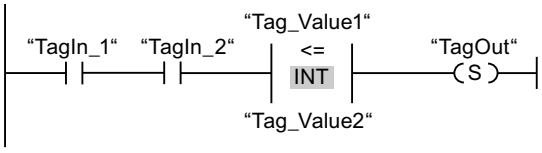
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Less or equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <= "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

CMP >: Greater than (S7-1200, S7-1500)

Description

You can use the "Greater than" instruction to determine if a first comparison value (<Operand1>) is greater than a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'AA'	'aa'	0
'AAA'	'a'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is greater (more recent) than the point of time at <Operand2>.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

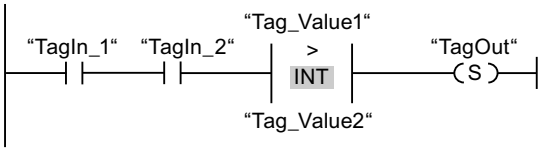
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Greater than" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" > "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

CMP <: Less than (S7-1200, S7-1500)

Description

You can use the "Less than" instruction to determine if a first comparison value (<Operand1>) is less than a second comparison value (<Operand2>). Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify the first comparison value (<Operand1>) at the operand placeholder above the instruction. Specify the second comparison value (<Operand2>) at the operand placeholder below the instruction.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'BB'	'AA'	0
'AAA'	'AA'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

When time values are compared, the RLO of the instruction is "1" if the point of time at <Operand1> is less (less recent) than the point of time at <Operand2>.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

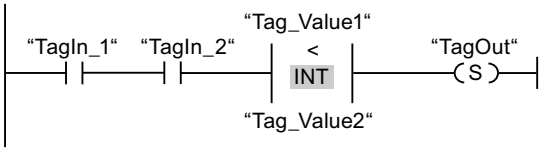
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Less than" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
<Operand2>	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" < "Tag_Value2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Example of detecting the fill level of a storage area (Page 4928)

Basic information on LAD (Page 4878)

IN_RANGE: Value within range (S7-1200, S7-1500)

Description

You can use the "Value within range" instruction to query whether of the value at input VAL is within a specific value range.

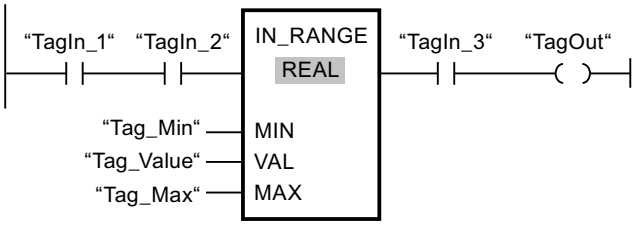
You specify the limits of the value range with the MIN and MAX inputs. The "Value within range" instruction compares the value at the VAL input with the values of the MIN and MAX inputs and sends the result to the box output. If the value at input VAL satisfies the comparison MIN <= VAL or VAL <=MAX, the box output has the signal state "1". If the comparison is not fulfilled, the box output has the signal state "0".

If the box input has the signal state "0", the "Value within range" instruction is not executed.

The comparison function can only execute if the values to be compared are of the same data type and the box input is interconnected.

Parameters

The following table shows the parameters of the "Value within range" instruction:



Parameters	Declaration	Data type	Memory area	Description
Box input	Input	BOOL	I, Q, M, D, L	Result of the previous logic operation
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The value of the operand "Tag_Value" is within the value range that is specified by the current values of the operands "Tag_Min" and "Tag_Max" (MIN <= VAL or VAL <= MAX).
- The operand "TagIn_3" has the signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

OUT_RANGE: Value outside range (S7-1200, S7-1500)

Description

You can use the "Value outside range" instruction to query whether of the value at input VAL is outside a specific value range.

You specify the limits of the value range with the MIN and MAX inputs. The "Value outside range" instruction compares the value at input VAL with the values of the inputs MIN and MAX and sends the result to the box output. If the value at input VAL satisfies the comparison MIN > VAL or VAL >MAX, the box output has the signal state "1". The box output also has the signal state "1" if a specified operand with the REAL data type shows an invalid value.

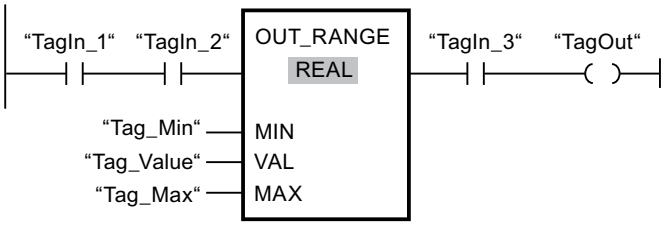
The box output returns the signal state "0", if the value at input VAL does not satisfy the MIN > VAL or VAL > MAX condition.

If the box input has the signal state "0", the "Value outside range" instruction is not executed.

The comparison function can only execute if the values to be compared are of the same data type and the box input is interconnected.

Parameters

The following table shows the parameters of the "Value outside range" instruction:



Parameters	Declaration	Data type	Memory area	Description
Box input	Input	BOOL	I, Q, M, D, L	Result of the previous logic operation
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The value of the operand "Tag_Value" is outside the value range that is specified by the values of the operands "Tag_Min" and "Tag_Max" (MIN > VAL or VAL > MAX).
- The operand "TagIn_3" has the signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

----I OK I----: Check validity (S7-1200, S7-1500)

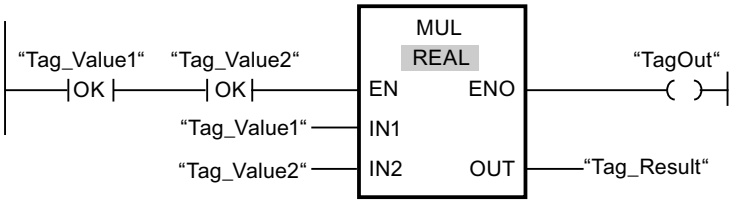
Description

You can use the "Check validity" instruction to check if the value of an operand (<operand>) is a valid floating-point number. The query is started in each program cycle when the signal state at the input of the instruction is "1".

The output of the instruction has signal state "1" when the value of the operand is a valid floating-point number at the time of the query and the input of the instruction has signal state "1". In all other cases, the signal state at the output of the "Check validity" instruction is "0".

You can use the "Check validity" instruction together with the EN mechanism. If you connect the instruction box to an EN enable input, the enable input is set only when the result of the validity query of the value is positive. You can use this function to ensure that an instruction is enabled only when the value of the specified operand is a valid floating-point number.

Parameters



The following table shows the parameters of the "Check validity" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be queried.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the values of the operands "Tag_Value1" and "Tag_Value2" show valid floating-point numbers, the "Multiply" instruction is executed. The value of operand "Tag_Value1" is multiplied by the value of operand "Tag_Value2". The product of the multiplication is then written in the operand "Tag_Result". If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

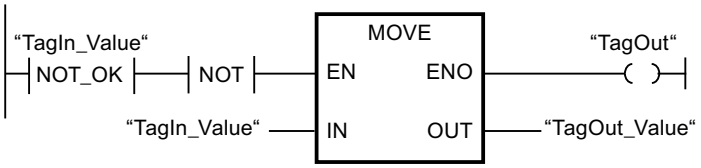
----| NOT_OK |----: Check invalidity (S7-1200, S7-1500)

Description

You can use the "Check invalidity" instruction to check if the value of an operand (<operand>) is an invalid floating-point number. The query is started in each program cycle when the signal state at the input of the instruction is "1".

The output of the instruction has signal state "1" when the value of the operand is an invalid floating-point number at the time of the query and the input of the instruction has signal state "1". In all other cases, the signal state at the output of the "Check invalidity" instruction is "0".

Parameters



The following table shows the parameters of the instruction "Check invalidity":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be queried.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

When the value of operand "TagIn_Value" is an invalid floating-point number, the instruction "Move value" is not executed. The "TagOut" operand at the ENO enable output is set to the signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

VARIANT (S7-1200, S7-1500)

EQ_Type: Compare data type for EQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

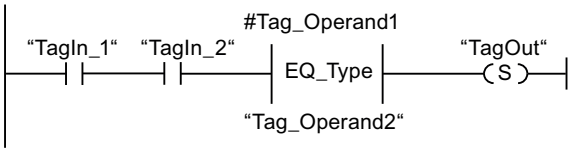
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP ==". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP ==: Equal (Page 2662)



Parameters

The following table shows the parameters of the "Compare data type for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is equal to "Tag_Operand2".

NE_Type: Compare data type for UNEQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type for UNEQUAL with the data type of a tag" instruction to query which data type a tag to which a VARIANT points does not have. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Not equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

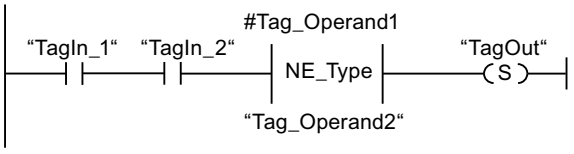
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP <>". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP <>: Not equal (Page 2667)



Parameters

The following table shows the parameters of the "Compare data type for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is not equal to "Tag_Operand2".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

EQ_ElemType: Compare data type of an ARRAY element for EQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag (<Operand1>) is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

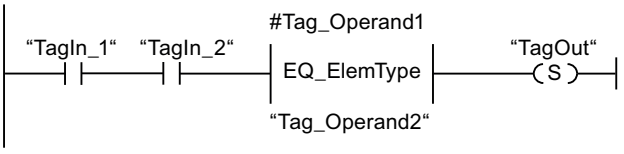
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP ==". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP ==: Equal (Page 2662)



Parameters

The following table shows the parameters of the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is equal to "Tag_Operand2".

NE_ElemType: Compare data type of an ARRAY element for UNEQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction to query which data type a tag does not have to which a VARIANT points. You are comparing the data type of the tag (<Operand1>), which you declared in the block interface, with the data type of a tag (<Operand2>) for "Not equal to".

<Operand1> must have the VARIANT data type. <Operand2> can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag (<Operand1>) is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0". The RLO of the instruction is logically combined with the RLO of the entire rung as follows:

- By AND, when the comparison instruction is connected in series.
- By OR, when the comparison instruction is connected in parallel.

Specify <Operand1> at the operand placeholder above the instruction. Specify <Operand2> at the operand placeholder below the instruction.

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

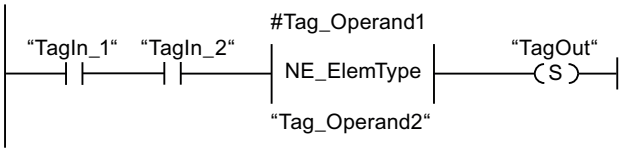
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP <>". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP <>: Not equal (Page 2667)



Parameters

The following table shows the parameters of the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
<Operand2>	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand1 operand is not equal to "Tag_Operand2".

IS_NULL: Check for EQUALS NULL pointer (S7-1200, S7-1500)

Description

You can use the instruction "Check for EQUALS NULL pointer" to query whether the VARIANT points to a NULL pointer and therefore does not point to an object.

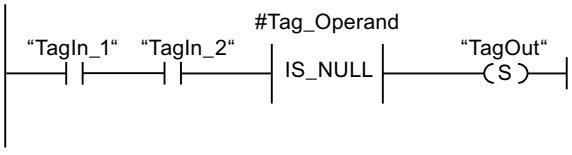
<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "0" even if the ANY pointer is NULL.

Parameters



The following table shows the parameters of the "Check for EQUALS NULL pointer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is compared for EQUALS NULL

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand does not point to an object.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

NOT_NULL: Check for UNEQUALS NULL pointer (S7-1200, S7-1500)

Description

You can use the instruction "Check for UNEQUALS NULL pointer" to query whether the VARIANT does not point to a NULL pointer and therefore points to an object.

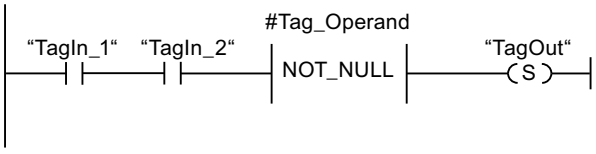
<Operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "1" even if the ANY pointer is NULL.

Parameters



The following table shows the parameters of the "Check for UNEQUALS NULL pointer" instruction:

Parameter	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is compared for UNEQUALS NULL

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand points to an object.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

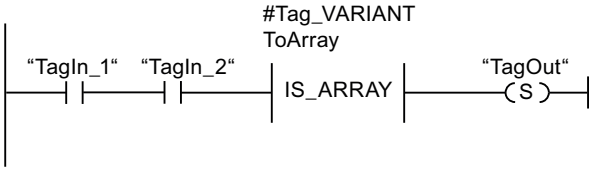
IS_ARRAY: Check for ARRAY (S7-1200, S7-1500)

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

<Operand> must have the VARIANT data type.

Parameters



The following table shows the parameters of the "Check for ARRAY" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is queried for ARRAY

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_VARIANTToArray" operand is of the ARRAY data type.

Math functions (S7-1200, S7-1500)

CALCULATE: Calculate (S7-1200, S7-1500)

Description

The "Calculate" instruction is used to define and execute an expression for the calculation of mathematical operations or complex logic operations depending on the selected data type.

You can select the data type of the instruction from the "???" drop-down list of the instruction box. Depending on the data type selected, you can combine the functions of certain instructions to perform a complex calculation. The expression to be calculated is specified via a dialog you can open via the "Calculator" icon at the top of the instruction box. The expression can contain names of input parameters and the syntax of the instructions. Operand names and operand addresses cannot be specified.

In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box.

The values of the inputs are used to execute the specified expression. Not all of the defined inputs have to be used in the expression. The result of the instruction is transferred to the output OUT.

Note

If one of the mathematical operations fails in the expression, no result is transferred to the output OUT and the enable output ENO returns the signal state "1".

If you use inputs in the expression that are not available in the box, they are inserted automatically. This requires that there are no gaps in the numbering of the inputs to be newly defined in the expression. For example, you cannot use the IN4 input in the expression unless the IN3 input has been defined.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The result of the "Calculate" instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.
- An error occurred during execution of one of the instructions in the expression.

The following table shows the instructions that can be executed together in the expression of the instruction "Calculate", depending on the selected data type:

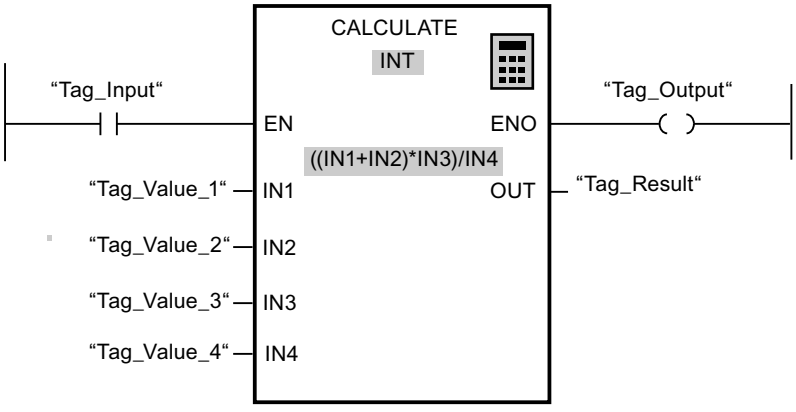
Data type	Instruction	Syntax	Example
Bit strings	AND: AND logic operation	AND	IN1 AND IN2 OR IN3
	OR: OR logic operation	OR	
	XOR: EXCLUSIVE OR logic operation	XOR	
	INV: Create ones complement	NOT	
	SWAP: Swap [1)]	SWAP	

Data type	Instruction	Syntax	Example
Integers	ADD: Add	+	(IN1 + IN2) * IN3; (ABS(IN2)) * (ABS(IN1))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	MOD: Return remainder of division	MOD	
	INV: Create ones complement	NOT	
	NEG: Create twos complement	-(in1)	
	ABS: Form absolute value	ABS( )	
Floating-point numbers	ADD: Add	+	((SIN(IN2) * SIN(IN2) + (SIN(IN3) * SIN(IN3)) / IN3)); (SQR(SIN(IN2)) + (SQR(COS(IN3)) / IN2))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	EXPT: Exponentiate	**	
	ABS: Form absolute value	ABS( )	
	SQR: Form square	SQR( )	
	SQRT: Form square root	SQRT( )	
	LN: Form natural logarithm	LN( )	
	EXP: Form exponential value	EXP( )	
	FRAC: Return fraction	FRAC( )	
	SIN: Form sine value	SIN( )	
	COS: Form cosine value	COS( )	
	TAN: Form tangent value	TAN( )	
	ASIN: Form arcsine value	ASIN( )	
	ACOS: Form arccosine value	ACOS( )	
	ATAN: Form arctangent value	ATAN( )	
	NEG: Create twos complement	-(in1)	
	TRUNC: Truncate numerical value	TRUNC( )	
	ROUND: Round numerical value	ROUND( )	
	CEIL: Generate next higher integer from floating-point number	CEIL( )	
	FLOOR: Generate next lower integer from floating-point number	FLOOR( )	

[1] Not possible for data type BYTE.

Parameters

The following table shows the parameters of the "Calculate" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P, or constant	First available input

Parameters	Declaration	Data type	Memory area	Description
IN2	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P, or constant	Second available input
INn	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P, or constant	Additionally inserted inputs
OUT	Output	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P	Output to which the end result is to be transferred.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN1	Tag_Value_1	4
IN2	Tag_Value_2	4
IN3	Tag_Value_3	3
IN4	Tag_Value_4	2
OUT	Tag_Result	12

If the "Tag_Input" input has the signal state"1", the "Calculate" instruction is executed. The value of operand "Tag_Value_1" is added to the value of operand "Tag_Value_2". The sum is multiplied with the value of operand "Tag_Value_3". The product is divided by the value of operand "Tag_Value_4". The quotient is transferred as end result to the operand "Tag_Result" at the OUT output of the instruction. If the instruction is executed without errors, the enable output ENO and operand "Tag_Output" are set to "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Example of calculating an equation (Page 4931)

Basic information on LAD (Page 4878)

ADD: Add (S7-1200, S7-1500)

Description

You can use the "Add" instruction to add the value at input IN1 and the value at input IN2 and query the sum at output OUT (OUT := IN1+IN2).

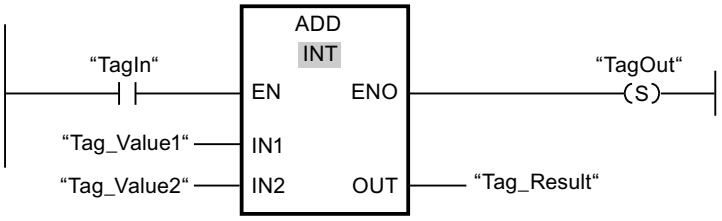
In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are added. The sum is stored at the OUT output.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Add" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	First number to be added
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Second number to be added
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Optional input values that are added.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Sum

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Add" instruction is executed. The value of operand "Tag_Value1" is added to the value of operand "Tag_Value2". The result of the addition is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SUB: Subtract (S7-1200, S7-1500)

Description

You can use the "Subtract" instruction to subtract the value at input IN2 from the value at input IN1 and query the difference at output OUT (OUT := IN1-IN2).

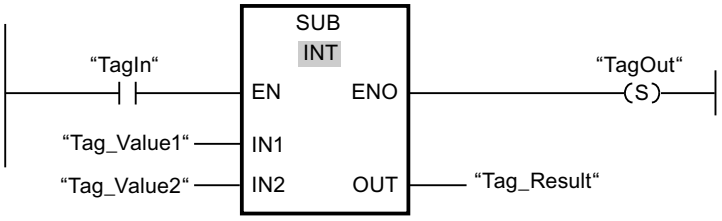
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Subtract" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output



Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Minuend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Subtracting
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Difference

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Subtract" instruction is executed. The value of operand "Tag_Value2" is subtracted from the value of operand "Tag_Value1". The result of the subtraction is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

MUL: Multiply (S7-1200, S7-1500)

Description

You can use the "Multiply" instruction to multiply the value at input IN1 with the value at input IN2 and query the product at output OUT (OUT := IN1*IN2).

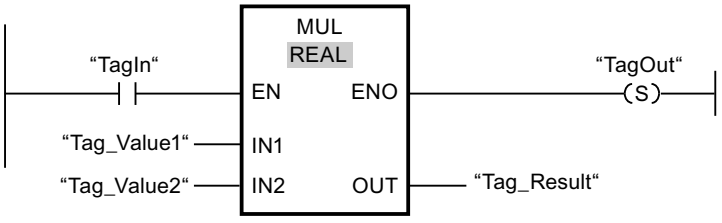
The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are multiplied. The product is stored at the OUT output.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN input has the signal state "0".
- The result is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Multiply" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Multiplier
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Number being multiplied
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Optional input values that can be multiplied.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Product

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Multiply" instruction is executed. The value of operand "Tag_Value1" is multiplied by the value of operand "Tag_Value2". The result of the multiplication is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

DIV: Divide (S7-1200, S7-1500)

Description

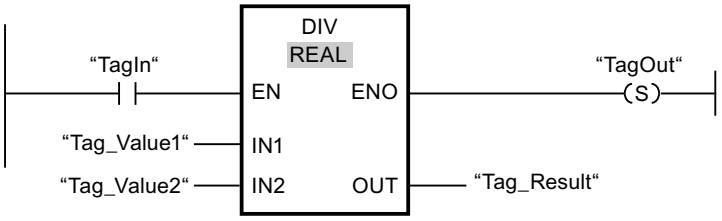
You can use the "Divide" instruction to divide the value at input IN1 by the value at input IN2 and query the quotient at output OUT (OUT := IN1/IN2).

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Divide" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Dividend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Divisor
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Quotient value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Divide" instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The division result is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

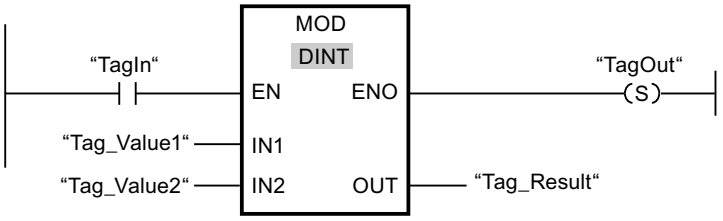
MOD: Return remainder of division (S7-1200, S7-1500)

Description

You can use the "Return remainder of division" instruction to divide the value at input IN1 by the value at input IN2 and query the remainder of division at output OUT.

Parameters

The following table shows the parameters of the "Return remainder of division" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers	I, Q, M, D, L, P, or constant	Dividend
IN2	Input	Integers	I, Q, M, D, L, P, or constant	Divisor
OUT	Output	Integers	I, Q, M, D, L, P	Remainder of division

You can select the data type of the instruction from the "Auto (???)" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Return remainder of division" instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The remainder of division is stored in operand "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

NEG: Create twos complement (S7-1200, S7-1500)

Description

You can use the "Create twos complement" instruction to change the sign of the value at the IN input and query the result at the OUT output. If there is a positive value at input IN, for example, the negative equivalent of this value is sent to output OUT.

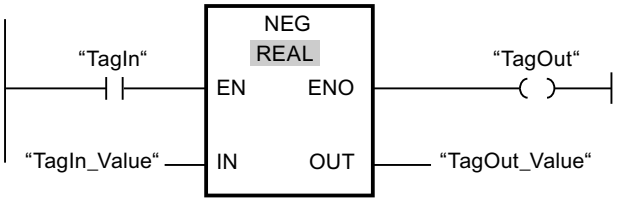
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at the OUT output.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Create twos complement" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Twos complement of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operand "TagIn" has the signal state "1", the "Create twos complement" instruction is executed. The sign of the value at input "TagIn_Value" is changed and the result is provided at output "TagOut_Value". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

INC: Increment (S7-1200, S7-1500)

Description

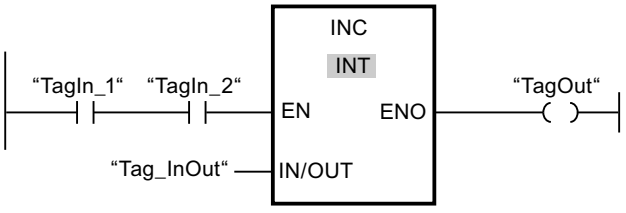
You can use the "Increment" instruction to change the value of the operand at the IN/OUT parameter to the next higher value and query the result. The "Increment" instruction is only started when the signal state at the EN enable input is "1". If no overflow error occurs during the execution, the ENO enable output also has the signal state "1".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Increment" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	Value to be incremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of operand "Tag_InOut" is incremented by one and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

DEC: Decrement (S7-1200, S7-1500)

Description

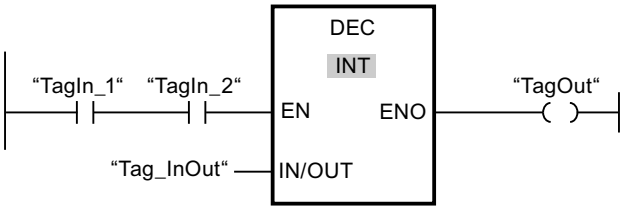
You can use the "Decrement" instruction to change the value of the operand at the IN/OUT parameter to the next lower value and query the result. The "Decrement" instruction is only started when the signal state at the EN enable input is "1". If the range of values of the selected data type is not exceeded during processing, the ENO output also has the signal state "1".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Decrement" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	Value to be decremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of operand "Tag_InOut" is decremented by one and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

ABS: Form absolute value (S7-1200, S7-1500)

Description

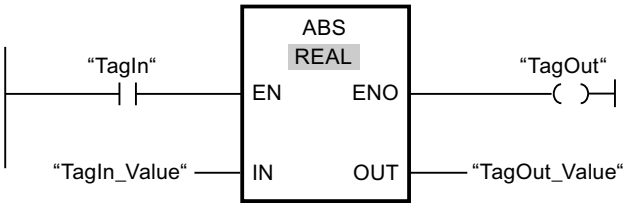
You can use the "Form absolute value" instruction to calculate the absolute value of the value specified at input IN. The result of the instruction is sent to the OUT output and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Form absolute value" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Absolute value of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	-6.234
OUT	TagOut_Value	6.234

If operand "TagIn" has the signal state "1", the "Form absolute value" instruction is executed. The instruction calculates the absolute value of the value at input "TagIn_Value" and sends the result to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

MIN: Get minimum (S7-1200, S7-1500)

Description

The "Get minimum" instruction compares the values at the available inputs and writes the lowest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

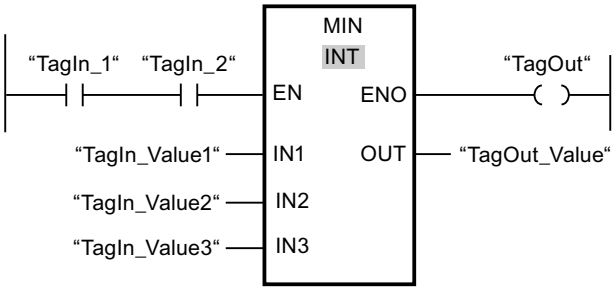
A minimum of two and a maximum of 100 inputs must be specified for the execution of the instruction.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get minimum" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	First input value
IN2	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	Second input value
INn	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P	Result
If the IEC check is not activated, you can also use tags with the data types TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string or integer with the same length as the data type of the instruction. (for example, instead of TIME => DINT, UDINT or DWORD = 32 bits).				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	12222

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the lowest value ("TagIn_Value1") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

MAX: Get maximum (S7-1200, S7-1500)

Description

The "Get maximum" instruction compares the values at the available inputs and writes the highest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

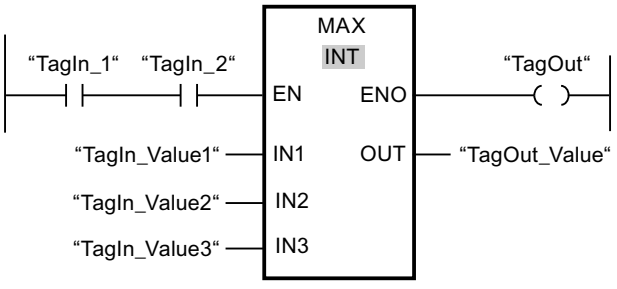
A minimum of two and a maximum of 100 inputs must be specified for the execution of the instruction.

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get maximum" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	First input value
IN2	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	Second input value
INn	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P, or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P	Result
If the IEC check is not activated, you can also use tags with the data types TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string or integer with the same length as the data type of the instruction. (for example, instead of TIME => DINT, UDINT or DWORD = 32 bits).				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	14444

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the highest value ("TagIn_Value2") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

LIMIT: Set limit value (S7-1200, S7-1500)

Description

You can use the "Set limit value" instruction to limit the value at input IN to the values at the inputs MN and MX. If the value at the IN input meets the MN condition <= IN <= MX, it is copied to the OUT output. If the condition is not fulfilled and the input value IN is below the low limit MN, the output OUT is set to the value of the MN input. If the high limit MX is exceeded, output OUT is set to the value of the input MX.

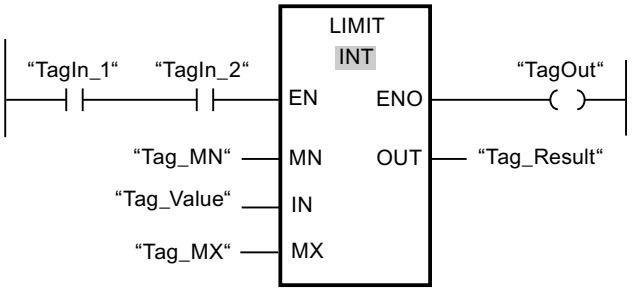
If the value at the MN input is greater than at the MX input, the result is the value specified at the IN parameter and the enable output ENO is "0".

The ENO enable output has the signal state "0" if one of the following conditions is fulfilled:

- Enable input EN has the signal state "0".
- The specified tags are not of the same data type.
- An operand has an invalid value.
- The value at the MN input is greater than the value of the MX input.

Parameters

The following table shows the parameters of the "Set limit value" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P, or constant	Low limit
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P, or constant	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P, or constant	High limit
OUT	Output	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P	Result
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
MN	Tag_MN	12000
IN	Tag_Value	8000
MX	Tag_MX	16000
OUT	Tag_Result	12000

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The value of operand "Tag_Value" is compared with the values of operands "Tag_MN" and "Tag_MX". Since the value of operand "Tag_Value" is less than the low limit, the value of operand "Tag_MN" is copied to the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

SQR: Form square (S7-1200, S7-1500)

Description

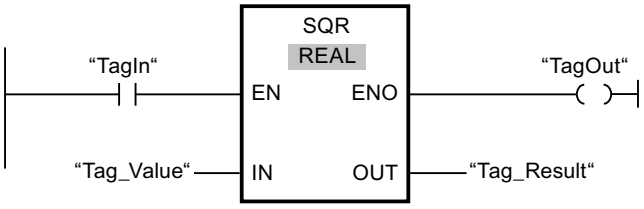
The instruction "Form square" is used to square the value of a floating-point number at input IN and to write the result to output OUT.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form square":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Square of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	5.0
OUT	Tag_Result	25.0

If the operand "TagIn" has the signal state "1", the "Form square" instruction is executed. The instruction squares the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SQRT: Form square root (S7-1200, S7-1500)

Description

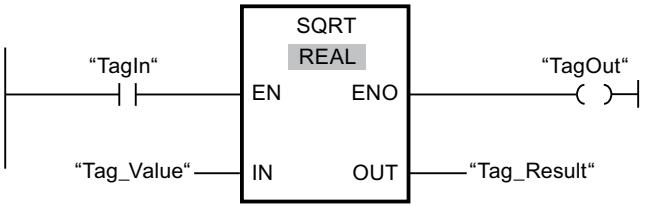
The instruction "Form square root" is used form the square root from the value of the floating-point number at input IN and to write the result to output OUT. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number. If the value at input IN is "0", the result is also "0".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form square root":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Square root of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	25.0
OUT	Tag_Result	5.0

If the operand "TagIn" has the signal state "1", the "Form square root" instruction is executed. The instruction calculates the square root of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

LN: Form natural logarithm (S7-1200, S7-1500)

Description

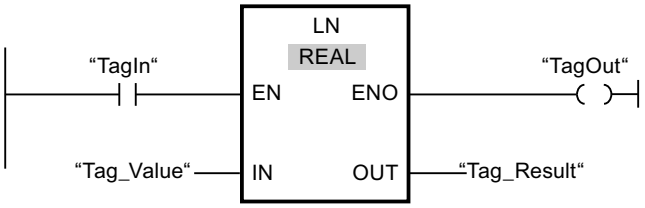
You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e = 2.718282) of the value at input IN. The result is sent to output OUT and can be queried there. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form natural logarithm":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Natural logarithm of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the operand "TagIn" has the signal state "1", the "Form natural logarithm" instruction is executed. The instruction forms the natural logarithm of the value at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

EXP: Form exponential value (S7-1200, S7-1500)

Description

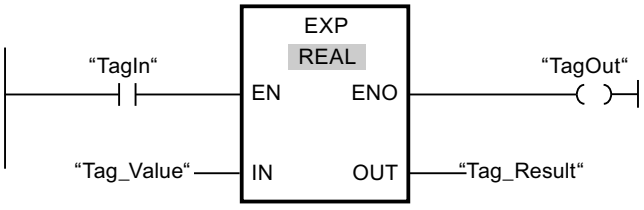
You can use the "Form exponential value" instruction to calculate the exponent from the base e (e = 2.718282) and the value specified at input IN. The result is provided at output OUT and can be queried there (OUT = e^{IN}).

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form exponential value":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Exponential value of input value IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the operand "TagIn" has the signal state "1", the "Form exponential value" instruction is executed. The instruction forms the exponent from base e and the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SIN: Form sine value (S7-1200, S7-1500)

Description

Use the "Form sine value" instruction to calculate the sine of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

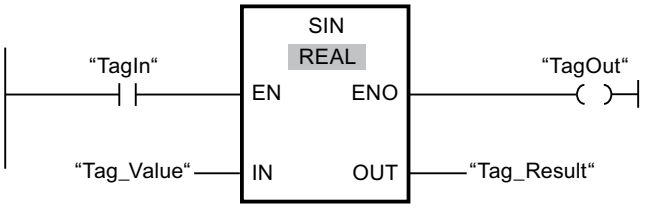
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form sine value" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output



Parameters	Declaration	Data type	Memory area	Description
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Sine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	1.0

If operand "TagIn" has the signal state "1", the "Form sine value" instruction is executed. The instruction calculates the sine of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

COS: Form cosine value (S7-1200, S7-1500)

Description

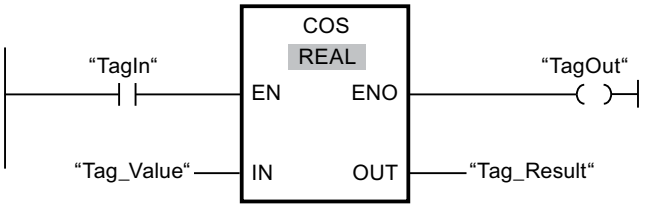
Use the "Form cosine value" instruction to calculate the cosine of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form cosine value" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Cosine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	0

If operand "TagIn" has the signal state "1", the "Form cosine value" instruction is executed. The instruction calculates the cosine of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

TAN: Form tangent value (S7-1200, S7-1500)

Description

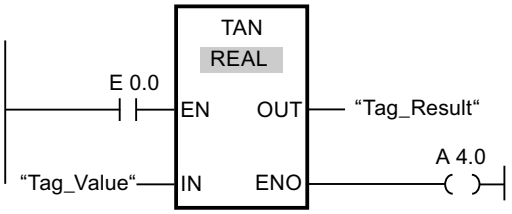
Use the "Form tangent value" instruction to calculate the tangent of the angle. The size of the angle is specified in radians at the IN input. The result of the instruction is sent to the OUT output and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Form tangent value" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Size of angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Tangent of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	+3.141593 (π)
OUT	Tag_Result	0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the tangent of the angle specified at the "Tag_Value" input and stores the result in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

ASIN: Form arcsine value (S7-1200, S7-1500)

Description

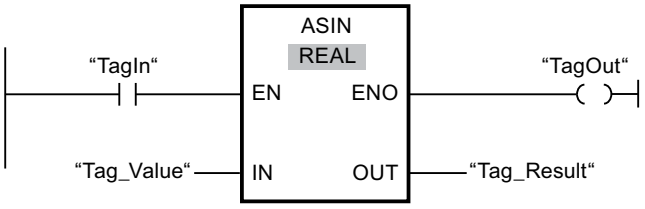
You can use the "Form arcsine value" instruction to calculate the size of the angle from the arcsine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at the IN input. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at the IN input is outside the permitted value range (-1 to +1).

Parameters

The following table shows the parameters of the "Form arcsine value" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Sine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+1.570796 (π/2)

If operand "TagIn" has the signal state "1", the "Form arcsine value" instruction is executed. The instruction calculates the size of the angle corresponding to the sine value at the "Tag_Value" input. The result of the instruction is stored in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

ACOS: Form arccosine value (S7-1200, S7-1500)

Description

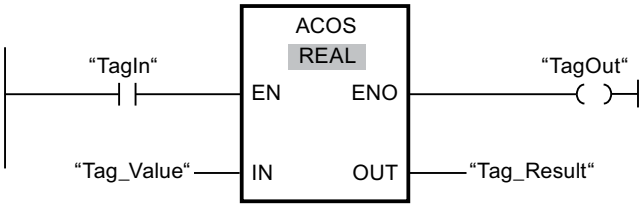
You can use the "Form arccosine value" instruction to calculate the size of the angle from the cosine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at the IN input. The calculated angle size is output in radians at the OUT output and can range in value from 0 to +π.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.
- The value at the IN input is outside the permitted value range (-1 to +1).

Parameters

The following table shows the parameters of the "Form arccosine value" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Cosine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	0
OUT	Tag_Result	+1.570796 (π/2)

If operand "TagIn" has the signal state "1", the "Form arccosine value" instruction is executed. The instruction calculates the size of the angle corresponding to the cosine value at the "Tag_Value" input. The result of the instruction is stored in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

ATAN: Form arctangent value (S7-1200, S7-1500)

Description

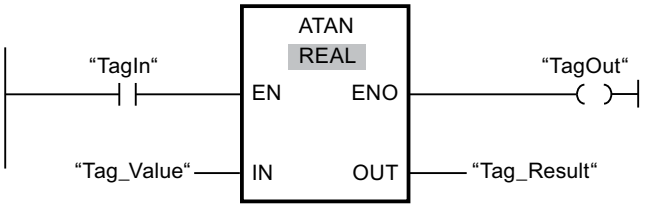
You can use the "Form arctangent value" instruction to calculate the size of the angle from the tangent value specified at input IN, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form arctangent value":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Tangent value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+0.785398 (π/4)

If the operand "TagIn" has the signal state "1", the "Form arctangent value" instruction is executed. The instruction calculates the size of the angle corresponding to the tangent value at input "Tag_Value". The result of the instruction is stored in the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Invalid floating-point numbers (Page 2259)

Basic information on LAD (Page 4878)

FRAC: Return fraction (S7-1200, S7-1500)

Description

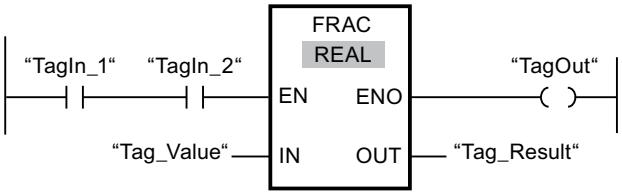
You can use the "Return fraction" instruction to determine the decimal places of the value at the IN input. The result of the query is stored at the OUT output and can be queried there. If, for example, the IN input has the value 123.4567, the OUT output returns the value 0.4567.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the IN input is not a valid floating-point number.

Parameters

The following table shows the parameters of the "Return fraction" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Value, whose decimal places are to be determined.
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Decimal places of the value at the IN input

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	2.555
OUT	Tag_Result	0.555

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the "Return fraction" instruction is started. The decimal places from the value of operand "Tag_Value" are copied to operand "Tag_Result". If the instruction is executed without errors, the ENO output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

EXPT: Exponentiate (S7-1200, S7-1500)

Description

You can use the "Exponentiate" instruction to raise the value at the IN1 input to a power specified with the value at the IN2 input. The result of the instruction is provided at the OUT output and can be queried there (OUT =$IN1^{IN2}$).

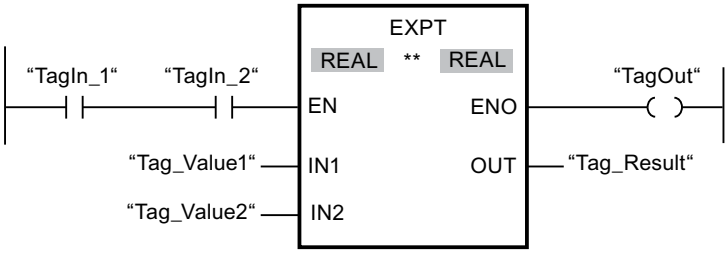
The IN1 input can only be assigned valid floating-point numbers. Integers can also be assigned to the IN2 input.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors occur during execution of the instruction, for example, an overflow occurs.

Parameters

The following table shows the parameters of the "Exponentiate" instruction:



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Base value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P, or constant	Value with which the base value is exponentiated
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If operands "TagIn_1" and "TagIn_2" have the signal state "1", the "Exponentiate" instruction is started. The value of operand "Tag_Value1" is raised to a power specified with the value of operand "Tag_Value2". The result is stored in the "Tag_Result" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Move operations (S7-1200, S7-1500)

MOVE: Move value (S7-1200, S7-1500)

Description

You use the "Move value" instruction to transfer the content of the operand at the IN input to the operand at the OUT1 output. The transfer is always made in the direction of ascending address.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data type at the IN parameter does not correspond to the specified data type at the OUT1 parameter.

The following table lists the possible transfers for the S7-1200 CPU series:

Source (IN)	Destination (OUT1)	
	With IEC check	Without IEC check
BYTE	BYTE, WORD, DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, TIME, DATE ,TOD, CHAR

[1] You can also use the "Move value" instruction to transfer individual characters of a string to operands of the CHAR or WCHAR data type. The number of the character to be transferred is specified in square brackets next to the operand name. "MyString[2]", for example, transfers the second character of the "MyString" string. The transfer of the operand of the data type CHAR or WCHAR to the individual character of a string is also possible. You can also replace a specific character of a string with the character of another string.

[2] Transferring entire arrays (ARRAY) is possible only when the array components of the operands at input IN and at output OUT1 are of the same data type.

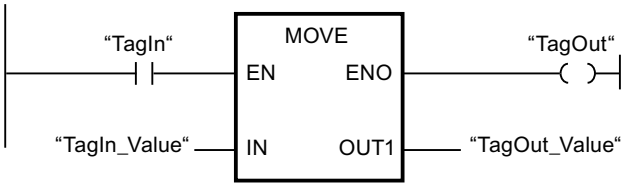
If the bit length of the data type at input IN exceeds the bit length of the data type at output OUT1, the higher-order bits of the source value are lost. If the bit length of the data type at input IN is less than the bit length of the data type at output OUT1, the higher-order bits of the destination value will be overwritten with zeros.

In its initial state, the instruction box contains 1 output (OUT1). The number of outputs can be extended. The added outputs are numbered in ascending order on the box. During the execution of the instruction, the content of the operand at the input IN is transferred to all available outputs. The instruction box cannot be extended if structured data types (DTL, STRUCT, ARRAY) or characters of a string are transferred.

You can also use the "Move block" (MOVE_BLK) and "Move block uninterruptible" (UMOVE_BLK) instructions to move operands of the ARRAY data type. Operand of the data type STRING or WSTRING can be copied with the instruction "Move character string" (S_MOVE).

Parameter

The following table shows the parameters of the "Move value" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L or constant	Source value
OUT1	Output	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L	Operands to which in the source value is transferred.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
OUT1	TagOut_Value	0011 1111 1010 1111

If the "TagIn" operand returns signal state "1", the instruction is executed. The instruction copies the contents of operand "TagIn_Value" to operand "TagOut_Value" and sets output "TagOut" to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Note

You can find more information on the MOVE instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Overview of the valid data types (Page 2239)

MOVE_BLK: Move block (Page 2743)

UMOVE_BLK: Move block uninterruptible (Page 2761)

S_MOVE: Move character string (Page 3490)

Basic information on LAD (Page 4878)

Deserialize: Deserialize (S7-1200, S7-1500)

Description

You can use the "Deserialize" instruction to convert back the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> is located must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized memory areas also permitted as of version 2.0. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion. If the memory area is filled using the instruction "Serialize" and it is possible that fill bytes were inserted, their conversion is not taken into account.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The instruction enables you to convert multiple sequential representations of converted data back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type>, you can also directly use the instruction "TRCV: Receive data via communication connection".

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To deserialize larger structures, you can declare the memory area for sequential representation with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The content of the sequential representation remains unchanged, as for a standard memory area. Only symbolic access to the bytes in the ARRAY is possible.

Parameters

The following table shows the parameters of the "Deserialize" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_ARRAY	Input	VARIANT ARRAY[*] of BYTE [1)]	D, block interface of an FB (The sections Input, Output, Static and Temp are possible.)	Tag of ARRAY of BYTE data type in which the generate data flow is stored
DEST_VARIABLE	InOut	VARIANT	D, block interface of an FB	Tag in which the reconverted PLC data type (UDT), STRUCT, ARRAY of <data type> is stored
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the number of bytes occupied by the converted customer data. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

[1)] Possible for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains a ZERO pointer.
8151	No valid reference at the SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8154	Invalid data type at the SRC_ARRAY parameter
8250	The VARIANT data type at the DEST_VARIABLE parameter contains a ZERO pointer.
8251	No valid reference at the DEST_VARIABLE parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

Error code* (W#16#...)	Explanation
8136	Access to the memory area at the SRC_ARRAY parameter is invalid.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

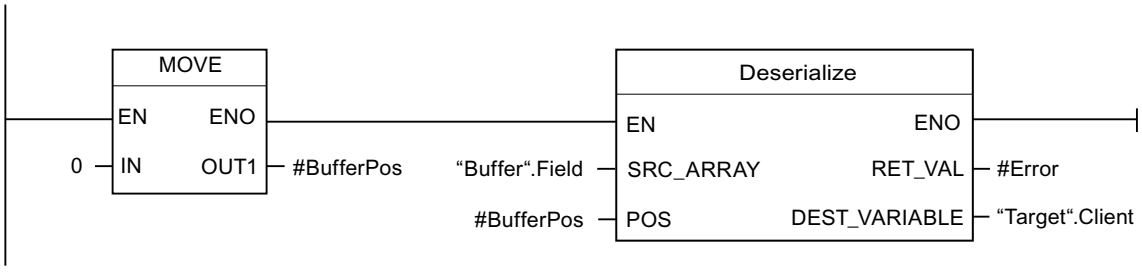
Example

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface of an FB or FC.
BufferPos	DINT	In the "Temp" section of the block interface of an FB or FC.
Error	INT	
Label	STRING[4]	

The following table shows the declarations of the PLC data types:

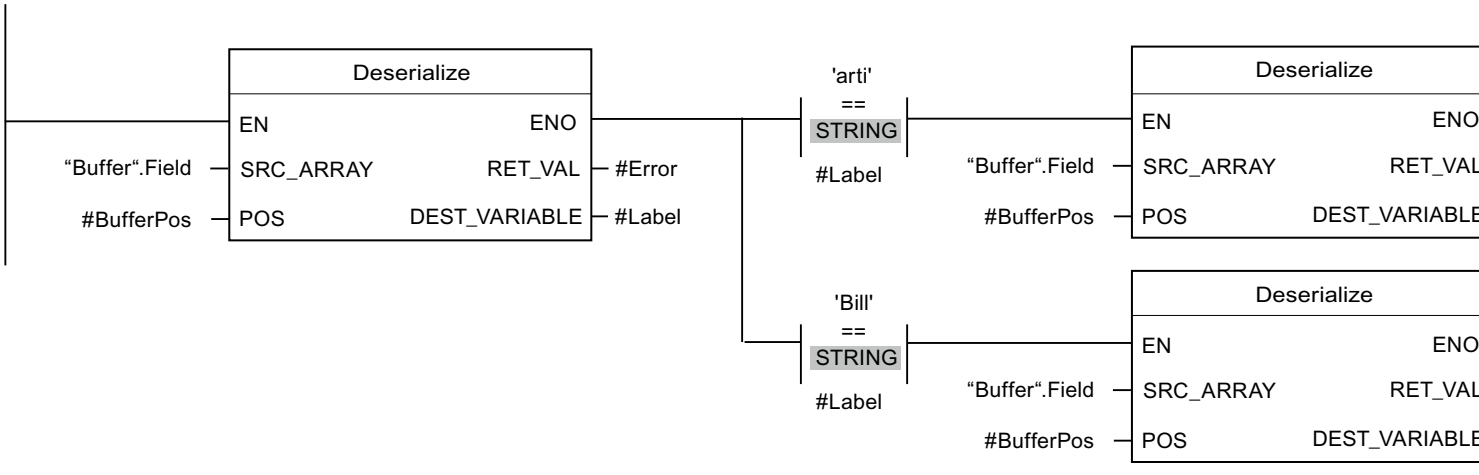
Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT



Name of the PLC data types	Name	Data type
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE



The following example shows how the instruction works:

Network 1:

The "Move value" instruction moves the value "0" to the #BufferPos operand. The "Deserialize" instruction deserializes the sequential representation of the customer data from the "Buffer" tag and writes it to the "Target" tag. The #BufferPos operand stores the index of the first byte based on the number of bytes occupied by the converted customer data.

Network 2:

The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was stored in the sequential representation after the customer data, from the "Buffer" tag and writes the characters to the #Label operand. The characters are compared using

comparison instructions "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" tag. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" tag.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Structure of a STRING tag (Page 2272)

Basic information on LAD (Page 4878)

Serialize: Serialize (S7-1200, S7-1500)

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT), STRUCT or ARRAY of <data type> to a sequential representation without losing parts of their structure.

You use the instruction to temporarily save multiple structured data items from your program in a buffer, which should preferably be in a global data block, and send them to another CPU. The memory area in which the converted data are stored must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized data is also permitted as of version 2.0. Fill bytes or fill bits of a data area (e.g. ARRAY, STRUCT or PLC data type (UDT)) as well as the characters of a string currently not in use are undefined in the destination ARRAY.

The capacity of the standard memory area is 64 KB. Structures that are larger than 64 KB in accordance with the rules for standard memory areas cannot be serialized if the operand at the DEST_ARRAY parameter is located in a standard memory area.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The operand at the POS parameter contains information about the number of bytes used by the data.

If you want to send a single PLC data type (UDT), STRUCT or ARRAY of <data type>, you can directly call the instruction "TSEND: Send data via communication connection".

Note

Comparison of structures

To compare structures, they have to be serialized first. Use the "CMP" instruction instead.

You can find additional information in the section "Comparator".

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To serialize larger structures, you can declare the memory area with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The sequential representation remains unchanged, as for a standard memory area.

Parameters

The following table shows the parameters of the instruction "Serialize":

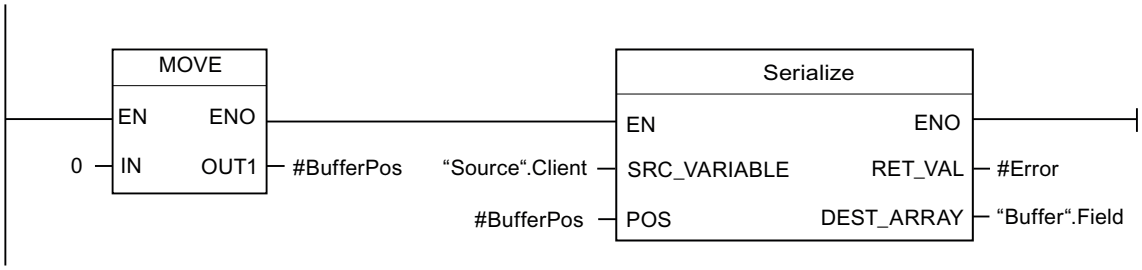
Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_VARIABLE	Input	VARIANT	D, block interface of an FB	PLC data type (UDT), STRUCT or ARRAY of <data type> that is converted to sequential representation.
DEST_ARRAY	InOut	VARIANT	D, block interface of an FB (the sections Input, Output, Static and Temp are possible.)	Data block in which the generated data stream is stored.

Parameters	Declaration	Data type	Memory area	Description
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the total number of bytes that the converted customer data has occupied. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

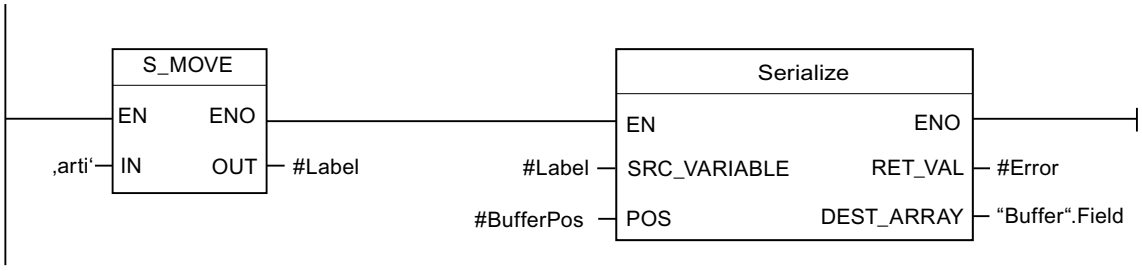
Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains a ZERO pointer.
8151	No valid reference at the SRC_VARIABLE parameter
8236	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains a ZERO pointer.
8251	No valid reference at the DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	



For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

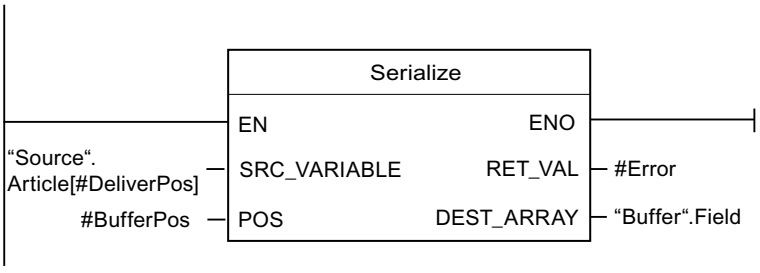
Error code* (W#16#...)	Explanation
8236	Access to the memory area at the DEST_ARRAY parameter is invalid.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example



The following example shows how the instruction works:

Network 1:



The "Move value" instruction moves the value "0" to the #BufferPos operand. The "Deserialize" instruction deserializes the customer data from the "Source" tag and writes the sequential representation to the "Buffer" tag. The index of the next unwritten byte of the "Buffer".Field operand is saved in the #BufferPos operand.

Network 2:

A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move character string" instruction moves the "arti" characters to the #Label operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" tag. The value of the #BufferPos operand is incremented accordingly.

Network 3:

The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" tag and writes it in sequential representation to the "Buffer" tag after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface

Operand	Data type	Declaration
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

MOVE_BLK: Move block (S7-1200, S7-1500)

Description

You use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). The number of elements to be moved to the target range is specified at input COUNT. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source range and the target range have the same data type.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

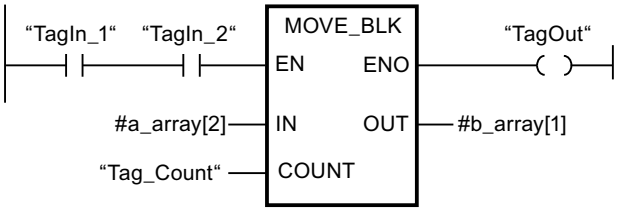
When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

Parameters



The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	Number of elements to be moved from the source range to the target range.
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the target range to which the contents of the source range are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Note

You can find more information on the MOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Basic information on LAD (Page 4878)

SCATTER: Parse the bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse the bit sequence into individual bits" splits a tag of the BYTE, WORD, DWORD or LWORD data type into individual bits and saves them in an ARRAY of BOOL.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse a status word, and read and change the status of the individual bits using the index. Using GATHER, you can merge the bits once again into a bit sequence.

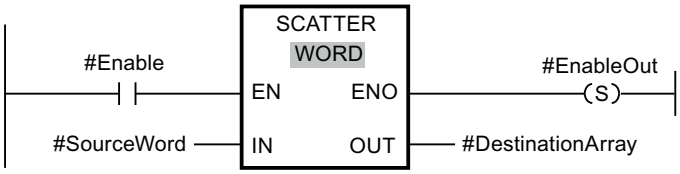
The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- If the ARRAY does not provide enough BOOL elements.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Bit sequence that is parsed
OUT	Output	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY in which the individual bits are saved



You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceWord		WORD
EnableOut	Output	BOOL
DestinationArray		ARRAY[0..15] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceWord	WORD (16 bits)
OUT	DestinationArray	The operand "DestinationArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD that is to be parsed.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The operand #SourceWord of the data type WORD is parsed into its individual bits (16) and assigned to the individual elements of the #DestinationArray operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

SCATTER_BLK: Parse elements of an ARRAY of bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse elements of an ARRAY of bit sequence into individual bits" parses one or more elements of an ARRAY of BYTE, WORD, DWORD or LWORD into individual bits and saves them in an ARRAY of BOOL. At the COUNT_IN parameter you specify how many elements of the source ARRAY are going to be parsed. The source ARRAY at the IN parameter may have more elements than specified at the COUNT_IN parameter. The ARRAY of BOOL must have sufficient elements to save the bits of the parsed bit strings. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n(number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse status words, and read and change the status of the individual bits using the index. Using GATHER, you can combine the bits once again into a bit string.

The enable output ENO returns signal state "0" if one of the following conditions applies:

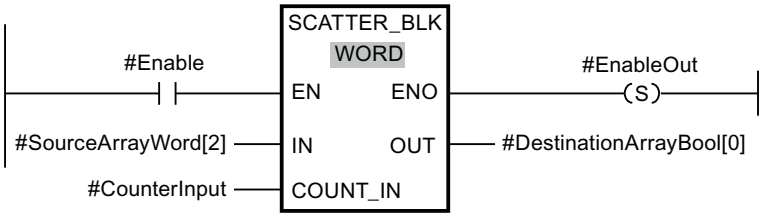
- Enable input EN has signal state "0".
- The source ARRAY has fewer elements than specified at the COUNT_IN parameter.
- The index of the destination ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of BOOL.
- The ARRAY[*] of BOOL does not provide the required number of elements. In this case as many bit strings as possible are parsed and written to the ARRAY of BOOL. The remaining bit strings are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> that is parsed
COUNT_IN	Input	UDINT	I, Q, M, D, L	Counter for the number of elements of the source ARRAY that are to be parsed
OUT	Output	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY in which the individual bits are saved

You can select the required bit string from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example of a destination ARRAY wit the low limit "0"

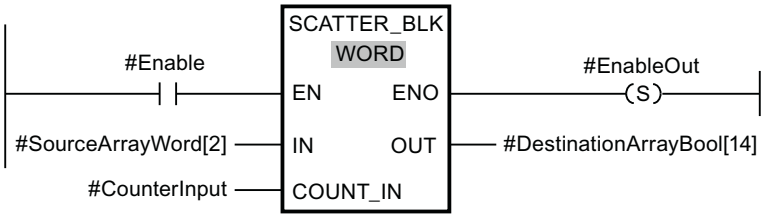
Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayWord		ARRAY[0..5] of WORD
CounterInput		UDINT
EnableOut	Output	BOOL
DestinationArrayBool		ARRAY[0..95] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be parsed.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[0]	The operand "DestinationArrayBool" is of the data type ARRAY[0..95] of BOOL. This means it provides 96 BOOL elements.



If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the first element assigned to the individual elements of the #DestinationArrayBool operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Example of a destination ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayWord		ARRAY[0..5] of WORD
CounterInput		UDINT
EnableOut	Output	BOOL
DestinationArrayBool		ARRAY[-2..93] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be parsed.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[14]	The operand "DestinationArray-Bool" is of the data type AR-RAY[-2..93] of BOOL. This means it provides 96 BOOL ele-ments.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the 16th element assigned to the individual elements of the #DestinationArrayBool operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO. The remaining 32 bits are not written.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

GATHER: Merge individual bits into a bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into a bit sequence" combines the bits from an ARRAY of BOOL into a bit sequence. The bit sequence is saved in a tag of the data type BYTE, WORD, DWORD or LWORD.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

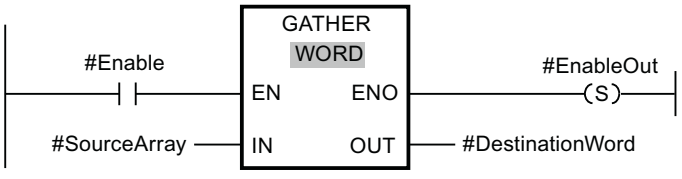
- Enable input EN has signal state "0".
- If the ARRAY has fewer or more BOOL elements than specified by the bit sequence, they are not transferred and the ENO returns signal state "0". The ENO also returns "0" if fewer than the necessary number of bits is available.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY whose bits are combined into a bit sequence
OUT	Output	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Combined bit sequence, saved in a tag

You can select the required bit sequence from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArray		WORD
EnableOut	Output	BOOL
DestinationWord		ARRAY[0..15] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArray	The operand "SourceArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD in which the bits are to be combined.
OUT	DestinationWord	WORD (16 bits)

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The bits of the operand #SourceArray are combined into a WORD. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

GATHER_BLK: Merge individual bits into multiple elements of an ARRAY of bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into multiple elements of an ARRAY of bit sequence" combines the bits from an ARRAY of BOOL into one or multiple elements of an ARRAY of <bit string>. At the COUNT_OUT parameter you specify how many elements of the destination ARRAY are going to be written. With this step you also implicitly specify how many elements of the ARRAY of BOOL are required. The destination ARRAY at the OUT parameter may have more elements than specified at the COUNT_OUT parameter. The ARRAY of <bit string> must have sufficient elements to save the bits that are going to be combined. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n(number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

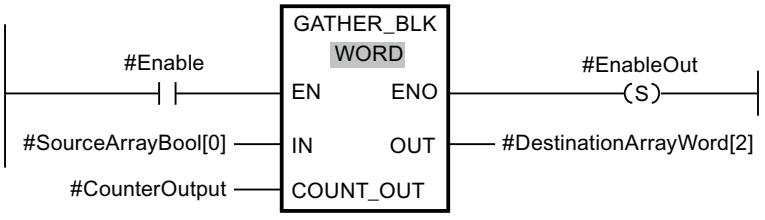
- Enable input EN has signal state "0".
- The index of the source ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of <bit string>.
- The ARRAY[*] of <bit string> does not provide the required number of elements. In this case as many bit strings as possible are combined and written to the ARRAY of <bit string>. The remaining bits are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY of BOOL whose bits are combined (source ARRAY)
COUNT_OUT	Input	UDINT	I, Q, M, D, L	Counter of the number of elements of the destination ARRAY that are going to be written
OUT	Output	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> to which the bits are saved (destination ARRAY)

You can select the required bit string from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example of a source ARRAY wit the low limit "0"

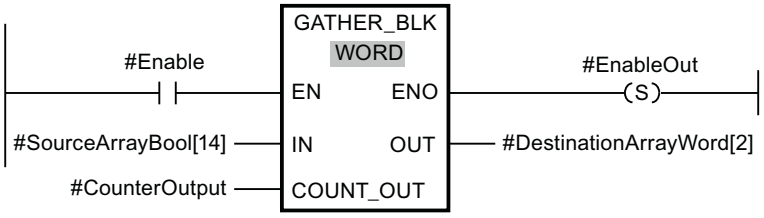
Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayBool		ARRAY[0..95] of BOOL
CounterOutput		UDINT
EnableOut	Output	BOOL
DestinationArrayWord		ARRAY[0..5] of WORD

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[0]	The operand "SourceArrayBool" is of the data type ARRAY[0..95] of BOOL. This means it provides 96 BOOL elements that can combined into words once again.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.



If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 1st element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits are written to the 3rd word, the second 16 bits to the 4th word, and the third 16 bits to the 5th word of the destination ARRAY. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Example of a source ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayBool		ARRAY[-2..93] of BOOL
CounterOutput		UDINT
EnableOut	Output	BOOL
DestinationArrayWord		ARRAY[0..5] of WORD

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[14]	The operand "SourceArrayBool" is of the data type ARRAY[-2..93] of BOOL. Because the starting point is the 14th element, only 80 BOOL elements that can be combined into words again are available.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 14th element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits of the source ARRAY are ignored. The second 16 bits are written to the 3rd word, the third 16 bits to the 4th word, and the fourth 16 bits to the 5th word of the destination ARRAY. The remaining 64 bits of the source ARRAY are not taken into account either. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

MOVE_BLK_VARIANT: Move block (S7-1200, S7-1500)

Description

You use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and destination ARRAY may be different. You can copy multiple or single elements within an ARRAY.

The number of elements that are to be copied must not exceed the selected source range or target range.

If you use the instruction at the time the block is being created, the ARRAY does not yet have to be known, as the source and the target are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is copied than is made available.

Parameters

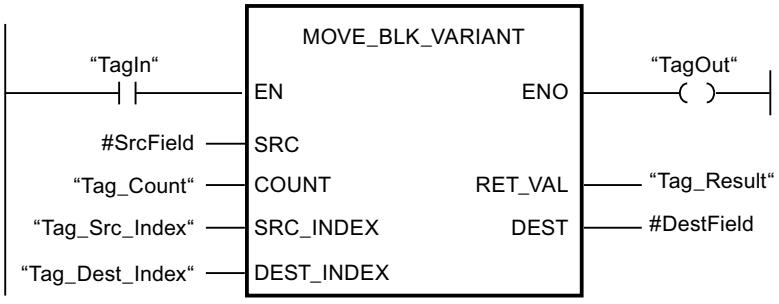
The following table shows the parameters of the "Move block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input [2)]	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	L (A declaration in the "Temp" section of the block interface is not possible.)	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L or constant	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no ARRAY is specified at parameter SRC or at parameter DEST.
SRC_INDEX	Input	DINT	I, Q, M, D, L or constant	Defines the first element to be copied: • The SRC_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter SRC, the integer at parameter SRC_INDEX specifies the first element within the source area from which it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter SRC or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.

Parameter	Declaration	Data type	Memory area	Description
DEST_INDEX	Input	DINT	I, Q, M, D, L or constant	Defines the start of the destination memory area: • The DEST_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter DEST, the integer at parameter DEST_INDEX specifies the first element within the target range that is to be copied into. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter DEST, then assign the value "0" at parameter DEST_INDEX.
DEST	Output [1]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Destination area into which the contents of the source block are copied.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface. 2) With the SRC parameter, the data types BOOL and ARRAY of BOOL are not permitted.				

You can find additional information on valid data types under "See also".

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data types do not correspond. Instead of an ARRAY of <Struct>, use an ARRAY of <PLC data type (UDT)>.
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at the SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.

Error code* (W#16#...)	Explanation
8383	The value at the SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at the DEST_INDEX is outside the high limit of the ARRAY.
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at the DEST parameter
8554	The operand at the DEST parameter has the data type BOOL.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT")
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT")

If the "TagIn" operand returns signal state "1", the instruction is executed. Two elements are moved from the source range, starting from the fourth element of the ARRAY [0..10] of MOVE_UDT, to the target range. The copies are pasted in the ARRAY [10..20] of MOVE_UDT starting from the fourth element. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Note

You can find more information on the MOVE_BLK_VARIANT instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

UMOVE_BLK: Move block uninterruptible (S7-1200, S7-1500)

Description

You use the "Move block uninterruptible" instruction to move the content of a memory area (source range) to another memory area (target range). The instruction cannot be interrupted. The number of elements to be moved to the target range is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

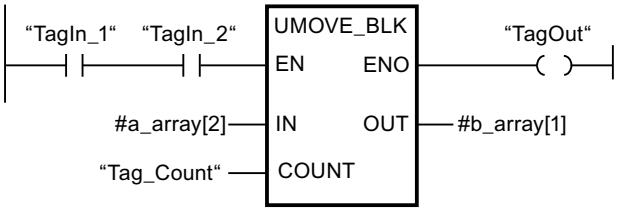
Note

Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

You use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters



The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	Number of elements to be moved from the source range to the target range.
OUT [1)]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the target range to which the contents of the source range are being copied
[1)] The specified data types can only be used as elements of an ARRAY structure.					

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is Array [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is Array [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the ENO output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Note

You can find more information on the UMOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

FILL_BLK: Fill block (S7-1200, S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (target range) with the value of the IN input. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

Use of ARRAYs

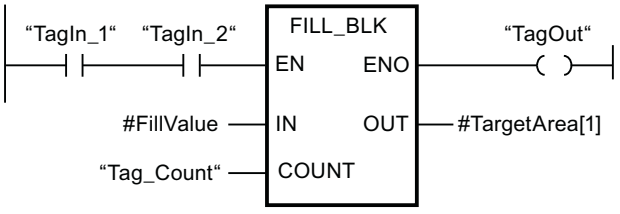
The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters

The following table shows the parameters of the "Fill block" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	Element used to fill the target range
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in target range from which filling starts

For additional information on valid data types, refer to "See also".

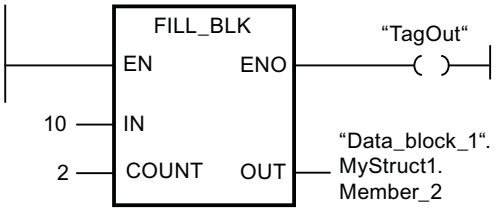
Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

The following table shows how the instruction works using specific operand values:

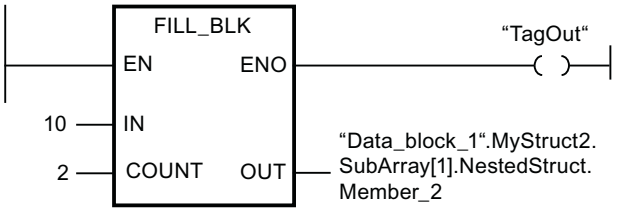
Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element. If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".



Examples with a structure

The following examples show how the instruction works when you want to fill a structure:



Create a global data block with the following elements:

Data_block_1					Data type
MyStruct1					STRUCT
	Member_1				INT
	Member_2				INT
	Member_3				INT
	Member_4				INT
MyStruct2					STRUCT
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

Generate the following program code to address the MyStruct2 tag:

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and

Member_4, are not changed. If the instruction is executed without errors, the TagOut operand is set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

UFILL_BLK: Fill block uninterruptible (S7-1200, S7-1500)

Description

You can use the "Fill block uninterruptible" instruction to fill a memory area (target range) with the value of the IN input. The instruction cannot be interrupted. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the alarm reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

Use of ARRAYs

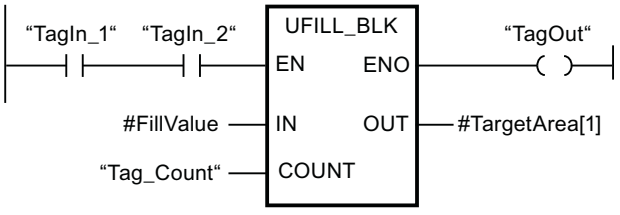
The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

You use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters



The following table shows the parameters of the "Fill block uninterruptible" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	Element used to fill the target range.
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in target range from which filling begins.

For additional information on valid data types, refer to "See also".

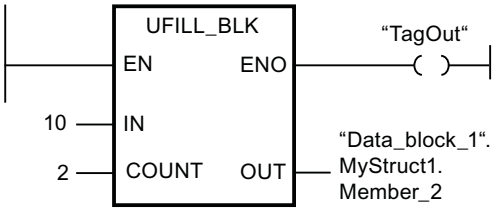
Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

The following table shows how the instruction works using specific operand values:

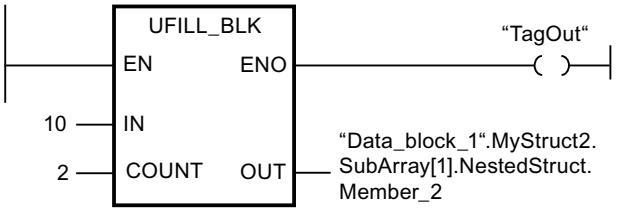
Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".



Examples with a structure

The following examples show how the instruction works when you want to fill a structure:



Create a global data block with the following elements:

Data_block_1					Data type
MyStruct1					STRUCT
	Member_1				INT
	Member_2				INT
	Member_3				INT
	Member_4				INT
MyStruct2					STRUCT
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

Generate the following program code to address the MyStruct2 tag:

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and Member_4, are not changed. If the instruction is executed without errors, the TagOut operand is set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

SWAP: Swap (S7-1200, S7-1500)

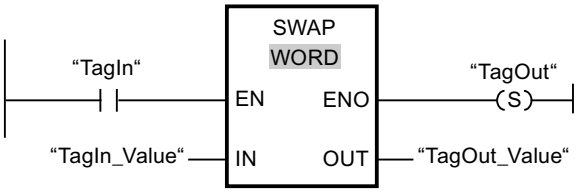
Description

You can use the "Swap" instruction to change the order of the bytes at input IN and query the result at output OUT.

The following figure shows how the bytes of an operand of the DWORD data type are swapped using the "Swap" instruction:

Parameters

The following table lists the parameters of the "Swap" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L or, P constant	Operand whose bytes are swapped.
OUT	Output	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 0101 0101
OUT	TagOut_Value	0101 0101 0000 1111

If operand "TagIn" has the signal state "1", the "Swap" instruction is executed. The order of the bytes is changed and stored in operand "TagOut_Value".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

ARRAY DB (S7-1500)

ReadFromArrayDB: Read from ARRAYdata block (S7-1500)

Description

The instruction "Read from ARRAY data block" is used to read the element from a data block of the ARRAY DB block type to which the index references, and write the value of the element to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Enable output ENO returns the signal state FALSE if one of the following conditions applies:

- Enable input EN returns the signal state FALSE.
- If an error occurs during the execution of the instruction.

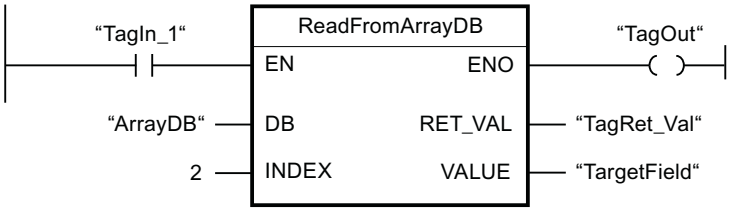
Parameters

The following table shows the parameters of the "Read from ARRAY data block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.

Parameters	Declaration	Data type	Memory area	Description
VALUE	Output [1)]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value that is read and output
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

You can find additional information on valid data types under "See also".



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.

If the "TagIn1" operand returns signal state "1", the instruction is executed. The 2nd element is read from "ArrayDB" and written to the "TargetField" operand. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

WriteToArrayDB: Write to ARRAY data block (S7-1500)

Description

The instruction "Write to ARRAY data block" is used to write the element to which the index references to a data block of the ARRAY DB block type.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Enable output ENO returns the signal state FALSE if one of the following conditions applies:

- Enable input EN returns the signal state FALSE.
- If an error occurs during the execution of the instruction.

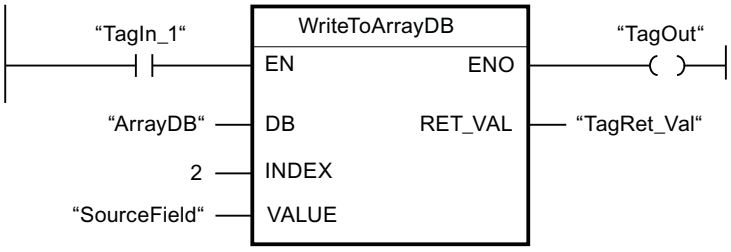
Parameters

The following table shows the parameters of the "Write to ARRAY data block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value to be written
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

You can find additional information on valid data types under "See also".

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error

Error code* (W#16#...)	Explanation
8353	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.

If the "TagIn1" operand returns signal state "1", the instruction is executed. The value of the "SourceField" operand is written to the 2nd element of the ARRAY DB. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

ReadFromArrayDBL: Read from ARRAY data block in load memory (S7-1500)

Description

The instruction "Read from ARRAY data block in load memory" is used to read the element ti which the index references from a data block of the ARRAY DB block type in the load memory and write it to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1" for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

Enable output ENO returns the signal state FALSE if one of the following conditions applies:

- Enable input EN returns the signal state FALSE.
- If an error occurs during the execution of the instruction.

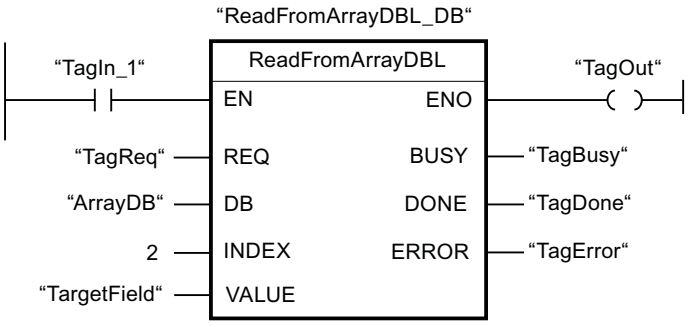
Parameters

The following table shows the parameters of the "Read from ARRAY data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Begin with the reading of the ARRAY DB
DB [1)]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block that is read.
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.
VALUE [1)]	InOut	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read

Parameter	Declaration	Data type	Memory area	Description
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

Parameter ERROR



The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq" operand, the instruction is executed. The 2nd element is read from "ArrayDB" and output at the VALUE parameter. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is no longer changed. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

WriteToArrayDBL: Write to ARRAY data block in load memory (S7-1500)

Description

The instruction "Write to ARRAY data block in load memory" is used to write the element to which the index references to a data block of the ARRAY DB block type in load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

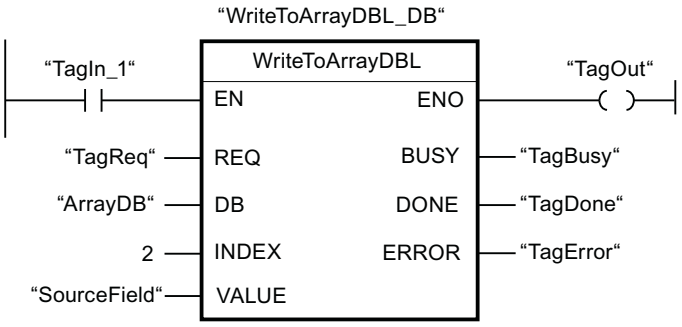
Parameters

The following table shows the parameters of the "Write to ARRAY data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Start writing to the array DB
DB [1)]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE [1)]	Input	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

Parameter ERROR



The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq" operand, the instruction is executed. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written to the 2nd element of the "ArrayDB". If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

VARIANT (S7-1200, S7-1500)

VariantGet: Read out VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag at the DST parameter must match the data type to which the VARIANT points.

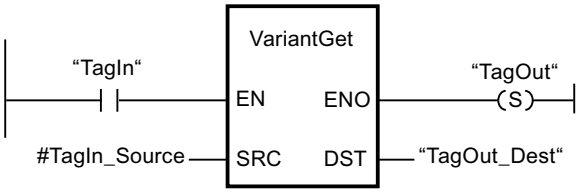
Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The data types do not correspond (no value is transferred).

Parameter



The following table shows the parameters of the instruction "Read out VARIANT tag value":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRC	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Result of the instruction

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of the tag to which the VARIANT at the "#TagIn_Source" operand points, is read and written to the "TagOut_Dest" operand.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

MOVE_BLK_VARIANT: Move block (Page 2757)

Basic information on LAD (Page 4878)

VariantPut: Write VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the memory at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

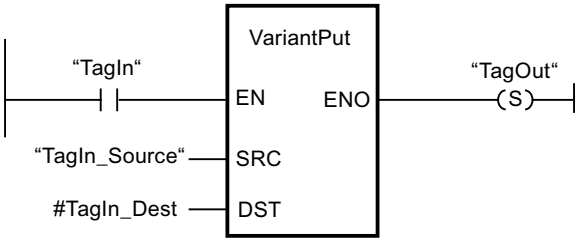
Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT instruction: Move block" instruction. For additional information, refer to "See also".

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameters



The following table shows the parameters of the instruction "Write VARIANT tag value":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Tag to be read
DST	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Result of the instruction

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand returns signal state "1", the instruction is executed. The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

MOVE_BLK_VARIANT: Move block (Page 2757)

Basic information on LAD (Page 4878)

CountOfElements: Get number of ARRAY elements (S7-1200, S7-1500)

Description

You use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag to which VARIANT points has.

If it is a multi-dimensional ARRAY, the number of ARRAY elements is output as the result. (The difference between the high and low limit +1). If it is a multi-dimensional ARRAY, the number of all dimensions is output as the result.

Note

Instances

The VARIANT pointer can point to no instance and therefore also to no multi-instance or an ARRAY of multi-instances.

Note

ARRAY within a data block

If you want to query the number of the elements of an ARRAY which is located in a data block, the block attribute "Data block write-protected in the device" must not be activated in this block. Otherwise, the RET_VAL parameter returns the result "0", irrespective of how many elements the ARRAY contains.

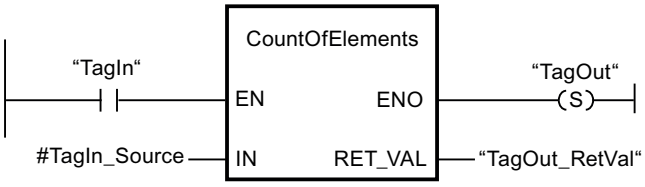
The result is also "0" if the VARIANT tag is not an ARRAY.

If the VARIANT points to an ARRAY of BOOL, the fill elements are included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL).

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The VARIANT tag is not an ARRAY. (The result is "0".)

Parameters



The following table shows the parameters of the "Get number of ARRAY elements" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be queried
RET_VAL	Output	UDINT	I, Q, M, D, L	Result of the instruction

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand returns signal state "1", the instruction is executed. The number of ARRAY elements of the tag to which the VARIANT at the #TagIn_Source operand points is read and output at the "TagOut_RetVal" operand.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

ARRAY[*] (S7-1200, S7-1500)

LOWER_BOUND: Read out low ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

The "Read out ARRAY low limit" instruction is used to read out the variable low limit of the ARRAY.

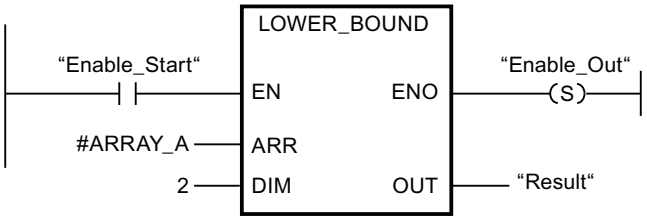
Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The dimension specified at input DIM does not exist.

Note

Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.



Parameters

The following table shows the parameters of the instruction "Read out ARRAY low limit":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable low limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable low limit is to be read.
OUT	Output	DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

If the "Enable_Start" operand returns signal state "1", the instruction is executed. It reads out the variable low limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Enable_Out" and operand "Result" is set.

See also

Overview of the valid data types (Page 2239)

Basic information on ARRAY (Page 2286)

Basic information on LAD (Page 4878)

UPPER_BOUND: Read out high ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

The instruction "Read out ARRAY high limit" is used to read out the variable high limit of the ARRAY.

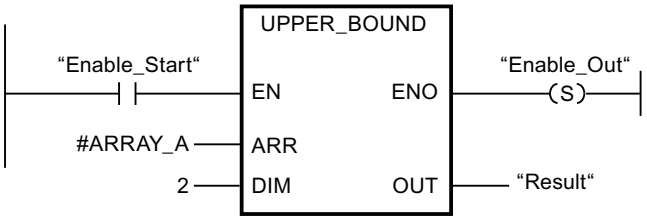
Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The dimension specified at input DIM does not exist.

Note

Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.



Parameters

The following table shows the parameters of the instruction "Read out ARRAY high limit":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable high limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable high limit is to be read.
OUT	Output	DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

If the "Enable_Start" operand returns signal state "1", the instruction is executed. It reads out the variable high limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Enable_Out" and operand "Result" is set.

Basic information on LAD (Page 4878)

Legacy (S7-1500)

FieldRead: Read field (S7-1500)

Description

You can use the "Read field" instruction to read out a specific component from the field specified at input MEMBER and transfer its content to the tag at output VALUE. You specify the index of the field component to be read at input INDEX. Specify the first component of the field from which reading is to occur at input MEMBER.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

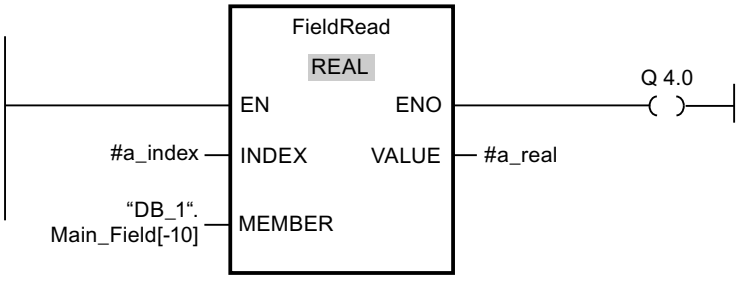
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The field component specified at input INDEX is not defined in the field specified at output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Read field":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P, or constant	Index of field component whose content is read out



Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
MEMBER	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	First component of the field from which reading occurs.
VALUE	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P	Operand to which the content of the field component is transferred

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Tag	Value
INDEX	a_index	4
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"
VALUE	a_real	Component with index 4 of the "Main_Field[-10..10] of REAL" field

The field component with index 4 is read from the "Main_Field[-10...10] of REAL" field and written to the "a_real" tag. The field component to be read is specified by the value at input INDEX.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

FieldWrite: Write field (S7-1500)

Description

The "Write field" instruction is used to transfer the content of the tag at the VALUE input to a specific component of the field at the MEMBER output. You can use the value at the INDEX input to specify the index of the field component that is described. At the MEMBER output, enter the first component of the field which is to be written to.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

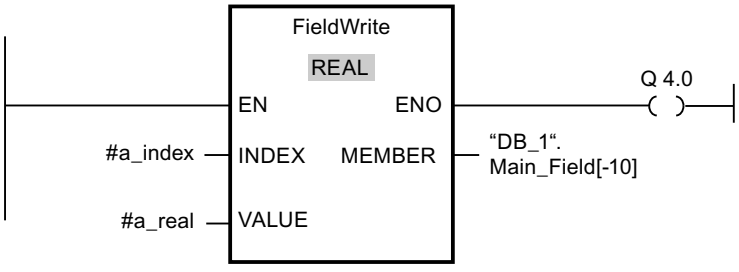
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The field component specified at the input INDEX is not defined in the field specified at the output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Write field":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P, or constant	Index of the field component that is being written with the content of VALUE.



Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR, WCHAR	I, Q, M, D, L, P, or constant	Operand whose content is copied.
MEMBER	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	First component of the field to which the content of VALUE is written.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
INDEX	a_index	4
VALUE	a_real	10.54
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"

The value "10.54" of the "a_real" tag is written to the field component with index 4 of the "Main_Field[-10..10] of REAL" field. The index of the field component to which the content of the tag "a_real" is transferred is specified by the value at the input INDEX.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

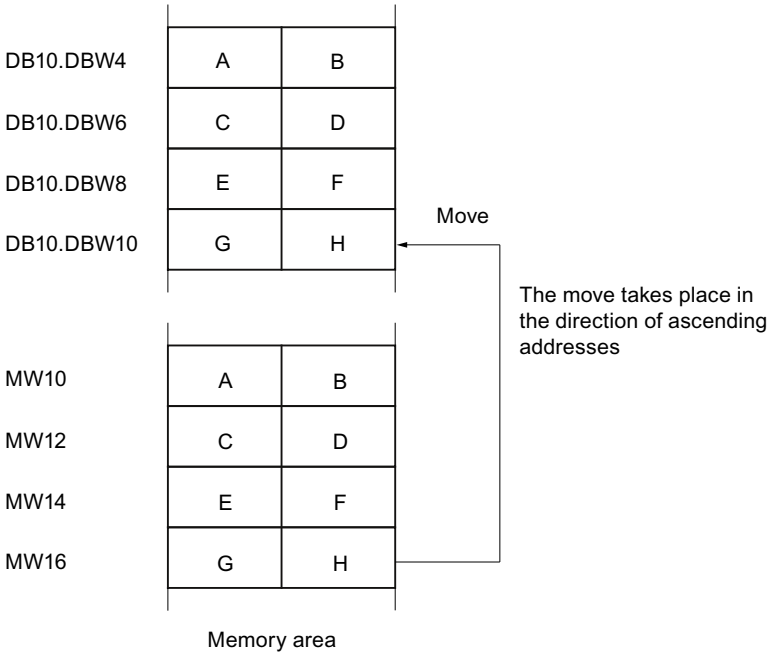
Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

BLKMOV: Move block (S7-1500)

Description



You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

The following figure shows the principle of the move operation:

Consistency of source and destination data

Make sure that the source data remain unchanged during the execution of the "Move block" instruction. Otherwise, consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination areas have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

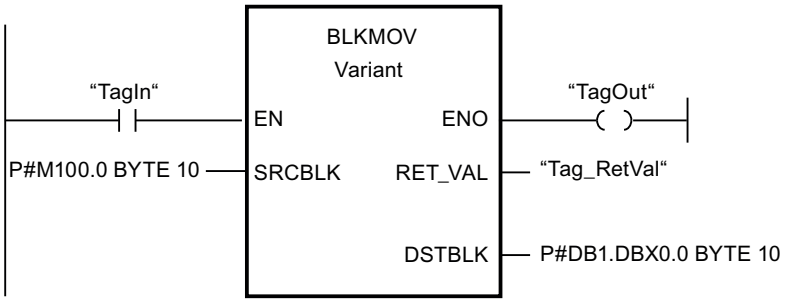
If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes in the SRCBLK and DSTBLK parameters.

Parameters

The following table shows the parameters of the "Move block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).

Parameters	Declaration	Data type	Memory area	Description
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
DSTBLK	Output [1]	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

UBLKMOV: Move block uninterruptible (S7-1500)

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result, the interrupt reaction time of the CPU can increase during the execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a destination or source area defined as a formal parameter is less than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

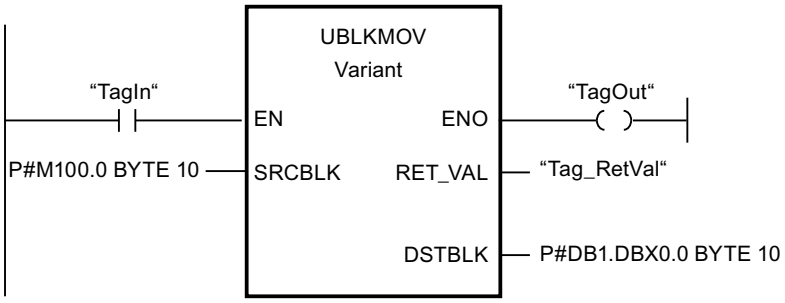
You can use the "Move block uninterruptible" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as area length.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
DSTBLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8091	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the DSTBLK parameter.

Error code* (W#16#...)	Explanation
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

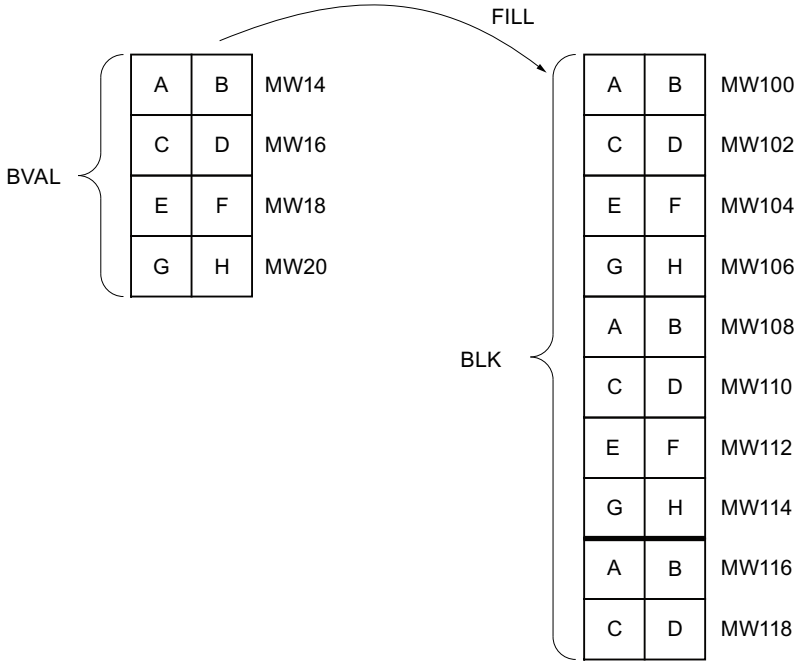
Basic information on LAD (Page 4878)

FILL: Fill block (S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

You use VARIANT to define the source and destination areas.



Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK instruction. Fill block" instruction.

The following figure shows the principle of the move operation:

Example: The contents of the range MW100 to MW118 are to be preassigned with the contents of the memory words MW14 to MW20.

Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory

- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the input parameter BVAL, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is STRING data type, the instruction writes the entire string including the administration information.

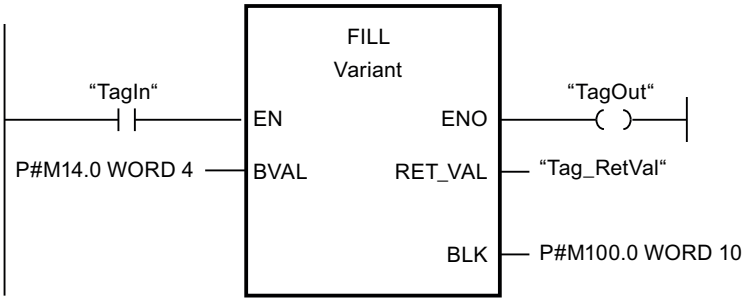
Rules for moving structures

When you transfer a structure as an input parameter you must bear in mind that the length of a structure is always oriented to an even number of bytes. The structure will need one byte of additional memory space if you declare a structure with an odd number of bytes.

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
BVAL	Input	VARIANT	I, Q, M, D, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
BLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specification of the memory area that will be filled with the content of the source area.
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the BVAL parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the BLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

Conversion operations (S7-1200, S7-1500)

CONVERT: Convert value (S7-1200, S7-1500)

Description

The "Convert value" instruction reads the content of the IN parameter and converts it according to the data types selected in the instruction box. The converted value is output at the OUT output.

For information on possible conversions, refer to the "Explicit conversion" section at "See also".

The enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors, such as an overflow, occur during execution.

Conversion options for bit strings

BYTE and WORD bit strings cannot be selected in the instruction box. However, it is possible to specify an operand of data type DWORD or LWORD at a parameter of the instruction if the lengths of the input and output operands match. The operand is then interpreted by the data type of a bit string according to the data type of the input or output parameter and is implicitly converted. The data type DWORD is for example interpreted as DINT/UDINT and LWORD as LINT/ULINT. These conversion options are also available to you when "IEC check" is enabled.

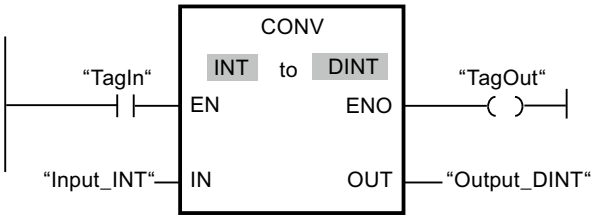
Note

For CPUs of the S7-1500 series: The data types DWORD and LWORD can only be converted to or from data type REAL or LREAL.

During the conversion, the bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If no errors occur during the conversion, the signal state of enable output ENO = 1; if an error occurs during processing, the signal state of the enable output ENO = 0.

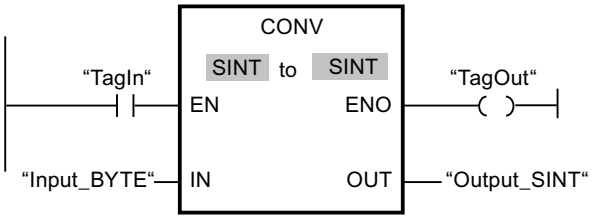
Parameters

The following table shows the parameters of the "Convert value" instruction:



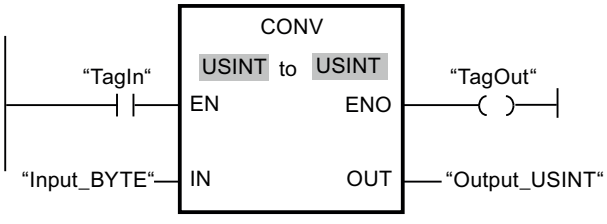
Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P or constant	Value to be converted.
OUT	Output	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P	Result of the conversion



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

Examples



The following example shows the conversion of an integer (16 bit) to another integer (32 bit):

The following example shows the conversion of a byte (8 bit) to the integer SINT (8 bit):

The following example shows the conversion of a byte (8 bit) to the unsigned integer USINT (8 bit):

The conversions are possible, because the length of the two operands is the same.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Data type conversion for S7-1200 (Page 2465)

Basic information on LAD (Page 4878)

ROUND: Round numerical value (S7-1200, S7-1500)

Description

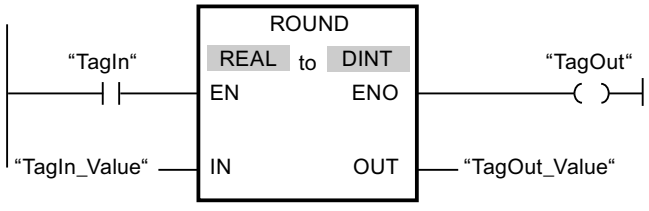
You can use the "Round numerical value" instruction to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts this to an integer of data type DINT. If the input value is exactly between an even and odd number, the even number is selected. The result of the instruction is sent to the OUT output and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Round numerical value" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value to be rounded.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result of rounding

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	2	-2

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the nearest even integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

CEIL: Generate next higher integer from floating-point number (S7-1200, S7-1500)

Description

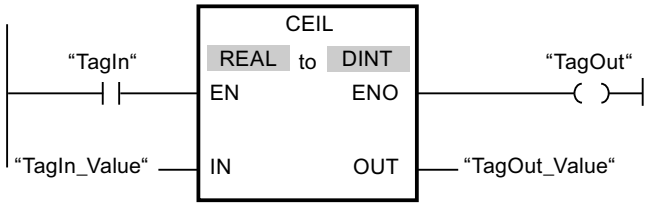
You can use the "Generate next higher integer from floating-point number" instruction to round the value at input IN to the next higher integer. The instruction interprets the value at the IN input as a floating-point number and converts this number to the next higher integer. The result of the instruction is sent to the OUT output and can be queried there. The output value can be greater than or equal to the input value.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Generate next higher integer from floating-point number" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result with next higher integer

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	1	0

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at the "TagIn_Value" input is rounded to the next higher integer and sent to the "TagOut_Value" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

FLOOR: Generate next lower integer from floating-point number (S7-1200, S7-1500)

Description

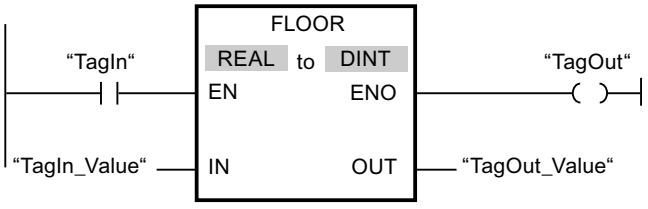
You can use the "Generate next lower integer from floating-point number" instruction to round the value at input IN to the next lower integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next lower integer. The result of the instruction is sent to the OUT output and can be queried there. The output value can be less than or equal to the input value.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Generate next lower integer from floating-point number" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	Result with next lower integer

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	0	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next lower integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

TRUNC: Truncate numerical value (S7-1200, S7-1500)

Description

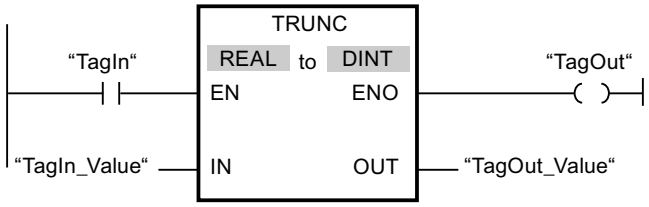
You can use the "Truncate numerical value" instruction to form an integer from the value at the IN input. The value at the IN input is interpreted as a floating-point number. The instruction selects only the integer part of the floating-point number and sends this to the OUT output without decimal places.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Truncate numerical value" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L or constant	Input value
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Integer part of the input value

You can select the data type for the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

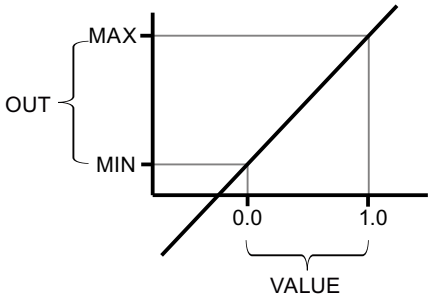
Parameter	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	1	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The integer part of the floating-point number at the "TagIn_Value" input is converted to an integer and sent to the "TagOut_Value" output. If the instruction is executed without errors, the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)



Basic information on LAD (Page 4878)

SCALE_X: Scale (S7-1200, S7-1500)

Description

You can use the "Scale" instruction to scale the value at the VALUE input by mapping it to a specified value range. When the "Scale" instruction is executed, the floating-point value at the VALUE input is scaled to the value range that was defined by the MIN and MAX parameters. The result of the scaling is an integer, which is stored in the OUT output.

The following figure shows an example of how values can be scaled:

The "Scale" instruction works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the MIN input is greater than or equal to the value at the MAX input.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- An overflow occurs.
- The value at the VALUE input is NaN (Not a Number = result of an invalid arithmetic operation).

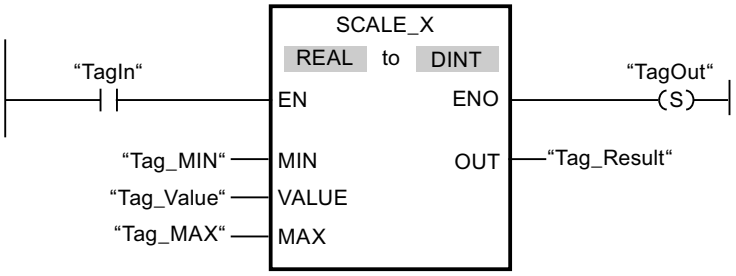
Note

For more information on the converting of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VALUE	Input	Floating-point numbers	I, Q, M, D, L or constant	Value to be scaled. If you enter a constant, you must declare it.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Result of scaling



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

You can find additional information on valid data types under "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

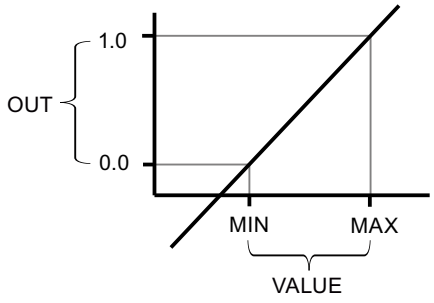
Parameter	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	0.5
MAX	Tag_MAX	30
OUT	Tag_Result	20

If the "TagIn" operand has signal state "1", the instruction is executed. The value at the "Tag_Value" input is scaled to the range of values defined by the values at the "Tag_MIN" and "Tag_MAX" inputs. The result is stored in the "Tag_Result" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)



Basic information on LAD (Page 4878)

NORM_X: Normalize (S7-1200, S7-1500)

Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the MIN and MAX parameters to define the limits of a value range that is applied to the scale. The result at the OUT output is calculated and stored as a floating-point number depending on the location of the value to be normalized within this value range. If the value to be normalized is equal to the value at the MIN input, the OUT output has the value "0.0". If the value to be normalized is equal to the value at input MAX, output OUT returns the value "1.0".

The following figure shows an example of how values can be normalized:

The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value at the MIN input is greater than or equal to the value at the MAX input.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- The value at the VALUE input is NaN (result of an invalid arithmetic operation).

Note

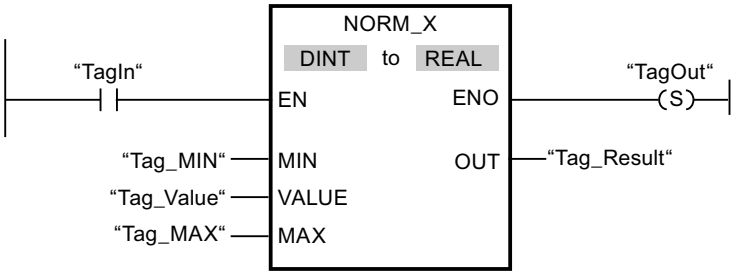
For more information on the converting of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Normalize" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MIN [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VALUE [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Value to be normalized.
MAX [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range

Parameter	Declaration	Data type	Memory area	Description
OUT	Output	Floating-point numbers	I, Q, M, D, L	Result of the normalization
[1] If you use constants in these three parameters, you only need to declare one of them.				



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

You can find additional information on valid data types under "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	20
MAX	Tag_MAX	30
OUT	Tag_Result	0.5

If the "TagIn" operand has signal state "1", the instruction is executed. The value at the "Tag_Value" input is mapped to the range of values that were defined by the values at the "Tag_MIN" and "Tag_MAX" inputs. The tag value at the "Tag_Value" input is normalized to the defined value range. The result is stored as a floating-point number in the "Tag_Result" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Legacy (S7-1500)

SCALE: Scale (S7-1500)

Description

Use the "Scale" instruction to convert the integer at the IN parameter into a floating-point number, which can be scaled in physical units between a low limit value and a high limit value. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output on the OUT parameter.

The "Scale" instruction works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the constants "K1" and "K2" are determined by the signal state on the BIPOLAR parameter. The following signal states are possible on the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case the "K1" constant has the value "-27648.0" and the "K2" constant the value "+27648.0".
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case the "K1" constant has the value "0,0" and the "K2" constant the value "+27648.0".

When the value at the IN parameter is greater than the value of the constant "K2", the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

When the value at the IN parameter is less than the value of the constant "K1", the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

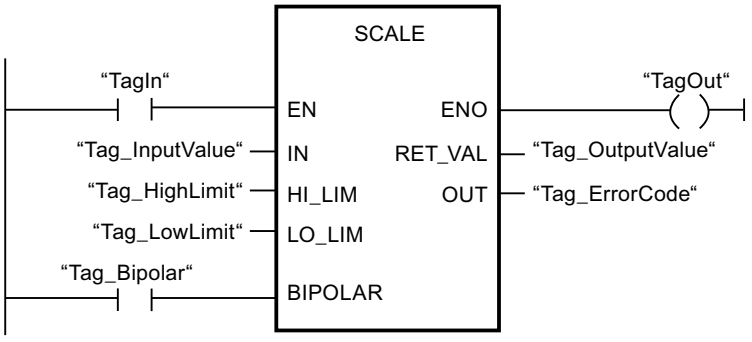
When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameter

The following table shows the parameters of the "Scale" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	INT	I, Q, M, D, L, P, or constant	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P, or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P, or constant	Low limit

Parameter	Declaration	Data type	Memory area	Description
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	Indicates if the value at IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	Error information



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the constant "K2" or less than the value of the constant "K1"
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0

Parameter	Operand	Value
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

UNSCALE: Unscale (S7-1500)

Description

You use the "Unscale" instruction to unscale the floating-point number in the IN parameter into physical units between a low limit and a high limit and convert it into an integer. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output at the OUT parameter.

The "Unscale" instruction works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the "K1" and "K2" constants are determined by the signal state at the BIPOLAR parameter. The following signal states are possible at the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case the "K1" constant has the value "-27648.0" and the "K2" constant the value "+27648.0".
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case the "K1" constant has the value "0.0" and the "K2" constant the value "+27648.0".

When the value at parameter IN is not within the limits defined by HI_LIM and LO_LIM, an error is output.

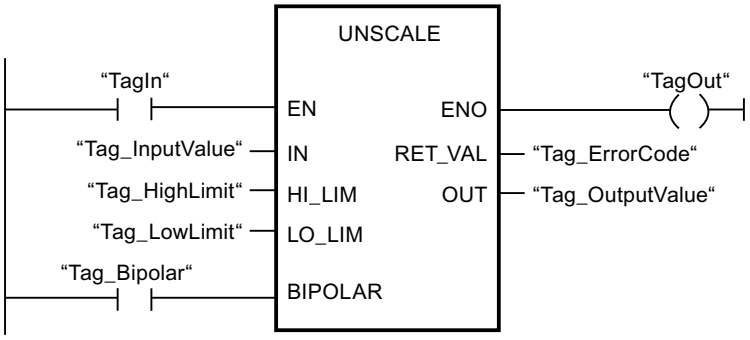
When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled inversely proportionate to the input value.

Parameter

The following table shows the parameters of the "Unscale" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Input	BOOL	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type	Memory area	Description
IN	Input	REAL	I, Q, M, D, L, P or constant	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	Indicates whether the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	Error information



RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally"
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats here: AUTOHOTSPOT	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	22
RET_VAL	Tag_ErrorCode	W#16#0000

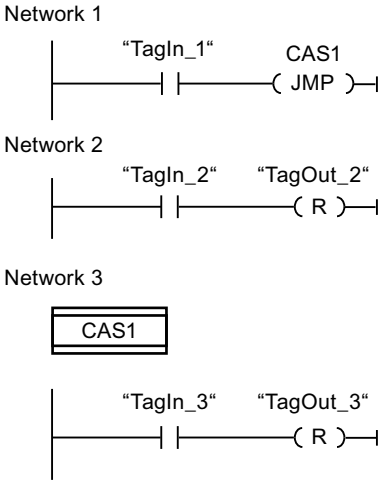
Basic information on LAD (Page 4878)

Program control operations (S7-1200, S7-1500)

---(JMP): Jump if RLO = 1 (S7-1200, S7-1500)

Description

You can use the "Jump if RLO = 1" instruction to interrupt the linear execution of the program and resume it in another network. The destination network must be identified by a jump label (LABEL). The name of this jump label is specified in the placeholder above the instruction.



The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil is permitted within a network.

If the result of logic operation (RLO) at the input of the instruction is "1", the jump to the network identified by the specified jump label is executed. The jump direction can be towards higher or lower network numbers.

If the condition at the input of the instruction is not fulfilled (RLO = 0), execution of the program continues in the next network.

Example

The following example shows how the instruction works:

If operand "TagIn_1" has the signal state "1", the "Jump if RLO = 1" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has signal state "1", the "TagOut_3" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

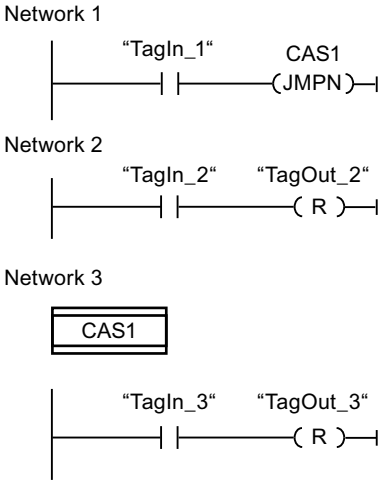
Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

---(JMPN): Jump if RLO = 0 (S7-1200, S7-1500)

Description

You can use the instruction "Jump if RLO = 0" to interrupt the linear execution of the program and resume it in another network, when the result of logic operation at the input of the instruction is "0". The destination network must be identified by a jump label (LABEL). The name of this jump label is specified in the placeholder above the instruction.



The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil is permitted within a network.

If the result of logic operation (RLO) at the input of the instruction is "0", the jump to the network identified by the specified jump label is executed. The jump direction can be towards higher or lower network numbers.

If the result of logic operation at the input of the instruction is "1", execution of the program continues in the next network.

Example

The following example shows how the instruction works:

If operand "TagIn_1" has the signal state "0", the "Jump if RLO = 0" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has signal state "1", the "TagOut_3" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

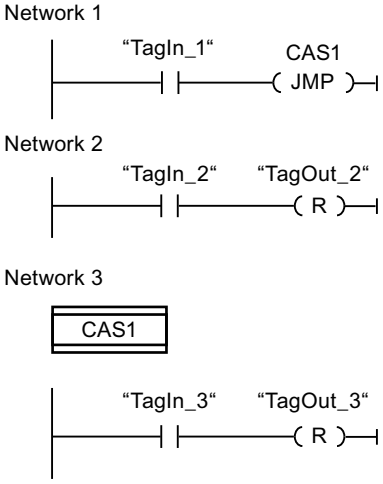
Basic information on LAD (Page 4878)

LABEL: Jump label (S7-1200, S7-1500)

Description

You can use a jump label to identify a destination network, in which the program execution should resume when a jump is executed.

The jump label and the instruction in which the jump label is specified must be located in the same block. The name of a jump label can only be assigned once in a block. You can declare up to 32 jump labels when you use a CPU S7-1200 and a maximum of 256 jump labels when you use a CPU S7-1500.



Only one jump label can be placed in a network. Each jump label can jump to several locations.

Adhere to the following grammatical rules for jump labels:

- Letters (a to z, A to Z)
- A combination of letters and numbers. Note the order, i.e. first the letters and then the letters (a - z, A - Z, 0 - 9).
- Special characters or a combination of letters and numbers in reverse order, i.e. first the numbers and then the letters (0 - 9, a - z, A - Z) must not be used.

Example

The following example shows how the instruction works:

If operand "TagIn_1" has the signal state "1", the "Jump if RLO = 1" instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has signal state "1", the "TagOut_3" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

JMP_LIST: Define jump list (S7-1200, S7-1500)

Description

You can use the "Define jump list" instruction to define several conditional jumps and continue the program execution in a specific network depending on the value of the K parameter.

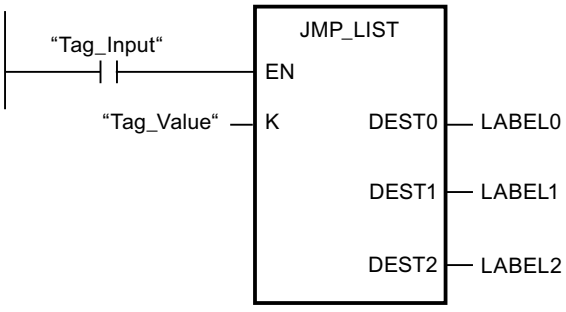
You define the jumps with jump labels (LABEL), which you specify at the outputs of the instruction box. The number of outputs can be expanded in the instruction box. You can declare up to 32 outputs when you use a CPU S7-1200 and a maximum of 256 outputs when you use a CPU S7-1500.

The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Only jump labels can be specified at the outputs of the instruction. Instructions or operands cannot be specified.

The value of the K parameter specifies the number of the output and thus the jump label where the program execution is to be resumed. If the value in the K parameter is greater than the number of available outputs, the program execution is resumed in the next network of the block.

The "Define jump list" instruction is only executed if the signal state is "1" at the EN enable input.

Parameters



The following table shows the parameters of the "Define jump list" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	I, Q, M, D, L or constant	Specifies the number of the output and thus the jump that is to be made.
DEST0	-	-	-	First jump label
DEST1	-	-	-	Second jump label
DESTn	-	-	-	Optional jump labels

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	1
Dest0	LABEL0	Jump to the network that is identified with the jump label "LABEL0".
Dest1	LABEL1	Jump to the network that is identified with the jump label "LABEL1".
Dest2	LABEL2	Jump to the network that is identified with the jump label "LABEL2".

If operand "Tag_Input" has the signal state "1", the "Define jump list" instruction is executed. The execution of the program is continued according to the value of the operand "Tag_Value" in the network that is identified with the jump label "LABEL1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

SWITCH: Jump distributor (S7-1200, S7-1500)

Description

You can use the "Jump distributor" instruction to define multiple program jumps to be executed depending on the result of one or more comparison instructions.

You specify the value to be compared in the K parameter. This value is compared with the values that are provided by the various inputs. You can select the comparison method for each individual input. The availability of the various comparison instructions depends on the data type of the instruction.

The following table shows the comparison instructions that are available depending on the selected data type:

Data type		Instruction	Syntax
S7-1200	S7-1500		
Bit strings	Bit strings	Equal	==
		Not equal	<>

Data type		Instruction	Syntax
S7-1200	S7-1500		
Integers, floating-point numbers, TIME, DATE, TOD	Integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	Equal	==
		Not equal	<>
		Greater or equal	>=
		Less or equal	<=
		Greater than	>
		Less than	<

You can select the data type of the instruction from the "???" drop-down list of the instruction box. If you select a comparison instruction and the data type of the instruction is not yet defined, then the "???" drop-down list will only list those data types that are permitted for the selected comparison instruction.

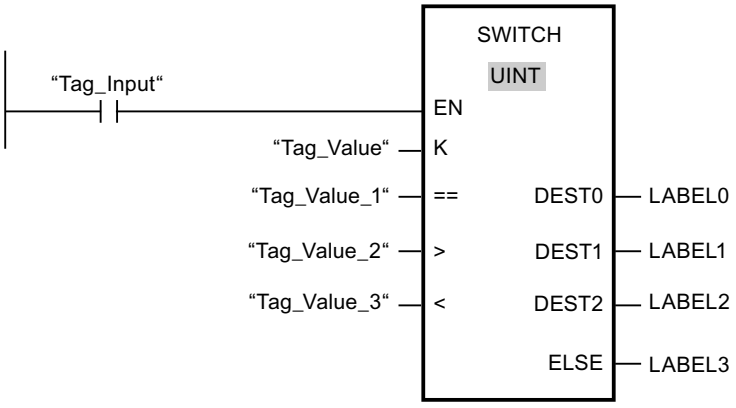
Execution of the instruction begins with the first comparison and runs until a comparison condition is met. If a comparison condition is met, the subsequent comparison conditions are not considered. If none of the specified comparison conditions are fulfilled, the jump is executed at output ELSE. If no program jump is defined at the ELSE output, execution of the program continues in the next network.

The number of outputs can be expanded in the instruction box. The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Specify jump labels (LABEL) at the outputs of the instruction. Instructions or operands cannot be specified at the outputs of the instruction.

An input is automatically inserted to each additional output. The jump programmed at an output is executed if the comparison condition of the corresponding input is fulfilled.

Parameters

The following table shows the parameters of the instruction "Jump distributor":



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	UINT	I, Q, M, D, L or constant	Specifies the value to be compared.
<Comparison values>	Input	Bit strings, integers, floating-point numbers, TIME, DATE, TOD	Bit strings, integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	I, Q, M, D, L or constant	Input values with which the value of the parameter K is compared.
DEST0	-	-	-	-	First jump label
DEST1	-	-	-	-	Second jump label

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
DEST(n)	-	-	-	-	Optional jump labels: • S7-1200: n = 2 to 32 • S7-1500: n = 2 to 256
ELSE	-	-	-	-	Program jump which is executed if none of the comparison conditions are fulfilled.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	23
==	Tag_Value_1	20
>	Tag_Value_2	21
<	Tag_Value_3	19
DEST0	LABEL0	Jump to jump label "LABEL0", if the value of parameter K is equal to 20.
DEST1	LABEL1	Jump to jump label "LABEL1", if the value of parameter K is greater than 21.
DEST2	LABEL2	Jump to jump label "LABEL2", if the value of parameter K is less than 19.
ELSE	LABEL3	Jump to jump label "LABEL3", if the none of the comparison conditions are fulfilled.

If the operand "Tag_Input" changes to signal state "1", the instruction "Jump distributor" is executed. The execution of the program is continued in the network that is identified with the jump label "LABEL1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

--(RET): Return (S7-1200, S7-1500)

Description

You can use the "Return" instruction to stop the execution of a program block conditionally or absolutely. The signal state of the return value (operand) is mapped in the enable output ENO of the calling program block when the program block is exited.

There are three ways that the execution of a program block can be ended:

Termination of the program block	Description
Without a call of the instruction	The program block is exited after the execution of the last network. The enable output ENO of the calling program block is set to signal state "1".
Call of the instruction with preceding logic operation (see example)	If the preceding logic operation is fulfilled, the program execution in the currently called program block is ended and the program block is exited. (Conditional program block end) The program execution is continued in the calling program block (e.g. an OB) after the program block call. The enable output ENO of the calling program block corresponds to the operand.
Call of the instruction without preceding logic or the instruction is directly connected to the left power rail.	The program block is exited unconditionally. (Absolute program block end) The enable output ENO of the calling program block corresponds to the operand.

If an organization block (OB) is ended, another program block is selected by the execution level system and started or further executed.

- If the OB program cycle is ended, it is restarted.
- If an OB is ended that has interrupted another program block (e.g. an interrupt OB), then the interrupted program block (e.g. program cycle OB) is further executed.

Note

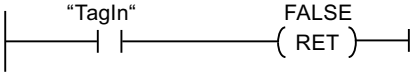
RET instruction in relation with JMP and JMPN

If a network already contains the "JMP: Jump if RLO = 1" or "JMPN: Jump if RLO = 0 instruction, the RET: Return" instruction must not be used. Only one jumping coil may be used in a network

Possible settings of the return value (operand)

The return value of the instruction can assume the following values:

- Ret (RLO, corresponds to the result of logic operation RLO. The signal state "1" is supplied to the enable output ENO of the calling program block because the RET instruction is only then executed as a conditional instruction when the condition is TRUE.)
- Ret True or Ret False (the respective value of the constant, TRUE or FALSE, is supplied to the calling program block.)
- Ret Value (the value of the Boolean tag <Operand> is supplied to the calling program block.)



To set the return value of the instruction, click the small yellow triangle of the instruction and select the desired value in the drop-down list.

The following table shows the status of the calling program block when the instruction is programmed in a network within the called program block:

RLO	Return value	ENO of the calling program block
1	RLO	1
	TRUE	1
	FALSE	0
	<Operand> Boolean tag with possible memory areas I, Q, M, D, L, T, and C	<Operand>
0	RLO	The program execution is continued in the next network of the called program block.
	TRUE	
	FALSE	
	<Operand>	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. Program execution is ended in the called program block and continues in the calling program block. The enable output ENO of the calling program block is reset to signal state "0".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Runtime control (S7-1200, S7-1500)

ENDIS_PW: Limit and enable password legitimation (S7-1200, S7-1500)

Description

You use the "Limit and enable password legitimation" instruction to specify whether configured passwords may be legitimated or not for the CPU. You can prevent legitimated connections, even when the correct password is known.

When you call the command and the REQ parameter has the signal state "0", only the currently set state is displayed at the output parameters. If changes are made to the input parameters, these changes are not transferred to the output parameters.

When the instruction is called and the REQ parameter has the signal state "1", the signal state is taken from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD).

- If signal state "0" is present, authorization via password is not allowed.
- If signal state "1" is present, the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited, except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Non-configured passwords must have the TRUE signal state at the input and return the TRUE signal state at the output. The fail-safe password can only be configured for an F-CPU and, therefore, must always be interconnected with theTRUE signal state in a standard CPU. If the instruction return an error, the call remains without effect, i.e. the previous lock remains in force.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.
- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".
- Set the operating mode switch to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Inserting an empty memory card (transfer card or program card) into S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access to the HMI system, if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing accidental lockout out with an S7-1500 CPU

The same setting can be made on the front panel of the S7-1500 CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode selector to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing accidental lockout with an S7-1200 CPU

The protection for POWER OFF - POWER ON is disabled because a S7-1200 CPU has no operating mode switch. As a result it is possible and advisable to use certain program sequences within your program to prevent an accidental lockout.

To do this, program a time control using either a cyclic interrupt OB or a timer in the main OB (OB 1). This provides you with the option to call the "Limit and enable password legitimation" instruction again without delay in the corresponding OB (e.g. OB 1 or OB 35) after a transition from POWER OFF - POWER ON. Call the instruction in the startup OB (OB 100) in order to keep as short as possible the time window in which the application is not active and thus ensure that no restrictions exist in the password legitimation. This procedure offers you the largest possible protection against unauthorized access.

If an unintended lockout occurs you can skip the call in the startup OB (for example, by querying an input parameter) and have the set time (for example 10 seconds to 1 minute), to establish a connection to the CPU before the lock becomes active again.

If you have set no timer in your program code and are locked out, insert an empty transfer card or empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then load the user program again from STEP 7 in the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

WARNING

Inserting empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

After you remove the transfer card the content of the transfer card is in the internal load memory. Make sure at this point that the card contains no program.

WARNING

Inserting empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. The internal load memory is empty after the removal of the formerly empty program card.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200-CPU: the lock is disabled and the instruction must be called again in the program (in the startup OB, for example). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Parameters

The following table shows the parameters of the "Limit and enable password legitimation" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password
FULL_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password

Parameters	Declaration	Data type	Memory area	Description
R_PWD	Input	BOOL	I, Q, M, D, L or constant	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password
HMI_PWD	Input	BOOL	I, Q, M, D, L or constant	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
RET_VAL	Output	WORD	I, Q, M, D, L	Error information

You can find additional information on valid data types under "See also".

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. With standard CPUs, the signal state must be TRUE.
80D1	The read/write access is not configured

Error code* (W#16#...)	Explanation
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

PC systems (S7-1200, S7-1500)

SHUT_DOWN: Shut down target system (S7-1200, S7-1500)

Description

You can use the instruction "SHUT_DOWN: Shutdown target system" to shut down the PC-based automation system and restart the S7 software controller CPU 150xS or Windows on the PC-based automation system.

The instruction is available in the "Instructions" task card under Basic instructions > Program control > Runtime control.

A restart is, for example, advisable in the following situations:

- An industrial UPS (uninterruptible power supply) reports a power failure via a digital input.
- Windows stops responding or shows a "blue screen".
- Too many error OBs are called in the user program.

Parameter

The following table shows the parameters of the "Shutdown target system" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	MODE = 1: Shut down CPU 150xS and Windows The CPU goes to STOP and saves the retentive data. Then the CPU and Windows are shut down. The system must be restarted manually. MODE = 2: Restart CPU 150xS The CPU goes to STOP and saves the retentive data. Then the CPU is shut down and restarted. MODE = 3: Restart Windows The CPU remains in RUN. Windows is restarted (as of TIA Portal V14, MODE 3 is only retained for backward compatibility. We recommend using MODE 4 or MODE 5). MODE = 4: Windows is shut down and restarted correctly. The CPU remains in RUN. MODE = 5: Restart Windows (Comparable with MODE 3; Exception: MODE 5 should only be used if Windows has crashed).
COM-MENT	Input	STRING	I, Q, M, D, L	With Mode = 1, 3 and 4, you can specify a reason for the restart. The reason is output in the Windows Event Log.
Ret_Val	Return	WORD	Q, M, D, L	Ret_Val = 0: No faults Ret_Val = 8090: The value passed to MODE is not supported. Ret_Val = 8091: Windows does not respond to the call of the Shut_Down instruction (only valid for Mode 3 and 4). Ret_Val = 8092: Please contact SIMATIC Customer Support if this error occurs (only valid for Mode 3 and 4).

RE_TRIGR: Restart cycle monitoring time (S7-1200, S7-1500)

Description

The "Restart cycle monitoring time" instruction is used to restart the cycle monitoring time of the CPU. The cycle monitoring time then restarts with the time you have set in the CPU configuration.

If the instruction is called in a block with a higher priority, such as a hardware interrupt or diagnostic error interrupt, the instruction is not executed and the enable output ENO returns signal state "0".

The instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Calling the instruction

The following call conditions apply:

- The following applies to a CPU of the S7-1200 series:
  In firmware versions <= 2.2, you can call the instruction only in a program cycle organization block of priority 1. This corresponds to the lowest priority of all organization blocks. If the instruction is called in an organization block with a higher priority, the instruction is not executed and the result (BR bit, enable output ENO) is always "0".
  In firmware versions >= 2.2, you can call the instruction regardless of the priority in all organization blocks.
- The following applies to a CPU of the S7-1500 series:
  You can call the instruction regardless of the priority in all organization blocks.

Parameters

The instruction "Restart cycle monitoring time" has no parameters.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

STP: Exit program (S7-1200, S7-1500)

Description

You use the "Exit program" instruction to set the CPU to STOP mode and thus end the program execution. The effects at a transition from RUN to STOP depend on the CPU configuration.

When the result of logic operation (RLO) at the input of the instruction is "1", the CPU changes to STOP mode and the program execution is ended. The signal state at the output of the instruction is not evaluated.

When the RLO is "0" at the input of the instruction, then the instruction will not be executed.

Parameters

The "Exit program" instruction has no parameters.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

GET_ERROR: Get error locally (S7-1200, S7-1500)

Description

The "Get error locally" instruction is used to query the occurrence of errors within a program block. This normally involves programming or access errors. If the system reports an error during the execution of the program block, detailed information is stored in the operand at the ERROR output for the first error to occur during the execution of the block since the last execution of the instruction.

Only operands of the "ErrorStruct" system data type can be specified at the ERROR output. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the program block, the error information about the next error to occur is output by the instruction only after the first error that occurred has been remedied.

Note

Output ERROR

The ERROR output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO is only set if the enable input EN returns signal state "1" and error information is present. If one of these conditions does not apply, then the remaining program execution is not affected by the instruction.

Note

Activation of the local error handling

As soon as you insert the instruction in the program code of a program block, the local error handling is activated and default system reactions are ignored when errors occur.

Options for error handling

You can find an overview of the options for error handling here: AUTOHOTSPOT

For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the "Get error locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ERROR	Output	ErrorStruct	D, L	Error information

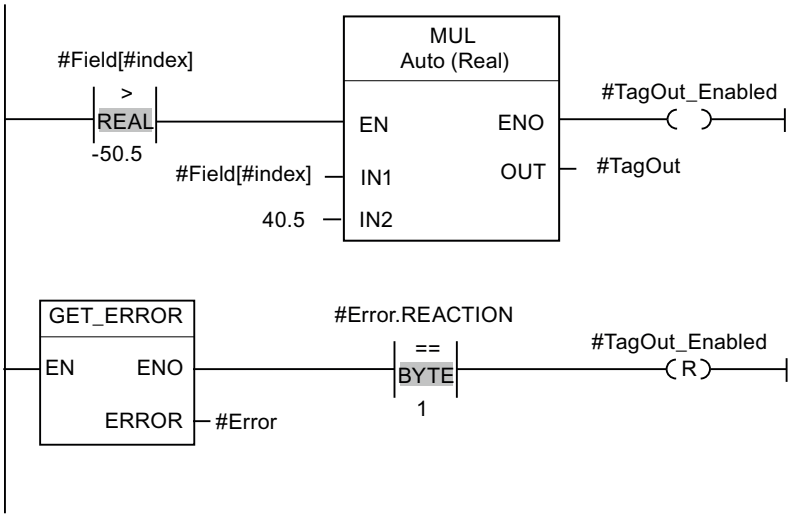
Data type "ErrorStruct"

The "ErrorStruct" data type can be inserted in a global data block or in the block interface. You can insert the data type more then once if you assign a different name for the data structure each time. The data structure and the name of individual structure elements cannot be changed. If you save the error information in a global data block, it can also be read out by other program blocks.

The following table shows the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows whether the error occurred during a program block call. 16#01: Error during a program block call 16#00: No error during a program block call
REACTION		BYTE	Default reaction: 0: Ignore (write error) 1: Continue with substitute value "0" (read error) 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of the program block
	BLOCK_TYPE	BYTE	Program block type in which the error occurred: 1: Organization block (OB) 2: Function (FC) 3: Function block (FB)
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40...16#7F, 16#86, 16#87, 16#8E, 16#8F, 16#C0...16#FF I: 16#81 Q: 16#82 M: 16#83 DB: 16#40, 16#84, 16#85, 16#8A, 16#8B PI: 16#01 PQ: 16#02 Technological objects: 16#04

Structure component		Data type	Description
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand



Structure component "ERROR_ID"

The following table shows the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2577	9591	The block property "Parameter passing via registers" is not selected.
2576	9590	Error in the local data distribution
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".		

Example

The following example shows how the instruction works:

An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error locally" instruction is evaluated with the comparison instruction "Equal". If the "#Error.REACTION" structure component has the value "1", this involves a read/access error and the #TagOut_Enabled output is reset.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

GET_ERR_ID: Get error ID locally (S7-1200, S7-1500)

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the error ID of the first error that occurred in the tag is stored at the ID output.

Only operands of the WORD data type can be specified at the ID output. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ID output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error ID locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Options for error handling

You can find an overview of the options for error handling here: AUTOHOTSPOT

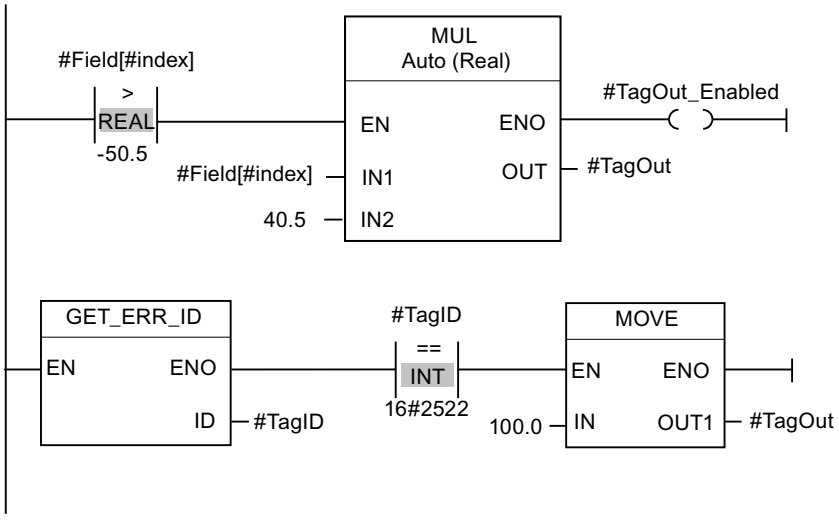
For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the "Get error ID locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ID	Output	WORD	I, Q, M, D, L	Error ID

Parameter ID



The following table shows the values that can be output at the ID parameter:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING

ID* (hexadecimal)	ID* (decimal)	Description
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".		

Example

The following example shows how the instruction works:

An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error ID locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error ID locally" instruction is evaluated with the comparison instruction "Equal". If the #TagID operand returns the ID 2522, this involves a read/access error and the value "100.0" is written to the #TagOut output.

INIT_RD: Initialize all retain data (S7-1500)

Description

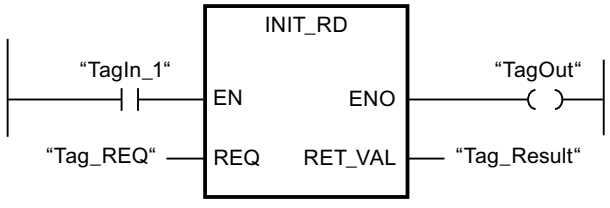
You can use the "Initialize all retain data" instruction to reset the retain data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution would exceed the program cycle duration.

Parameters

The following table shows the parameters of the "Initialize all retain data" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	If the input "REQ" has the signal state "1", all retain data are reset.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

You can find additional information on valid data types under "See also".



Parameters RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "Tag_REQ" have signal state "1", the instruction is executed. The retain data of all data blocks, bit memories and SIMATIC timers and counters are reset If the instruction is executed without errors, the ENO enable output has the signal state "1".

Basic information on LAD (Page 4878)

WAIT: Configure time delay (S7-1500)

Description

The "Configure time delay" instruction pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to +32767 microseconds (µs). The smallest possible delay time depends on the CPU and corresponds to the execution time of the instruction.

The execution of the instruction can be interrupted by higher priority events and does not return any error information.

Note

Negative delay time

If you specify a negative delay time at parameter WT, the enable output ENO, or the RLO and the BR bit, will return the signal state FALSE. A negative delay time does not affect the CPU. The following instructions linked to enable output ENO are not executed in LAD or FBD.

Parameters

The following table shows the parameters of the "Configure time delay" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
WT	Input	INT	I, Q, M, D, L, P, or constant	Time delay in microseconds (µs)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

RUNTIME: Measure program runtime (S7-1200, S7-1500)

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and write the value to the IN-OUT parameter MEM. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

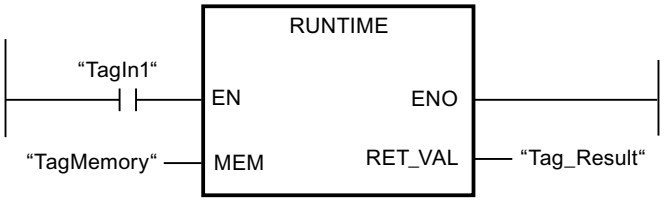
If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the IN-OUT parameter MEM as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The "Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overruns, the instruction returns values <= 0.0. This can occur up to once per minute for S7-1200 CPUs with firmware version <V4.2. Ignore these runtime values.

Note

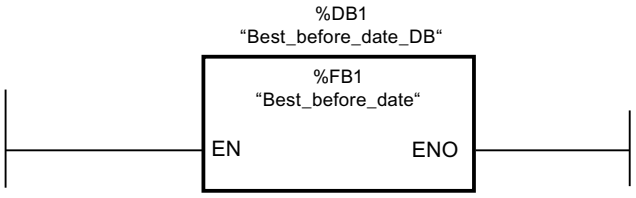
The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Parameter



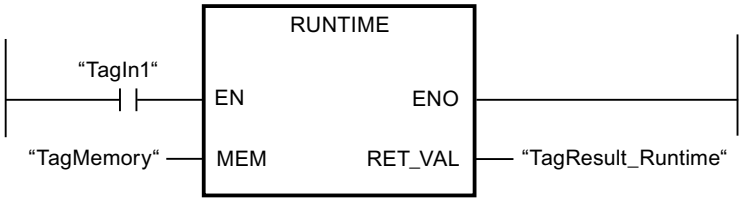
The following table lists the parameters of the "Measure program runtime" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MEM	InOut	LREAL	I, Q, M, D, L	The content is for internal purposes only.
RET_VAL	Output	LREAL	I, Q, M, D, L	Returns the measured runtime in seconds



Example

The following example shows how the instruction works based on the runtime calculation of a program block:



Network 1:

Network 2:

Network 3:

When the "TagIn1" operand in network 1 has the signal state "1", the instruction is executed. The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called in network 2.

When the FB1 program block has been executed and the "TagIn1" operand has the signal state "1", the instruction in network 3 is executed. The second call of the instruction calculates the runtime of the program block and writes the result to the output RET_VAL.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

You can find a more detailed example of how you can measure the total cycle time of a program in the Siemens Industry Online Support under the following entry ID: 87668055 (https://support.industry.siemens.com/cs/ww/en/view/87668055)

Basic information on LAD (Page 4878)

Word logic operations (S7-1200, S7-1500)

AND: AND logic operation (S7-1200, S7-1500)

Description

You can use the "AND logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by AND logic and query the result at the OUT output.

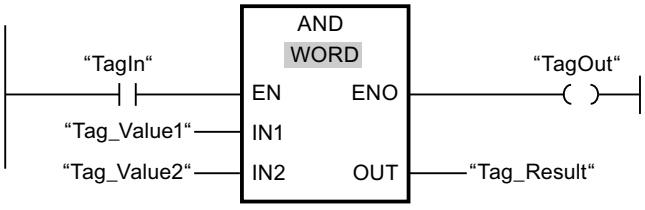
When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are logically ANDed. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified values.

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with AND logic (ANDed). The result is stored in the OUT output.

The result bit has signal state "1" only when both of the bits in the logic operation also have signal state "1". If one of the two bits of the logic operation has signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "AND logic operation" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0000 0000 0000 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are ANDed. The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

OR: OR logic operation (S7-1200, S7-1500)

Description

You can use the "OR logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by OR logic and query the result at the OUT output.

When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are combined by OR logic operation. The result is stored in bit 0 of output OUT. The same logic operation is executed for all bits of the specified tags.

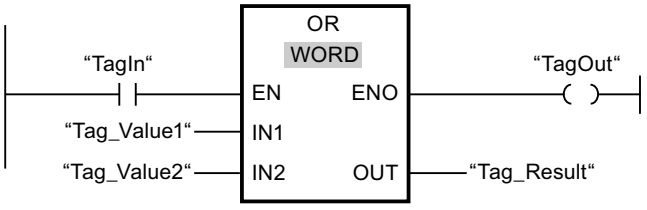
The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with OR logic (ORed). The result is stored in the OUT output.

The result bit has signal state "1" when at least one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "OR logic operation" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation



Parameter	Declaration	Data type	Memory area	Description
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are ORed. The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

XOR: EXCLUSIVE OR logic operation (S7-1200, S7-1500)

Description

You can use the "EXCLUSIVE OR logic operation" instruction to combine the value at the IN1 input and the value at the IN2 input bit-by-bit by EXCLUSIVE OR logic and query the result at the OUT output.

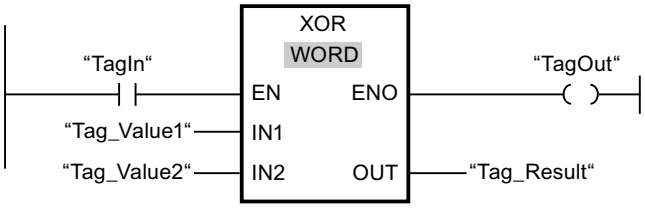
When the instruction is executed, bit 0 of the value at the IN1 input and bit 0 of the value at the IN2 input are combined by EXCLUSIVE OR logic operation. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified value.

The number of inputs can be expanded in the instruction box. The added inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are combined with EXCLUSIVE OR logic. The result is stored in the OUT output.

The result bit has signal state "1" when one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "1" or "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the "EXCLUSIVE OR logic operation" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P, or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P, or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P, or constant	Other inputs whose values are logically combined.
OUT	Output	Bit strings	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1010

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" and the value of operand "Tag_Value2" are combined by EXCLUSIVE OR logic.

The result is mapped bit-for-bit and output in operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

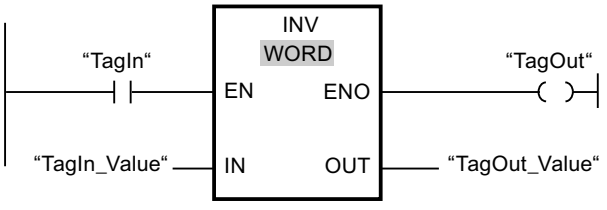
INVERT: Create ones complement (S7-1200, S7-1500)

Description

You can use the instruction "Create ones complement" to invert the signal status of the bits at input IN. When the instruction is processed, the value at input IN is linked to EXCLUSIVE OR by a hexadecimal mask (W#16#FFFF for 16-bit numbers or DW#16#FFFF FFFF for 32-bit number). This inverts the signal state of the individual bits that are then stored at output OUT.

Parameters

The following table shows the parameters of the instruction "Create ones complement":



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Bit strings, integers	I, Q, M, D, L, P	Ones complement of the value at input IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
IN	TagIn_Value	W#16#000F	W#16#7E
OUT	TagOut_Value	W#16#FFF0	W#16#81

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction inverts the signal state of the individual bits at input "TagIn_Value" and writes the result to output "TagOut_Value". The enable output ENO and the output "TagOut" are set to signal state "1".

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

DECO: Decode (S7-1200, S7-1500)

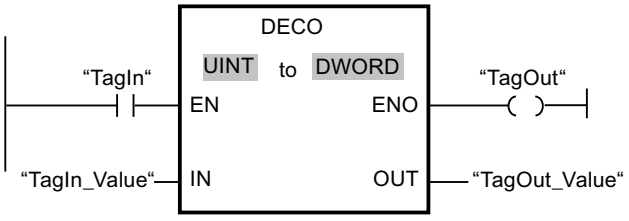
Description

You can use the "Decode" instruction to set a bit in the output value that is specified by the input value.

The "Decode" instruction reads the value at the IN input and sets the bit in the output value whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. When the value at the IN input is greater than 31, a modulo 32 instruction is executed.

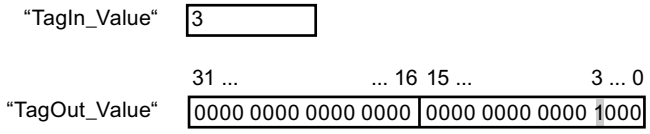
Parameters

The following table shows the parameters of the "Decode" instruction:



Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	UINT	I, Q, M, D, L, P, or constant	Position of the bit in the output value which is set.
OUT	Output	Bit strings	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following figure shows how the instruction works using specific operand values:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction reads bit number "3" from the value of the operand "TagIn_Value" at the input and sets the third bit to the value of the operand "TagOut_Value" at the output.

If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

ENCO: Encode (S7-1200, S7-1500)

Description

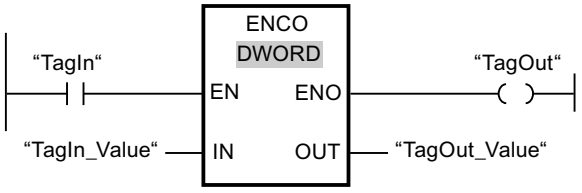
You can use the "Encode" instruction to read the bit number of the least significant bit in the input value and to send it to the OUT output.

The "Encode" instruction selects the least significant bit of the value at the IN input and writes its bit number to the tag in the OUT output.

Parameters

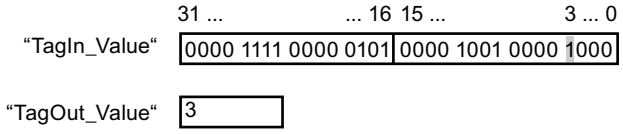
The following table shows the parameters of the "Encode" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output



Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P, or constant	Input value
OUT	Output	INT	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following figure shows how the instruction works using specific operand values:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction selects the least significant bit at the "TagIn_Value" input and writes bit position "3" to the tag in the "TagOut_Value" output.

If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

SEL: Select (S7-1200, S7-1500)

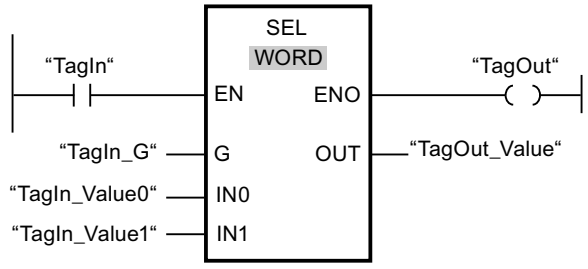
Description

Depending on a switch (G input), the "Select" instruction selects one of the inputs, IN0 or IN1 and copies its content to the OUT output. When the input G has signal state "0", the value at the input IN0 is moved. When the input G has signal state "1", the value at the input IN1 is moved to the output OUT.

All tags at all parameters must have the same data type.

Parameters

The following table shows the parameters of the "Select" instruction:



Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
G	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Switch
IN0	Input	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	First input value
IN1	Input	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Second input value
OUT	Output	Bit strings, integers, floating-point numbers, timers, TOD, CHAR, WCHAR, DATE	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, LDT, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
G	TagIn_G	0	1
IN0	TagIn_Value0	W#16#0000	W#16#4C
IN1	TagIn_Value1	W#16#FFFF	W#16#5E
OUT	TagOut_Value	W#16#0000	W#16#5E

If the "TagIn" operand has signal state "1", the instruction is executed. Based on the signal state at the "TagIn_G" input, the value at the "TagIn_Value0" or "TagIn_Value1" input is selected and moved to the "TagOut_Value" output. If the instruction is executed without errors, the enable output ENO has signal state "1" and the output "TagOut" is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

MUX: Multiplex (S7-1200, S7-1500)

Description

You can use the instruction "Multiplex" to copy the content of a selected input to output OUT. The number of selectable inputs of the instruction box can be expanded. You can declare a maximum of 32 inputs.

The inputs are numbered automatically in the box. Numbering starts at IN0 and is incremented continuously with each new input. You can use the K parameter to define the input whose content is to be copied to the OUT output. If the value of the parameter K is greater than the number of available inputs, the content of the ELSE parameter is copied to the OUT output and the ENO enable output is assigned the signal state "0".

The "Multiplex" instruction can only be executed if the tags have the same data type in all inputs and in the OUT output. The K parameter is an exception, since only integers can be specified for it.

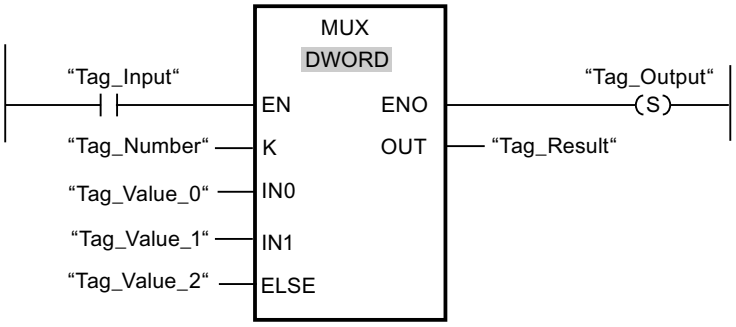
Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The input at the K parameter is located outside the available inputs. This applies regardless of whether the ELSE input is used. The value at the OUT output remains changed.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the "Multiplex" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	Specifies the input whose content is to be copied. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Second input value



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
INn	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Optional input values
ELSE	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Specifies the value to be copied when K > n.
OUT	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Output to which the value is to be copied.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
K	Tag_Number	1
IN0	Tag_Value_0	DW#16#00000000
IN1	Tag_Value_1	DW#16#003E4A7D
ELSE	Tag_Value_2	DW#16#FFFF0000
OUT	Tag_Result	DW#16#003E4A7D

If the "Tag_Input" operand has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "Tag_Value_1" is copied and assigned to the operand at output "Tag_Result". If the instruction is executed without errors, the "ENO" and "Tag_Output" enable outputs are set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

DEMUX: Demultiplex (S7-1200, S7-1500)

Description

You can use the instruction "Demultiplex" to copy the content of the input IN to a selected output. The number of selectable outputs can be extended in the instruction box. The outputs are numbered automatically in the box. Numbering starts at OUT0 and continues consecutively with each new output. You can use the K parameter to define the output to which the content of the IN input is to be copied. The other outputs are not changed. If the value of the parameter K is greater than the number of available outputs, then the content of input IN is copied to the parameter ELSE and the enable output ENO is assigned the signal state "0".

The instruction "Demultiplex" can only be executed if the tags at the input IN and at all outputs are of the same data type. The K parameter is an exception, since only integers can be specified for it.

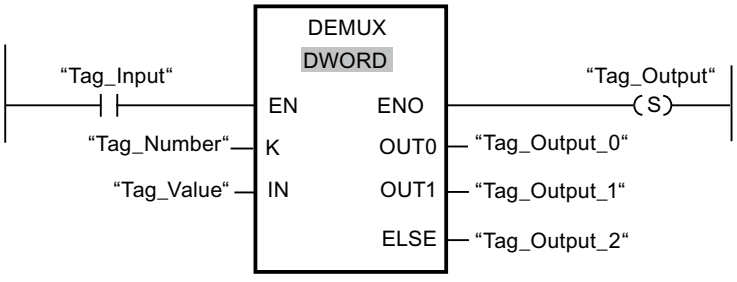
The enable output ENO is reset if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the instruction "Demultiplex":

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	Specifies the output to which the input value (IN) is copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	First output



Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Second output
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Optional outputs
ELSE	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	Output to which the input value (IN) at K > n is copied.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:

The following tables show how the instruction works using specific operand values:

Table 11-14 Input values of the "Demultiplex" instruction before network execution

Parameter	Operand	Values	
K	Tag_Number	1	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Table 11-15 Output values of the "Demultiplex" instruction after network execution

Parameter	Operand	Values	
OUT0	Tag_Output_0	Unchanged	Unchanged
OUT1	Tag_Output_1	DW#16#FFFFFFFF	Unchanged
ELSE	Tag_Output_2	Unchanged	DW#16#003E4A7D

If the "Tag_Input" has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "IN" is copied to the corresponding output.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

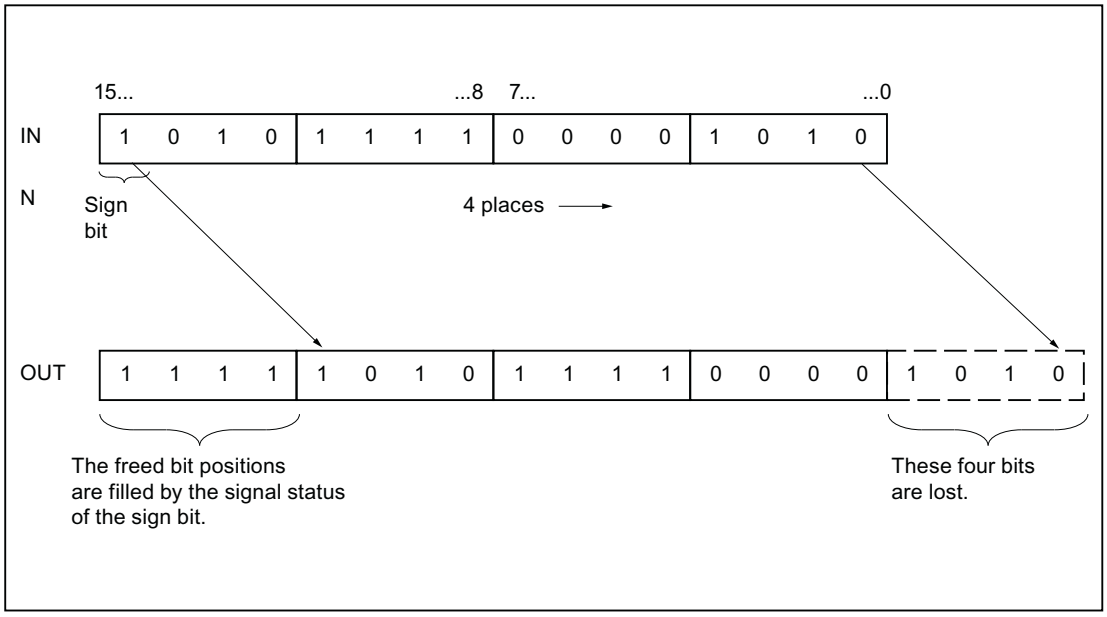
Shift and rotate (S7-1200, S7-1500)

SHR: Shift right (S7-1200, S7-1500)

Description



You can use the "Shift right" instruction to shift the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be shifted.

If the value at the parameter N is "0", the value at input IN is copied to the operand at output OUT.

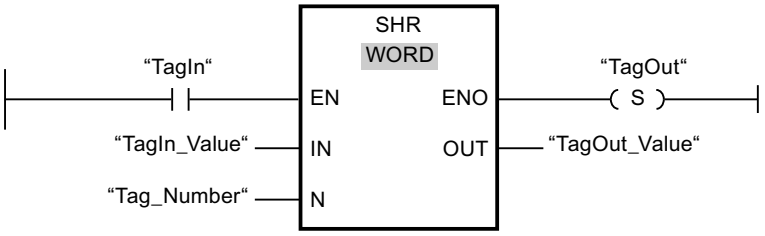
If the value at the parameter N is greater than the number of bit positions, the operand value at input IN is shifted to the right by the available number of bit positions.

The freed bit positions in the left area of the operand are filled by zeroes when values without signs are shifted. If the specified value has a sign, the free bit positions are filled with the signal state of the sign bit.

The following figure show how the content of an operand of integer data type is shifted four bit positions to the right:

Parameters

The following table shows the parameters of the "Shift right" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	3
OUT	TagOut_Value	0000 0111 1111 0101

If operand "TagIn" has the signal state "1", the "Shift right" instruction is executed. The content of operand "TagIn_Value" is shifted three bit positions to the right. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

Overview of the valid data types (Page 2239)

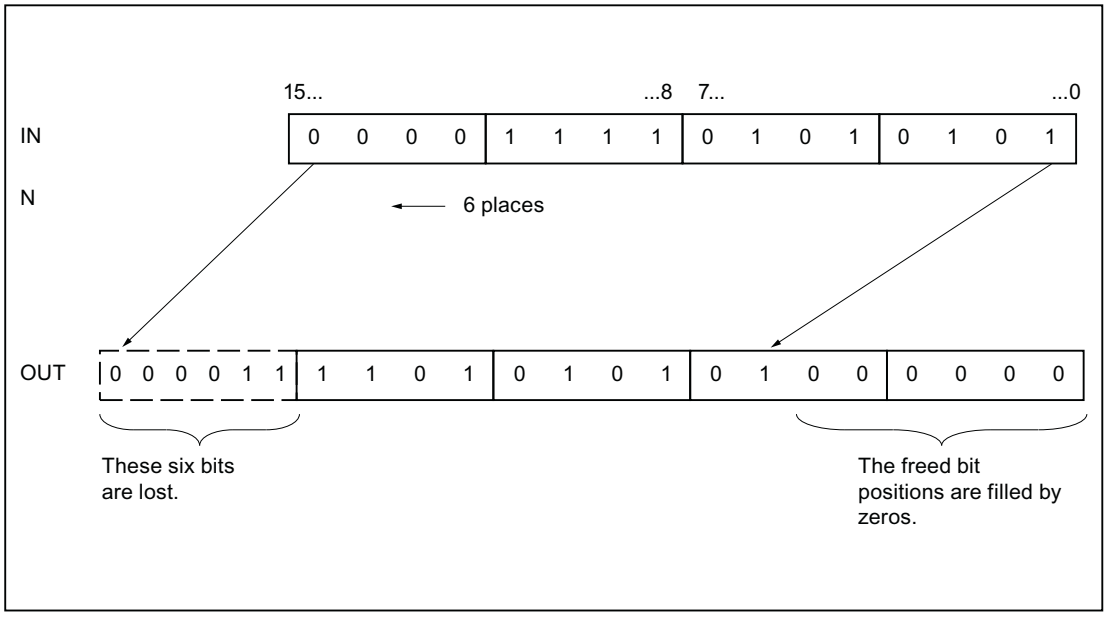
SHL: Shift left (S7-1200, S7-1500)

Description



You can use the "Shift left" instruction to shift the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be shifted.

If the value at the parameter N is "0", the value at input IN is copied to the operand at output OUT.

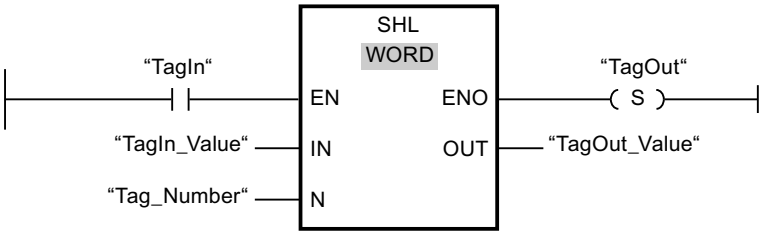
If the value at the parameter N is greater than the number of bit positions, the operand value at input IN is shifted to the right by the available number of bit positions.

The bit positions in the right part of the operand freed by shifting are filled with zeros.

The following figure shows how the content of an operand of the WORD data type is shifted by six bit positions to the left:

Parameters

The following table shows the parameters of the "Shift left" instruction:



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	4
OUT	TagOut_Value	1111 1010 1111 0000

If operand "TagIn" has the signal state "1", the "Shift left" instruction is executed. The content of operand "TagIn_Value" is shifted four bit positions to the left. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

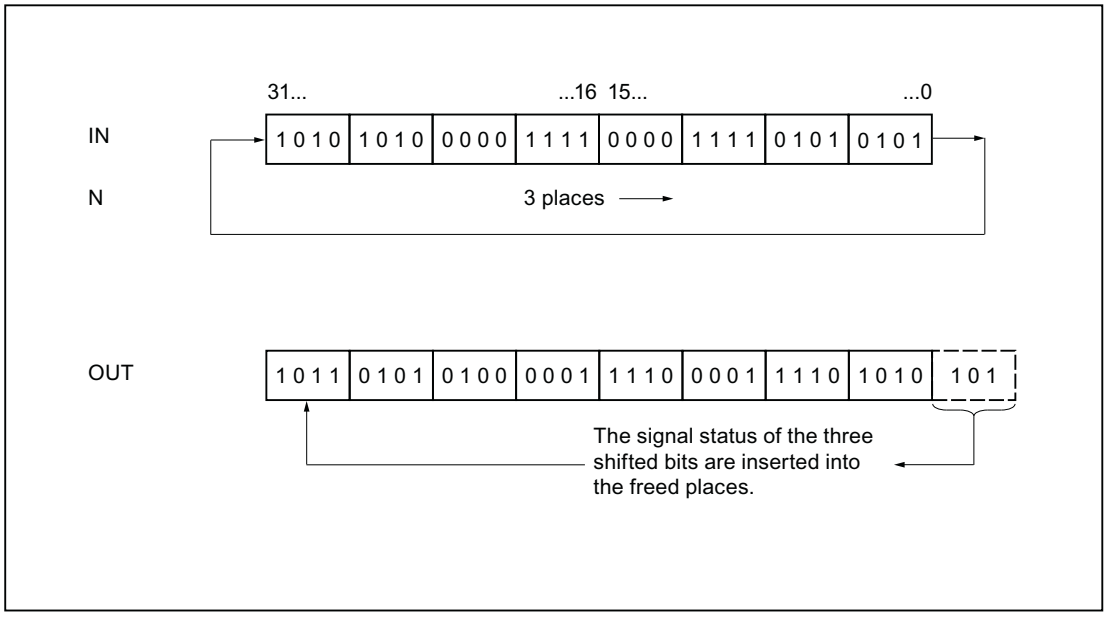
ROR: Rotate right (S7-1200, S7-1500)



Description

You can use the "Rotate right" instruction to rotate the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

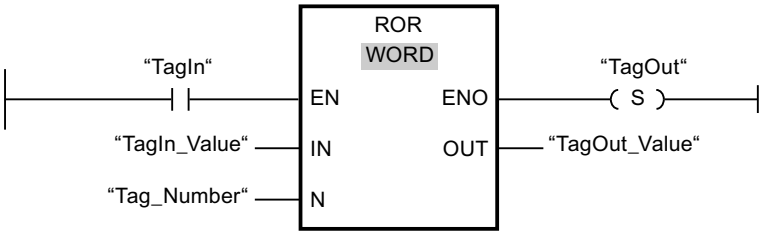
If the value at the parameter N is "0", the value at input IN is copied to the operand at output OUT.

If the value at the parameter N is greater than the number of available bit positions, the operand value at input IN is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of DWORD data type is rotated three positions to the right:

Parameters

The following table shows the parameters of the instruction "Rotate right":



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 1001 0101
N	Tag_Number	5
OUT	TagOut_Value	1010 1000 0111 1100

If operand "TagIn" has the signal state "1", the "Rotate right" instruction is executed. The content of operand "TagIn_Value" is rotated five bit positions to the right. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

See also

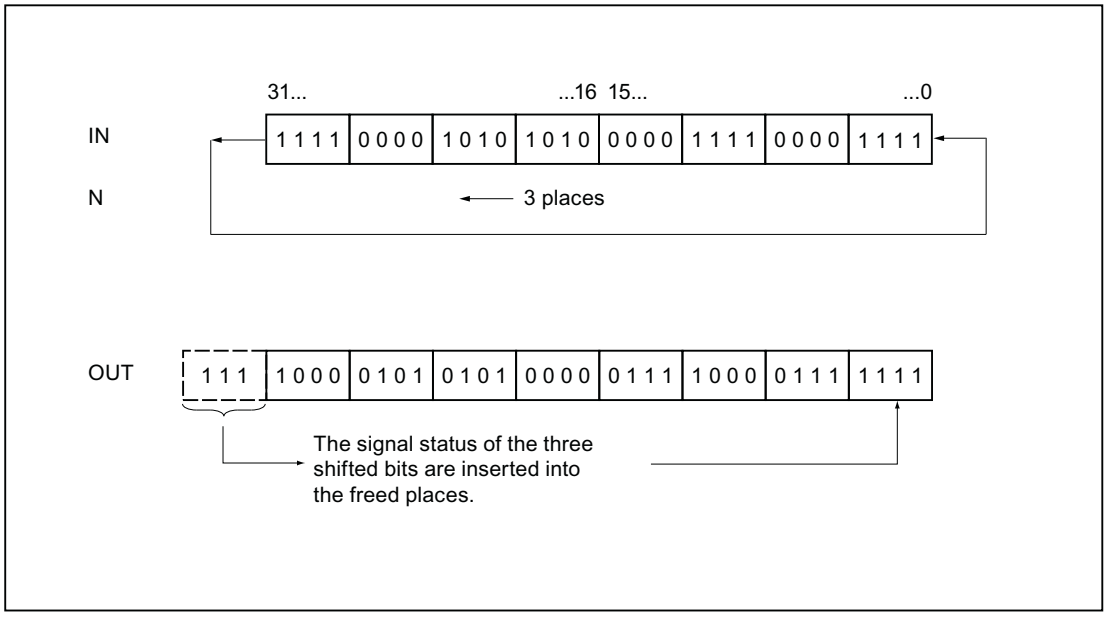
ROL: Rotate left (S7-1200, S7-1500)



Description

You can use the "Rotate left" instruction to rotate the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. You use the N parameter to specify the number of bit positions by which the specified value is to be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

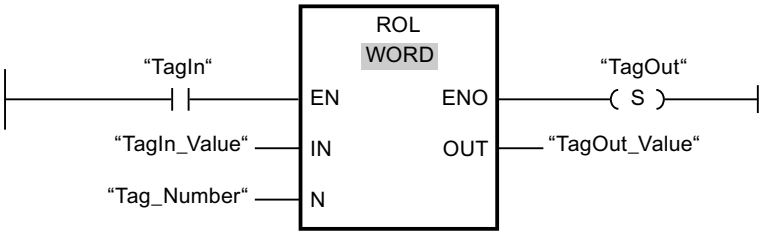
If the value at the parameter N is "0", the value at input IN is copied to the operand at output OUT.

If the value at the parameter N is greater than the number of available bit positions, the operand value at input IN is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of DWORD data type is rotated three positions to the left:

Parameters

The following table shows the parameters of the instruction "Rotate left":



Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	1010 1000 1111 0110
N	Tag_Number	5
OUT	TagOut_Value	0001 1110 1101 0101

If input "TagIn" has the signal state "1", the instruction "Rotate left" is executed. The content of operand "TagIn_Value" is rotated five bit positions to the left. The result is sent to the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has signal state "1" and the "TagOut" output is set.

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

Basic information on LAD (Page 4878)

Legacy (S7-1500)

DRUM: Implement sequencer (S7-1500)

Description

You can use the "Implement sequencer" instruction to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset when the signal state of the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the

current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a timer value, an event, or both. Steps that have an event bit and the timer value "0" advance to the next step as soon as the signal state of the event bit is "1". Steps that are programmed only with a timer value start the time immediately. Steps that are programmed with an event bit and a timer value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the parameter Q is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK) you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). When a bit of the configurable mask has a signal state of "1", the OUT_VAL value sets/resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit at the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit at the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

Parameters

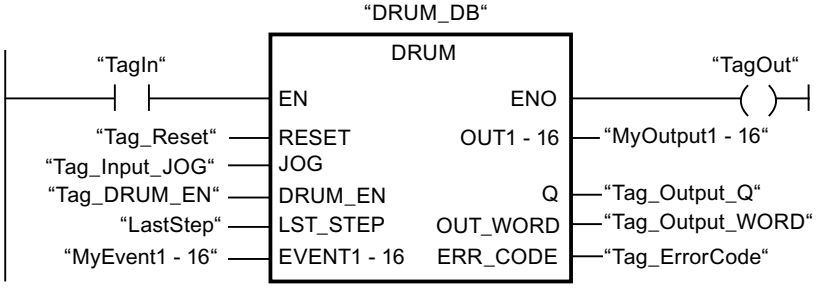
The following table shows the parameters of the "Implement sequencer" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
RESET	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates a reset condition.
JOG	Input	BOOL	I, Q, M, D, L or constant	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" allows the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L or constant	Maximum step number (for example: LST_STEP = 16#08; a maximum of 8 steps is possible.)
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L or constant	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.

Parameter	Declaration	Data type	Memory area	Description
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P or constant	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P or constant	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P or constant	Current numerical value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P or constant	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L or constant	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L or constant	Preset counter value for each step [1 to 16] where one clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:



ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value of the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value of the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameter	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001
DCC	DBD16	DW#16#0000000A

Parameter	Address	Value
DTBP	DBW20	W#16#0001
S_PRESET[1]	DBW26	W#16#0064
S_PRESET[2]	DBW28	W#16#00C8
OUT_VAL[1,0]	DBX58.0	TRUE
OUT_VAL[1,1]	DBX58.1	TRUE
OUT_VAL[1,2]	DBX58.2	TRUE
OUT_VAL[1,3]	DBX58.3	TRUE
OUT_VAL[1,4]	DBX58.4	TRUE
OUT_VAL[1,5]	DBX58.5	TRUE
OUT_VAL[1,6]	DBX58.6	TRUE
OUT_VAL[1,7]	DBX58.7	TRUE
OUT_VAL[1,8]	DBX59.0	TRUE
OUT_VAL[1,9]	DBX59.1	TRUE
OUT_VAL[1,10]	DBX59.2	TRUE
OUT_VAL[1,11]	DBX59.3	TRUE
OUT_VAL[1,12]	DBX59.4	TRUE
OUT_VAL[1,13]	DBX59.5	TRUE
OUT_VAL[1,14]	DBX59.6	TRUE
OUT_VAL[1,15]	DBX59.7	TRUE
OUT_VAL[2,0]	DBX60.0	FALSE
OUT_VAL[2,1]	DBX60.1	FALSE
OUT_VAL[2,2]	DBX60.2	FALSE
OUT_VAL[2,3]	DBX60.3	FALSE
OUT_VAL[2,4]	DBX60.4	FALSE
OUT_VAL[2,5]	DBX60.5	FALSE
OUT_VAL[2,6]	DBX60.6	FALSE
OUT_VAL[2,7]	DBX60.7	FALSE
OUT_VAL[2,8]	DBX61.0	FALSE
OUT_VAL[2,9]	DBX61.1	FALSE
OUT_VAL[2,10]	DBX61.2	FALSE
OUT_VAL[2,11]	DBX61.3	FALSE
OUT_VAL[2,12]	DBX61.4	FALSE
OUT_VAL[2,13]	DBX61.5	FALSE
OUT_VAL[2,14]	DBX61.6	FALSE
OUT_VAL[2,15]	DBX61.7	FALSE
S_MASK[2,0]	DBX92.0	FALSE
S_MASK[2,1]	DBX92.1	TRUE
S_MASK[2,2]	DBX92.2	TRUE
S_MASK[2,3]	DBX92.3	TRUE
S_MASK[2,4]	DBX92.4	TRUE
S_MASK[2,5]	DBX92.5	FALSE
S_MASK[2,6]	DBX92.6	TRUE
S_MASK[2,7]	DBX92.7	TRUE

Parameter	Address	Value
S_MASK[2,8]	DBX93.0	FALSE
S_MASK[2,9]	DBX93.1	FALSE
S_MASK[2,10]	DBX93.2	TRUE
S_MASK[2,11]	DBX93.3	TRUE
S_MASK[2,12]	DBX93.4	TRUE
S_MASK[2,13]	DBX93.5	TRUE
S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameter	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE

Parameter	Operand	Address	Value
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

DCAT: Discrete control-timer alarm (S7-1500)

Description

You can use the "Discrete control-timer alarm" to count the time from the point at which the CMD parameter issues the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state of the command input changes before the preset time, the time is restarted.

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

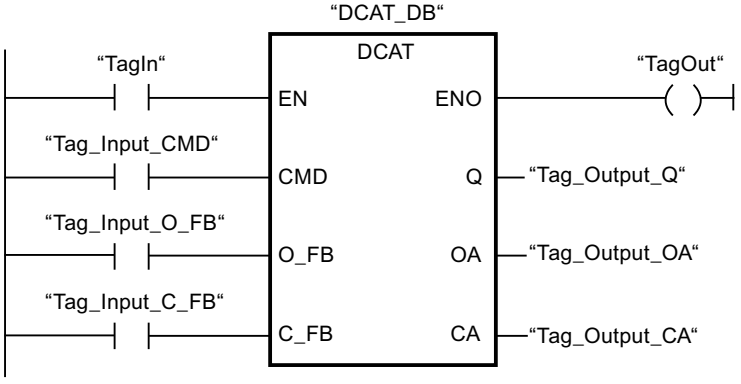
- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET is < PT) OA and CA are influenced as follows:
  - The parameters Q and CMD_HIS are set to "1".
  - The parameters ET, OA and CA are reset to "0".
- When the signal state of the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".
- When the signal state of the parameters CMD and CMD_HIS is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the ET parameter exceeds the value of the PT parameter, the signal state at the OA parameter is set to "1". If the value of the ET parameter does not exceed the value of the PT parameter, the signal state of the OA parameter is reset to "0". The value at the parameter CMD_HIS is reset to the value of the parameter CMD.
- If the signal state of the CMD, CMD_HIS and O_FB parameters are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the O_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters CMD, CMD_HIS and C_FB have the value "0", the time difference (ms) since the last execution of the instruction is added to the value of the parameter ET. If the value of the ET parameter exceeds the value of the PT parameter, the signal state of the parameter CA is reset to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the C_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction has no error information.

Parameters

The following table shows the parameters of the "Discrete control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
CMD	Input	BOOL	I, Q, M, D, L or constant	A signal state of "0" indicates a "close" command. A signal state of "1" indicates an "open" command.



Parameter	Declaration	Data type	Memory area	Description
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L or constant	Currently elapsed time, where one clock pulse = 1 ms
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
CMD_HIS	Static	BOOL	D, L or constant	CMD history bit

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The CMD_HIS parameter of the instance data block is set to the signal state "1" and the ET parameter is reset to "0".

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE

Parameter	Operand	Value
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

MCAT: Motor control-timer alarm (S7-1500)

Description

The "Motor control-timer alarm" instruction is used to accumulate the time from the point at which one of the command inputs (opening or closing) is switched on. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

Parameters

The following table shows the parameters of the "Motor control-timer alarm" instruction:

Parameters	Declaration	Data type	Memory space	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
O_CMD	Input	BOOL	I, Q, M, D, L or constant	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L or constant	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L or constant	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	A signal state of "0" indicates an error condition.
ET	Static	DINT	D, L or constant	Currently elapsed time, where one count = 1 ms
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
O_HIS	Static	BOOL	D, L or constant	"Open" history bit
C_HIS	Static	BOOL	D, L or constant	"Close" history bit

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the "Motor control-timer alarm" instruction to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	Status
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened

Input parameters								Output parameters								
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped

Legend:	
INC	Add the time difference (ms) since the last processing of the FB to ET
PT	PT is set to the same value as ET
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT

If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to signal state "0". In this case, the last row in the table (X) mentioned above is valid. Because it is therefore no longer possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case:

OO = FALSE

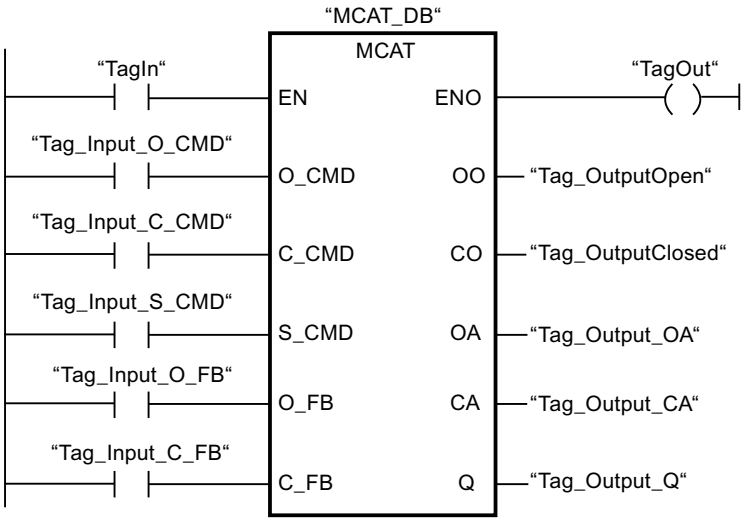
CO = FALSE

OA = FALSE

CA = FALSE

ET = PT

Q = TRUE



The "Motor control-timer alarm" instruction returns no error information.

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE

Parameter	Operand	Value
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Basic information on LAD (Page 4878)

IMC: Compare input bits with the bits of a mask (S7-1500)

Description

You can use the "Compare input bits with the bits of a mask" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. In the CMP_STEP parameter, you specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise, the OUT parameter is set to "0".

If the value of the CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

Parameters

The following table shows the parameters of the "Compare input bits with the bits of a mask" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P or constant	The step number of the mask used for the comparison.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

Overview of the valid data types (Page 2239)

SMC: Compare scan matrix (S7-1500)

Description

You can use the "Compare scan matrix" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bit of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written in the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value at the LAST parameter.

Parameters

The following table shows the parameters of the "Compare scan matrix" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. The signal state "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask or the step number which is greater by "1" than the value of the LAST parameter, provided no match is found.
LAST	Static	BYTE	I, Q, M, D, L, P or constant	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

Basic information on LAD (Page 4878)

LEAD_LAG: Lead and lag algorithm (S7-1500)

Description

You can use the "Lead and lag algorithm" instruction to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the instruction "Lead and lag algorithm" is calculated using the following equation:

$$OUT = \left[\frac{LG_TIME}{LG_TIME + SAMPLE_T}\right] PREV_OUT + GAIN \left[\frac{LD_TIME + SAMPLE_T}{LG_TIME + SAMPLE_T}\right] IN - GAIN \left[\frac{LD_TIME}{LG_TIME + SAMPLE_T}\right] * PREV_IN$$

The "Lead and lag algorithm" instruction supplies plausible results only when processing is in fixed program cycles. The same units must be specified for the LD_TIME, LG_TIME, and SAMPLE_T parameters. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output on the ERR_CODE parameter.

You can use the instruction "Lead and lag algorithm" in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The "Lead" operation shifts the phase of the OUT output so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two operations together (Lead and Lag) result in the output phase lagging behind the the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

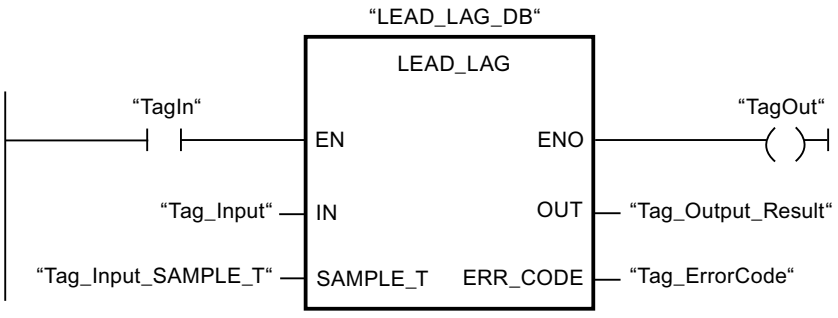
Parameters

The following table shows the parameters of the "Lead and lag algorithm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	The input value of the current sample time (cycle time) to be processed. Constants can also be specified on the IN parameter.
SAMPLE_T	Input	INT	I, Q, M, D, L, P or constant	Sample time Constants can also be specified on the SAMPLE_T parameter.
OUT	Output	REAL	I, Q, M, D, L	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L	Error information
LD_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lag time in in the same unit as sample time.
GAIN	Static	REAL	I, Q, M, D, L, P or constant	Gain as % / % (the ratio of the change in output to a change in input as a steady state).
PREV_IN	Static	REAL	I, Q, M, D, L, P or constant	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P or constant	Previous output

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:



Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input parameters:

Parameter	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_InputSampleTime	10

The following values are saved in the "LEAD_LAG_DB" instance data block of the instruction:

Parameter	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameter	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

For more information and the program code to the above named example, refer to: Sample Library for Instructions (Page 2568)

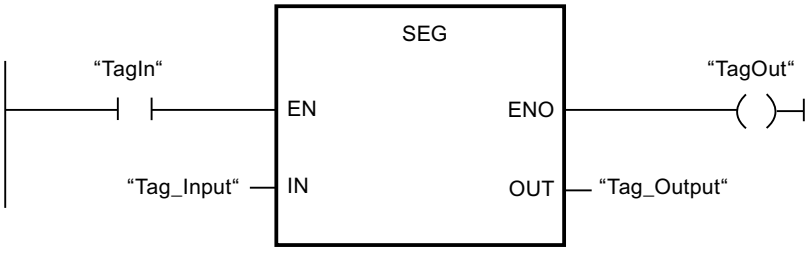
SEG: Create bit pattern for seven-segment display (S7-1500)

Description

The instruction "Create bit pattern for seven-segment display" is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a seven-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	Assignment of the segments - g f e d c b a	Display (Hexadecimal)	Seven-segment display
0000	00111111	0	
0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	



Parameter

The following table shows the parameters of the "Create bit pattern for seven-segment display" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD	I, Q, M, D, L, P, or constant	Source word with four hexadecimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Value	
Hexadecimal	Binary		
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW#16065B4F66	000 00110 0101 1011 0100 1111 0110 0110 Display: 1234

BCDCPL: Create tens complement (S7-1500)

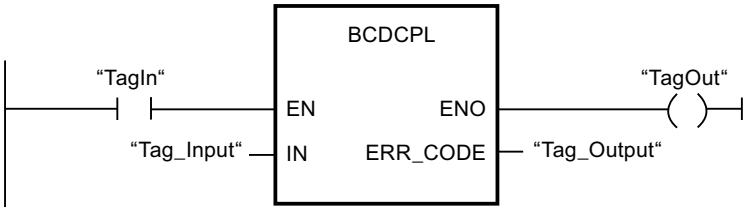
Description

You can use the "Create tens complement" instruction to create the tens complement of a seven-digit BCD number specified in the IN parameter. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)



Parameters

The following table shows the parameters of the "Create tens complement" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Bit strings	I, Q, M, D, L, P, or constant	7-digit BCD number
ERR_CODE	Output	DWORD	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:

The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#01234567
ERR_CODE	Tag_Output	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

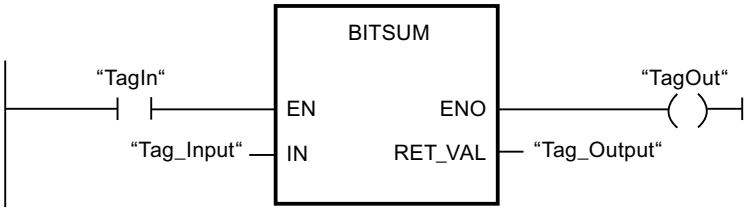
BITSUM: Count number of set bits (S7-1500)

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that is set to the signal state "1". The operand whose bits are to be counted is specified on the IN parameter. The result of the instruction is output on the RET_VAL parameter.



Parameters

The following table shows the parameters of the "Count number of set bits" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	DWORD	I, Q, M, D, L, P, or constant	Operand whose set bits are counted
RET_VAL	Output	INT	I, Q, M, D, L, P	Number of bits to be set

Example

The following example shows how the instruction works:

The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#12345678
RET_VAL	Tag_Output	W#16#000D (13 Bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

11.4.3.2 FBD (S7-1200, S7-1500)

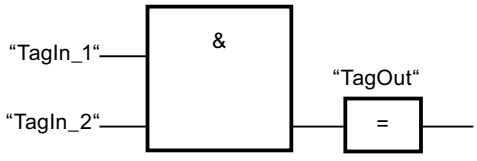
Bit logic operations (S7-1200, S7-1500)

&: AND logic operation (S7-1200, S7-1500)

Description

You can use the instruction "AND logic operation" to query the signal states of two or more specified operands and evaluate them according to the AND truth table.

If the signal state of all the operands is "1", then the condition is fulfilled and the instruction returns the result "1". If the signal state of one of the operands is "0", then the condition is not fulfilled and the instruction generates the result "0".



Parameters

The following table shows the parameters of the instruction "AND logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:

Output "TagOut" is set, when the signal state of the operands "TagIn_1" and "TagIn_2" is "1" and reset when the state of the operands "TagIn_1" and "TagIn_2" is "0".

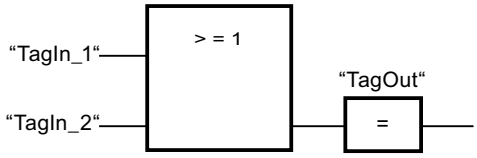
>=1: OR logic operation (S7-1200, S7-1500)

Description

You can use the instruction "OR logic operation" to query the signal states of two or more specified operands and evaluate them according to the OR truth table.

If the signal state of one of the operands is "1", then the condition is fulfilled and the instruction returns the result "1". If the signal state of all the operands is "0", then the condition is not fulfilled and the instruction generates the result "0".



Parameters

The following table shows the parameters of the instruction "OR logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:

Output "TagOut" is set, when the signal state of the operands "TagIn_1" or "TagIn_2" is "1".

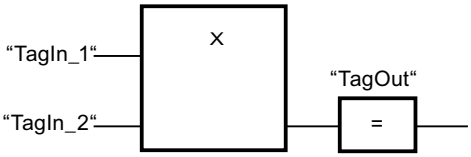
X: EXCLUSIVE OR logic operation (S7-1200, S7-1500)

Description

You can use the "EXCLUSIVE OR logic operation" instruction to query the result of a signal state query according to the EXCLUSIVE OR truth table.

With an "EXCLUSIVE OR logic operation" instruction, the signal state is "1" when the signal state of one of the two specified operands is "1". When more than two operands are queried, the common RLO is "1" if an odd number of the queried operands returns the result "1".



Parameters

The following table shows the parameters of the instruction "EXCLUSIVE OR logic operation":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:

Output "TagOut" is set when the signal state of the operands "TagIn_1" and "TagIn_2" is "1". When both operands return the signal state "1" or "0", the output "TagOut" is reset.

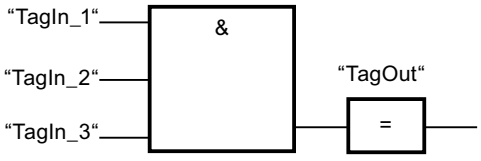
Insert input (S7-1200, S7-1500)

Description

The "Insert input" instruction is used to add an input to the box of one of the following instructions:

- "AND logic operation"
- "OR logic operation"
- "EXCLUSIVE OR logic operation"

You can query the signal state of several operands by the extension of an instruction box.



Parameters

The following table shows the parameters of the "Insert input" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	The operand indicates the bit whose signal state will be queried.

Example

The following example shows how the instruction works:

The box of the "AND logic operation" instruction was extended by an additional input at which the signal state of the operand "TagIn_3" is queried. The "TagOut" output is set, when the operands "TagIn_1" and "TagIn_2" and "TagIn_3" return signal state "1".

Invert RLO (S7-1200, S7-1500)

Description

You use the "Invert RLO" instruction to invert the signal state of the result of logic operation (RLO).

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The input "TagIn_1" and/or "TagIn_2" has signal state "0".
- The input "TagIn_3" and/or "TagIn_4" has signal state "0" or the input "TagIn_5" has signal state "1".

Editing FBD elements (Page 4964)

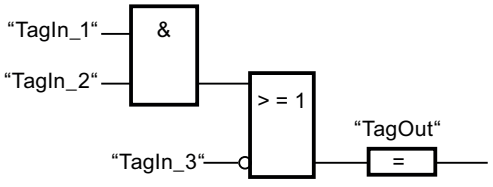
Inserting operands in FBD instructions (Page 4970)

=: Assignment (S7-1200, S7-1500)

Description

You can use the instruction "Assignment" to set the bit of a specified operand. If the result of logic operation (RLO) at the box input has the signal state "1", the specified operand is set to signal state "1". If the signal state at the box input is "0", the bit of the specified operand is reset to "0".

The instruction does not influence the RLO. The RLO at the box input is assigned directly to the operand above the assignment box.



Parameters

The following table shows the parameters of the instruction "Assignment":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the RLO is assigned.

Example

The following example shows how the instruction works:

The operand "TagOut" is set at the output of the "Assignment" instruction when one of the following conditions is fulfilled:

- The inputs "TagIn_1" and "TagIn_2" have the signal state "1".
- The signal state at the input "TagIn_3" is "0".

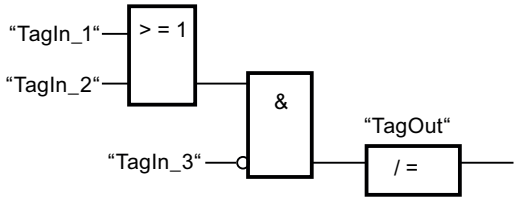
/=: Negate assignment (S7-1200, S7-1500)

Description

The instruction "Negate assignment" inverts the result of logic operation (RLO) and assigns this to the operand above the box. If the RLO at the input of the box is "1", the binary operand is reset. If the RLO at the input of the box is "0", the operand is set to signal state "1".



Parameters

The following table shows the parameters of the instruction "Negate assignment":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand to which the negated RLO is assigned.

Example

The following example shows how the instruction works:

The operand "TagOut" is reset when the following conditions are fulfilled:

- The operand "TagIn_1" or "TagIn_2" has the signal state "1".
- The operand "TagIn_3" has the signal state "0".

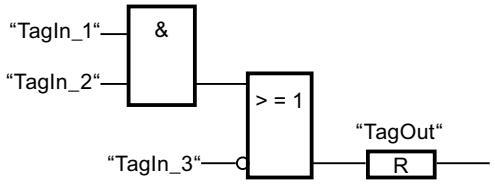
R: Reset output (S7-1200, S7-1500)

Description

You can use the "Reset output" instruction to reset the signal state of a specified operand to "0".

The instruction is only executed if the result of logic operation (RLO) at the box input is "1". If the box input has the signal state "1", the specified operand is reset to "0". If there is an RLO of "0" at the box input, the signal state of the specified operand remains unchanged.



Parameters

The following table shows the parameters of the "Reset output" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand>	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Operand that is reset if RLO = "1".

Example

The following example shows how the instruction works:

Operand "TagOut" is reset when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

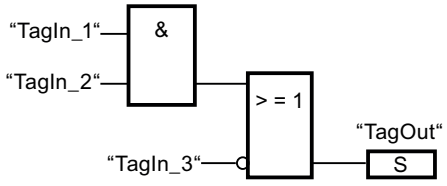
S: Set output (S7-1200, S7-1500)

Description

You can use the instruction "Set output" to set the signal state of a specified operand to "1".

The instruction is only executed if the result of logic operation (RLO) at the box input is "1". If the box input has the signal state "1", the specified operand is set to "1". If there is an RLO of "0" at the box input, the signal state of the specified operand remains unchanged.



Parameters

The following table shows the parameters of the instruction "Set output":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Output	BOOL	I, Q, M, D, L	Operand which is set with RLO = "1".

Example

The following example shows how the instruction works:

The "TagOut" operand is set when one of the following conditions is fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "0".

SET_BF: Set bit field (S7-1200, S7-1500)

Description

You use the "Set bit field" instruction to set several bits starting from a certain address.

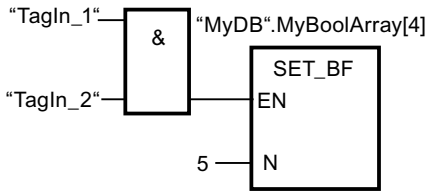
You specify the number of bits to be set with the value of the constant at the N input. The address of the first bit to be set is defined by <Operand>. If the value of <Operand> may not be greater than the number of bits in a selected byte. If this value is greater, the instruction is not executed and the error message "Range violation for index <Operand1>" is displayed. The bits remain set until they are explicitly reset by another instruction.

The instruction is only executed if the enable input EN has the signal state "1".

Bit fields of the type PLC data type, STRUCT or ARRAY

With structures of the type PLC data type, STRUCT or ARRAY, the number of bits contained in the structure represents the maximum number of bits that can be reset:

- If you specify the value "20" at the N input, for example, and the structure only contains 10 bits, then only these 10 bits are set.
- If you specify the value "5" at the N input, for example, and the structure contains 10 bits, then exactly 5 bits are set.



Parameters

The following table shows the parameters of the "Set bit field" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
N	Input	UINT	Constant	Constant	Number of bits to be set
<Operand>	Output	BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be set.

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are set starting at the address of the operand "MyDB".MyBoolArray[4].

RESET_BF: Reset bit field (S7-1200, S7-1500)

Description

You use the "Reset bit field" instruction to reset several bits starting from a certain address.

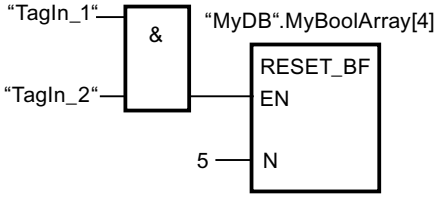
You specify the number of bits to be reset with the value of the constant at the N input. The address of the first bit to be reset is defined by <Operand>. If the value of the constant may not be greater than the number of bits in a selected byte. If this value is greater, the instruction is not executed and the error message "Range violation for index <Operand 1>" is displayed. The bits remain set until they are explicitly reset by another instruction.

The instruction is only executed if the enable input EN has the signal state "1".

Bit fields of the type PLC data type, STRUCT or ARRAY

With structures of the type PLC data type, STRUCT or ARRAY, the number of bits contained in the structure represents the maximum number of bits that can be set:

- If you specify the value "20" at the N input, for example, and the structure only contains 10 bits, then only these 10 bits are reset.
- If you specify the value "5" at the N input, for example and the structure contains 10 bits, then exactly 5 bits are reset.



Parameters

The following table shows the parameters of the "Reset bit field" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
N	Input	UINT	Constant	Constant	Number of bits to be reset
<Operand>	Output	BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	I, Q, M With a DB or an IDB, an element of an ARRAY[..] of BOOL	Pointer to the first bit to be reset.

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have the signal state "1", 5 bits are reset starting at the address of the operand "MyDB".MyBoolArray[4].

SR: Set/reset flip-flop (S7-1200, S7-1500)

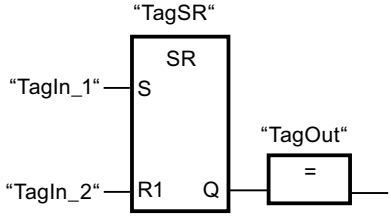
Description

You can use the "Set/reset flip-flop" instruction to set or reset the bit of a specified operand based on the signal state of the inputs S and R1. If the signal state is "1" at input S and "0" at input R1, the specified operand is set to "1". If the signal state is "0" at input S and "1" at input R1, the specified operand will be reset to "0".

Input R1 takes priority over input S. When the signal state is "1" on both inputs S and R1, the signal state of the specified operand is reset to "0".

The instruction is not executed if the signal state at the two inputs S and R1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.



Parameters

The following table shows the parameters of the "Set/reset flip-flop" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
S	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
R1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable resetting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is set or reset
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:

The operands "TagSR" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagSR" and "TagOut" are reset when one of the following conditions is fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

RS: Reset/set flip-flop (S7-1200, S7-1500)

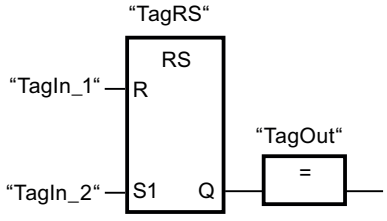
Description

You can use the "Reset/set flip-flop" instruction to reset or set the bit of a specified operand based on the signal state of the inputs R and S1. If the signal state is "1" at input R and "0" at input S1, the specified operand will be reset to "0". If the signal state is "0" at input R and "1" at input S1, the specified operand is set to "1".

Input S1 takes priority over input R. When the signal state is "1" at both inputs R and S1, the signal state of the specified operand is set to "1".

The instruction is not executed if the signal state at the two inputs R and S1 is "0". The signal state of the operand then remains unchanged.

The current signal state of the operand is transferred to output Q and can be queried there.



Parameters

The following table shows the parameters of the "Reset/set flip-flop" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
R	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable resetting
S1	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable setting
<Operand>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Operand that is reset or set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Signal state of the operand

Example

The following example shows how the instruction works:

The operands "TagRS" and "TagOut" are reset when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The operand "TagIn_2" has the signal state "0".

The operands "TagRS" and "TagOut" are set when the following conditions are fulfilled:

- The operand "TagIn_1" has signal state "0" and the operand "TagIn_2" has signal state "1".
- The operands "TagIn_1" and "TagIn_2" have signal state "1".

P: Scan operand for positive signal edge (S7-1200, S7-1500)

Description

You can use the "Scan operand for positive signal edge" instruction to determine whether there is a "0" to "1" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan, which is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "0" to "1", there is a positive, rising edge.

The following figure shows the change in the signal state in case of a negative and a positive signal edge:

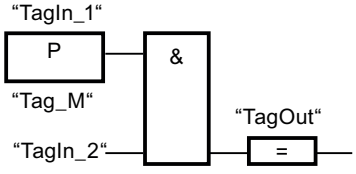
The positive signal edge is queried each time the instruction executes. When a positive signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the "Scan operand for positive signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous scan is saved.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- There is a rising edge at input "TagIn_1".
- The signal state of the operand "TagIn_2" is "1".

N: Scan operand for negative signal edge (S7-1200, S7-1500)

Description

You can use the "Scan operand for negative signal edge" instruction to determine whether there is a "1" to "0" change in the signal state of a specified operand (<Operand1>). The instruction compares the current signal state of <Operand1> with the signal state of the previous scan, which is saved in an edge memory bit (<Operand2>). If the instruction detects a change in the result of logic operation (RLO) from "1" to "0", there is a negative, falling edge.

The following figure shows the change in the signal state in case of a negative and a positive signal edge:

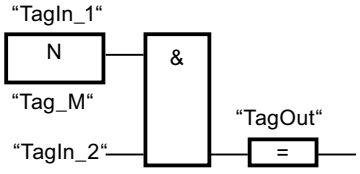
The negative signal edge is queried each time the instruction executes. When a negative signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

Specify the operand to be queried (<Operand1>) in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the "Scan operand for negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
<Operand1>	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Signal to be scanned
<Operand2>	InOut	BOOL	I, Q, M, D, L	I, Q, M, D, L	Edge memory bit in which the signal state of the previous scan is saved.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- There is a falling edge at input "TagIn_1".
- The signal state of the operand "TagIn_2" is "1".

P=: Set operand on positive signal edge (S7-1200, S7-1500)

Description

You can use the instruction "Set operand on positive signal edge" to set a specified operand (<Operand2>) when there is a "0" to "1" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand1>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

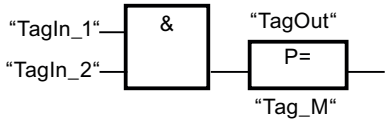
The positive signal edge is queried each time the instruction executes. When a positive edge is detected, <Operand2> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand2>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand1>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the instruction "Set operand on positive signal edge":

Parameters	Declaration	Data type	Memory area	Description
<Operand2>	Output	BOOL	I, Q, M, D, L	Operand which is set when there is a positive signal edge.
<Operand1>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows the parameters of the instruction:

The "TagOut" output is set for one program cycle, when the signal state at the input of the instruction box switches from "0" to "1" (positive signal edge). In all other cases, the "TagOut" output has signal state "0".

N=: Set operand on negative signal edge (S7-1200, S7-1500)

Description

You can use the instruction "Set operand on negative signal edge" to set a specified operand (<Operand1>) when there is a "1" to "0" change in the result of logic operation (RLO). The instruction compares the current RLO with the RLO from the previous query, which is saved in the edge memory bit (<Operand2>). If the instruction detects a change in the RLO from "1" to "0", there is a negative signal edge.

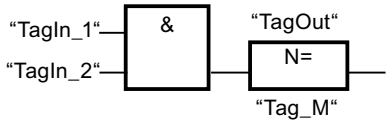
The negative signal edge is queried each time the instruction executes. When a negative signal edge is detected, <Operand1> is set to signal state "1" for one program cycle. In all other cases, the operand has the signal state "0".

You specify the operand (<Operand1>) to be set in the operand placeholder above the instruction. Specify the edge memory bit (<Operand2>) in the operand placeholder below the instruction.

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the instruction "Set operand on negative signal edge":

Parameters	Declaration	Data type	Memory area	Description
<Operand1>	Output	BOOL	I, Q, M, D, L	Operand which is set when there is a negative signal edge.
<Operand2>	InOut	BOOL	I, Q, M, D, L	Edge memory bit

Example

The following example shows how the instruction works:

The operand "TagOut" is set for one program cycle if the signal state at the input of the instruction box changes from "1" to "0" (negative signal edge). In all other cases, the operand "TagOut" has the signal state "0".

P_TRIG: Scan RLO for positive signal edge (S7-1200, S7-1500)

Description

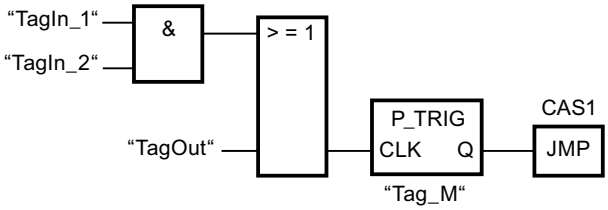
Use the instruction "Scan RLO for positive signal edge" to query a "0" to "1" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query, which is saved in an edge memory bit (<operand>). If the instruction detects a change in the RLO from "0" to "1", there is a positive signal edge.

The positive signal edge is queried each time the instruction executes. As soon as a positive single edge is detected, the output Q of the instruction returns the signal state "1" for the length of a program cycle. In all other cases, the output returns the signal state "0".

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the instruction "Scan RLO for positive signal edge":

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The RLO of the preceding bit logic operation is saved in the edge memory bit "Tag_M". If a "0" to "1" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

N_TRIG: Scan RLO for negative signal edge (S7-1200, S7-1500)

Description

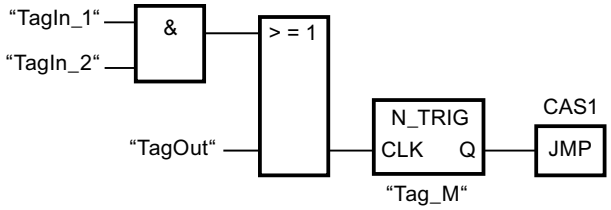
Use the instruction "Scan RLO for negative signal edge" to query a "1" to "0" change in the signal state of the result of logic operation (RLO). The instruction compares the current signal state of the RLO with the signal state of the previous query saved in the edge memory bit (<Operand>). If the instruction detects a change in the RLO from "1" to "0", there is a negative signal edge.

The negative signal edge is queried each time the instruction executes. As soon as a negative single edge is detected, the output Q of the instruction returns the signal state "1" for the length of a program cycle. In all other cases, the signal state at the output of the instruction is "0".

Note

Modification of the address of the edge memory bit

The address of the edge memory bit must not be used more than once in the program, otherwise the bit memory is overwritten. This would influence edge evaluation and the result would no longer be unequivocal. The memory area of the edge memory bit has to be located in a DB (static area for FB) or in the bit memory area.



Parameters

The following table shows the parameters of the "Scan RLO for negative signal edge" instruction:

Parameter	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Current RLO
<Operand>	InOut	BOOL	M, D	Edge memory bit in which the RLO of the previous query is saved.
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The RLO of the preceding bit logic operation is saved in the edge memory bit "Tag_M". If a "1" to "0" change is detected in the signal state of the RLO, the program jumps to jump label CAS1.

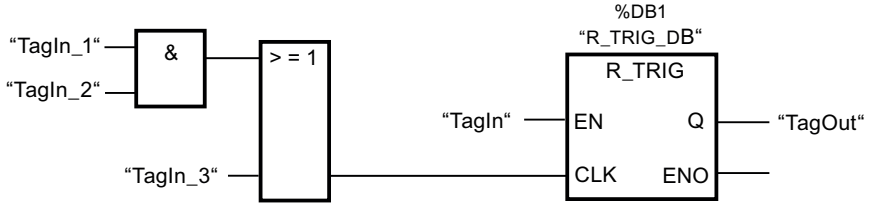
R_TRIG: Detect positive signal edge (S7-1200, S7-1500)

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".



Parameters

The following table shows the parameters of the "Detect positive signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change in the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

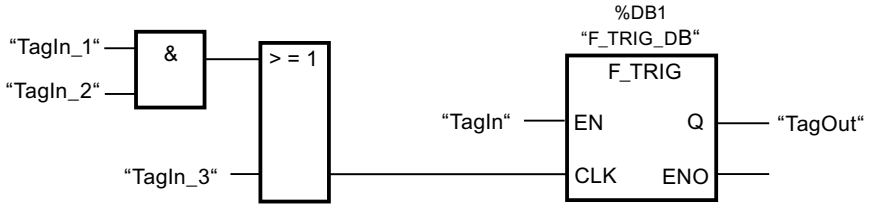
Inserting operands in FBD instructions (Page 4970)

F_TRIG: Detect negative signal edge (S7-1200, S7-1500)

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".



Parameters

The following table shows the parameters of the "Detect negative signal edge" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
CLK	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Incoming signal, the edge of which is to be queried.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

Inserting operands in FBD instructions (Page 4970)

Timer operations (S7-1200, S7-1500)

TP: Generate pulse (S7-1200, S7-1500)

Description

You can use the "Generate pulse" instruction to set the Q output for a programmed duration. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. Output Q is set for the duration PT, regardless of the subsequent course of the input signal. Even when a new positive signal edge is detected, the signal state of the Q output is not affected as long as the PT duration is running.

You can query the current time value at the ET output. The timer value starts at T#0s and ends when the value of the time duration PT is reached. If the configured time duration PT is reached and the signal state at input IN is "0", the ET output is reset.

Each call of the "Generate pulse" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

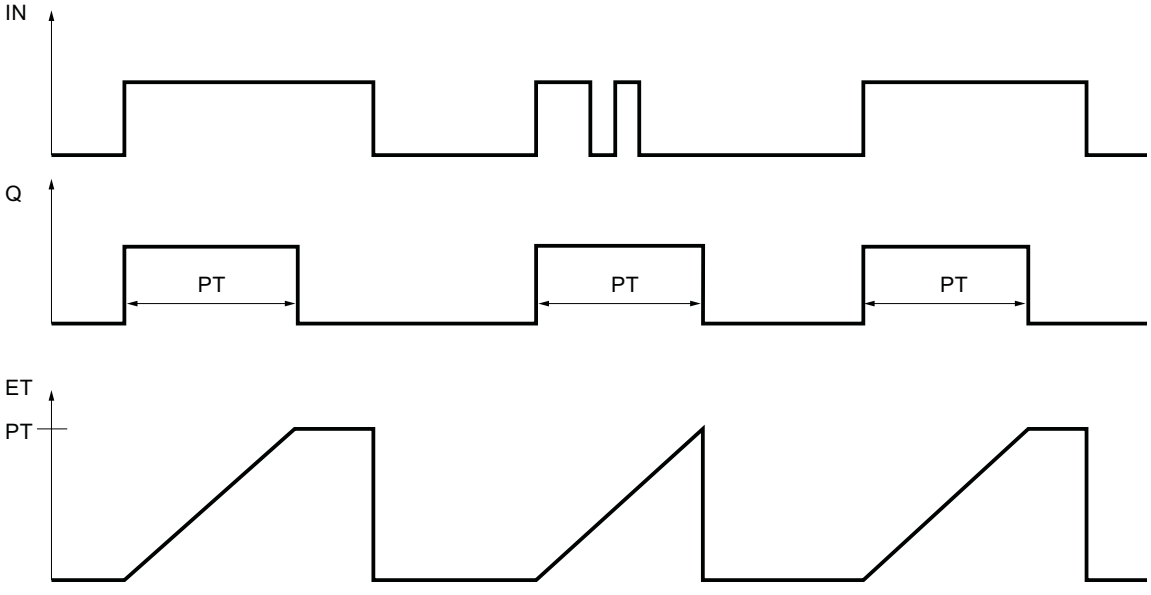
An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

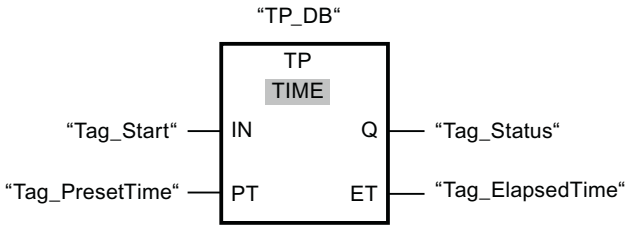
The execution of the "Generate pulse" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate pulse" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the pulse. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Pulse output
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current timer value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	TRUE
ET	Tag_ElapsedTime	from T#0s => T#10s

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started and the "Tag_Status" operand is set to "1". The current time value is stored in the "Tag_ElapsedTime" operand. When the time expires, the "Tag_Status" operand is reset to signal state "0".

TON: Generate on-delay (S7-1200, S7-1500)

Description

You can use the instruction "Generate on-delay" to delay setting of the Q output by the time configured with the PT time. The instruction is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the time PT has elapsed, the output Q has the signal state "1". Output Q remains set as long as the start input is still "1". When the signal state at the start input changes from "1" to "0", the Q output is reset. The timer function is started again when a new positive signal edge is detected at the start input.

The current time value can be queried at the output ET. The timer value starts at T#0s and ends when the value of the time duration PT is reached. The ET output is reset as soon as the signal state at the IN input changes to "0".

Each call of the "Generate on-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

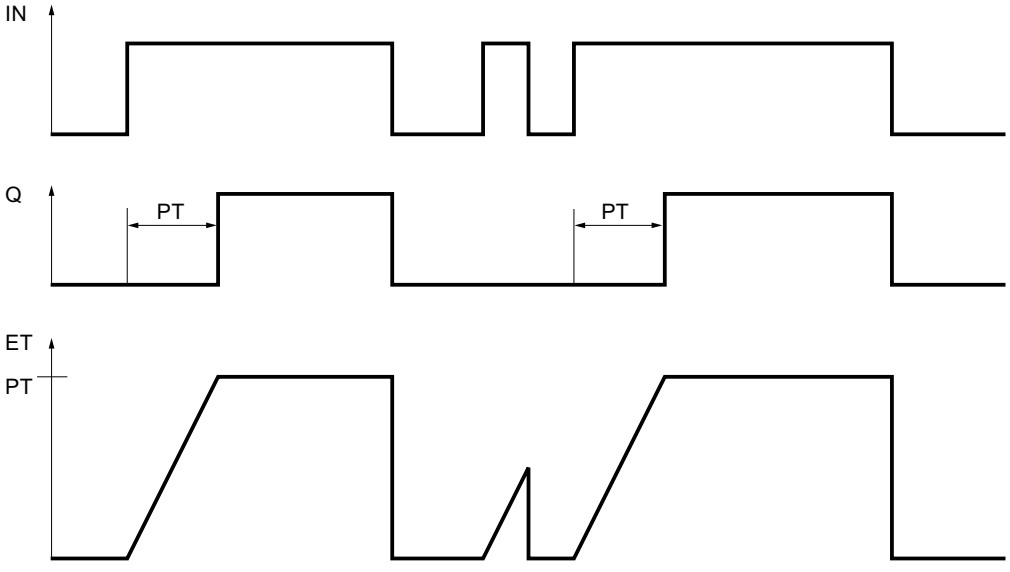
An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

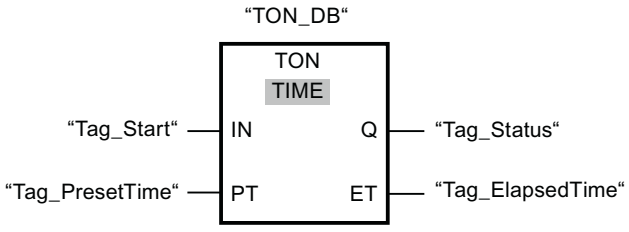
The execution of the "Generate on-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate on-delay" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the on delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current timer value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	FALSE; after 10 s => TRUE
ET	Tag_ElapsedTime	from T#0s => T#10s

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. When the time duration expires, the "Tag_Status" operand is set to the signal state "1". The Tag_Status operand remains set to "1" as long as the Tag_Start operand has signal state "1". The current time value is stored in the "Tag_ElapsedTime" operand. When the signal state at the operand "Tag_Start" changes from "1" to "0", the "Tag_Status" operand is reset.

TOF: Generate off-delay (S7-1200, S7-1500)

Description

You can use the "Generate off-delay" instruction to delay setting of the Q output by the time configured with the PT time. The output Q is set when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive signal edge). When the signal state at input IN changes back to "0" (positive signal edge), the configured time duration PT starts. Output Q remains set as long as the time duration PT is running. When the PT time duration expires, the Q output is reset. If the signal state at input IN changes to "1" before the PT time duration expires, the timer is reset. The signal state at the output Q continues to be "1".

The current time value can be queried at the output ET. The timer value starts at T#0s and ends when the value of the time duration PT is reached. When the PT time duration expires, the ET output remains set to the current value until input IN changes back to "1". If input IN changes to "1" before the time duration PT has expired, the ET output is reset to the value T#0s.

Each call of the "Generate off-delay" instruction must be assigned to an IEC Timer in which the instruction data is stored.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

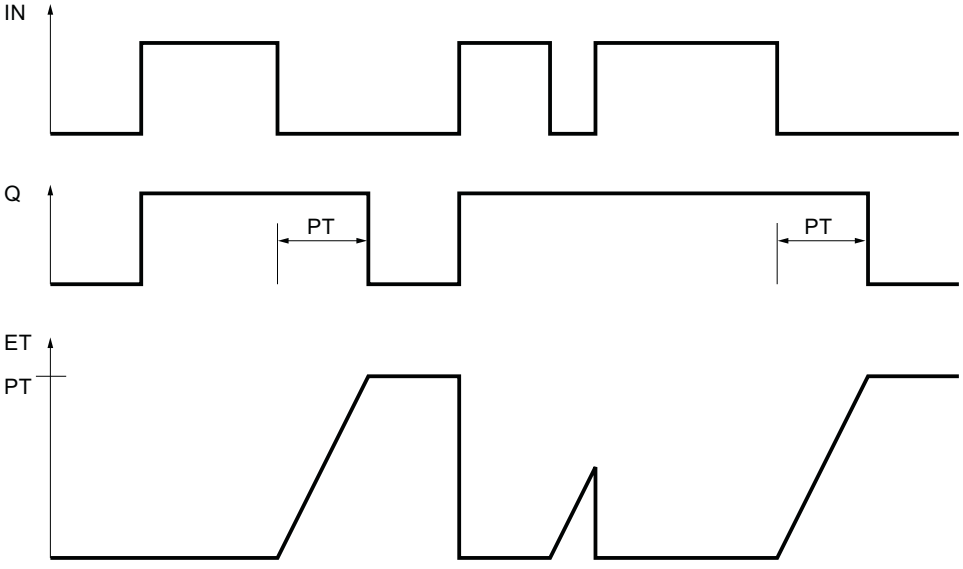
An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

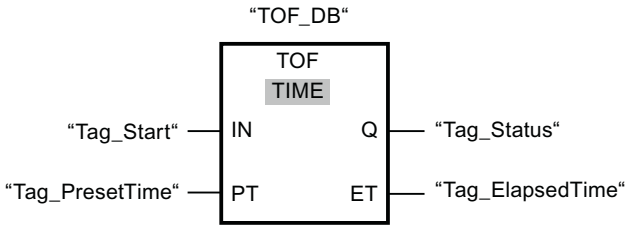
The execution of the "Generate off-delay" instruction requires a preceding logic operation. It can be placed within or at the end of the network.



Parameters

The following table shows the parameters of the "Generate off-delay" instruction:

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Duration of the off delay The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is reset when the timer PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current timer value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate off-delay" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"; signal transition "1" => "0"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	TRUE
ET	Tag_ElapsedTime	from T#10s => T#0s

When the signal state of the operand "Tag_Start" changes from "0" to "1", the "Tag_Status" operand is set to signal state "1". When the signal state of the "Tag_Start" operand changes from "1" to "0", the time programmed for the PT parameter is started. As long as the time is running, the "Tag_Status" operand remains set to TRUE. When the time has expired, the "Tag_Status" operand is reset to FALSE. The current time value is stored in the "Tag_ElapsedTime" operand.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

TONR: Time accumulator (S7-1200, S7-1500)

Description

The instruction "Time accumulator" is used to accumulate time values within a period set by the parameter PT. The instruction is executed and the configured time duration PT is started when the result of logic operation (RLO) at input IN changes from "0" to "1" (positive edge). While the time PT is running, the time values are accumulated that are recorded when the IN input has signal state "1". The accumulated time is written to the ET output and can be queried there. When the current time value PT is reached, the output Q has the signal state "1". Output Q remains set at "1", even when the signal state at input IN changes to "0".

The R input resets the outputs ET and Q regardless of the signal state at the start input.

Each call of the "Time accumulator" instruction must be assigned an IEC timer in which the instruction data is stored.

For S7-1200 CPU

An IEC Timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

An IEC timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

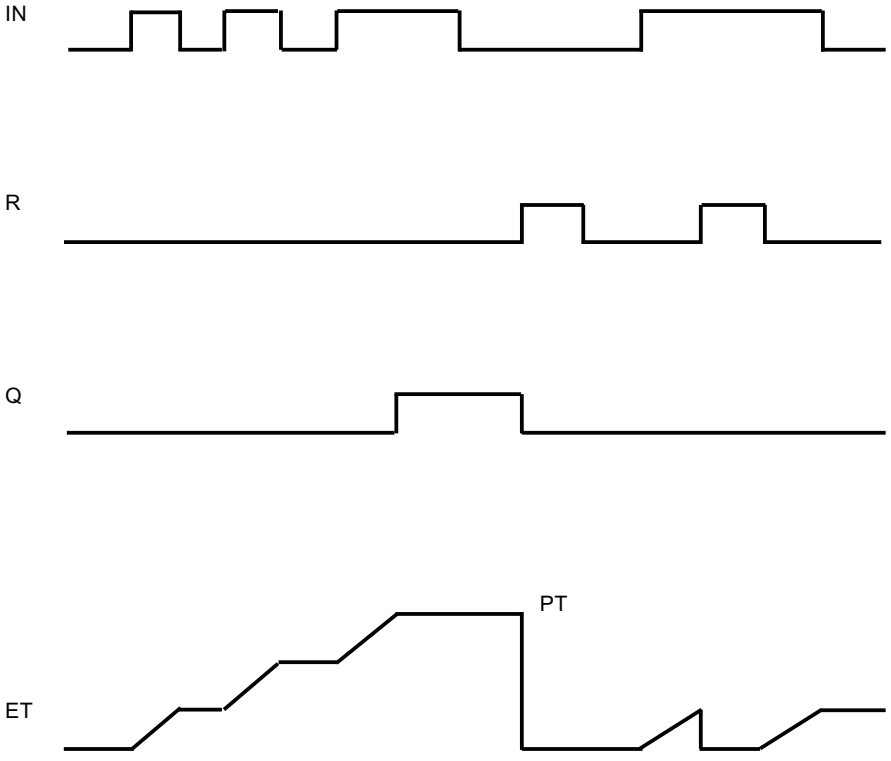
- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

The execution of the Time accumulator" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

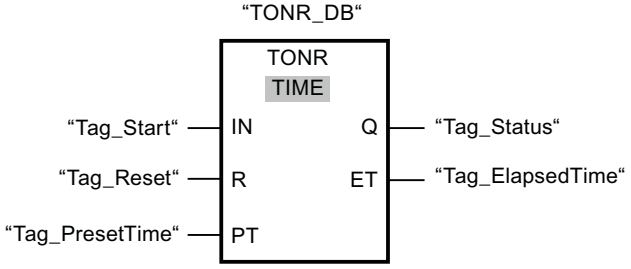
Parameters



The following table shows the parameters of the "Time accumulator" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Reset input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	I, Q, M, D, L, P or constant	Maximum duration of time recording. The value of the PT parameter must be positive.

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
Q	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, P	Output that is set when time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L	I, Q, M, D, L, P	Current timer value



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Start	Signal transition "0" => "1"
PT	Tag_PresetTime	T#10s
Q	Tag_Status	FALSE; after 10 s => TRUE
ET	Tag_ElapsedTime	Signal transition from "0" => "1" The time T#10s expires. After 5 s signal transition from "1" => "0": The time at the "Tag_Elapsed-Time" operand remains at T#5s. After approx. 2 s, renewed signal transition from "0" => "1": The time at the "Tag_Elapsed-Time" operand continues to run at T#5s.

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. The time continues to run as long as the "Tag_Start" operand has the signal state "1". When the signal state of the "Tag_Start" operand changes from "1" to "0", the time stops and the current time value at the Tag_ElapsedTime operand is recorded. When the signal state at the "Tag_Start" operand changes again from "0" to "1", the time continues to run starting at the time value that was recorded at the transition from "1" to "0". When the time value specified for the PT parameter is reached, the "Tag_Status" operand is set to the signal state "1". The current time value is stored in the "Tag_ElapsedTime" operand.

TP: Start pulse timer (S7-1200, S7-1500)

Description

Use the instruction "Start pulse timer" to start an IEC Timer with a specified duration as pulse. The IEC Timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC Timer runs for the specified time duration regardless of the subsequent course of the RLO. The expiry of the IEC Timer is also not affected by the detection of a new rising edge. As long as the IEC Timer is running, the querying of the timer status for "1" returns the signal state "1". When the IEC Timer has expired, the timer status returns the signal state "0".

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER or TP_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The instruction "Start pulse timer" stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TP_TIME, TP_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

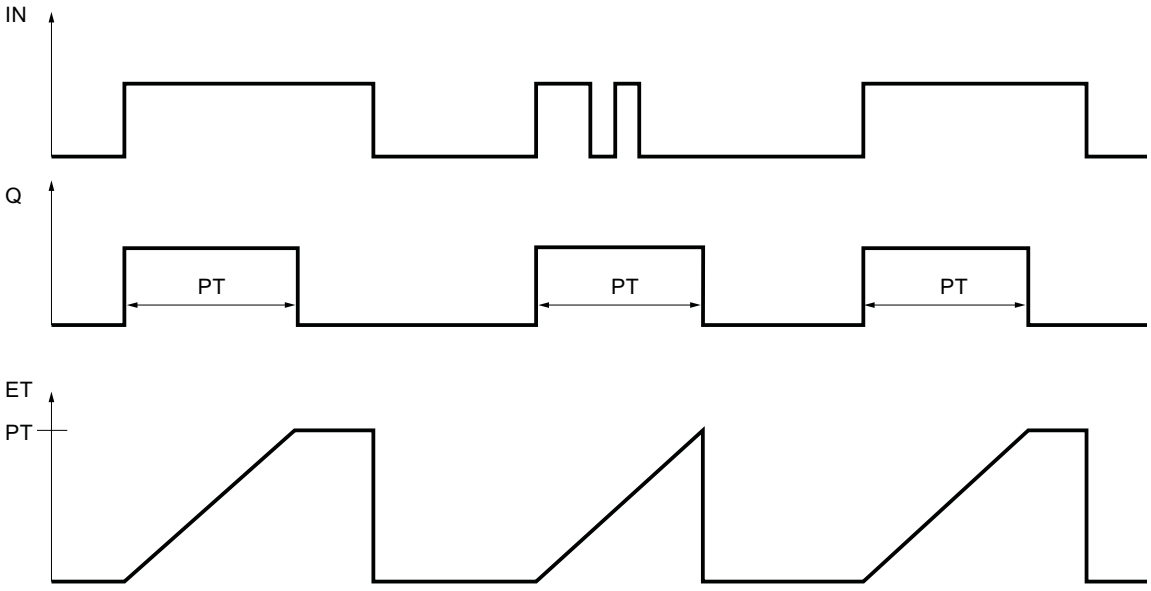
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is saved in the structure components Q of the IEC Timer. You can query the timer status with the help of a binary logic operation.

The execution of the instruction "Start pulse timer" assumes a preceding logic operation. It can be placed only at the end of the network.

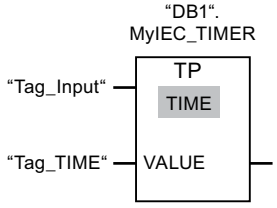
Parameters



The following table shows the parameters of the instruction "Start pulse timer":

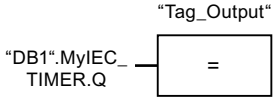
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TP_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME	D, L	IEC Timer which is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The instruction "Start pulse timer" is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The timer "DB1".MyIEC_TIMER is started for the time stored in the operand "TagTime".

As long as the timer "DB1".MyIEC_TIMER is running, the timer status ("DB1".MyIEC_TIMER.Q) has signal state "1" and the operand "Tag_Output" is set. When the IEC Timer has expired, the signal state of the time status changes back to "0" and the "Tag_Output" operand is reset.

TON: Start on-delay timer (S7-1200, S7-1500)

Description

Use the "Start on-delay timer" instruction to start an IEC Timer with a specified duration as on-delay. The IEC Timer is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The IEC Timer runs for the specified time duration. The output returns the signal state "1" if the RLO at the input of the instruction has the signal state "1". If the RLO changes to "0" before the end of the timer, the running IEC Timer is reset. The query of the timer status for "1" returns the signal state "0". The IEC Timer restarts when the next rising signal edge is detected at the input of the instruction.

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start on-delay timer" stores its data in a structure of the data type IEC_TIMER or TON_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start on-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TON_TIME, TON_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

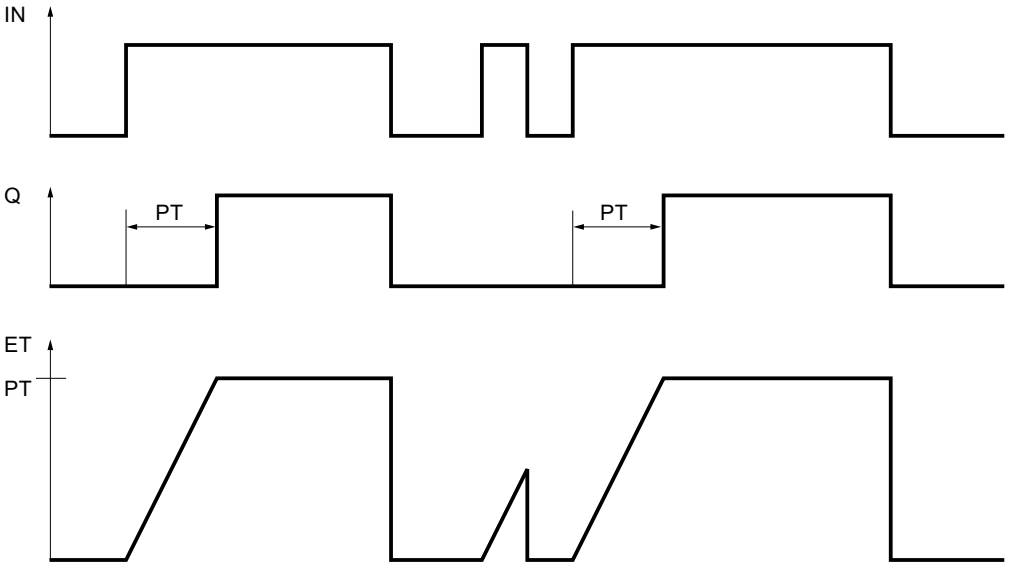
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation.

The execution of the "Start on-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

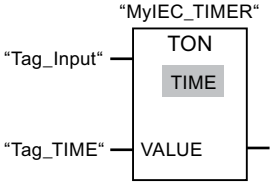
Parameters



The following table shows the parameters of the instruction "Start on-delay timer":

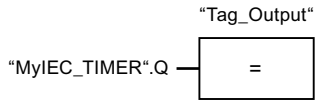
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TON_TIME	IEC_TIMER, IEC_LTIMER, TON_TIME, TON_LTIME	D, L	IEC Timer which is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Start on-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "0" to "1". The "MyIEC_TIMER" timer is started for the time stored in the "Tag_TIME" operand.

If the timer "MyIEC_TIMER" has expired and the operand "Tag_Input" has the signal state "1", querying the timer status ("MyIEC_TIMER".Q) returns signal state "1" and the "Tag_Output" operand is set. When the signal state of the operand "Tag_Input" changes to "0", the querying of the timer status returns the signal state "0" and the operand "Tag_Output" is reset.

TOF: Start off-delay timer (S7-1200, S7-1500)

Description

Use the "Start off-delay timer" instruction to start an IEC Timer with a specified duration as off-delay. The query of the timer status for "1" returns the signal state "0" if the result of the logic operation (RLO) at the input of the instruction has the signal state "1". When the RLO changes from "1" to "0" (negative signal edge), the IEC Timer starts with the specified time duration. The timer status remains at signal state "1" as long as the IEC Timer is running. When the timer has run out and the RLO at the input of the instruction has the signal state "0", the timer status is set to the signal state "0". If the RLO changes to "1" before the end of the timer, the running IEC Timer is reset and the timer status remain at the signal state "1".

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The instruction "Start off-delay timer" stores its data in a structure of the data type IEC_TIMER or TOF_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Start off-delay timer" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TOF_TIME, TOF_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

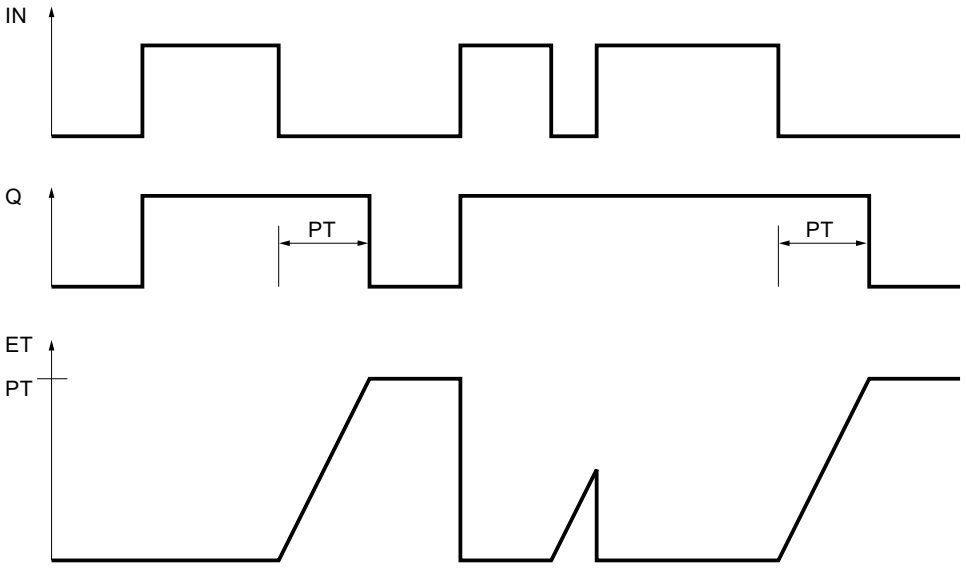
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation.

The execution of the "Start off-delay timer" instruction assumes a preceding logic operation. It can be placed only at the end of the network.

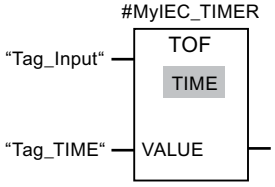
Parameters



The following table shows the parameters of the instruction "Start off-delay timer":

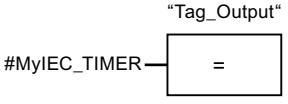
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TOF_TIME	IEC_TIMER, IEC_LTIMER, TOF_TIME, TOF_LTIME	D, L	IEC Timer which is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Start off-delay timer" instruction is executed when the signal state of the operand "Tag_Input" changes from "1" to "0". The #MyIEC_TIMER timer is started for the time stored in the operand "Tag_TIME".

As long as timer #MyIEC_TIMER is running, the query of the time status (#MyIEC_TIMER.Q) returns the signal state "1" and operand "Tag_Output" is set. If the timer has expired and the operand "Tag_Input" has the signal state "0", the query of the timer status returns the signal state "0". If the signal state of the operand "Tag_Input" changes to "1" before timer #MyIEC_TIMER expires, the timer is reset. When the signal state of the operand "Tag_Input" is "1", the query of the timer status returns the signal state "1".

TONR: Time accumulator (S7-1200, S7-1500)

Description

You can use the "Time accumulator" instruction to record how long the signal is at the input of instruction "1". The instruction is started when the result of logic operation (RLO) changes from "0" to "1" (positive signal edge). The time is recorded as long at the RLO is "1". If the RLO changes to "0", the instruction is halted. If the RLO changes back to "1", the time recording is continued. The query of the timer status for "1" returns the signal state "1" if the recorded time exceeds the value of the specified time duration and the RLO at the input of coil is "1".

The timer status and the currently expired timer can be reset to "0" using the "Reset timer" instruction.

Note

The start and the query of the IEC Timer may be on different expiry levels as each query of the outputs Q or ET updates the IEC_TIMER structure.

For S7-1200 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER or TONR_TIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME or IEC_TIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

For S7-1500 CPU

The "Time accumulator" instruction stores its data in a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME. You can declare the structure as follows:

- Declaration of a data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER")
- Declaration as a local tag of the type TONR_TIME, TONR_LTIME, IEC_TIMER or IEC_LTIMER in the "Static" section of a block (for example, #MyIEC_TIMER)

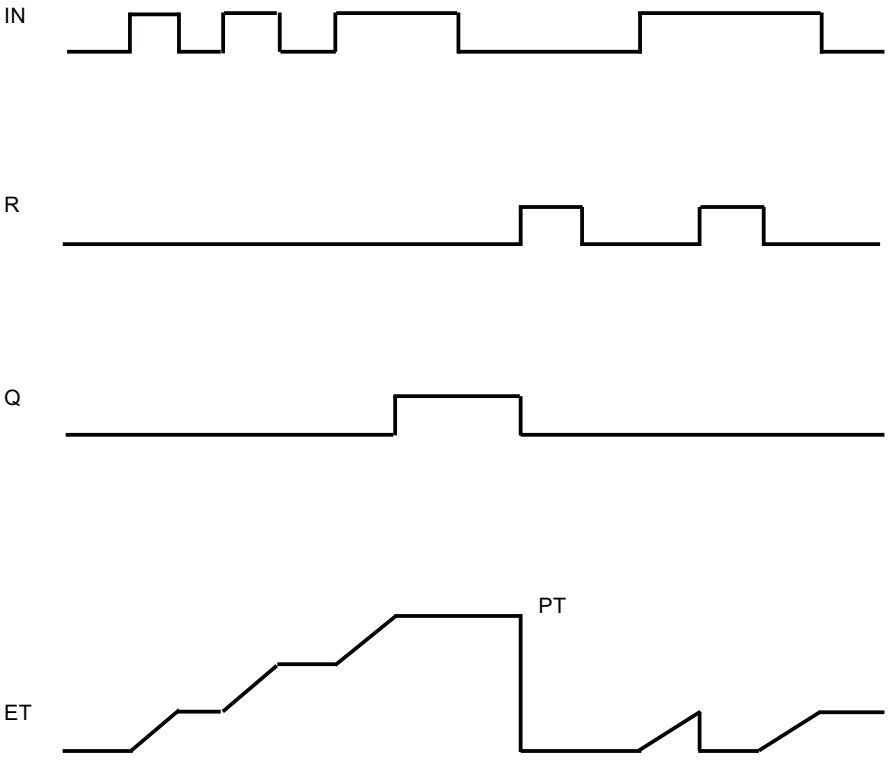
The instruction data is updated in the following cases:

- The IEC_Timer structure is updated when the instruction is called. The time value at the ET output is only updated if the ET or Q outputs are scanned (e.g. "MyTimer".Q or "MyTimer".ET).
- When the assigned timer is accessed.

The current timer status is saved in the structure components ET of the IEC Timer. You can query the timer status with the help of a binary logic operation.

The execution of the "Time accumulator" instruction requires a preceding logic operation. It can be placed only at the end of the network.

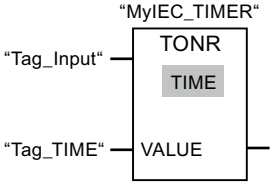
Parameters



The following table shows the parameters of the "Time accumulator" instruction:

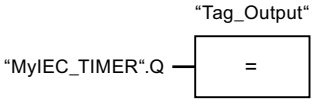
Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
VALUE	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Duration with which the IEC Timer runs.
<IEC Timer>	InOut	IEC_TIMER, TONR_TIME	IEC_TIMER, IEC_LTIMER, TONR_TIME, TONR_LTIME	D, L	IEC Timer which is started.

You can find additional information on valid data types under "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the instruction:



Example

The following example shows how the instruction works:

The "Time accumulator" instruction is executed if there is a positive signal edge in the RLO. The time is recorded as long as the operand "Tag_Input" has the signal state "1".

If the recorded time exceeds the value of the operand "Tag_TIME", then the query of the timer status ("MyIEC_TIMER".Q) will return the signal state "1" and the operand "Tag_Output" will be set.

Overview of the valid data types (Page 2239)

RT: Reset timer (Page 2944)

Basic information on FBD (Page 4937)

RT: Reset timer (S7-1200, S7-1500)

Description

You can use the "Reset timer" instruction to reset an IEC Timer to "0". You specify the IEC Timer to be reset by entering the name of the data block that contains the structure of the IEC Timer in the placeholder above the instruction.

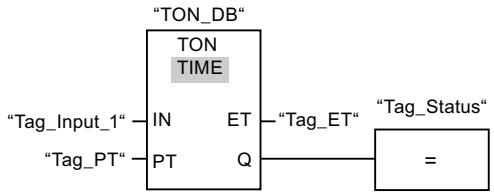
The instruction is only executed if the result of logic operation (RLO) at the box input is "1". When the instruction is executed the structure components of the IEC Timer are reset to "0" in the specified data block. If the RLO at box input is "0", the instruction is not executed.

The instruction does not influence the RLO. The RLO at the box input is transferred directly to the box output.

You must assign a IEC Timer declared in the program to the "Reset timer" instruction.

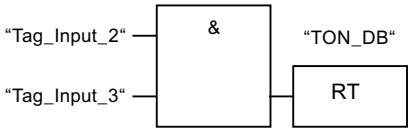
The instruction data is updated only when the instruction is called and not each time the assigned IEC Timer is accessed. The query of the data is only identical from the call of the instruction to the next call of the instruction.

Parameters



The following table shows the parameters of the instruction "Reset timer":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC Timer>	InOut	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC Timer, which is reset.



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC Timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".

If the operands "Tag_Input_2" and "Tag_Input_3" have the signal state "1", the "Reset timer" instruction is executed and the IEC Timer stored in the data block "TON_DB" is reset.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

PT: Load time duration (S7-1200, S7-1500)

Description

Use the "Load time duration" instruction to set the time duration of an IEC Timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time duration to the structure of the specified IEC Timer.

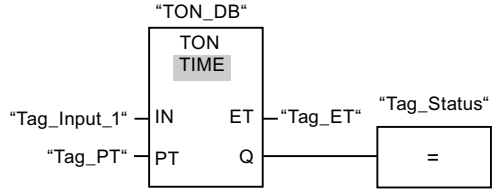
Note

If the specified IEC Timer is running during the execution, the instruction overwrites the current time duration of the specified IEC Timer. As a result, the timer status of the IEC Timer can change.

You must assign a IEC Timer declared in the program to the "Load time duration" instruction.

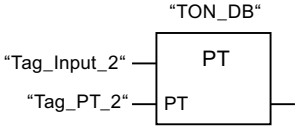
The instruction data is updated when the instruction is called and each time the assigned IEC Timer is accessed. The query for Q or ET (e. g. "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Parameters



The following table shows the parameters of the instruction "Load time duration":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L or constant	Time duration
<IEC Timer>	InOut	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC Timer, the duration of which is set.



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The "Generate on-delay" instruction executes when the signal state of the "Tag_Input_1" operand changes from "0" to "1". The IEC Timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PT".

The "Load time duration" instruction is executed when the operand "Tag_Input_2" has the signal state "1". The instruction writes the time duration "Tag_PT_2" in the instance data block "TON_DB" and at the same time overwrites the value of the operand "Tag_PT" within the data block. As a result, the signal state of the timer status can change at the next query or upon access to "MyTimer".Q or "MyTimer".ET.

Note

The "Tag_Input_2" is executed as pulse flag in order that the time duration is loaded only throughout one program cycle.

Legacy (S7-1500)

S_PULSE: Assign pulse timer parameters and start (S7-1500)

Description

The "Assign pulse timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as long as the signal state at input S is "1". If the signal state at input S changes to "0" before the programmed duration expires, the timer is stopped. In this case, the signal state at output Q is "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1", the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign pulse timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

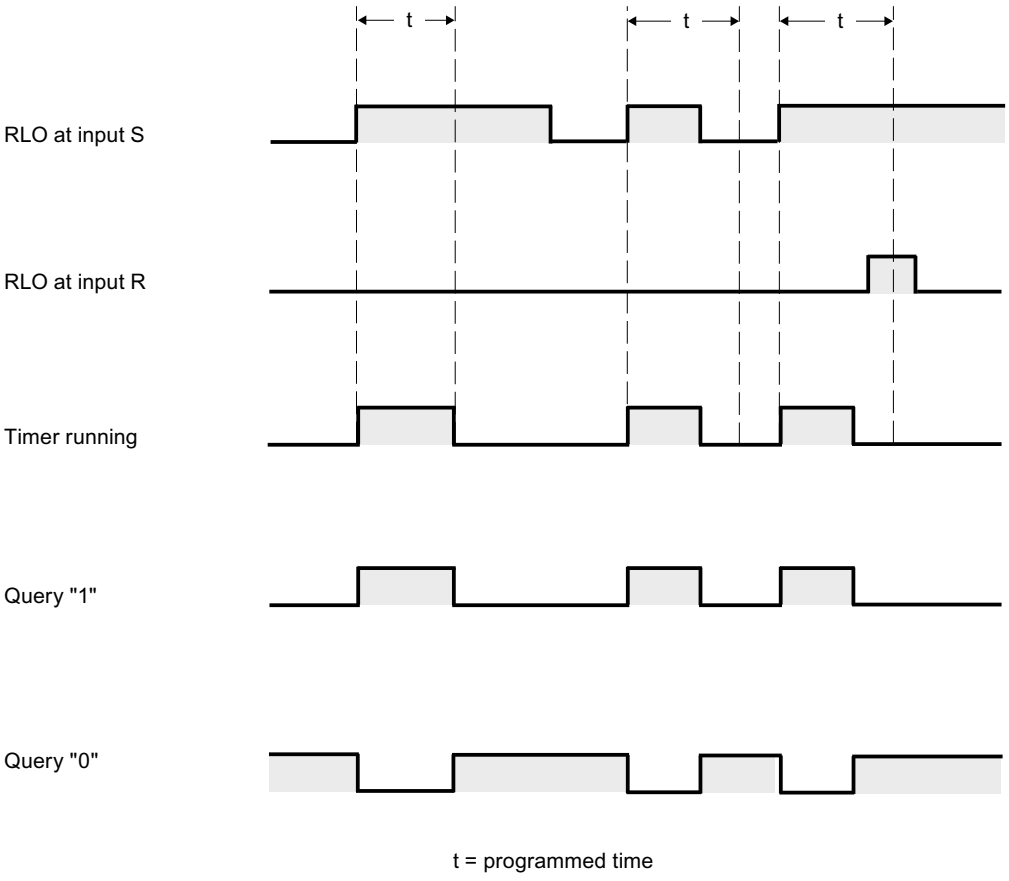
The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

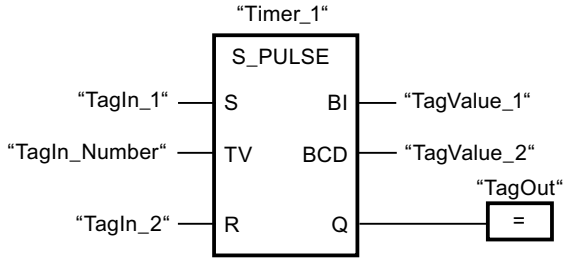


The following table shows the parameters of the "Assign pulse timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the "Assign pulse timer parameters and start" instruction:

t = programmed time

Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer runs for the time value of the "TagIn_Number" operand as long as the "TagIn_1" operand has the signal state "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer "Timer_1" is stopped. The "TagOut" operand is reset to signal state "0".

The "TagOut" operand has the signal state "1" as long as the timer is running and the "TagIn_1" operand has the signal state "1". When the time has expired or is reset, the "TagOut" operand is reset to "0".

S_PEXT: Assign extended pulse timer parameters and start (S7-1500)

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". As long as the timer is running, output Q has the signal state "1". When the timer has expired, output Q is reset to "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input TV.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the timer is running and the signal state at input R changes to "1", the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

The "Assign extended pulse timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

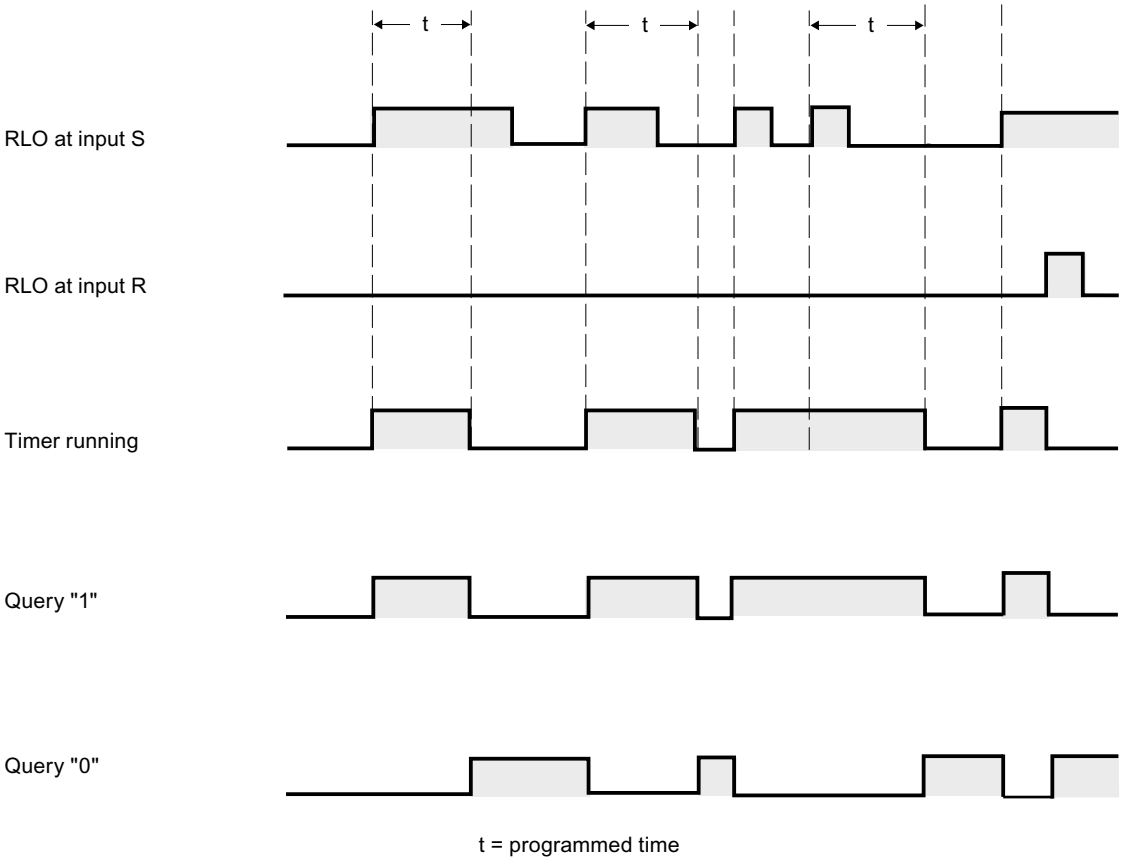
The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

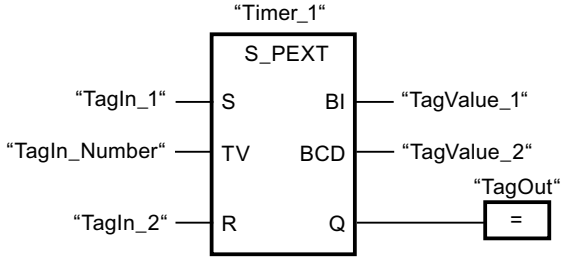
Parameters



The following table shows the parameters of the "Assign extended pulse timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:

Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer runs for the time value of the "TagIn_Number" operand without being affected by a negative edge at the S input. If the signal state at the "TagIn_1" operand changes from "0" to "1" before the timer expires, the timer is restarted.

The "TagOut" operand has the signal state "1" as long as the timer is running. When the time has expired or is reset, the "TagOut" operand is reset to "0".

S_ODT: Assign on-delay timer parameters and start (S7-1500)

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV) as long as the signal state at input S is "1". If the timer expires correctly and input S still has signal state "1", output Q returns signal state "1". If the signal state at input S changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

If the time is running and the signal state at input R changes from "0" to "1", the current time value and the time base are also set to zero. In this case, the signal state at output Q is "0". The timer is reset if the signal state is "1" at the R input even if the timer is not running and the RLO at input S is "1".

The "Assign on-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

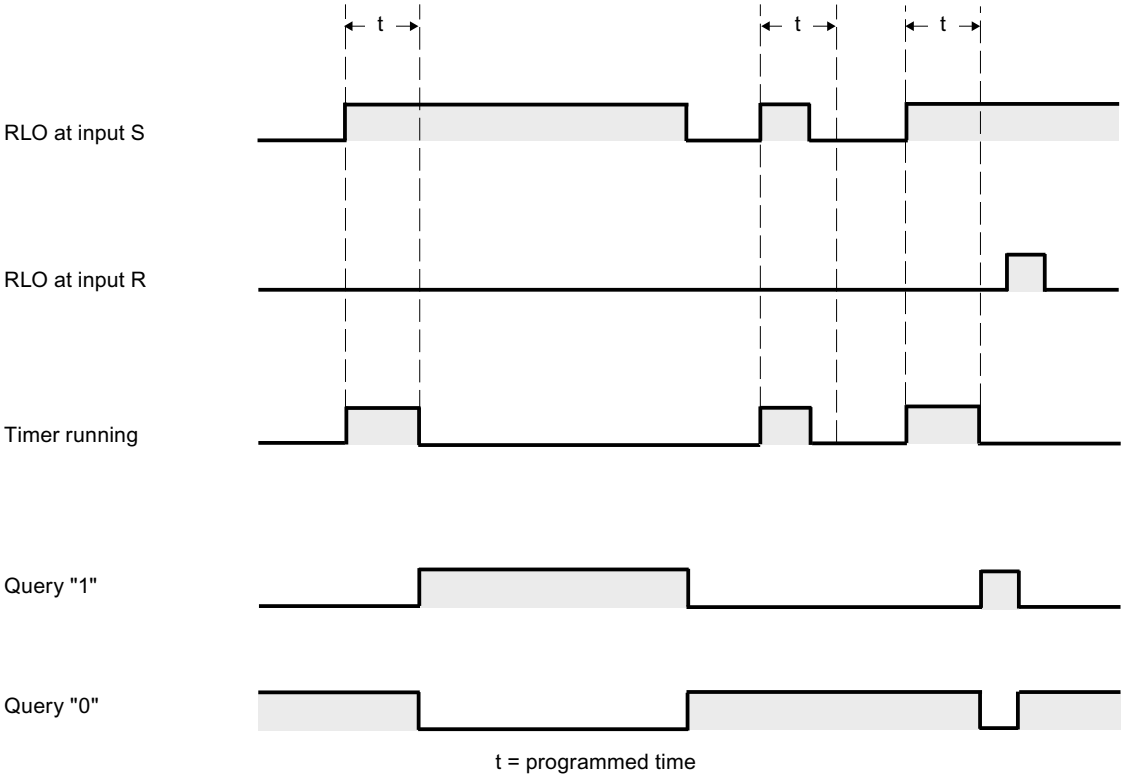
The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

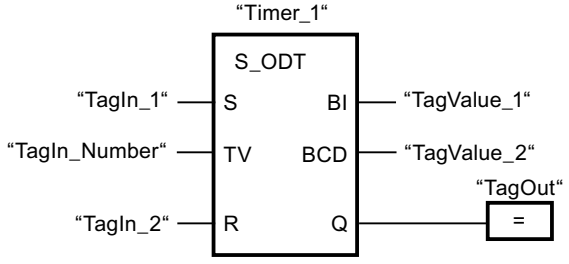
Parameters



The following table shows the parameters of the "Assign on-delay timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:

Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "TagIn_Number". If the timer expires and the signal state of the operand is "1", the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is stopped. The "TagOut" operand has the signal state "0".

S_ODTS: Assign retentive on-delay timer parameters and start (S7-1500)

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a transition from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV), even if the signal state at input S changes to "0". If the timer expires, the "Q" output returns signal state "1" regardless of the signal state at input "S". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is restarted with the duration programmed at input (TV).

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0" regardless of the signal state at start input S. In this case, the signal state at output Q is "0".

The "Assign retentive on-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

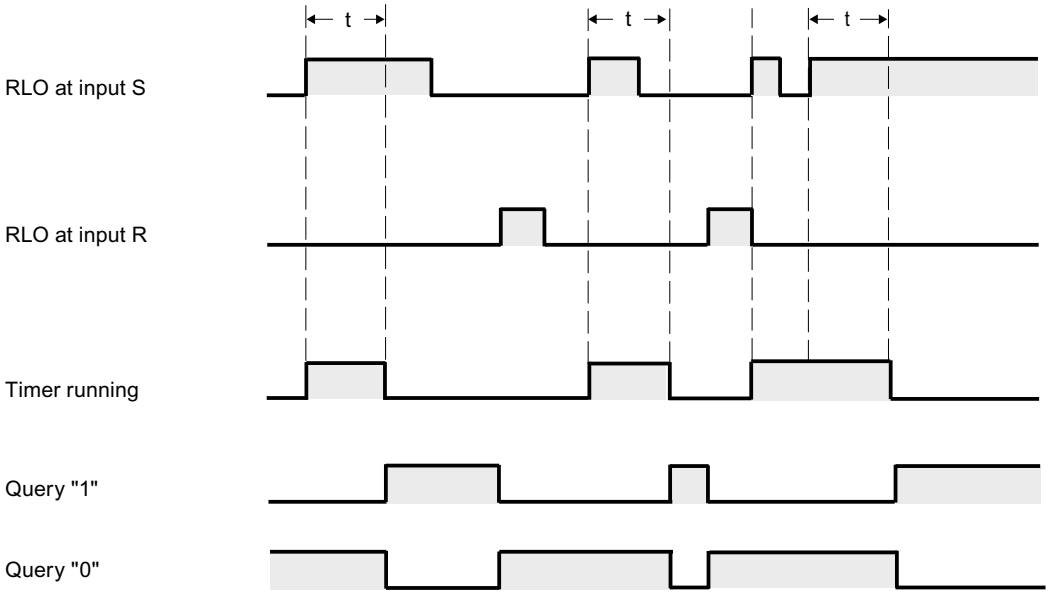
Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

The following table shows the parameters of the "Assign retentive on-delay timer parameters and start" instruction:

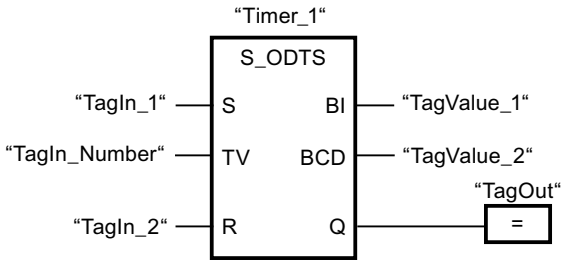


Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input

Parameters	Declaration	Data type	Memory area	Description
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".

Pulse timing diagram



The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:

t = programmed time

Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand, even when the signal state of the "TagIn_1" operand changes to "0". When the time expires, the "TagOut" operand is reset to "1". If the signal state at the "TagIn_1" operand changes from "0" to "1" while the timer is running, the timer is restarted.

S_OFFDT: Assign off-delay timer parameters and start (S7-1500)

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a transition from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at input S. The timer expires with the programmed duration (TV). As long as the timer is running or input S returns signal state "1", output Q has signal state "1". If the timer expires and the signal state is "0", output Q is reset to signal state "0". If the signal state at input S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at input S.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value. The current time value is output binary-coded at output BI and BCD-coded at output BCD.

Signal state "1" at input R resets the current time value and time base to "0". In this case, the signal state at output Q is "0".

The "Assign off-delay timer parameters and start" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

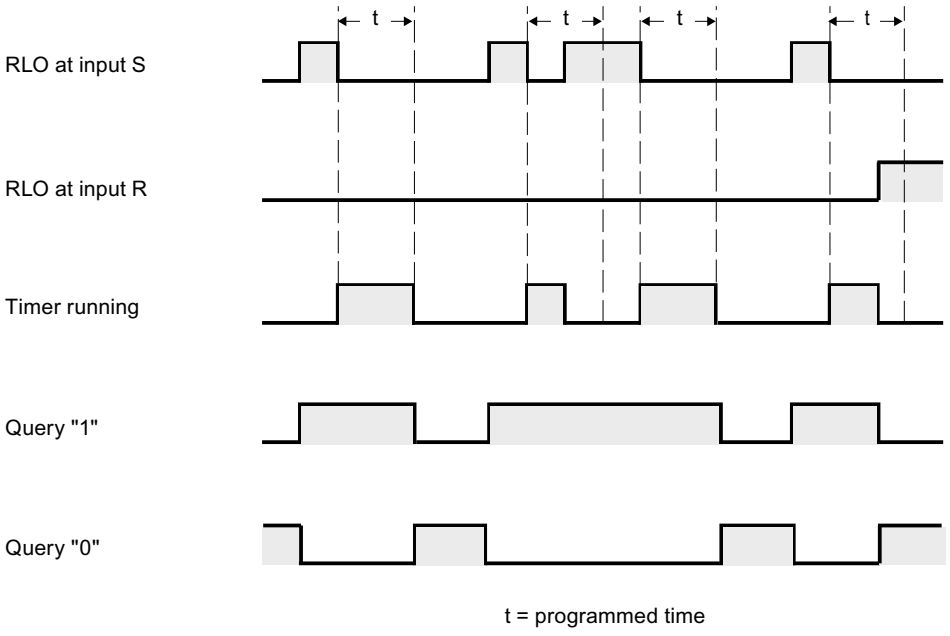
The instruction data is updated with each access. It can therefore happen that the query of the data at the start of the cycle returns different values than at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

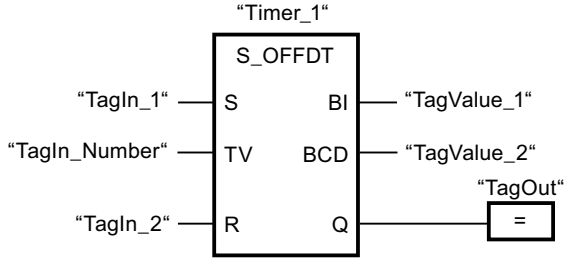
Parameters



The following table shows the parameters of the "Assign off-delay timer parameters and start" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Timer>	InOut/Input	TIMER	T	Time of the instruction The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
R	Input	BOOL	I, Q, M, T, C, D, L, P or constant	Reset input
BI	Output	WORD	I, Q, M, D, L, P	Current time value (binary-coded)
BCD	Output	WORD	I, Q, M, D, L, P	Current time value (BCD format)
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer

For additional information on valid data types, refer to "See also".



Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:

Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "1" to "0". The timer expires with the value of operand "TagIn_Number". The "TagOut" operand is set to "1" if the timer is running or the "TagIn_1" operand has the signal state "0". If the signal state at the "TagIn_1" operand changes from "0" to "1" while the timer is running, the timer is reset.

SP: Start pulse timer (S7-1500)

Description

The instruction "Start pulse timer" starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs with the specified duration as long as the RLO has the signal state "1". As long as the timer is running, the query of timer status "1" returns the signal state "1". If there is a change from "1" to "0" in the RLO before the time value has elapsed, the timer stops. In this case, the query for timer status for "1" returns the signal state "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

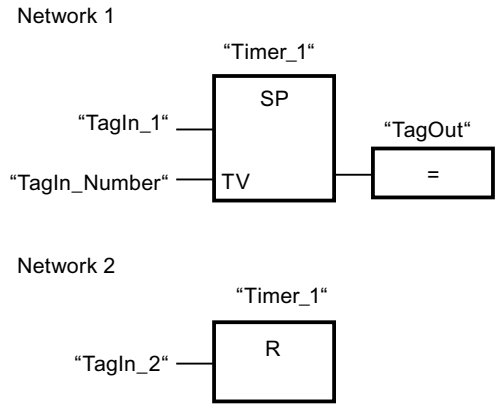
The "Start pulse timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

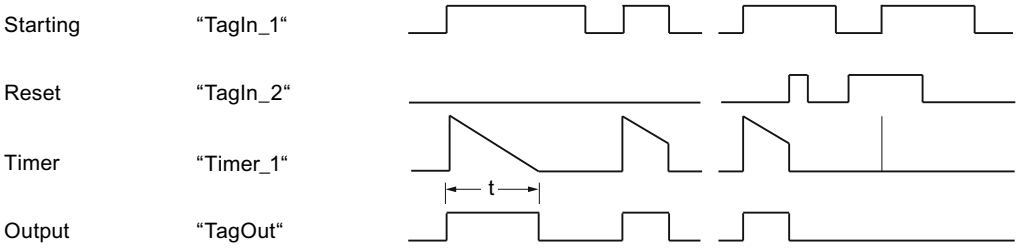
Parameters



The following table shows the parameters of the instruction "Start pulse timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the "TagIn_Number" operand as long as the signal state of the "TagIn_1" operand is "1". If the signal state of the operand "TagIn_1" changes from "1" to "0" before the timer expires, the timer is stopped. As long as the timer is running, the "TagOut" operand returns signal state "1". A signal state change of the operand "TagIn_2" from "0" to "1" resets the timer, which stops the timer and sets the current time value to "0".

The figure below shows the timer diagram of the example:

t = programmed duration

SE: Start extended pulse timer (S7-1500)

Description

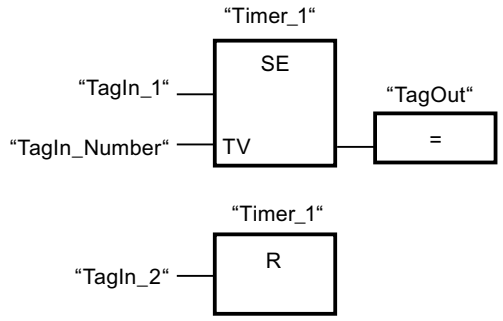
The "Start extended pulse timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified time period even when the RLO changes to signal state "0". As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is restarted with the programmed time period. The querying of the timer status for "1" returns the signal state "0" when the timer expires.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

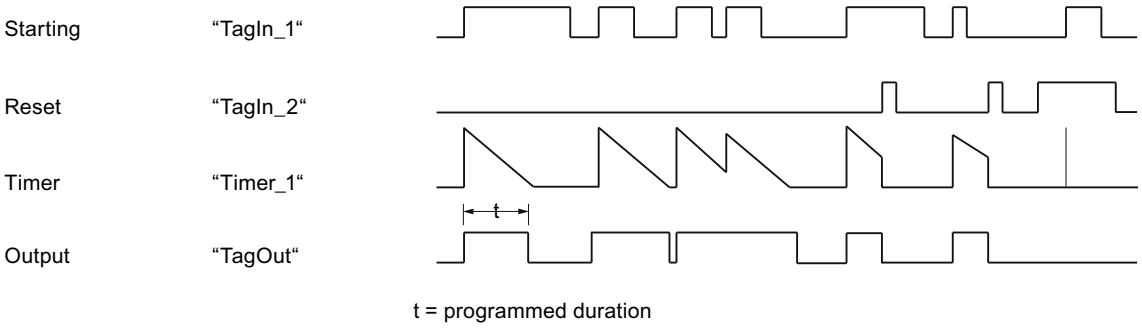
You can find an example of how a time cell can be formed here: AUTOHOTSPOT



Parameters

The following table shows the parameters of the "Start extended pulse timer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the time value of the operand "TagIn_Number" without being affected by a negative signal edge in the RLO. As long as the timer is running, the "TagOut" operand returns signal state "1". If the signal state of the operand "TagIn_1" changes again from "0" to "1" before the timer expires, the timer is restarted.

The figure below shows the timer diagram of the example:

t = programmed duration

SD: Start on-delay timer (S7-1500)

Description

The "Start on-delay timer" instruction starts a programmed timer when the signal state "1" is detected at the start input. As long as this signal state remains "1", the timer expires with the specified duration. When the timer expires and the signal state at the start input is still "1", the query for timer status also returns "1". If the signal at the start input is "0", the timer is reset. In this case, querying the timer status returns the signal state "0". As soon as the signal at the start input changes to "1" again, the timer starts running again.

The signal state of the timer output is identical to the signal state of the start input. The start input is directly interconnected to the output and is not linked to the timer.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero.

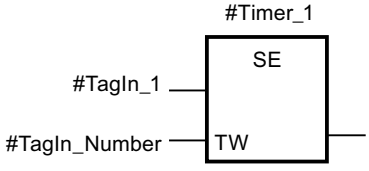
Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

Parameters

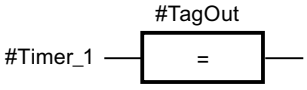
The following table shows the parameters of the instruction "Start on-delay timer":



Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

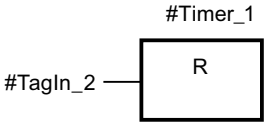
You can find additional information on valid data types under "See also".

Example



The following example shows how the instruction works:

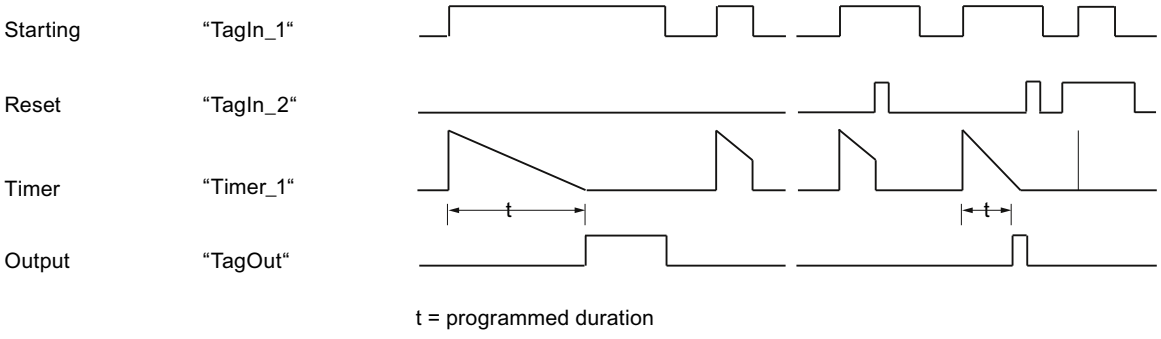
Network 1:



"#Timer_1" starts when the signal state of the "#TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "#TagIn_Number". If the signal state of the "#TagIn_1" operand changes from "1" to "0" before the timer expires, the timer is reset.

Network 2:

When the timer has expired, the #TagIn_1 operand at the start input has signal state "1" and the timer was not reset, the #TagOut operand is "1".



Network 3:

When the signal state of the #TagIn_2 operand has signal state "1", the timer #Timer_1 and the output #TagOut are reset.

If you want to restart #Timer_1, the signal state at the #TagIn_2 operand must be "0" and the signal state at the start input #TagIn_1 must change from "0" to "1".

The figure below shows the timer diagram of the example:

SS: Start retentive on-delay timer (S7-1500)

Description

The "Start retentive on-delay timer" instruction starts a programmed timer when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) at the start input. The timer runs for the specified time period even when the RLO changes to signal state "0". When the timer expires, the query for timer status for "1" returns the signal state "1". When the timer expires, the timer can only be restarted if it is explicitly reset.

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down to zero. The time base determines the time period of the time value.

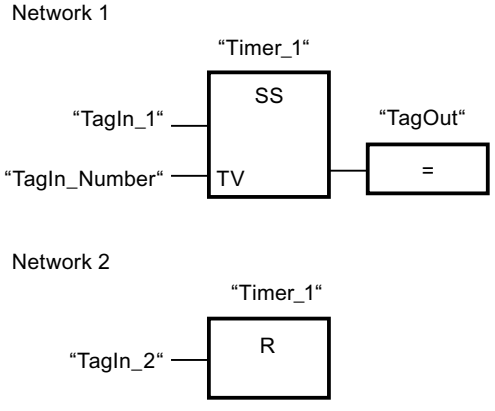
The "Start retentive on-delay timer" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

Parameters

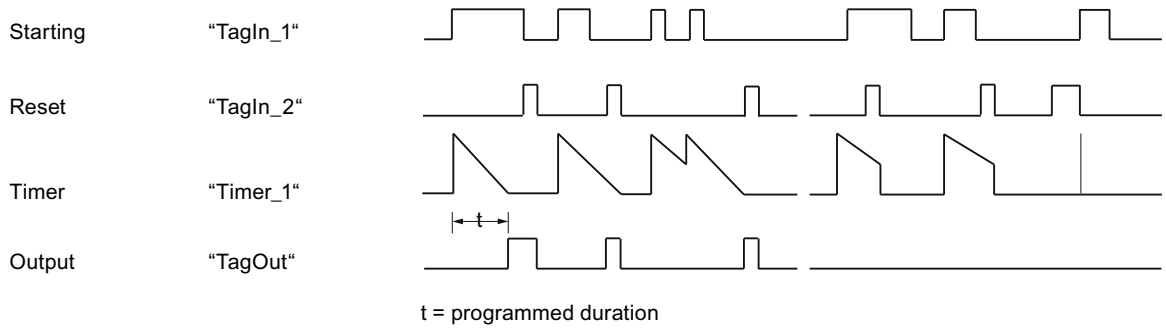


The following table shows the parameters of the instruction "Start retentive on-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".

Example



The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "0" to "1". The timer expires with the value of operand "TagIn_Number". When the time expires, the "TagOut" operand is reset to "1". If the signal state at the "TagIn_1" operand changes from "0" to "1"

while the timer is running, the timer is restarted. If the signal state of the "TagIn_2" operand changes to "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

The figure below shows the timer diagram of the example:

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

SF: Start off-delay timer (S7-1500)

Description

The "Start off-delay timer" instruction starts a programmed timer when a change from "1" to "0" (negative signal edge) is detected in the result of logic operation (RLO) at the start input. The timer expires with the specified duration. As long as the timer is running, the query of timer status "1" returns the signal state "1". If the RLO changes from "0" to "1" while the timer is running, the timer is reset. The timer is always restarted when the RLO changes from "1" to "0".

The duration is made up internally of a time value and a time base and is programmed at parameter TV. When the instruction is started, the programmed time value is counted down towards zero. The time base indicates the time period with which the time value is changed.

The queries of the timer status for "1" return the query result "1" if the signal state of the result of logic operation is "1" at the execution of the instruction. If the RLO is "0", queries of the timer status for "1" return the query result "0".

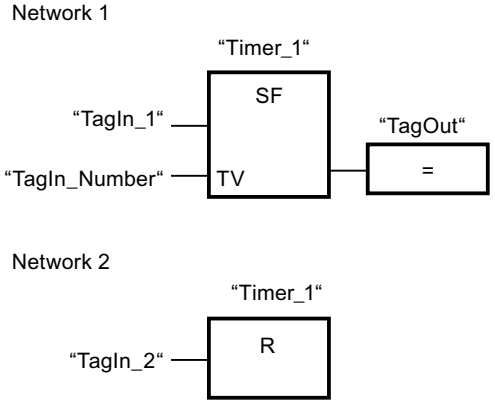
The "Start off-delay timer" instruction requires a preceding logic operation for edge evaluation and can only be placed at the right side of the network.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed here: AUTOHOTSPOT

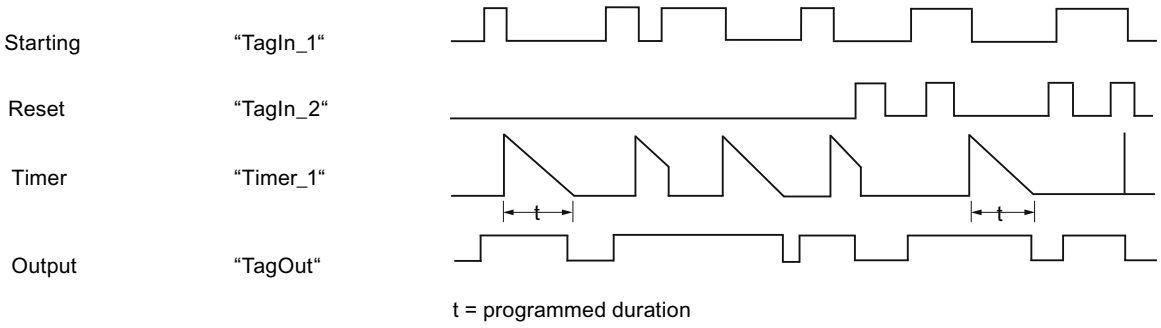
Parameters



The following table shows the parameters of the instruction "Start off-delay timer":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, T, C, D, L, P	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L or constant	Time duration
<Timer>	InOut/Input	TIMER	T	Timer which is started. The number of timers depends on the CPU.

You can find additional information on valid data types under "See also".



Example

The following example shows how the instruction works:

"Timer_1" starts when the signal state of the "TagIn_1" operand changes from "1" to "0". The timer expires with the time value of the operand "TagIn_Number". As long as the timer is running, the "TagOut" operand is set to "1". If the signal state at the "TagIn_1" operand changes from "1" to "0" while the timer is running, the timer is restarted. If the signal state of the "TagIn_2" operand is "1", "Timer_1" is reset, i.e. the timer is stopped and the current time value is set to "0".

The figure below shows the timer diagram of the example:

Basic information on FBD (Page 4937)

Counter operations (S7-1200, S7-1500)

CTU: Count up (S7-1200, S7-1500)

Description

You can use the "Count up" instruction to increment the value at output CV. When the signal state at the CU input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit for the data type specified at the output CV. When the high limit is reached, the signal state at the CU input no longer has an effect on the instruction.

You can query the counter status in the Q output. The signal state at the Q output is determined by the PV parameter. If the current counter value is greater than or equal to the value of the PV parameter, the Q output is set to signal state "1". In all other cases, the Q output has signal state "0". You can also specify a constant for the PV parameter.

The value at the CV output is reset to "0" and saved to an edge memory bit when the signal state at input R changes to "1". As long as the R input has signal state "1", the signal state at the CU input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_SINT / CTU_USINT • CTU_INT / CTU_UINT • CTU_DINT / CTU_UDINT • CTU_LINT / CTU_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

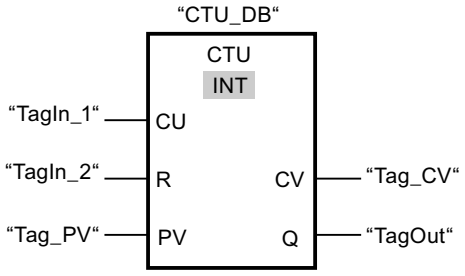
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTU_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count up" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
R	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Reset input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value at which the output Q is set.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CV" operand is incremented by one. With each additional positive signal edge, the counter value is incremented until the high limit of the specified data type (INT = 32767) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PV" operand. In all other cases, the "TagOut" output returns the signal state "0".

CTD: Count down (S7-1200, S7-1500)

Description

You can use the "Count down" instruction to decrement the value at output CV. When the signal state at the CD input changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value at the CV output is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state at the CD input no longer has an effect on the instruction.

You can query the counter status in the Q output. If the current counter value is less than or equal to "0", the Q output is set to signal state "1". In all other cases, the Q output has signal state "0". You can also specify a constant for the PV parameter.

The value at the CV output is set to the value of the PV parameter and saved to a edge memory bit when the signal state at the LD input changes from "0" to "1". As long as the LD input has signal state "1", the signal state at the CD input has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • CTD_LINT / CTD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

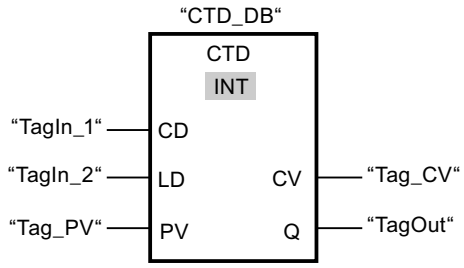
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count down" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count input
LD	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value to which the CV output is set with LD = 1.
Q	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

When the signal state of the "TagIn_1" operand changes from "0" to "1", the instruction is executed and the value at the "Tag_CV" output is decremented by one. With each additional positive signal edge, the counter value is decremented until the low limit of the specified data type (INT = -32768) is reached.

The value of the PV parameter is adopted as the limit for determining the "TagOut" output. The "TagOut" output has signal state "1" as long as the current counter value is less than or equal to "0". In all other cases, the "TagOut" output returns the signal state "0".

CTUD: Count up and down (S7-1200, S7-1500)

Description

You can use the "Count up and down" instruction to increment and decrement the counter value at the CV output. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one and stored at the CV output. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the current counter value at the CV output is decremented by one. If there is a positive signal edge at the CU and CD inputs in one program cycle, the current counter value at the CV output remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV output. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state at the LD input changes to "1", the counter value at the CV output is set to the value of the PV parameter and stored in a edge memory bit. As long as the LD input has signal state "1", the signal state at the CU and CD inputs has no effect on the instruction.

The counter value is set to "0" and stored in an edge memory bit when the signal state at input R changes to "1". As long as the R input has signal state "1", a change in the signal state of the CU, CD and LD inputs has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU output. If the current counter value is greater than or equal to the value of the PV parameter, the QU output is set to signal state "1". In all other cases, the QU output has signal state "0". You can also specify a constant for the PV parameter.

You can query the status of the down counter at the QD output. If the current counter value is less than or equal to zero, the QD output is set to signal state "1". In all other cases, the QD output has signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For S7-1200 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER

For S7-1500 CPU

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_SINT / CTUD_USINT • CTUD_INT / CTUD_UINT • CTUD_DINT / CTUD_UDINT • CTUD_LINT / CTUD_ULINT • IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER

You can declare an IEC counter as follows:

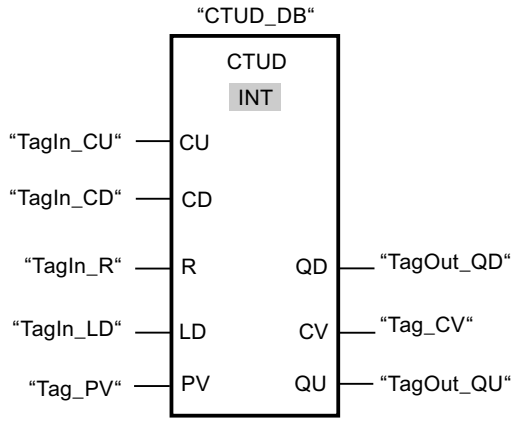
- Declaration of a data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER")
- Declaration as a local tag of the type CTUD_<Data type> or IEC_<Counter> in the "Static" section of a block (for example #MyIEC_COUNTER)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive. For additional information on setting retentivity in an instance data block, refer to "See also".

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

The execution of the "Count up and down" instruction requires a preceding logic operation. It can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Count up and down" instruction:

Parameter	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
CU	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count up input
CD	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Count down input
R	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Reset input
LD	Input	BOOL	I, Q, M, D, L, P or constant	I, Q, M, T, C, D, L, P or constant	Load input
PV	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value at which the QU output is set / value to which the CV output is set when LD = 1.
QU	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Up-counter status
QD	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Down-counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	I, Q, M, D, L, P	Current counter value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

If the signal state at the "TagIn_CU" or "TagIn_CD" input changes from "0" to "1" (positive signal edge), the "Count up and down" instruction is executed. When there is a positive signal edge at the "TagIn_CU" input, the current counter value is incremented by one and stored at the "Tag_CV" output. When there is a positive signal edge at the "TagIn_CD" input, the counter value is decremented by one and stored at the "Tag_CV" output. When there is a positive edge at the CU input, the counter value is incremented until it reaches the high limit (INT = 32767). If input CD has a positive signal edge, the counter value is decremented until it reaches the low limit (INT = -32768).

The "TagOut_GU" output has signal state "1" as long as the current counter value is greater than or equal to the value at the "Tag_PV" input. In all other cases, the "TagOut_QU" output returns the signal state "0".

The "TagOut_QD" output has signal state "1" as long as the current counter value is less than or equal to "0". In all other cases, the "TagOut_QD" output has signal state "0".

Legacy (S7-1500)

S_CU: Assign parameters and count up (S7-1500)

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The count is incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CU is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU and S inputs has no effect on the counter value.

The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

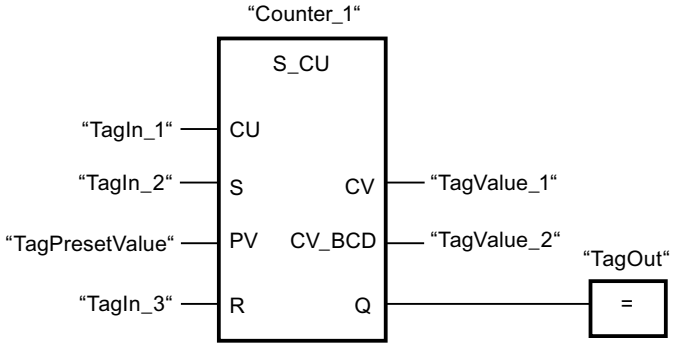
Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters

The following table shows the parameters of the "Assign parameters and count up" instruction:



Parameters	Declaration	Data type	Memory area	Description
<counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L, T, C	Count up input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)

Parameters	Declaration	Data type	Memory area	Description
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. When the signal state at the "TagIn_2" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

S_CD: Assign parameters and count down (S7-1500)

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. The count is decremented until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decremented on a positive signal edge.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO at input CD is "1", the counter will count accordingly in the next scan cycle, even when no change has been detected in the signal edge.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CD and S inputs has no effect on the counter value.

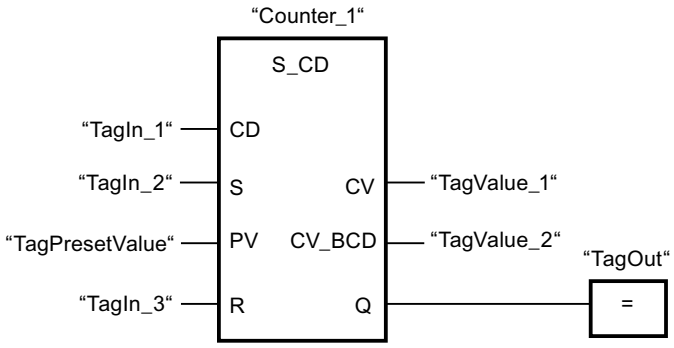
The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count down" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Assign parameters and count down" instruction:

Parameters	Declaration	Data type	Memory area	Description
<counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

When the signal state at the "TagIn_1" input changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decremented by one. When the signal state at the "TagIn_2" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_3" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

S_CUD: Assign parameters and count up / down (S7-1500)

Description

You can use the "Assign parameters and count up / down" instruction to increment or decrement the value of a counter. If the signal state at the CU input changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. If the signal state at the CD input changes from "0" to "1" (positive signal edge), the counter value is decremented by one. The current counter value is output as a hexadecimal value at output CV and BCD-coded at output CV_BCD. If there is a positive signal edge at the CU and CD inputs in one program cycle, the counter value remains unchanged.

The counter value is incremented until the high limit of "999" is reached. When the high limit value is reached, the counter value is no longer incremented on a positive signal edge. When the low limit of "0" is reached, the counter value is no longer decremented.

When the signal state at input S changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if RLO is "1" at the inputs CU and CD, the counter counts accordingly in the next scan cycle, even if no change in the signal edge is detected.

The counter value is set to zero when the signal state at the R input changes to "1". As long as the R input has the signal state "1", processing of the signal state of the CU, CD and S inputs has no effect on the counter value.

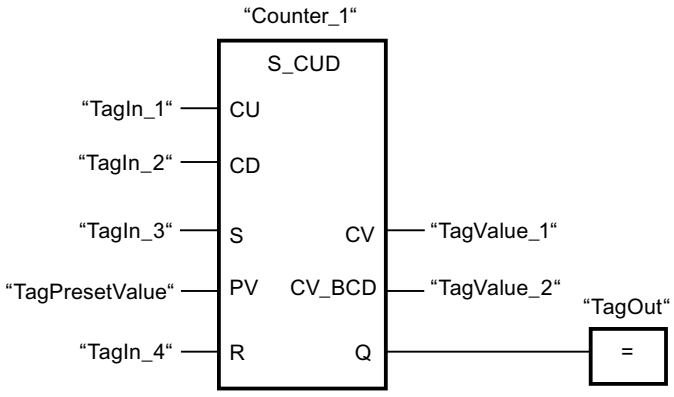
The signal state at output Q is "1" if the counter value is greater than zero. If the counter value is equal to zero, output Q has the signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

The "Assign parameters and count up / down" instruction needs a preceding logic operation for the edge evaluation and can be placed within or at the end of the network.

Parameters



The following table shows the parameters of the "Assign parameters and count up / down" instruction:

Parameters	Declaration	Data type	Memory area	Description
<counter>	InOut/Input	COUNTER	C	Counter of the instruction The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L, T, C	Count up input
CD	Input	BOOL	I, Q, M, D, L, T, C or constant	Count down input
S	Input	BOOL	I, Q, M, D, L, T, C or constant	Input for presetting counter
PV	Input	WORD	I, Q, M, D, L or constant	Preset counter value (C#0 to C#999)
R	Input	BOOL	I, Q, M, D, L, T, C or constant	Reset input
CV	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (hexadecimal)
CV_BCD	Output	WORD, S5TIME, DATE	I, Q, M, D, L	Current counter value (BCD format)
Q	Output	BOOL	I, Q, M, D, L	Status of the counter

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the signal state at the input "TagIn_1" or at the input "TagIn_2" changes from "0" to "1" (positive edge), the instruction "Assign parameters and count up / down is executed. When there is a positive signal edge at the "TagIn_1" input and the current counter value is less than "999", the counter value is incremented by one. When there is a positive signal edge at the "TagIn_2" input and the current counter value is greater than "0", the counter value is decremented by one.

When the signal state at the "TagIn_3" input changes from "0" to "1", the counter value is set to the value of the "TagPresetValue" operand. The counter value is reset to "0" when the "TagIn_4" operand has signal state "1".

The current counter value is hexadecimal in the "TagValue_1" operand and BCD-coded in the "TagValue_2" operand.

The "TagOut" output has the signal state "1" as long as the current counter value is not equal to "0".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

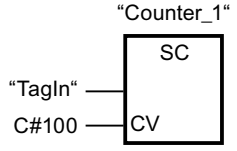
SC: Set counter value (S7-1500)

Description

You can use the "Set counter value" instruction to set the value of a counter. The instruction is executed when the result of logic operation (RLO) at the start input of the instruction changes from "0" to "1". When the instruction is executed, the counter is set to the specified counter value.

The "Set counter value" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

Parameters



The following table lists the parameters of the "Set counter value" instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
PV	Input	WORD	I, Q, M, D, L or constant	Value with which the counter is preset in the BCD format. (C#0 to C#999)
<counter>	InOut/Input	COUNTER	C	Counter that is preset.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

the counter "Counter_1" starts with the value "100" when the signal state of the "TagIn" operand changes from "0" to "1".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CU: Count up (S7-1500)

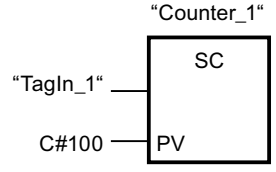
Description

You use the "Count up" instruction to increment the value of the specified counter by the count of one on a rising edge at the start input. The count is incremented until the limit of "999" is reached. When the limit is reached, the counter value is no longer incremented on a positive signal edge.

The "Count up" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

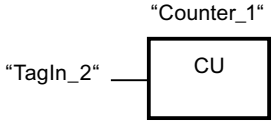
Parameters

The following table shows the parameters of the "Count up" instruction:



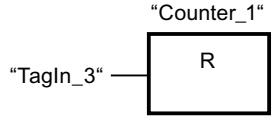
Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
<counter>	InOut/Input	COUNTER	C	Counter whose value is incremented.

For additional information on valid data types, refer to "See also".



Example

The following example shows how the instruction works:



Network 1

Network 2

Network 3

When the signal state of the operand "TagIn_1" changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of "Counter_1" is incremented by the count of one when the signal state of the "TagIn_2" operand changes from "0" to "1".

If the "TagIn_3" operand returns signal state "1", the value of "Counter_1" is reset to "0".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CD: Count down (S7-1500)

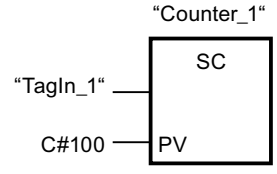
Description

You use the "Count down" instruction to decrement the value of the specified counter by the count of one on a rising edge at the start input. The count is decremented until the limit of "0" is reached. When the limit is reached, the counter value is no longer changed on a positive signal edge.

The "Count down" instruction needs a preceding logic operation for the edge evaluation and can only be placed on the right edge of the network.

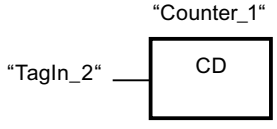
Parameters

The following table shows the parameters of the "Count down" instruction:



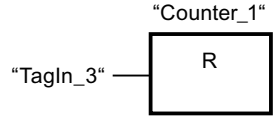
Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	BOOL	I, Q, M, T, C, D, L	Start input
<counter>	InOut/Input	COUNTER	C	Counter whose value is decremented.

For additional information on valid data types, refer to "See also".



Example

The following example shows how the instruction works:



Network 1

Network 2

Network 3

When the signal state of the operand "TagIn_1" changes from "0" to "1" (positive signal edge), the counter "Counter_1" is preset with the value "100".

The value of "Counter_1" is incremented by the count of one when the signal state of the "TagIn_2" operand changes from "0" to "1".

If the "TagIn_3" operand returns signal state "1", the value of "Counter_1" is reset to "0".

Basic information on FBD (Page 4937)

Comparator operations (S7-1200, S7-1500)

CMP ==: Equal (S7-1200, S7-1500)

Description

You can use the "Equal" instruction to query whether the value at input IN1 is equal to the value at input IN2.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width of the operands must be the same.

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, then instead of the instruction "CMP ==: Equal" we recommend using the instruction "IN_RANGE: Value within range".

If floating-point numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

The special bit patterns of invalid floating-point numbers (NaN) that are the outcome of undefined results (e.g. root of -1) are not comparable. This means that if one of the operands has the value NaN, the instruction "CMP ==: Equal" has the result FALSE.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table shows examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'AA'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'aa'	'aaa'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

Bit patterns of invalid timers, date and times, e.g. DT#2015-13-33-25:62:99.999_999_999, cannot be compared. This means that if one of the operands has an invalid value, the instruction "CMP ==: Equal" has the result FALSE.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Comparison of hardware data types

To be able to compare the operands of the PORT data type, you need to select the WORD data type from the drop-down list in the instruction box.

If you want to compare the two data types, you must first create a tag of data type HW_ANY in the "Temp" section of the the block interface and then copy the LADDR (from data type HW_DEVICE) to the tag. It is then possible to compare HW_ANY and HW_IO.

Comparison of structures

Note

Availability of comparison of structures

The option to compare structures is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

You can compare the values of two structured operands when both tags are of the same structure data type. When structures are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check. An exception is comparisons in which one of the two operands is a VARIANT or an ANY. If the data type is not yet known when the program is created, you can use the VARIANT data type. In this case you can also compare the operand with a structured tag of any data type. You can also compare two tags of the data type VARIANT or ANY with each other.

You can select the data type VARIANT for the comparison of structures from the drop-down list in the instruction box. The following data types are possible:

- PLC data type
- STRUCT (the structure of the data type STRUCT must be contained in a PLC data type (UDT) or the two structures to be compared are two elements of an ARRAY of STRUCT. Anonymous structures are not permitted.)
- Tag to which ANY is pointing
- Tag to which VARIANT is pointing

The following requirements must be met to compare two tags of the data type ARRAY with VARIANT selected:

- The elements must each have the same data type.
- The two ARRAYs must have the same dimension.
- All dimensions must have the same number of elements. The exact ARRAY limits do not have to match.

Note

ARRAY of BOOL

When you compare two operands of the data type ARRAY of BOOL with each other, you have selected the data type VARIANT from the drop-down list, and the number of elements cannot be divided by 8, the fill bits are compared as well. This may affect the comparison result.

If an element within the structures that you want to compare is an invalid STRING/WSTRING, an invalid time or date or an invalid floating-point number, the comparison result in the RLO (result of logic operation) will return the signal state "0".

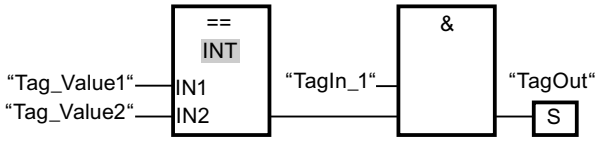
The table below shows an example of a comparison of structures:

<Operand1>			**<Operand2>**			**RLO of the instruction**
Tag of data type A <PLC data type>		Tag value	Tag of data type A <PLC data type>		Tag value	1
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

<Operand1>			**<Operand2>**			**RLO of the instruction**
Tag of data type A <PLC data type>		Tag value	Tag of data type B <PLC data type>		Tag value	0
	BOOL	FALSE		BOOL	TRUE	
	INT	2		INT	3	

<Operand1>			<Operand2>			RLO of the instruction
Tag of data type A <PLC data type>		Tag value	VARIANT (supplied with tag of data type A)		Tag value	1
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

Parameters



The following table shows the parameters of the instruction "Equal":

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	Second value to compare
As detailed above, the data types ARRAY, STRUCT (in a PLC data type), VARIANT, ANY and PLC data type (UDT) are only available as of firmware version 2.0 or 4.2.				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" = "Tag_Value2".

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CMP <>: Not equal (S7-1200, S7-1500)

Description

You can use the "Not equal" instruction to query whether the value at input IN1 is not equal to the value at input IN2.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

If IEC check is enabled, the operands to be compared must be of the same data type. If IEC check is not enabled, the width of the operands must be the same.

Comparison of floating-point numbers

If you want to compare the data types REAL or LREAL, then instead of the instruction "CMP <>: Not equal" we recommend using the instruction "OUT_RANGE: Value outside range".

If floating-point numbers are being compared, the operands to be compared must be of the same data type regardless of the IEC check setting.

The special bit patterns of invalid floating-point numbers (NaN) that are the outcome of undefined results (e.g. root of -1) are not comparable. This means that if one of the operands has the value NaN, the instruction "CMP <>: Not equal" has the result FALSE.

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison.

The following table shows examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'aa'	1
'Hello World'	'HelloWorld'	1
'AA'	'AA'	0
'aa'	'aaa'	1

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

Bit patterns of invalid timers, date and times, e.g. DT#2015-13-33-25:62:99.999_999_999, cannot be compared. This means that if one of the operands has an invalid value, the instruction "CMP <>: Not equal" has the result FALSE.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Comparison of hardware data types

To be able to compare the operands of the PORT data type with the "Not equal" instruction, you need to select the WORD data type from the drop-down list of the instructions box.

If you want to compare the two hardware data types HW_IO and HW_DEVICE, you must first create a tag of data type HW_ANY in the section "Temp" of the block interface and then copy the LADDR (of data type HW_DEVICE) to the tag. It is then possible to compare HW_ANY and HW_IO.

Comparison of structures

Note

Availability of comparison of structures

The option to compare structures is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

You can compare the values of two structured operands when both tags are of the same structure data type. When structures are compared, the operands to be compared must have the same data type regardless of the setting for the IEC Check. An exception is comparisons in which one of the two operands is a VARIANT or an ANY. If the data type is not yet known when the program is created, you can use the VARIANT data type. In this case you can also compare the operand with a structured tag of any data type. You can also compare two tags of the data type VARIANT or ANY with each other.

You can select the data type VARIANT for the comparison of structures from the drop-down list in the instruction box. The following data types are possible:

- PLC data type
- STRUCT (the structure of the data type STRUCT must be contained in a PLC data type (UDT) or the two structures to be compared are two elements of an ARRAY of STRUCT. Anonymous structures are not permitted.)
- Tag to which ANY is pointing
- Tag to which VARIANT is pointing

The following requirements must be met to compare two tags of the data type ARRAY with VARIANT selected:

- The elements must each have the same data type.
- The two ARRAYs must have the same dimension.
- All dimensions must have the same number of elements. The exact ARRAY limits do not have to match.

Note

ARRAY of BOOL

When you compare two operands of the data type ARRAY of BOOL with each other, you have selected the data type VARIANT from the drop-down list, and the number of elements cannot be divided by 8, the fill bits are compared as well. This may affect the comparison result.

If an element within the structures that you want to compare is an invalid STRING/WSTRING, an invalid time or date or an invalid floating-point number, the comparison result in the RLO (result of logic operation) will return the signal state "0".

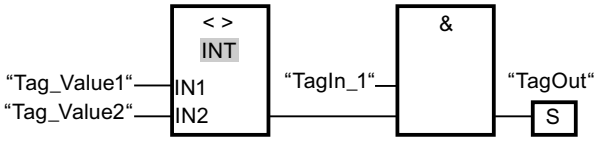
The table below shows an example of a comparison of structures:

<Operand1>			**<Operand2>**			**RLO of the instruction**
Tag of data type A <PLC data type>		Tag value	Tag of data type A <PLC data type>		Tag value	0
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

<Operand1>			**<Operand2>**			**RLO of the instruction**
Tag of data type A <PLC data type>		Tag value	Tag of data type B <PLC data type>		Tag value	1
	BOOL	FALSE		BOOL	TRUE	
	INT	2		INT	3	

<Operand1>			**<Operand2>**			**RLO of the instruction**
Tag of data type A <PLC data type>		Tag value	VARIANT (supplied with tag of data type A)		Tag value	0
	BOOL	FALSE		BOOL	FALSE	
	INT	2		INT	2	

Parameters



The following table shows the parameters of the "Not equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time, ARRAY of <data type> with fixed and variable ARRAY limits, STRUCT, VARIANT, ANY, PLC data type	I, Q, M, D, L, P, or constant	Second value to compare
As detailed above, the data types ARRAY, STRUCT (in a PLC data type), VARIANT, ANY and PLC data type (UDT) are only available as of firmware version 2.0 or 4.2.				

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <> "Tag_Value2".

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CMP >=: Greater or equal (S7-1200, S7-1500)

Description

You can use the "Greater or equal" instruction to query whether the value at input IN1 is greater or equal to the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table shows examples of string comparisons:

IN1	IN2	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'Hello World'	'Hello World'	1
'Hello World'	'HelloWorld'	0
'AA'	'aa'	0
'AAA'	'a'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is greater (more recent) than or equal to the timer at input IN2.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

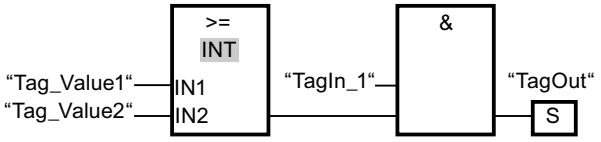
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Greater or equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" >= "Tag_Value2".

FBD programming examples (Page 4978)

Basic information on FBD (Page 4937)

CMP <=: Less or equal (S7-1200, S7-1500)

Description

You can use the "Less or equal" instruction to query whether the value at input IN1 is less or equal to the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table shows examples of string comparisons:

IN1	IN2	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'Hello World'	'Hello World'	1
'HelloWorld'	'Hello World'	0
'BB'	'AA'	0
'AAA'	'AA'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is smaller (less recent) than or equal to the timer at input IN2.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

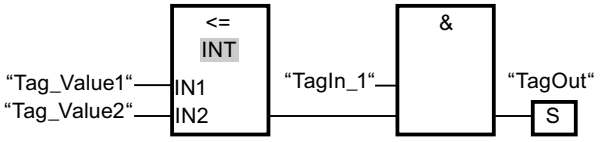
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Less or equal" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" <= "Tag_Value2".

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CMP >: Greater than (S7-1200, S7-1500)

Description

You can use the "Greater than" instruction to query whether the value at input IN1 is greater than the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.

The following table shows examples of string comparisons:

IN1	IN2	RLO of the instruction
'BB'	'AA'	1
'AAA'	'AA'	1
'AA'	'aa'	0
'AAA'	'a'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is greater (more recent) than the timer at input IN2.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

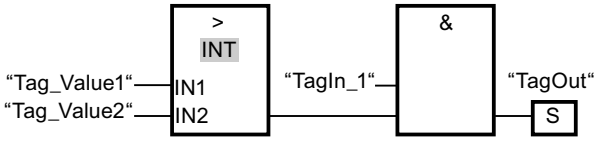
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Greater than" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" > "Tag_Value2".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

CMP <: Less than (S7-1200, S7-1500)

Description

You can use the "Less than" instruction to query whether the value at input IN1 is less than the value at input IN2. Both values to be compared must be of the same data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of character strings

The individual characters are compared by means of their code (for example, 'a' is greater than 'A') during the comparison of the strings. The comparison is performed from left to right. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the shorter string is considered smaller.

The following table shows examples of string comparisons:

<Operand1>	<Operand2>	RLO of the instruction
'AA'	'aa'	1
'AAA'	'a'	1
'BB'	'AA'	0
'AAA'	'AA'	0

You can also compare individual characters of a string. The number of the character to be compared is specified in square brackets next to the operand name. "MyString[2]", for example, compares the second character of the "MyString" string.

Comparison of timers, date and time

In comparing timer values, the RLO of the instruction is "1" if the timer at input IN1 is less (less recent) than the timer at input IN2.

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

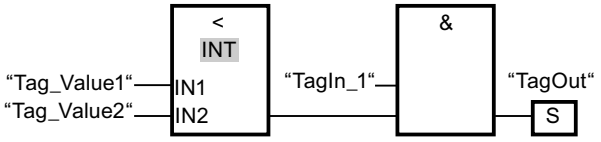
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparing tags of WORD data type to tags of the S5TIME data type

Both tags are converted to the TIME data type when comparing a tag of WORD data type to a tag of S5TIME data type. The WORD tag is interpreted as an S5TIME value. If one of the two tags cannot be converted, the comparison is not performed and the result is FALSE. If the conversion is successful the comparison is performed based on the selected comparison instruction.

Parameters



The following table shows the parameters of the "Less than" instruction:

Parameters	Declaration	Data type	Memory area	Description
IN1	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	First comparison value
IN2	Input	Bit strings, integers, floating-point numbers, character strings, timers, date and time	I, Q, M, D, L, P, or constant	Second value to compare

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn_1" has the signal state "1".
- The condition of the comparison instruction is fulfilled if "Tag_Value1" < "Tag_Value2".

IN_RANGE: Value within range (S7-1200, S7-1500)

Description

You can use the "Value within range" instruction to query whether of the value at VAL input is within a specific value range.

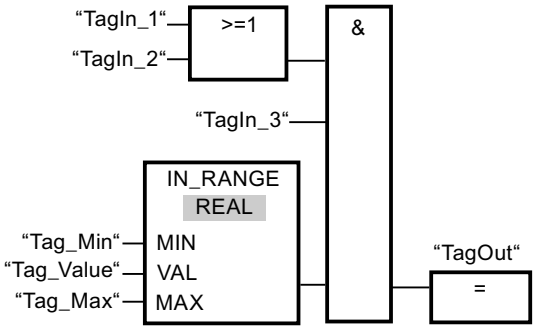
You specify the limits of the value range with the MIN and MAX inputs. The "Value within range" instruction compares the value at input VAL with the values of the inputs MIN and MAX and sends the result to the box output. If the value at input VAL satisfies the comparison MIN <=

VAL or VAL <=MAX, the box output has the signal state "1". If the comparison is not fulfilled, the signal state is "0" at the box output.

The comparison function can only execute if the values to be compared are of the same data type.

Parameters

The following table shows the parameters of the "Value within range" instruction:



Parameters	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

Output "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1" or "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "1".
- The value of the operand "Tag_Value" is within the value range that is specified by the current values of the operands "Tag_Min" and "Tag_Max" (MIN <= VAL or VAL <= MAX).

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

OUT_RANGE: Value outside range (S7-1200, S7-1500)

Description

You can use the "Value outside range" instruction to query whether of the value at input VAL is outside a specific value range.

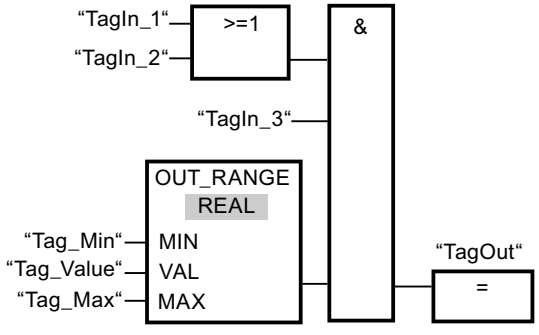
You specify the limits of the value range with the MIN and MAX inputs. The "Value outside range" instruction compares the value at input VAL with the values of the inputs MIN and MAX and sends the result to the box output. If the value at input VAL satisfies the comparison MIN > VAL or VAL >MAX, the box output has the signal state "1". The box output has the signal state "1" if a specified operand of data type REAL has an invalid value.

The box output returns the signal state "0", if the value at input VAL does not satisfy the MIN > VAL or VAL > MAX condition.

The comparison function can only execute if the values to be compared are of the same data type.

Parameters

The following table shows the parameters of the "Value outside range" instruction:



Parameters	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Low limit of the value range
VAL	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	Comparison value
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	High limit of the value range
Box output	Output	BOOL	I, Q, M, D, L	Result of the comparison

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

Output "TagOut" is set when the following conditions are fulfilled:

- The operands "TagIn_1" and "TagIn_2" have signal state "1".
- The operand "TagIn_3" has the signal state "1".
- The value of the operand "Tag_Value" is outside the value range that is specified by the values of the operands "Tag_Min" and "Tag_Max" (MIN > VAL or VAL > MAX).

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

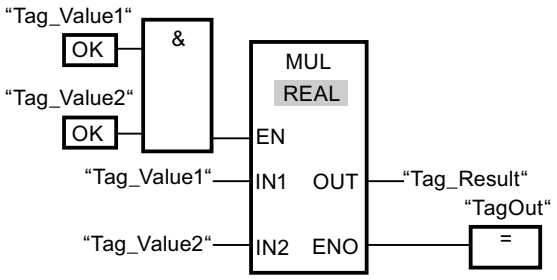
OK: Check validity (S7-1200, S7-1500)

Description

You can use the "Check validity" instruction to check if the value of an operand (<Operand>) is a valid floating-point number. The check is performed in every program cycle. If the operand value at the time of the query is a valid floating-point number, the output box will return the signal state"1". In all other cases, the signal state at the output of the "Check validity" instruction is "0".

You can use the "Check validity" instruction together with the EN mechanism. If you connect the instruction box to an EN enable input, the enable input is set only when the result of the validity query of the value is positive. You can use this function to ensure that an instruction is enabled only when the value of the specified operand is a valid floating-point number.

Parameters



The following example shows how the "Check validity" instruction works:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be checked.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

When the values of the operands "Tag_Value1" and "Tag_Value2" show valid floating-point numbers, the "Multiply" instruction is executed. The value of operand "Tag_Value1" is multiplied with the value of operand "Tag_Value2". The product of the multiplication is then written in the operand "Tag_Result". If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".

Overview of the valid data types (Page 2239)

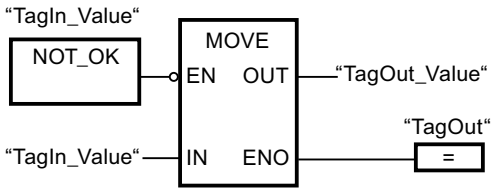
Basic information on FBD (Page 4937)

NOT_OK: Check invalidity (S7-1200, S7-1500)

Description

You can use the "Check invalidity" instruction to check if the value of an operand (<Operand>) is an invalid floating-point number. The check is performed in every program cycle. If the operand value at the time of the query is a valid floating-point number, then the output box will return the signal state "1". In all other cases, the signal state on the output box is "0".

Parameters



The following table shows the parameters of the instruction "Check invalidity":

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Floating-point numbers	I, Q, M, D, L	Value to be checked.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

When the value of operand "TagIn_Value" is an invalid floating-point number, the instruction "Move value" is not executed. The "TagOut" operand at the ENO enable output is set to the signal state "0".

VARIANT (S7-1200, S7-1500)

EQ_Type: Compare data type for EQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Equal".

The tag at the IN1 parameter must have the VARIANT data type. The tag at the IN2 parameter can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

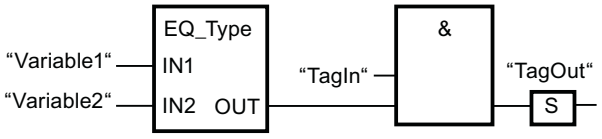
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP ==". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP ==: Equal (Page 2988)



Parameters

The following table shows the parameters of the "Compare data type for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN1	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "Variable1" operand is equal to "Variable2".

NE_Type: Compare data type for UNEQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type for UNEQUAL with the data type of a tag" instruction to query which data type a tag to which a VARIANT points does not have. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Not equal".

The tag at the IN1 parameter must have the VARIANT data type. The tag at the IN2 parameter can be an elementary data type or a PLC data type.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

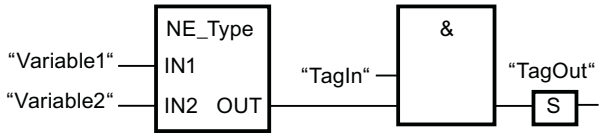
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP <>". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP <>: Not equal (Page 2992)



Parameters

The following table shows the parameters of the "Compare data type for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN1	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "Variable1" operand is not equal to "Variable2".

EQ_ElemType: Compare data type of an ARRAY element for EQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction to query the data type of a tag to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Equal".

The tag at the IN1 parameter must have the VARIANT data type. The tag at the IN2 parameter can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

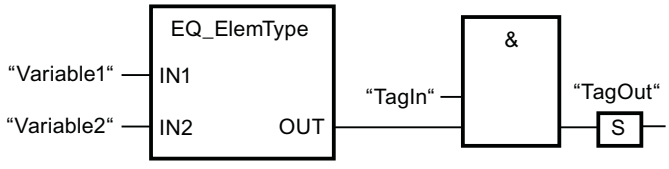
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP ==". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP ==: Equal (Page 2988)



Parameters

The following table shows the parameters of the "Compare data type of an ARRAY element for EQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN1	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "Variable1" operand is equal to "Variable2".

NE_ElemType: Compare data type of an ARRAY element for UNEQUAL with the data type of a tag (S7-1200, S7-1500)

Description

You can use the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction to query which data type a tag does not have to which a VARIANT points. You are comparing the data type of the tag at IN1 parameter, which you declared in the block interface, with the data type of a tag at IN2 parameter for "Not equal".

The tag at the IN1 parameter must have the VARIANT data type. The tag at the IN2 parameter can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

If the condition of the comparison is fulfilled, the instruction returns the result of logic operation (RLO) "1". If the comparison condition is not fulfilled, the instruction returns RLO "0".

Comparison of timers, date and time

Not all times can be compared directly with each other, such as S5TIME. In this case they are implicitly converted into another time so that they can be compared, for example to TIME.

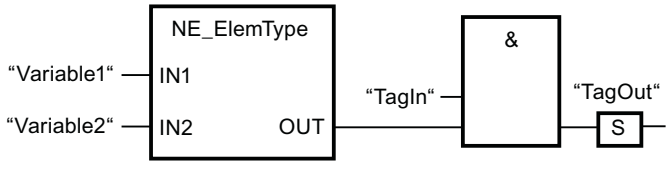
If you want to compare dates and times of different data types, the value of the smaller date or time data type is implicitly converted into the larger date or time data type. This means the two date and time data types DATE and DTL, for example, are compared on the basis of DTL.

When the implicit conversions fail, the comparison result is FALSE.

Comparison of structures

For the comparison of structures, you can use the instruction "CMP <>". Anonymous structures cannot generally be compared unless they are part of the same ARRAY.

For additional information on the comparison of structures, please refer to: CMP <>: Not equal (Page 2992)



Parameters

The following table shows the parameters of the "Compare data type of an ARRAY element for UNEQUAL with the data type of a tag" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN1	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand
IN2	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Second operand

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operand "TagIn" has the signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "Variable1" operand is not equal to "Variable2".

IS_NULL: Check for EQUALS NULL pointer (S7-1200, S7-1500)

Description

You use the instruction "Check for EQUALS NULL pointer" to query whether the VARIANT points to a NULL pointer and therefore does not point to an object.

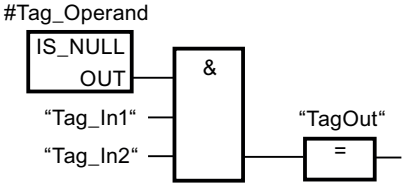
The <operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "0" even if the ANY pointer is NULL.

Parameters



The following table shows the parameters of the "Check for EQUALS NULL pointer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is compared for EQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand does not point to an object.

See also

Overview of the valid data types (Page 2239)

NOT_NULL: Check for UNEQUALS NULL pointer (S7-1200, S7-1500)

Description

You can use the instruction "Check for UNEQUALS NULL pointer" to query whether the VARIANT does not point to a NULL pointer and therefore points to an object.

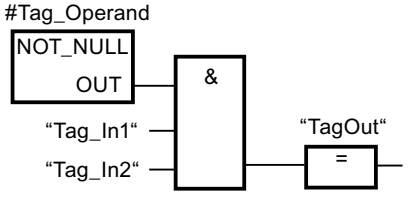
The <operand> must have the VARIANT data type.

Note

VARIANT tag points to an ANY pointer

If the VARIANT tag points to an ANY pointer, the instruction always returns the result RLO = "1" even if the ANY pointer is NULL.

Parameters



The following table shows the parameters of the "Check for UNEQUALS NULL pointer" instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is compared for UNEQUALS NULL

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the #Tag_Operand operand points to an object.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

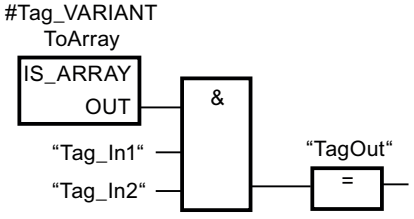
IS_ARRAY: Check for ARRAY (S7-1200, S7-1500)

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

The <operand> must have the VARIANT data type.

Parameters



The following table shows the parameters of the "Check for ARRAY" instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is queried for ARRAY

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The "TagOut" output is set when the following conditions are fulfilled:

- The operands "Tag_In1" and "Tag_In2" have signal state "1".
- The condition of the comparison instruction is fulfilled, i.e. the "#Tag_VARIANTToArray" operand is of the ARRAY data type.

Math functions (S7-1200, S7-1500)

CALCULATE: Calculate (S7-1200, S7-1500)

Description

The "Calculate" instruction is used to define and execute an expression for the calculation of mathematical operations or complex logic operations depending on the selected data type.

You can select the data type of the instruction from the "???" drop-down list of the instruction box. Depending on the selected data type, you can combine the functionality of specific instructions to execute a complex calculation. The expression to be calculated is specified via a dialog you can open via the "Calculator" icon at the top of the instruction box. The expression can contain the names of the input parameters and the syntax of the instructions. It is not permitted to specify operand names or operand addresses.

In its initial state, the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box.

The values of the inputs are use to execute the specified expression. Not all defined inputs have to be used in the expression. The result of the instruction is transferred to the box output OUT.

Note

If one of the mathematical operations fails in the expression, then no result is transferred to the OUT output and the ENO enable output has the signal state "1".

If, in the expression, you use inputs that are not available in the box, these inputs are automatically inserted. Provided that there are no gaps in the numbering of the inputs that are to be newly defined in the expression. You cannot, for example, use the input IN4 in the expression if the input IN3 is not defined.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result or an interim result of the "Calculate" instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.
- An error occurred during the execution of one of the instructions specified in the expression.

The following table shows the instructions that, depending on the selected data type, can be combined and executed in the expression of the "Calculate" instruction:

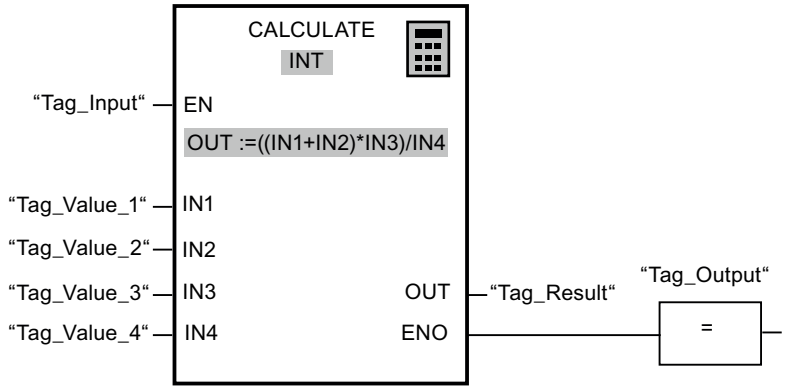
Data type	Instruction	Syntax	Example
Bit strings	AND: AND logic operation	AND	IN1 AND IN2 OR IN3
	OR: OR logic operation	OR	
	XOR: EXCLUSIVE OR logic operation	XOR	
	INV: Create ones complement	NOT	
	SWAP: Swap [1)]	SWAP	

Data type	Instruction	Syntax	Example
Integers	ADD: Add	+	(IN1 + IN2) * IN3; (ABS(IN2)) * (ABS(IN1))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	MOD: Return remainder of division	MOD	
	INV: Create ones complement	NOT	
	NEG: Create twos complement	-(in1)	
	ABS: Form absolute value	ABS( )	
Floating-point numbers	ADD: Add	+	((SIN(IN2) * SIN(IN2) + (SIN(IN3) * SIN(IN3)) / IN3)); (SQR(SIN(IN2)) + (SQR(COS(IN3)) / IN2))
	SUB: Subtract	-	
	MUL: Multiply	*	
	DIV: Divide	/	
	EXPT: Exponentiate	**	
	ABS: Form absolute value	ABS( )	
	SQR: Form square	SQR( )	
	SQRT: Form square root	SQRT( )	
	LN: Form natural logarithm	LN( )	
	EXP: Form exponential value	EXP( )	
	FRAC: Return fraction	FRAC( )	
	SIN: Form sine value	SIN( )	
	COS: Form cosine value	COS( )	
	TAN: Form tangent value	TAN( )	
	ASIN: Form arcsine value	ASIN( )	
	ACOS: Form arccosine value	ACOS( )	
	ATAN: Form arctangent value	ATAN( )	
	NEG: Create twos complement	-(in1)	
	TRUNC: Truncate numerical value	TRUNC( )	
	ROUND: Round numerical value	ROUND( )	
	CEIL: Generate next higher integer from floating-point number	CEIL( )	
	FLOOR: Generate next lower integer from floating-point number	FLOOR( )	

[1] Not possible for data type BYTE.

Parameters

The following table shows the parameters of the instruction "Calculate":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN1	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First available input
IN2	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second available input
INn	Input	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs
OUT	Output	Bit strings, integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the end result is to be transferred.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN1	Tag_Value_1	4
IN2	Tag_Value_2	4
IN3	Tag_Value_3	3
IN4	Tag_Value_4	2
OUT	Tag_Result	12

If the "Tag_Input" has the signal state "1", the instruction is executed. The value of operand "Tag_Value_1" is added to the value of operand "Tag_Value_2". The sum is multiplied with the value of the operand "Tag_Value_3". The product is divided by the value of the operand "Tag_Value_4". The quotient is transferred as end result to the operand "Tag_Result" at the OUT output of the instruction. If no errors occur during the execution of the individual instructions, output ENO and the operand "Tag_Output" are set to "1".

Overview of the valid data types (Page 2239)

Example of calculating an equation (Page 4986)

Basic information on FBD (Page 4937)

ADD: Add (S7-1200, S7-1500)

Description

You can use the "Add" instruction to add the value at input IN1 to the value at input IN2 and query the sum at output OUT (OUT := IN1+IN2).

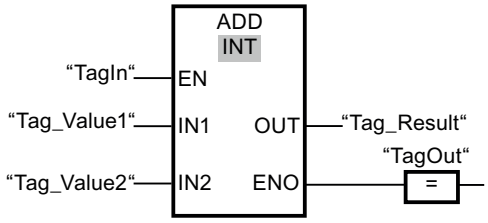
In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are added. The sum is stored at output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Add":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First number to be added
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second number to be added
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values, which are added.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Sum

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also":

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is added to the value of operand "Tag_Value2". The result of the addition is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

SUB: Subtract (S7-1200, S7-1500)

Description

You can use the "Subtract" instruction to subtract the value at input IN2 from the value at input IN1 and query the difference at output OUT (OUT := IN1-IN2).

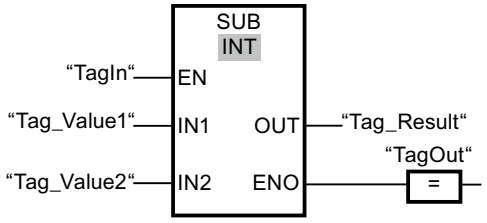
The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Subtract":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Minuend



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Subtrahend
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Difference

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value2" is subtracted from the value of operand "Tag_Value1". The result of the subtraction is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

MUL: Multiply (S7-1200, S7-1500)

Description

You can use the "Multiply" instruction to multiply the value at input IN1 with the value at input IN2 and query the total at output OUT (OUT := IN1*IN2).

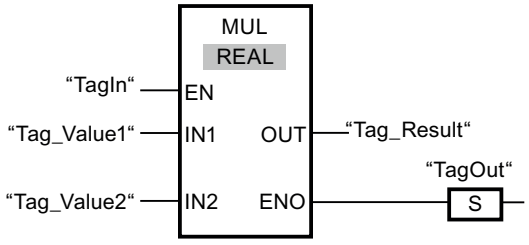
In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. When the instruction is executed, the values of all available input parameters are multiplied. The product is stored at the OUT output.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Multiply":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for multiplication
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for multiplication
INn	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values, which are multiplied.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Product

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is multiplied with the value of operand "Tag_Value2". The result of the multiplication is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

DIV: Divide (S7-1200, S7-1500)

Description

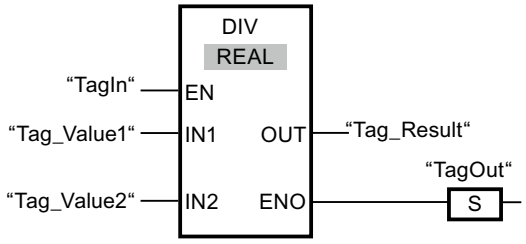
You can use the "Divide" instruction to divide the value at input IN1 by the value at input IN2 and query the quotient at output OUT (OUT := IN1/IN2).

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Divide":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Dividend
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Divisor
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Quotient value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The result of the division is stored in the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

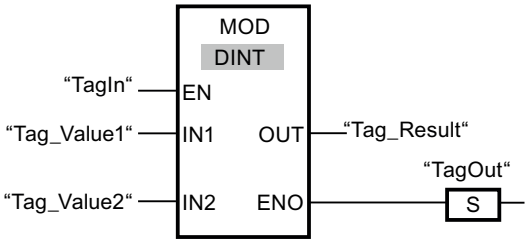
MOD: Return remainder of division (S7-1200, S7-1500)

Description

You can use the "Return remainder of division" instruction to divide the value at input IN1 by the value at input IN2 and query the remainder of division at output OUT.

Parameters

The following table shows the parameters of the "Return remainder of division" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Dividend
IN2	Input	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Divisor
OUT	Output	Integers	I, Q, M, D, L, P	I, Q, M, D, L, P	Remainder of division

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is divided by the value of operand "Tag_Value2". The remainder of division is stored in operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

NEG: Create twos complement (S7-1200, S7-1500)

Description

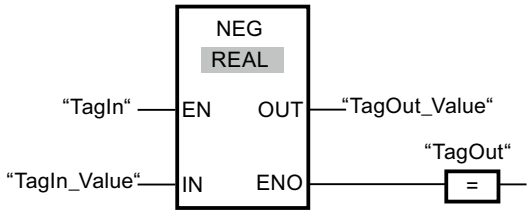
You can use the "Create twos complement" instruction to change the sign of the value at input IN and query the result at output OUT. If there is a positive value at input IN, for example, the negative equivalent of this value is sent to output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The result of the instruction is outside the range permitted for the data type specified at output OUT.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Create twos complement" instruction:



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Twos complement of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The sign of the value at input "TagIn_Value" is changed and the result is stored at output "TagOut_Value". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

INC: Increment (S7-1200, S7-1500)

Description

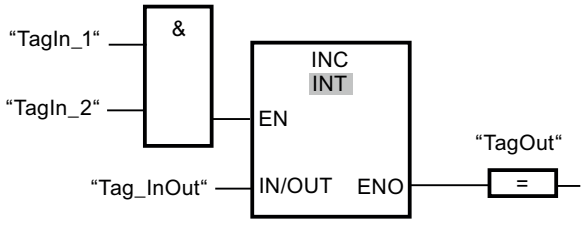
You can use the "Increment" instruction to change the value of the operand at parameter IN/OUT to the next higher value and query the result.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Increment" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	I, Q, M, D, L	Value to be incremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the operands TagIn_1 and TagIn_2 have the signal state "1", the value of the operand "Tag_InOut" is incremented by one and the output "TagOut" is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

DEC: Decrement (S7-1200, S7-1500)

Description

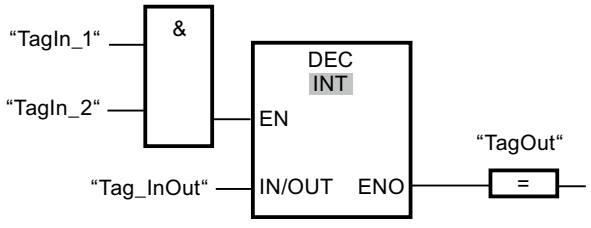
You can use the "Decrement" instruction to change the value of the operand at parameter IN/OUT to the next lower value and query the result.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Decrement":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN/OUT	InOut	Integers	I, Q, M, D, L	I, Q, M, D, L	Value to be decremented.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have the signal state "1", the value of the operand "Tag_InOut" is decremented by one and the output "TagOut" is set.

ABS: Form absolute value (S7-1200, S7-1500)

Description

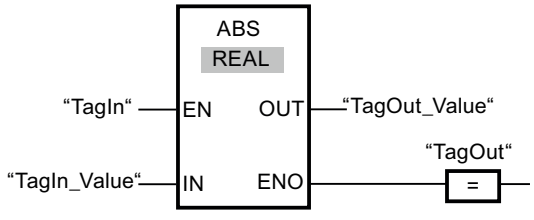
You can use the "Form absolute value" instruction to calculate the absolute value of the value specified at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the instruction "Form absolute value":



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Absolute value of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	-6.234
OUT	TagOut_Value	6.234

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the absolute value of the value at input "TagIn_Value" and sends the result to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

MIN: Get minimum (S7-1200, S7-1500)

Description

The "Get minimum" instruction compares the values at the available inputs and writes the lowest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

In its initial state the instruction contains at least two inputs (IN1 and IN2) and no more than 100 inputs.

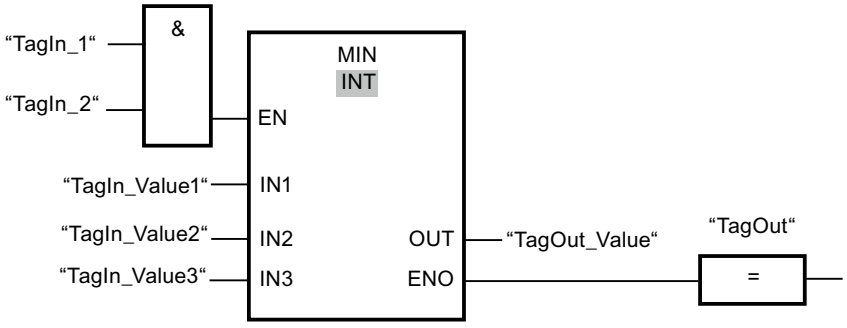
The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get minimum" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN2	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
INn	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs whose values are to be compared
OUT	Output	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
If the IEC check is not enabled, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string of the same length as the data type. (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bits)					

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	12222

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the lowest value ("TagIn_Value1") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

MAX: Get maximum (S7-1200, S7-1500)

Description

The "Get maximum" instruction compares the values at the available inputs and writes the highest value to the OUT output. The number of inputs can be expanded at the instruction box by additional inputs. The inputs are numbered in ascending order in the box.

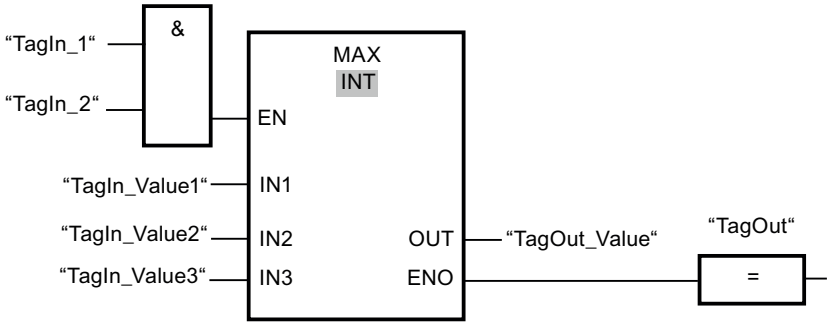
In its initial state the instruction contains at least two inputs (IN1 and IN2) and no more than 100 inputs.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get maximum" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN2	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
INn	Input	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Additionally inserted inputs whose values are to be compared.
OUT	Output	Integers, floating-point numbers, DTL, DT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
If the IEC check is not enabled, you can also use tags of the data type TIME, LTIME, TOD, LTOD, DATE and LDT by selecting a bit string of the same length as the data type. (e.g. instead of TIME => DINT, UDINT or DWORD = 32 bits)					

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	TagIn_Value1	12222
IN2	TagIn_Value2	14444
IN3	TagIn_Value3	13333
OUT	TagOut_Value	14444

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction compares the values of the specified operands and copies the highest value ("TagIn_Value2") to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

LIMIT: Set limit value (S7-1200, S7-1500)

Description

You can use the "Set limit value" instruction to limit the value at input IN to the values at the inputs MN and MX. If the value at the IN input meets the MN condition <= IN <= MX, it is copied to the OUT output. If the condition is not fulfilled and the input value IN is below the low limit MN, output OUT is set to the value of the input MN. If the high limit MX is exceeded, output OUT is set to the value of the input MX.

If the value at the MN input is greater than at the MX input, the result is the value specified at the IN parameter and the enable output ENO is "0".

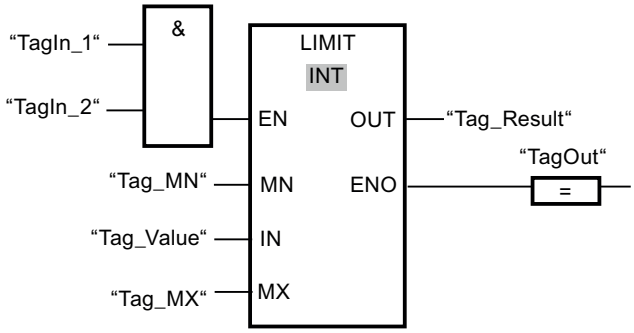
The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The specified tags are not of the same data type.

- An operand has an invalid value.
- The value at the MN input is greater than the value at the MX input.

Parameters

The following table shows the parameters of the "Set limit value" instruction:



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
OUT	Output	Integers, floating-point numbers, TIME, TOD, DATE, DTL, DT	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DTL, DT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.						

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MN	Tag_MN	12000
IN	Tag_Value	8000
MX	Tag_MX	16000
OUT	Tag_Result	12000

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The value of operand "Tag_Value" is compared with the values of operands "Tag_MN" and "Tag_MX". Since the value of the operand "Tag_Value" is less than the low limit, the value of the operand "Tag_MN" is copied to the "Tag_Result" output. If the instruction is executed without errors, the "TagOut" output is set.

SQR: Form square (S7-1200, S7-1500)

Description

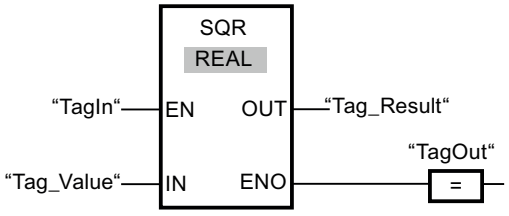
The instruction "Form square" is used to square the value of a floating-point number at input IN and to write the result to output OUT.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form square":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Square of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	5.0
OUT	Tag_Result	25.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction squares the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

SQRT: Form square root (S7-1200, S7-1500)

Description

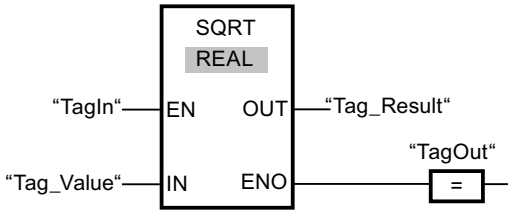
The instruction "Form square root" is used form the square root from the value of the floating-point number at input IN and to write the result to output OUT. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number. If the value at input IN is "0", the result is also "0".

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form square root":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Square root of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	25.0
OUT	Tag_Result	5.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the square root of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

LN: Form natural logarithm (S7-1200, S7-1500)

Description

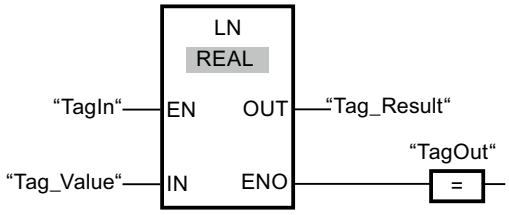
You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e = 2.718282) of the value at input IN. The result is sent to output OUT and can be queried there. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, output OUT returns an invalid floating-point number.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is negative.

Parameters

The following table shows the parameters of the instruction "Form natural logarithm":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Natural logarithm of the input value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction forms the natural logarithm of the value at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

EXP: Form exponential value (S7-1200, S7-1500)

Description

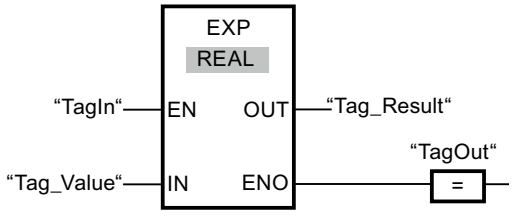
You can use the "Form exponential value" instruction to calculate the exponent from the base e (e = 2.718282) and the value specified at input IN. The result is provided at output OUT and can be queried there (OUT = e^{IN}).

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form exponential value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Exponential value of input value IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction forms the exponent from base e and the value of the operand "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

SIN: Form sine value (S7-1200, S7-1500)

Description

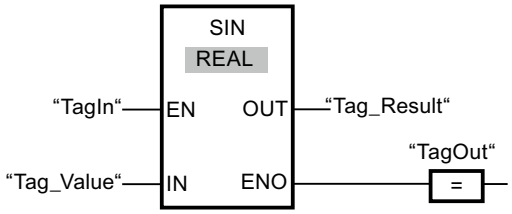
You can use the "Form sine value" instruction to calculate the sine of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form sine value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of the angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Sine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	1.0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the sine of the angle specified at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

COS: Form cosine value (S7-1200, S7-1500)

Description

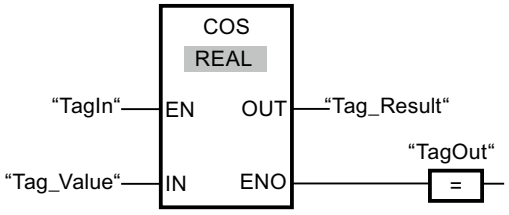
You can use the "Form cosine value" instruction to calculate the cosine of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form cosine value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of the angle in radians
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Cosine of the specified angle

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	+1.570796 (π/2)
OUT	Tag_Result	0

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the cosine of the angle specified at input "Tag_Value" and sends the result to output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

TAN: Form tangent value (S7-1200, S7-1500)

Description

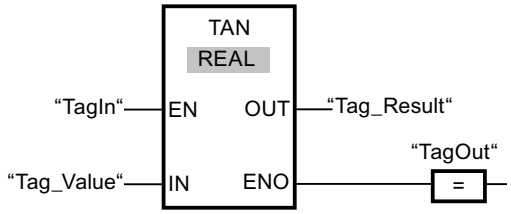
You can use the "Form tangent value" instruction to calculate the tangent of an angle. The size of the angle is specified in the radian measure at input IN. The result of the instruction is provided at output OUT and can be queried there.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form tangent value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Size of angle in the radian measure
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Tangent of the specified angle

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	+3.141593 (π)
OUT	Tag_Result	0

If the operand "TagIn" has the signal state "1", the "Form tangent value" instruction is executed. The instruction calculates the tangent of the angle specified at input "Tag_Value" and stores the result at output "Tag_Result". If no errors occur during the execution of the instruction, the output "TagOut" is set.

ASIN: Form arcsine value (S7-1200, S7-1500)

Description

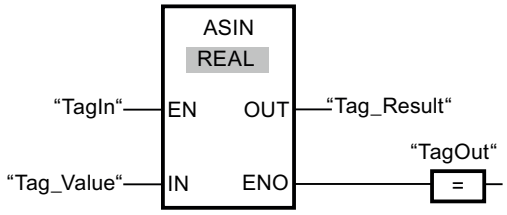
You can use the "Form arcsine value" instruction to calculate the size of the angle from the sine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is outside the permitted range (-1 to +1).

Parameters

The following table shows the parameters of the instruction "Form arcsine value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Sine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+1.570796 (π/2)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the sine value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

ACOS: Form arccosine value (S7-1200, S7-1500)

Description

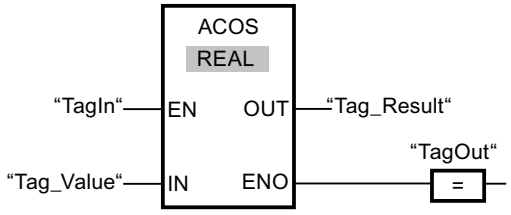
You can use the "Form arccosine value" instruction to calculate the size of the angle from the cosine value specified at input IN, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified at input IN. The calculated angle size is output in radians at output OUT and can range in value from 0 to +π.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.
- The value at input IN is outside the permitted range (-1 to +1).

Parameters

The following table shows the parameters of the instruction "Form arccosine value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Cosine value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	0
OUT	Tag_Result	+1.570796 (π/2)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the cosine value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

ATAN: Form arctangent value (S7-1200, S7-1500)

Description

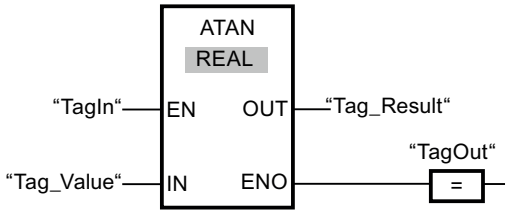
You can use the "Form arctangent value" instruction to calculate the size of the angle from the tangent value specified at input IN, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) at input IN. The calculated angle size is output in radians at the OUT output and can range in value from -π/2 to +π/2.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input IN is not a valid floating-point number.

Parameters

The following table shows the parameters of the instruction "Form arctangent value":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Tangent value
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Size of the angle in radians

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	1.0
OUT	Tag_Result	+0.785398 (π/4)

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction calculates the size of the angle corresponding to the tangent value at input "Tag_Value". The result of the instruction is stored at output "Tag_Result". If the instruction is executed without errors, the "TagOut" output is set.

Invalid floating-point numbers (Page 2259)

Basic information on FBD (Page 4937)

FRAC: Return fraction (S7-1200, S7-1500)

Description

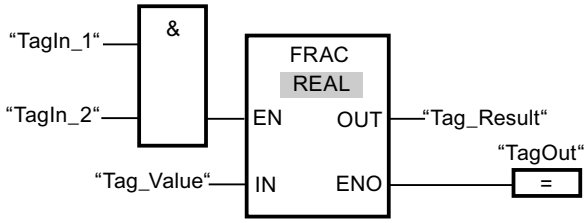
You can use the "Return fraction" instruction to determine the decimal places of the value at the IN input. The result of the query is stored at output OUT and can be queried there. If the input IN has e.g. the value 123.4567, the output OUT has the value 0.4567.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors occur during the execution of the instruction, for example there is no valid floating-point number at the input.

Parameters

The following table shows the parameters of the "Return fraction" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value, whose decimal places are to be determined.
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Decimal places of the input value at input IN

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_Value	2.555
OUT	Tag_Result	0.555

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is started. The decimal places from the value at the operand "Tag_Value" are copied to the operand "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

EXPT: Exponentiate (S7-1200, S7-1500)

Description

You can use the "Exponentiate" instruction to raise the value at the input IN1 by a power specified with the value at input IN2. The result of the instruction is stored at output OUT and can be queried there (OUT = $IN1^{IN2}$).

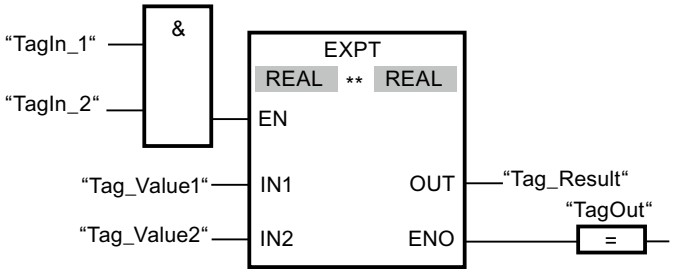
The value at input IN1 must be a valid floating-point number. Integers are also allowed for setting the input IN2.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors occur during the instruction processing, for example, if there is an overflow.

Parameters

The following table shows the parameters of the instruction "Exponentiate":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Base value
IN2	Input	Integers, floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value with which the base value is exponentiated
OUT	Output	Floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the "Exponentiate" instruction is executed. The value of operand "Tag_Value1" is raised by the power of the value of the operand "Tag_Value2". The result is stored at output "Tag_Result". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Move operations (S7-1200, S7-1500)

MOVE: Move value (S7-1200, S7-1500)

Description

You use the "Move value" instruction to transfer the content of the operand at the IN input to the operand at the OUT1 output. The transfer is always made in the direction of ascending address.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data type at the IN parameter does not correspond to the specified data type at the OUT1 parameter.

The following table lists the possible transfers for the S7-1200 CPU series:

Source (IN)	Destination (OUT1)	
	With IEC check	Without IEC check
BYTE	BYTE, WORD, DWORD	BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, TIME, DATE ,TOD, CHAR

[1] You can also use the "Move value" instruction to transfer individual characters of a string to operands of the CHAR or WCHAR data type. The number of the character to be transferred is specified in square brackets next to the operand name. "MyString[2]", for example, transfers the second character of the "MyString" string. The transfer of the operand of the data type CHAR or WCHAR to the individual character of a string is also possible. You can also replace a specific character of a string with the character of another string.

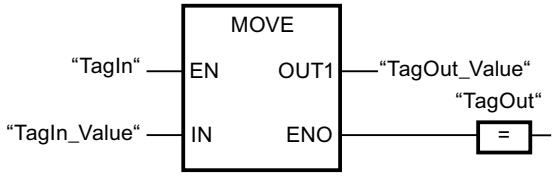
[2] Transferring entire arrays (ARRAY) is possible only when the array components of the operands at input IN and at output OUT1 are of the same data type.

If the bit length of the data type at input IN exceeds the bit length of the data type at output OUT1, the higher-order bits of the source value are lost. If the bit length of the data type at input IN is less than the bit length of the data type at output OUT1, the higher-order bits of the destination value will be overwritten with zeros.

In its initial state, the instruction box contains 1 output (OUT1). The number of outputs can be extended. The added outputs are numbered in ascending order on the box. During the execution of the instruction, the content of the operand at the input IN is transferred to all available outputs. The instruction box cannot be extended if structured data types (DTL, STRUCT, ARRAY) or characters of a string are transferred.

You can also use the "Move block" (MOVE_BLK) and "Move block uninterruptible" (UMOVE_BLK) instructions to move operands of the ARRAY data type. Operand of the data type STRING or WSTRING can be copied with the instruction "Move character string" (S_MOVE).

Parameters



The following table shows the parameters of the "Move value" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Element used to overwrite the destination address.
OUT1	Output	Bit strings, integers, floating-point numbers, timers, date and time, CHAR, WCHAR, STRUCT, ARRAY, IEC data types, PLC data type (UDT)	Bit strings, integers, floating-point numbers, timers, date and time, CHAR; WCHAR, STRUCT, ARRAY, TIMER, COUNTER, IEC data type, PLC data type (UDT)	I, Q, M, D, L	I, Q, M, D, L	Destination address

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
OUT1	TagOut_Value	0011 1111 1010 1111

If the "TagIn" operand returns signal state TRUE, the instruction is executed. The instruction moves the contents of the "TagIn_Value" operand to the "TagOut_Value" operand. If the instruction is executed without errors, the ENO and "TagOut" enable outputs are set to signal state TRUE.

Note

You can find more information on the MOVE instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Deserialize: Deserialize (S7-1200, S7-1500)

Description

You can use the "Deserialize" instruction to convert back the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> is located must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized memory areas also permitted as of version 2.0. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion. If the memory area is filled using the instruction "Serialize" and it is possible that fill bytes were inserted, their conversion is not taken into account.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The instruction enables you to convert multiple sequential representations of converted data back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type>, you can also directly use the instruction "TRCV: Receive data via communication connection".

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To deserialize larger structures, you can declare the memory area for sequential representation with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The content of the sequential representation remains unchanged, as for a standard memory area. Only symbolic access to the bytes in the ARRAY is possible.

Parameters

The following table shows the parameters of the "Deserialize" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_ARRAY	Input	VARIANT ARRAY[*] of BYTE [1)]	D, block interface of an FB (The sections Input, Output, Static and Temp are possible.)	Tag of ARRAY of BYTE data type in which the generate data flow is stored
DEST_VARIABLE	InOut	VARIANT	D, block interface of an FB	Tag in which the reconverted PLC data type (UDT), STRUCT, ARRAY of <data type> is stored

Parameters	Declaration	Data type	Memory area	Description
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the number of bytes occupied by the converted customer data. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information
[1] Possible for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.				

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains a ZERO pointer.
8151	No valid reference at the SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8154	Invalid data type at the SRC_ARRAY parameter
8250	The VARIANT data type at the DEST_VARIABLE parameter contains a ZERO pointer.
8251	No valid reference at the DEST_VARIABLE parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

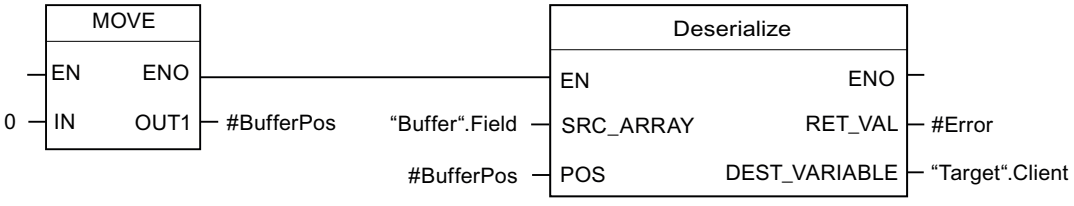
Error code* (W#16#...)	Explanation
8136	Access to the memory area at the SRC_ARRAY parameter is invalid.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface of an FB or FC.
BufferPos	DINT	In the "Temp" section of the block interface of an FB or FC.
Error	INT	
Label	STRING[4]	

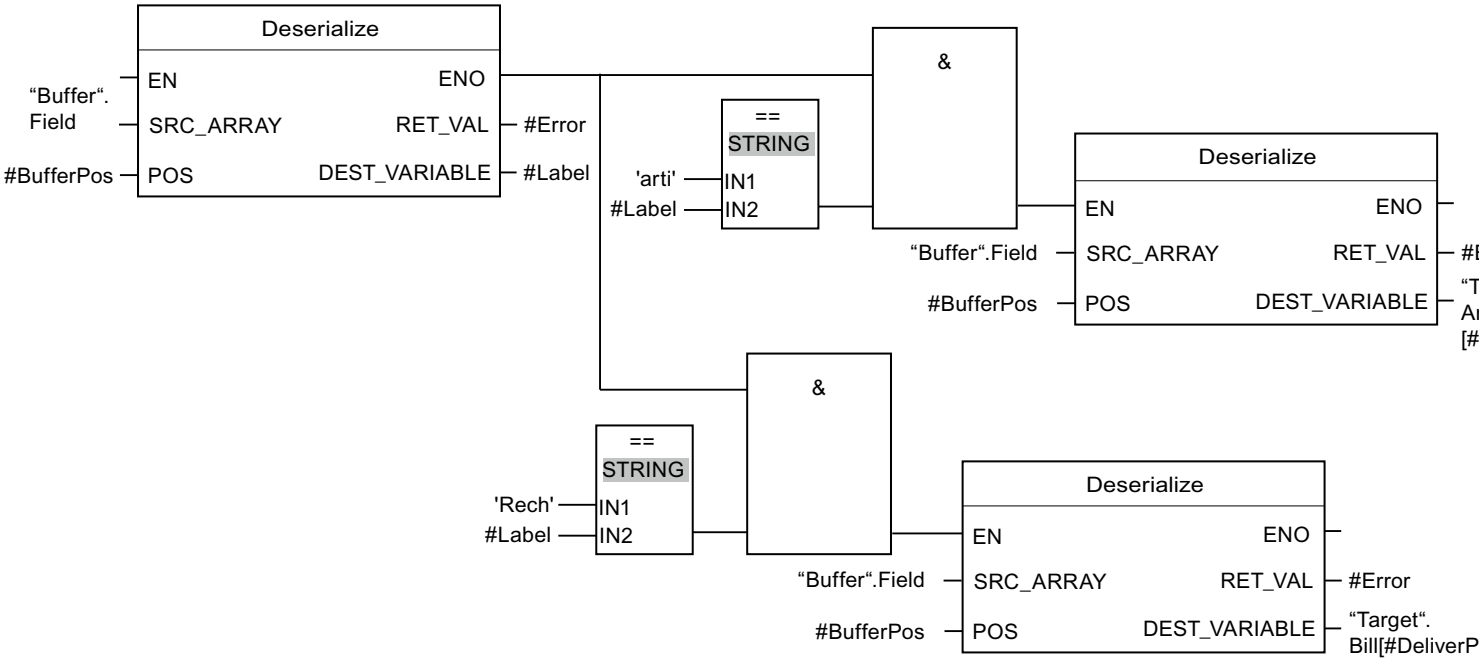
The following table shows the declarations of the PLC data types:



Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE



The following example shows how the instruction works:

Network 1:

The "Move value" instruction moves the value "0" to the #BufferPos operand. The "Deserialize" instruction deserializes the sequential representation of the customer data from the "Buffer" tag and writes it to the "Target" tag. The #BufferPos operand stores the index of the first byte based on the number of bytes occupied by the converted customer data.

Network 2:

The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was stored in the sequential representation after the customer data, from the "Buffer" tag and writes the characters to the #Label operand. The characters are compared using comparison instructions "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" tag. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" tag.

Structure of a STRING tag (Page 2272)

Basic information on FBD (Page 4937)

Serialize: Serialize (S7-1200, S7-1500)

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT), STRUCT or ARRAY of <data type> to a sequential representation without losing parts of their structure.

You use the instruction to temporarily save multiple structured data items from your program in a buffer, which should preferably be in a global data block, and send them to another CPU.

The memory area in which the converted data are stored must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized data is also permitted as of version 2.0. Fill bytes or fill bits of a data area (e.g. ARRAY, STRUCT or PLC data type (UDT)) as well as the characters of a string currently not in use are undefined in the destination ARRAY.

The capacity of the standard memory area is 64 KB. Structures that are larger than 64 KB in accordance with the rules for standard memory areas cannot be serialized if the operand at the DEST_ARRAY parameter is located in a standard memory area.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The operand at the POS parameter contains information about the number of bytes used by the converted data.

If you want to send a single PLC data type (UDT), STRUCT or ARRAY of <data type>, you can directly call the instruction "TSEND: Send data via communication connection".

Note

Comparison of structures

To compare structures, they have to be serialized first. Use the "CMP" instruction instead.

You can find additional information in the section "Comparator".

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To serialize larger structures, you can declare the memory area with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The sequential representation remains unchanged, as for a standard memory area.

Parameters

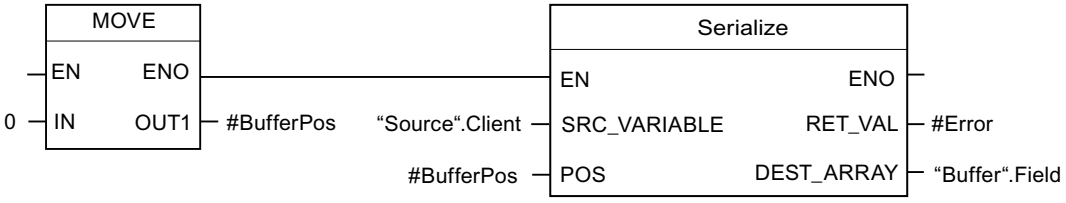
The following table shows the parameters of the instruction "Serialize":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC_VARIABLE	Input	VARIANT	D, block interface of an FB	PLC data type (UDT), STRUCT or ARRAY of <data type> that is converted to sequential representation.
DEST_ARRAY	InOut	VARIANT	D, block interface of an FB (the sections Input, Output, Static and Temp are possible.)	Data block in which the generated data stream is stored.
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the total number of bytes that the converted customer data has occupied. The POS parameter is calculated zero-based.
RET_VAL	Output	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

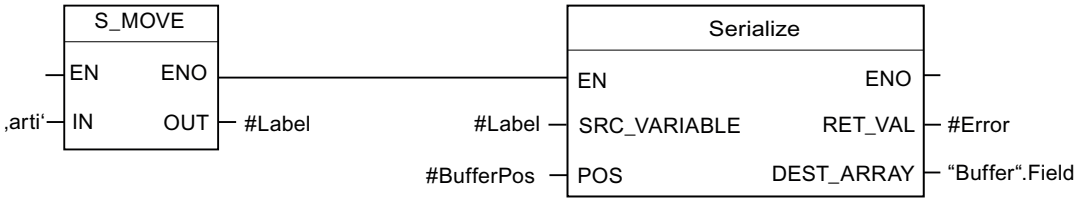
Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains a ZERO pointer.
8151	No valid reference at the SRC_VARIABLE parameter
8236	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains a ZERO pointer.
8251	No valid reference at the DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	



For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

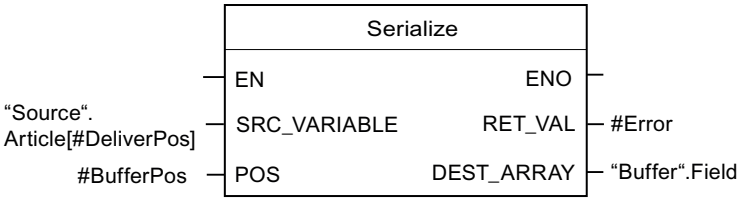
Error code* (W#16#...)	Explanation
8236	Access to the memory area at the DEST_ARRAY parameter is invalid.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example



The following example shows how the instruction works:

Network 1:



The "Move value" instruction moves the value "0" to the #BufferPos operand. The "Deserialize" instruction deserializes the customer data from the "Source" tag and writes the sequential representation to the "Buffer" tag. The index of the next unwritten byte of the "Buffer".Field operand is saved in the #BufferPos operand.

Network 2:

A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move character string" instruction moves the "arti" characters to the #Label operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" tag. The value of the #BufferPos operand is incremented accordingly.

Network 3:

The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" tag and writes it in sequential representation to the "Buffer" tag after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

MOVE_BLK: Move block (S7-1200, S7-1500)

Description

You use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). The number of elements to be moved to the target range is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source range and the target range have the same data type.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

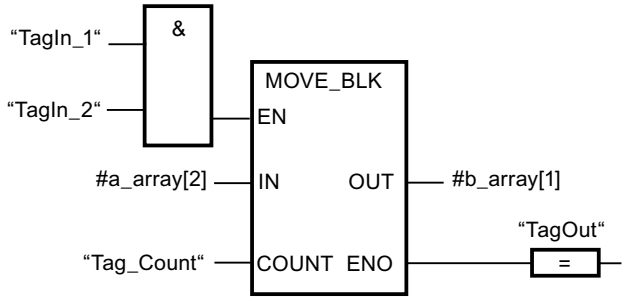
Note

Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

Parameters

The following table shows the parameters of the "Move block" instruction:



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1)]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the source area that is being copied

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of elements to be copied from the source range to the target range
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the target range to which the contents of the source range are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.						

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is ARRAY [0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is ARRAY [0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element.

If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Note

You can find more information on the MOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Editing FBD elements (Page 4964)

Inserting operands in FBD instructions (Page 4970)

SCATTER: Parse the bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse the bit sequence into individual bits" disassembles a tag of the BYTE, WORD, DWORD or LWORD data type into individual bits and saves them in an ARRAY of BOOL.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse a status word, and read and change the status of the individual bits using the index. Using GATHER, you can merge the bits once again into a bit sequence.

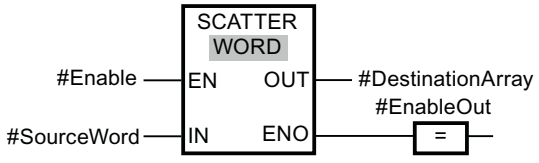
The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- If the ARRAY does not provide enough BOOL elements.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Bit sequence that is parsed
OUT	Output	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY in which the individual bits are saved



You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceWord		WORD
EnableOut	Output	BOOL
DestinationArray		ARRAY[0..15] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceWORD	WORD (16 bits)
OUT	DestinationArray	The operand "DestinationArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD that is to be parsed.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The operand #SourceWord of the data type WORD is parsed into its individual bits (16) and assigned to the individual elements of the #DestinationArray operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

SCATTER_BLK: Parse elements of an ARRAY of bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse elements of an ARRAY of bit sequence into individual bits" parses one or more elements of an ARRAY of BYTE, WORD, DWORD or LWORD into individual bits and saves them in an ARRAY of BOOL. At the COUNT_IN parameter you specify how many elements of the source ARRAY are going to be disassembled. The source ARRAY at the IN parameter may have more elements than specified at the COUNT_IN parameter. The ARRAY of BOOL must have sufficient elements to save the bits of the disassembled bit strings. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n (number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse status words, and read and change the status of the individual bits using the index. Using GATHER, you can combine the bits once again into a bit string.

The enable output ENO returns signal state "0" if one of the following conditions applies:

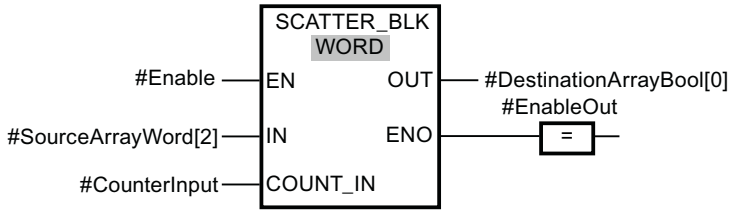
- Enable input EN has signal state "0".
- The source ARRAY has fewer elements than specified at the COUNT_IN parameter.
- The index of the destination ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of BOOL.
- The ARRAY[*] of BOOL does not provide the required number of elements. In this case as many bit strings as possible are parsed and written to the ARRAY of BOOL. The remaining bit strings are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> that is disassembled
COUNT_IN	Input	UDINT	I, Q, M, D, L	Counter for the number of elements of the source ARRAY that are going to be disassembled
OUT	Output	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY in which the individual bits are saved

You can select the required bit string from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example of a destination ARRAY wit the low limit "0"

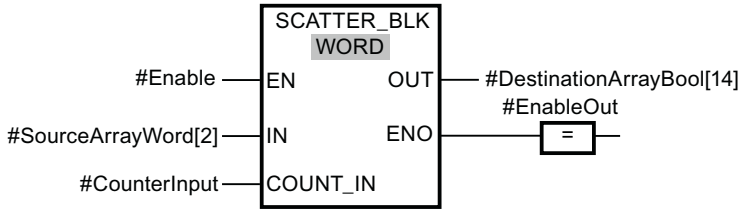
Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayWord		ARRAY[0..5] of WORD
CounterInput		UDINT
EnableOut	Output	BOOL
DestinationArrayBool		ARRAY[0..95] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be disassembled.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[0]	The operand "DestinationArray-Bool" is of the data type AR-RAY[0..95] of BOOL. This means it provides 96 BOOL ele-ments.



If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the first element assigned to the individual elements of the #DestinationArrayBool operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Example of a destination ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayWord		ARRAY[0..5] of WORD
CounterInput		UDINT
EnableOut	Output	BOOL
DestinationArrayBool		ARRAY[-2..93] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be disassembled.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[14]	The operand "DestinationArray-Bool" is of the data type AR-RAY[-2..93] of BOOL. This means it provides 96 BOOL ele-ments.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the 16th element assigned to the individual elements of the #DestinationArrayBool operand. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO. The remaining 32 bits are not written.

GATHER: Merge individual bits into a bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into a bit sequence" combines the bits from an ARRAY of BOOL into a bit sequence. The bit sequence is saved in a tag of the data type BYTE, WORD, DWORD or LWORD.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

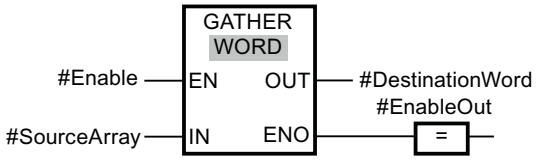
- Enable input EN has signal state "0".
- If the ARRAY has fewer or more BOOL elements than specified by the bit sequence, they are not transferred and the ENO returns signal state "0". The ENO also returns "0" if fewer than the necessary number of bits is available.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY whose bits are combined into a bit sequence
OUT	Output	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Combined bit sequence, saved in a tag

You can select the required bit sequence from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArray		WORD
EnableOut	Output	BOOL
DestinationWord		ARRAY[0..15] of BOOL

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArray	The operand "SourceArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD in which the bits are to be combined.
OUT	DestinationWord	WORD (16 bits)

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. The bits of the operand #SourceArray are combined into a WORD. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

GATHER_BLK: Merge individual bits into multiple elements of an ARRAY of bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into multiple elements of an ARRAY of bit sequence" combines the bits from an ARRAY of BOOL into one or multiple elements of an ARRAY of <bit string>. At the COUNT_OUT parameter you specify how many elements of the destination ARRAY are going to be written. With this step you also implicitly specify how many elements of the ARRAY of BOOL are required. The destination ARRAY at the OUT parameter may have more elements than specified at the COUNT_OUT parameter. The ARRAY of <bit string> must have sufficient elements to save the bits that are going to be combined. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n(number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

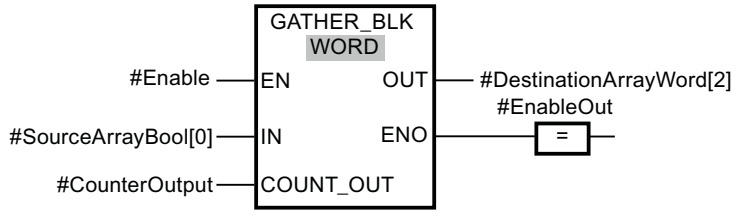
- Enable input EN has signal state "0".
- The index of the source ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of <bit string>.
- The ARRAY[*] of <bit string> does not provide the required number of elements. In this case as many bit strings as possible are combined and written to the ARRAY of <bit string>. The remaining bits are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY of BOOL whose bits are combined (source ARRAY)
COUNT_OUT	Input	UDINT	I, Q, M, D, L	Counter of the number of elements of the destination ARRAY that are going to be written
OUT	Output	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> to which the bits are saved (destination ARRAY)

You can select the required bit string from the "???" drop-down list of the instruction box.



You can find additional information on valid data types under "See also".

Example of a source ARRAY wit the low limit "0"

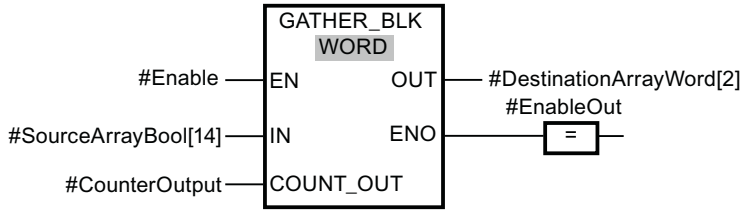
Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayBool		ARRAY[0..95] of BOOL
CounterOutput		UDINT
EnableOut	Output	BOOL
DestinationArrayWord		ARRAY[0..5] of WORD

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[0]	The operand "SourceArrayBool" is of the data type ARRAY[0..95] of BOOL. This means it provides 96 BOOL elements that can combined into words once again.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.



If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 1st element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits are written to the 3rd word, the second 16 bits to the 4th word, and the third 16 bits to the 5th word of the destination ARRAY. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Example of a source ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
Enable	Input	BOOL
SourceArrayBool		ARRAY[-2..93] of BOOL
CounterOutput		UDINT
EnableOut	Output	BOOL
DestinationArrayWord		ARRAY[0..5] of WORD

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[14]	The operand "SourceArrayBool" is of the data type ARRAY[-2..93] of BOOL. Because the starting point is the 14th element, only 80 BOOL elements that can be combined into words again are available.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 14th element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits of the source ARRAY are ignored. The second 16 bits are written to the 3rd word, the third 16 bits to the 4th word, and the fourth 16 bits to the 5th word of the destination ARRAY. The remaining 64 bits of the source ARRAY are not taken into account either. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Basic information on FBD (Page 4937)

MOVE_BLK_VARIANT: Move block (S7-1200, S7-1500)

Description

You use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and target ARRAY can be different. You can copy multiple or single elements within an ARRAY.

The number of elements that are to be copied must not exceed the selected source range or target range.

If you use the instruction at the time the block is being created, the ARRAY does not yet have to be known, as the source and the target are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is copied than is made available.

Parameters

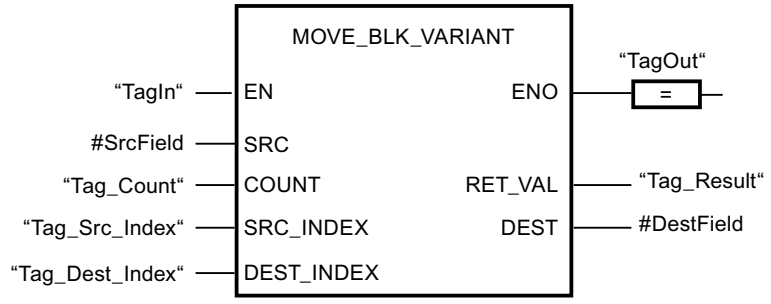
The following table shows the parameters of the "Move block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRC	Input [2)]	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	L (A declaration in the "Temp" section of the block interface is not possible.)	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L or constant	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no ARRAY is specified at parameter SRC or at parameter DEST.
SRC_INDEX	Input	DINT	I, Q, M, D, L or constant	Defines the first element to be copied: • The SRC_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter SRC, the integer at parameter SRC_INDEX specifies the first element within the source area from which it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter SRC or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.

Parameters	Declaration	Data type	Memory area	Description
DEST_INDEX	Input	DINT	I, Q, M, D, L or constant	Defines the start of the destination memory area: • The DEST_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter DEST, the integer at parameter DEST_INDEX specifies the first element within the target range that is to be copied into. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter DEST, then assign the value "0" at parameter DEST_INDEX.
DEST	Output [1]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Destination area into which the contents of the source block are copied.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface. 2) With the SRC parameter, the data types BOOL and ARRAY of BOOL are not permitted.				

You can find additional information on valid data types under "See also".

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data types do not correspond. Instead of an ARRAY of <Struct>, use an ARRAY of <PLC data type (UDT)>.
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at the SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.

Error code* (W#16#...)	Explanation
8383	The value at the SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at the DEST_INDEX is outside the high limit of the ARRAY.
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at the DEST parameter
8554	The operand at the DEST parameter has the data type BOOL.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT")
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT")

If the "TagIn" operand returns signal state "1", the instruction is executed. Two elements are moved from the source range, starting from the fourth element of the ARRAY [0..10] of MOVE_UDT, to the target range. The copies are pasted in the ARRAY [10..20] of MOVE_UDT starting from the fourth element. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

Note

You can find more information on the MOVE_BLK_VARIANT instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

UMOVE_BLK: Move block uninterruptible (S7-1200, S7-1500)

Description

You use the "Move block uninterruptible" instruction to move the content of a memory area (source range) to another memory area (target range). The instruction cannot be interrupted. The number of elements to be moved to the target range is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the element at input IN.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- More data is moved than is made available at input IN or output OUT.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

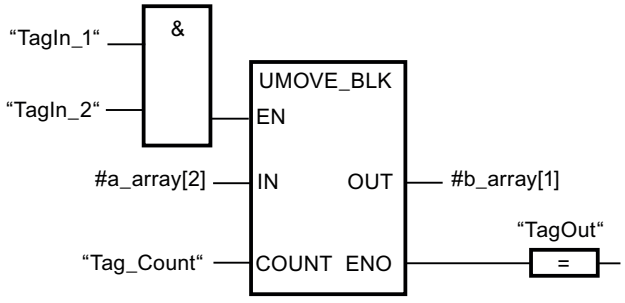
Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

You use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Number of elements to be copied from the source range to the target range
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	The first element of the target range to which the contents of the source range are being copied

[1] The specified data types can only be used as elements of an array structure.

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is ARRAY[0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is ARRAY[0..6] of INT. It consists of seven elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Note

You can find more information on the UMOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Editing FBD elements (Page 4964)

Inserting operands in FBD instructions (Page 4970)

FILL_BLK: Fill block (S7-1200, S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (target range) with the value of the IN input. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

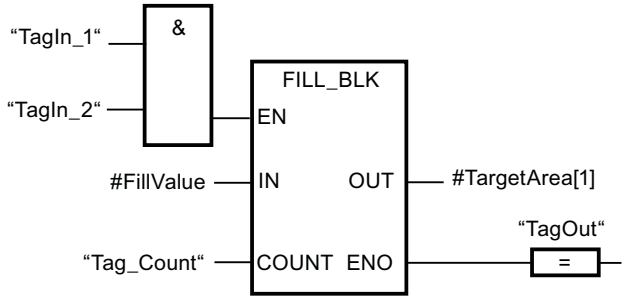
Use of ARRAYs

The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters



The following table shows the parameters of the "Fill block" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Element used to fill the target range
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	Address in target range from which filling starts

For additional information on valid data types, refer to "See also".

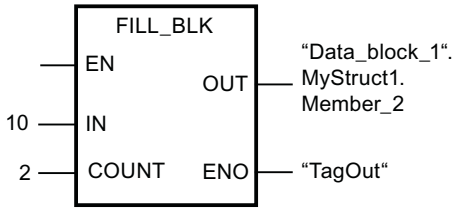
Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

The following table shows how the instruction works using specific operand values:

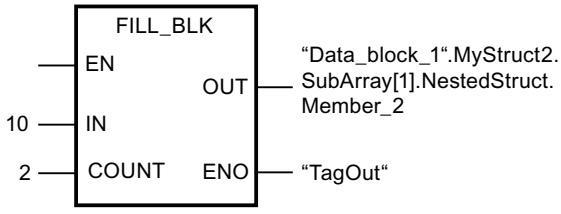
Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element. If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".



Examples with a structure

The following examples show how the instruction works when you want to fill a structure:



Create a global data block with the following elements:

Data_block_1					Data type
MyStruct1					STRUCT
	Member_1				INT
	Member_2				INT
	Member_3				INT
	Member_4				INT
MyStruct2					STRUCT
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

Generate the following program code to address the MyStruct2 tag:

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and Member_4, are not changed. If the instruction is executed without errors, the TagOut operand is set to signal state "1".

Basic information on FBD (Page 4937)

UFILL_BLK: Fill block uninterruptible (S7-1200, S7-1500)

Description

You can use the "Fill block uninterruptible" instruction to fill a memory area (target range) with the value of the IN input. The instruction cannot be interrupted. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the alarm reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

Enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

When a ARRAY of BOOL is copied, the enable output ENO for an overflow is set to "1" until the byte limit of the ARRAY structure is exceeded. If the byte limit of the ARRAY structure is exceeded by the value at the COUNT input, the ENO enable output is reset to "0".

Note

Use of ARRAYs

The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

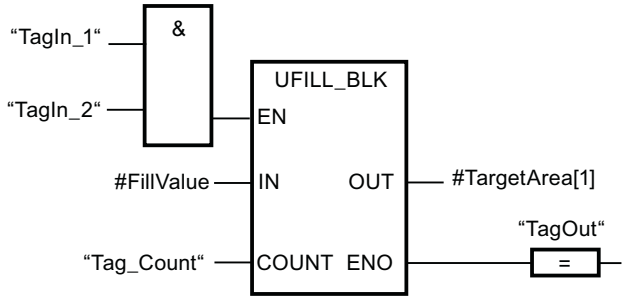
You use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters

The following table shows the parameters of the "Fill block uninterruptible" instruction:



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Element used to fill the target range

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	D, L	Address in target range from which filling starts

For additional information on valid data types, refer to "See also".

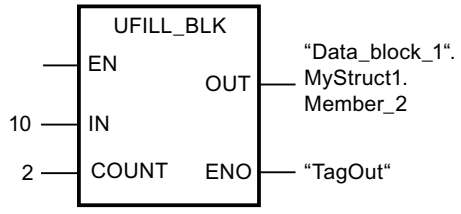
Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

The following table shows how the instruction works using specific operand values:

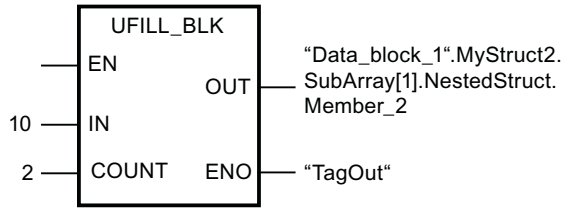
Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

If the operands "TagIn_1" and "TagIn_2" have signal state "1", the instruction is executed. The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element. The move operation cannot be interrupted by other operating system activities. If the instruction is executed without errors, the TagOut operand at the "ENO" enable output is set to signal state "1".



Examples with a structure

The following examples show how the instruction works when you want to fill a structure:



Create a global data block with the following elements:

Data_block_1					Data type
MyStruct1					STRUCT
	Member_1				INT
	Member_2				INT
	Member_3				INT
	Member_4				INT
MyStruct2					STRUCT
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

Generate the following program code to address the MyStruct2 tag:

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and

Member_4, are not changed. If the instruction is executed without errors, the TagOut operand is set to signal state "1".

SWAP: Swap (S7-1200, S7-1500)

Description

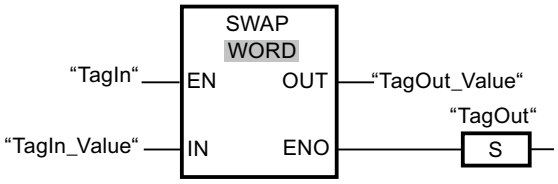
You can use the instruction "Swap" to change the order of the bytes within the tag at input IN and query the result at output OUT.

The following figure shows how the bytes of a DWORD data type operand are swapped using the "Swap" instruction:

Parameters

The following table shows the parameters of the "Swap" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Operand whose bytes are swapped.
OUT	Output	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 0101 0101
OUT	TagOut_Value	0101 0101 0000 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The arrangement of the bytes is changed and stored in the operand "TagOut_Value".

ARRAY DB (S7-1500)

ReadFromArrayDB: Read from ARRAY data block (S7-1500)

Description

The instruction "Read from ARRAY data block" is used to read the element from a data block of the ARRAY DB block type to which the index references, and write the value of the element to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Enable output ENO returns the signal state FALSE if one of the following conditions applies:

- Enable input EN returns the signal state FALSE.
- If an error occurs during the execution of the instruction.

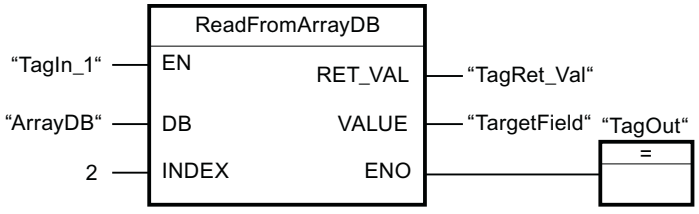
Parameters

The following table shows the parameters of the "Read from ARRAY data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.
VALUE	Output [1)]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value that is read and output
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

You can find additional information on valid data types under "See also".

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.

Error code* (W#16#...)	Explanation
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.

If the "TagIn1" operand returns signal state "1", the instruction is executed. The 2nd element is read from "ArrayDB" and written to the "TargetField" operand. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

WriteToArrayDB: Write to ARRAY data block (S7-1500)

Description

The instruction "Write to ARRAY data block" is used to write the element to which the index references to a data block of the ARRAY DB block type.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Enable output ENO returns the signal state FALSE if one of the following conditions applies:

- Enable input EN returns the signal state FALSE.
- If an error occurs during the execution of the instruction.

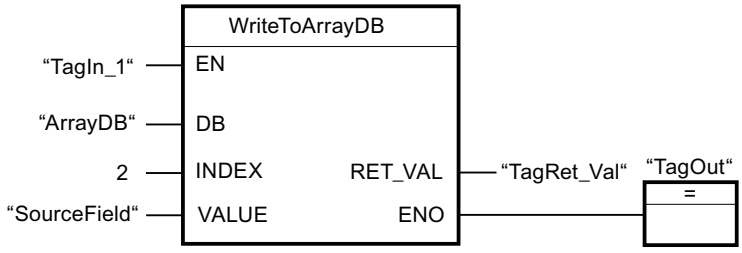
Parameters

The following table shows the parameters of the "Write to ARRAY data block" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value to be written
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the RET_VAL parameter.

You can find additional information on valid data types under "See also".

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.

Error code* (W#16#...)	Explanation
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error
8353	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.

If the "TagIn1" operand returns signal state "1", the instruction is executed. The value of the "SourceField" operand is written to the 2nd element of the ARRAY DB. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set.

ReadFromArrayDBL: Read from ARRAY data block in load memory (S7-1500)

Description

The instruction "Read from ARRAY data block in load memory" is used to read the element ti which the index references from a data block of the ARRAY DB block type in the load memory and write it to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1" for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

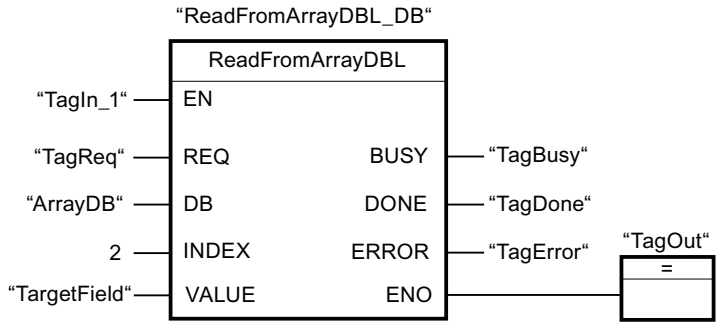
Parameters

The following table shows the parameters of the "Read from ARRAY data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Begin with the reading of the ARRAY DB
DB [1)]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block that is read.
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.

Parameter	Declaration	Data type	Memory area	Description
VALUE [1]	InOut	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

Parameter ERROR



The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the parameter does not match the element length in the ARRAY data block.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq" operand, the instruction is executed. The 2nd element is read from "ArrayDB" and output at the VALUE parameter. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is no longer changed. If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

WriteToArrayDBL: Write to ARRAY data block in load memory (S7-1500)

Description

The instruction "Write to ARRAY data block in load memory" is used to write the element to which the index references to a data block of the ARRAY DB block type in load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- If an error occurs during the execution of the instruction.

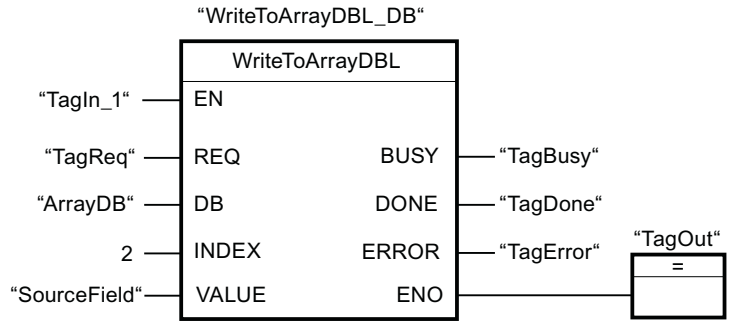
Parameters

The following table shows the parameters of the "Write to ARRAY data block in load memory" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = "1": Start writing to the array DB
DB [1)]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P or constant	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE [1)]	Input	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

Parameter ERROR



The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

If the "TagIn1" operand has the signal state "1" and a positive edge is detected at the "TagReq" operand, the instruction is executed. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written to the 2nd element of the "ArrayDB". If the instruction is executed without errors, the enable output ENO has the signal state TRUE and the "TagOut" output is set. After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

VARIANT (S7-1200, S7-1500)

VariantGet: Read out VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag specified at the DST parameter must match the data type to which the VARIANT points.

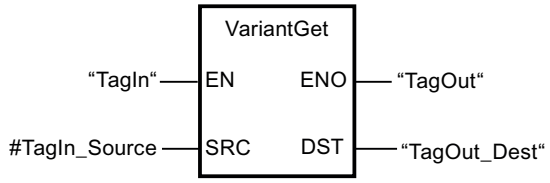
Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT instruction: Move block" instruction. For additional information, refer to "See also".

Enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not match (no value is transferred).

Parameters



The following table shows the parameters of the "Read out VARIANT tag value" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRC	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The value of the tag to which the VARIANT at the "#TagIn_Source" operand points, is read and written to the "TagOut_Dest" operand.

Overview of the valid data types (Page 2239)

Basic information on VARIANT (Page 2308)

MOVE_BLK_VARIANT: Move block (Page 3082)

Basic information on FBD (Page 4937)

VariantPut: Write VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the memory at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

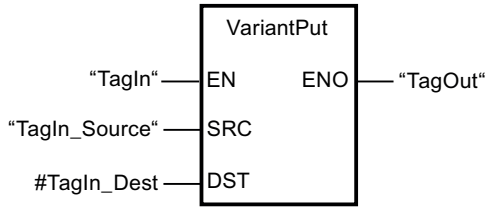
Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT instruction: Move block" instruction. For additional information, refer to "See also".

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The data types do not correspond. (No value is transferred.)

Parameters



The following table shows the parameters of the instruction "Write VARIANT tag value":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Tag to be read
DST	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Result of the instruction

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand returns signal state "1", the instruction is executed. The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

MOVE_BLK_VARIANT: Move block (Page 3082)

Basic information on FBD (Page 4937)

CountOfElements: Get number of ARRAY elements (S7-1200, S7-1500)

Description

You use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag to which VARIANT points has.

If it is a multi-dimensional ARRAY, the number of ARRAY elements is output as the result. (The difference between the high and low limit +1). If it is a multi-dimensional ARRAY, the number of all dimensions is output as the result.

Note

Instances

The VARIANT pointer can point to no instance and therefore also to no multi-instance or an ARRAY of multi-instances.

Note

ARRAY within a data block

If you want to query the number of the elements of an ARRAY which is located in a data block, the block attribute "Data block write-protected in the device" must not be activated in this block. Otherwise, the RET_VAL parameter returns the result "0", irrespective of how many elements the ARRAY contains.

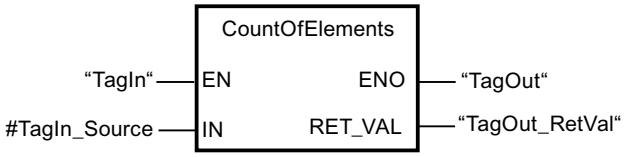
The result is also "0" if the VARIANT tag is not an ARRAY.

If the VARIANT points to an ARRAY of BOOL, the fill elements are included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL).

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The VARIANT tag is not an ARRAY. (The result is "0".)

Parameters



The following table shows the parameters of the "Get number of ARRAY elements" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be queried
RET_VAL	Output	UDINT	I, Q, M, D, L	Result of the instruction

You can find additional information on valid data types under "See also".

Example

The following example shows how the instruction works:

If the "TagIn" operand returns signal state "1", the instruction is executed. The number of ARRAY elements of the tag to which the VARIANT at the #TagIn_Source operand points is read and output at the "TagOut_RetVal" operand.

ARRAY[*] (S7-1200, S7-1500)

LOWER_BOUND: Read out low ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

The "Read out ARRAY low limit" instruction is used to read out the variable low limit of the ARRAY.

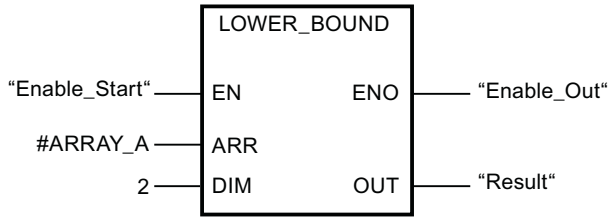
Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The dimension specified at input DIM does not exist.

Note

Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.



Parameters

The following table shows the parameters of the instruction "Read out ARRAY low limit":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable low limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable low limit is to be read.
OUT	Output	DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

If the "Enable_Start" operand returns signal state "1", the instruction is executed. It reads out the variable low limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Enable_Out" and operand "Result" is set.

Overview of the valid data types (Page 2239)

Basic information on ARRAY (Page 2286)

Basic information on FBD (Page 4937)

UPPER_BOUND: Read out high ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

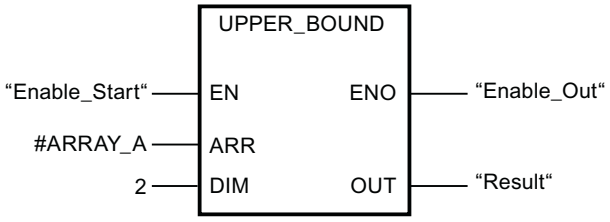
The instruction "Read out ARRAY high limit" is used to read out the variable high limit of the ARRAY.

Enable output ENO returns the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The dimension specified at input DIM does not exist.

Note
Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.



Parameters

The following table shows the parameters of the instruction "Read out ARRAY high limit":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable high limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable high limit is to be read.
OUT	Output	DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

If the "Enable_Start" operand returns signal state "1", the instruction is executed. It reads out the variable high limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Enable_Out" and operand "Result" is set.

Legacy (S7-1500)

FieldRead: Read field (S7-1500)

Description

You can use the "Read field" instruction to read out a specific component from the field specified in the MEMBER parameter and transfer its content to the tag in the VALUE parameter. You use the parameter INDEX to define the index of the field components that are to be read. At the parameter MEMBER you specify the first component of the field to be read.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

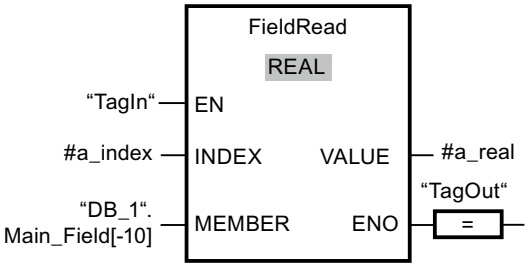
The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The field component specified at the parameter INDEX is not defined in the field specified at the parameter MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Read field":

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Index of field components whose content is read out



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
MEMBER	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	D, L	First component of the field from which will be read
VALUE	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P	I, Q, M, D, L, P	Operand to which the contents of the field component are transferred.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Tag	Value
INDEX	a_index	4
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"
VALUE	a_real	Component with index 4 of the "Main_Field[-10..10] of REAL" field

The field component with index 4 is read from the "Main_Field[-10...10] of REAL" field and written to the "a_real" tag. The field component to be read is defined by the value at the parameter INDEX.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

FieldWrite: Write field (S7-1500)

Description

The "Write field" instruction is used to transfer the content of the tag at the VALUE input to a specific component of the field at the MEMBER output. You use the value at the INDEX input to specify the index of the field component that is described. At the MEMBER output, enter the first component of the field which is to be written to.

The data types of the field component at parameter MEMBER, the index and the tags at parameter VALUE must correspond to the data type of the instruction "Read field" because implicit conversion is not possible.

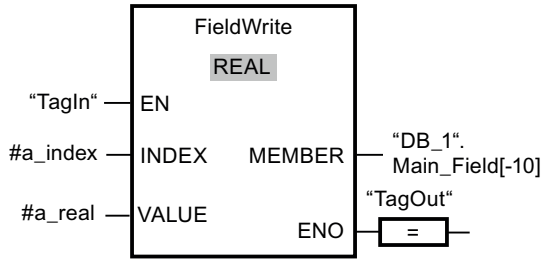
The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The field component specified at the input INDEX is not defined in the field specified at the output MEMBER.
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Write field":

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
INDEX	Input	DINT	DINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Index of field component that is written with the content of VALUE



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
VALUE	Input	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Operand whose contents are copied
MEMBER	Output	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, CHAR and WCHAR as components of an ARRAY tag	Binary numbers, integers, floating-point numbers, timers, DATE, TOD, LTOD, CHAR and WCHAR as components of an ARRAY tag	D, L	D, L	First component of the field to which the content of VALUE is written.

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
INDEX	a_index	4
VALUE	a_real	10.54
MEMBER	"DB_1".Main_Field[-10]	First component of the "Main_Field[-10..10] of REAL" field in the data block "DB_1"

The value "10.54" of the "a_real" tag is written to the field component with index 4 of the "Main_Field[-10 ... 10] of REAL" field. The index of the field component to which the content of the tag "a_real" is transferred is specified by the value at the input INDEX.

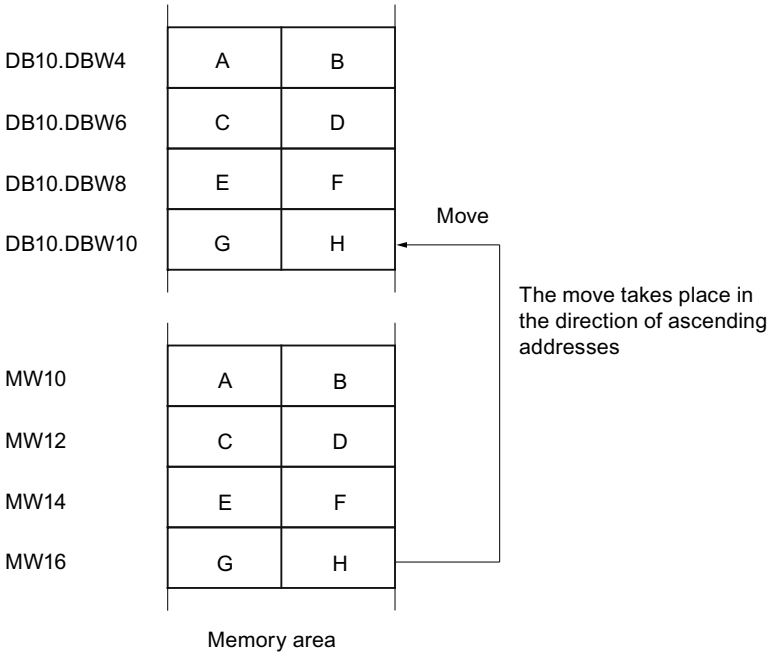
Basic information on FBD (Page 4937)

BLKMOV: Move block (S7-1500)

Description



You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

The following figure shows the principle of the move operation:

Consistency of source and destination data

Make sure that the source data remain unchanged during the execution of the "Move block" instruction. Otherwise, consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination area have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

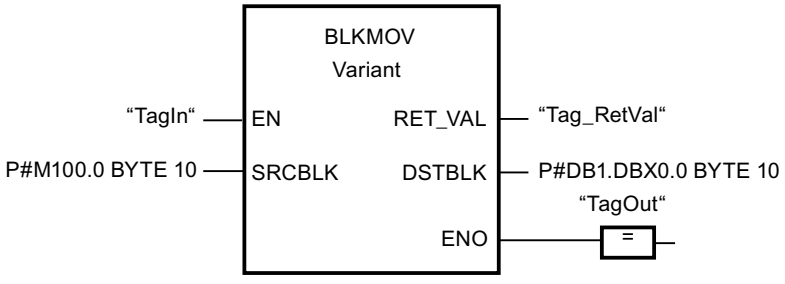
If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes to the SRCBLK and DSTBLK parameters.

Parameters

The following table shows the parameters of the instruction "Move block":

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type	Memory area	Description
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
DSTBLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

UBLKMOV: Move block uninterruptible (S7-1500)

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result the interrupt reaction time of the CPU can increase during the execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination area must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a source or destination area defined as a formal parameter is smaller than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

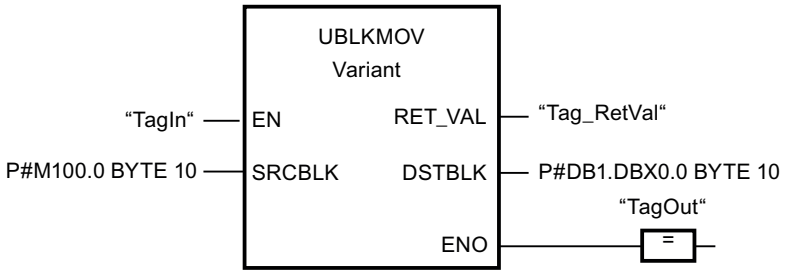
You can use the "Move block uninterruptible" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as area length.

Parameters

The following table shows the parameters of the "Move block uninterruptible" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
DSTBLK	Output [1]	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

Parameter RET_VAL



The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8091	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the DSTBLK parameter.

Error code (W#16#...)	Explanation
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

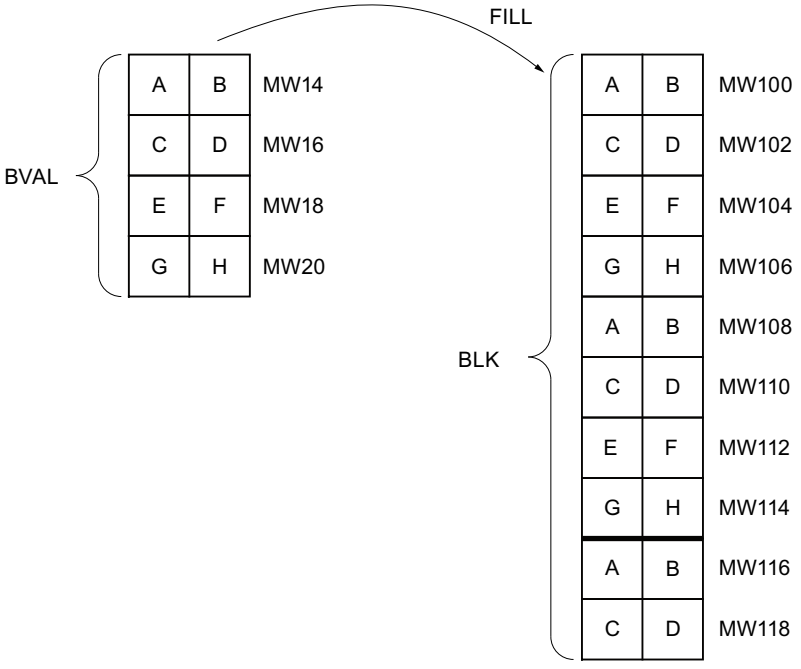
Basic information on FBD (Page 4937)

FILL: Fill block (S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

You use VARIANT to define the source and destination areas.



Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can use this tag in memory areas "with optimized block access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK instruction. Fill block" instruction.

The following figure shows the principle of the move operation:

Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the BVAL input parameter, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is data type STRING, the instruction writes the entire string including the administration information.

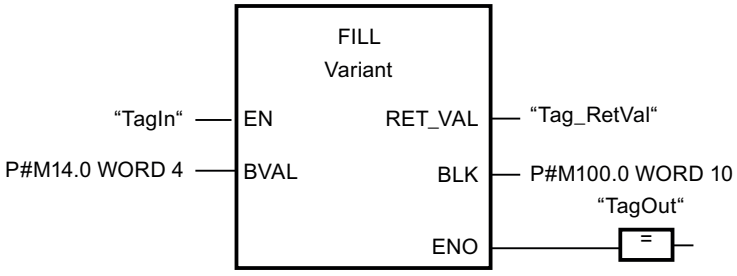
Rules for moving structures

When you transfer a structure as an input parameter you must bear in mind that the length of a structure is always oriented to an even number of bytes. The structure will need one byte of additional memory space if you declare a structure with an odd number of bytes.

Parameters

The following table shows the parameters of the "Fill block" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
BVAL	Input	VARIANT	I, Q, M, D, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
RET_VAL	Output	INT	I, Q, M, D, L, P	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.
BLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specification of the memory area that will be filled with the content of the source area.
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				



RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or destination area is located in the load memory only.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the BVAL parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the BLK parameter. The WSTRING, WCHAR, and BOOL, data types are not supported.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

Basic information on FBD (Page 4937)

Conversion operations (S7-1200, S7-1500)

CONVERT: Convert value (S7-1200, S7-1500)

Description

The "Convert value" instruction reads the content of the IN parameter and converts it according to the data types set in the instruction box. The converted value is output at the OUT output.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- The EN enable input has the signal state "0".
- Errors, such as an overflow, occur during execution.

Conversion options for bit strings

The bit strings BYTE and WORD cannot be selected in the instruction box. However, it is possible to specify an operand of data type DWORD or LWORD at a parameter of the instruction if the lengths of the input and output operands match. The operand will be interpreted and implicitly converted from the data type of a bit string according to the data type of the input or output parameter. The data type DWORD is for example interpreted as DINT/ UDINT and LWORD as LINT/ULINT. These conversion options are also available to you when "IEC check" is enabled.

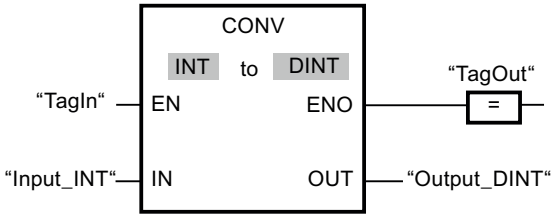
Note

For CPUs of the S7-1500 series: The data types DWORD and LWORD can only be converted to or from data type REAL or LREAL.

During the conversion, the bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If no errors occur during the conversion, the signal state of enable output ENO = 1; if an error occurs during processing, the signal state of the enable output ENO = 0.

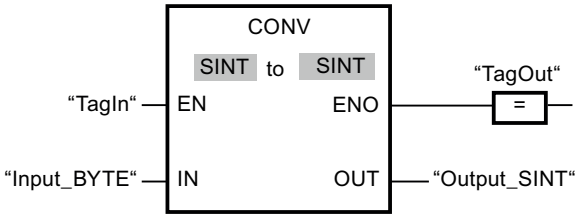
Parameters

The following table shows the parameters of the "Convert value" instruction:



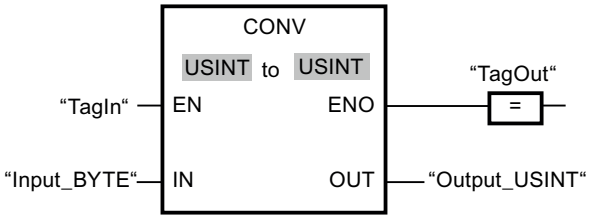
Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN	Input	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Value to be converted.
OUT	Output	Bit strings, integers, floating-point numbers, CHAR, WCHAR, BCD16, BCD32	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the conversion



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

Example



The following example shows conversion of an integer (16 bit) to another integer (32 bit):

The following example shows conversion of a byte (8 bit) to the integer SINT (8 bit):

The following example shows the conversion of a byte (8 bit) to the unsigned integer USINT (8 bit):

The conversions are possible, because the length of the two operands is the same.

ROUND: Round numerical value (S7-1200, S7-1500)

Description

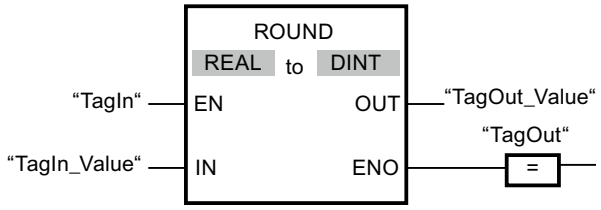
You can use the "Round numerical value" instruction to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts this to the nearest integer. If the input value is exactly between an even and odd number, then the even number is converted. The result of the instruction is output at the OUT output and can be queried there.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the "Round numerical value" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be rounded.
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the rounding

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	2	-2

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the nearest even integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Basic information on FBD (Page 4937)

CEIL: Generate next higher integer from floating-point number (S7-1200, S7-1500)

Description

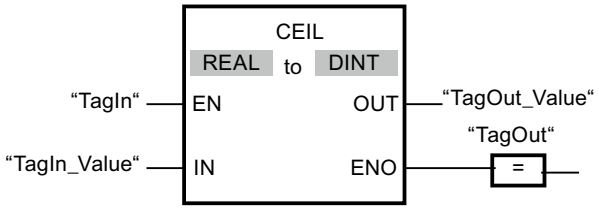
You can use the "Generate next higher integer from floating-point number" instruction to round the value at input IN to the next higher integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next higher integer. The result of the instruction is output at the OUT output and can be queried there. The output value can be greater than or equal to the input value.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Generate next higher integer from floating-point number":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result with the next higher integer

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	1	0

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next higher integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

FLOOR: Generate next lower integer from floating-point number (S7-1200, S7-1500)

Description

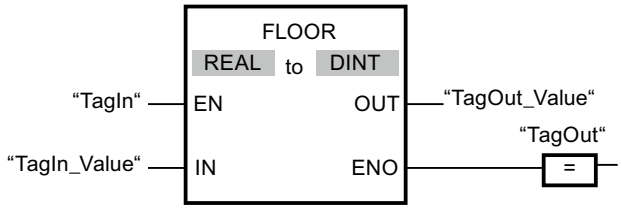
You can use the "Generate next lower integer from floating-point number" instruction to round the value at input IN to the next lower integer. The instruction interprets the value at input IN as a floating-point number and converts this to the next lower integer. The result of the instruction is provided at output OUT and can be queried there. The output value can be less than or equal to the input value.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Generate next lower integer from floating-point number":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L, P	I, Q, M, D, L, P	Result with the next lower integer

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	0.50000000	-0.50000000
OUT	TagOut_Value	0	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The floating-point number at input "TagIn_Value" is rounded to the next lower integer and displayed at output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

Basic information on FBD (Page 4937)

TRUNC: Truncate numerical value (S7-1200, S7-1500)

Description

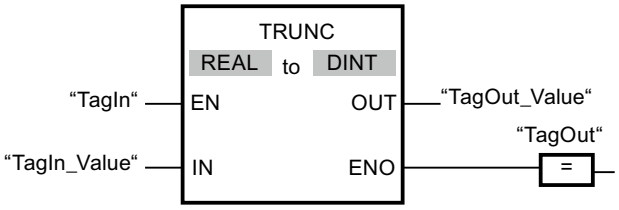
You can use the "Truncate numerical value" instruction to form an integer from the value at input IN. The value at input IN is interpreted as a floating-point number. The instruction selects only the integer part of the floating-point number and sends this to output OUT without decimal places.

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- Errors, such as an overflow, occur during execution.

Parameters

The following table shows the parameters of the instruction "Truncate numerical value":



Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	Floating-point numbers	I, Q, M, D, L or constant	Input value as floating-point number
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	Result with integer part of the floating-point number

You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
IN	TagIn_Value	1.50000000	-1.50000000
OUT	TagOut_Value	1	-1

If the "TagIn" operand has signal state "1", the instruction is executed. The integer part of the floating-point number at input "TagIn_Value" is converted to an integer and sent to output "TagOut_Value". If the instruction is executed without errors, the "TagOut" output is set.

SCALE_X: Scale (S7-1200, S7-1500)

Description

You can use the "Scale" instruction to scale the value at the VALUE input by mapping it to a specified value range. When the instruction "Scale" is executed, the floating-point value at input VALUE is scaled to the value range, which is defined by the parameters MIN and MAX. The result of the scaling is an integer, which is stored at output OUT.

The following figure shows an example of how values can be scaled:

The "Scale" instruction works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input MIN is greater than or equal to the value at input MAX.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- An overflow occurs.
- The value at input VALUE is NaN (Not a number = result of an invalid arithmetic operation).

Note

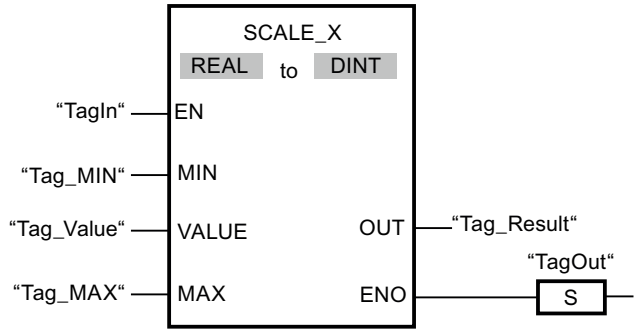
For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Low limit of the value range

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
VALUE	Input	Floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be scaled. If you enter a constant, you must declare it.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Integers, floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Result of scaling



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	0.5
MAX	Tag_MAX	30
OUT	Tag_Result	20

If the "TagIn" operand has signal state "1", the instruction is executed. The value at input "Tag_Value" is scaled to the range of values defined by the values at inputs "Tag_MIN" and "Tag_MAX". The result is stored at output "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

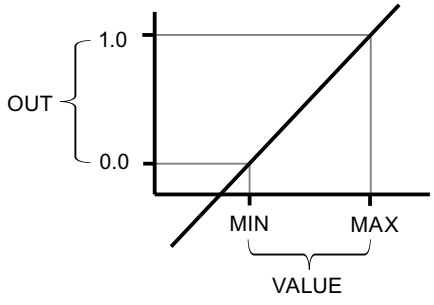
Overview of the valid data types (Page 2239)



Basic information on FBD (Page 4937)

NORM_X: Normalize (S7-1200, S7-1500)

Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the parameters MIN and MAX to define the limits of a value range that is applied to the scale. Depending on the location of the normalized value in this value range, the result at output OUT is calculated and stored as a floating-point number. If the value to be normalized is equal to the value at input MIN, output OUT returns the value "0.0". If the value to be normalized is equal to the value at input MAX, output OUT returns the value "1.0".

The following figure shows an example of how values can be normalized:

The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

The enable output ENO has the signal state "0" if one of the following conditions applies:

- Enable input EN has the signal state "0".
- The value at input MIN is greater than or equal to the value at input MAX.
- The value of a specified floating-point number is outside the range of the normalized numbers according to IEEE-754.
- The value at input VALUE is NaN (result of an invalid arithmetic operation).

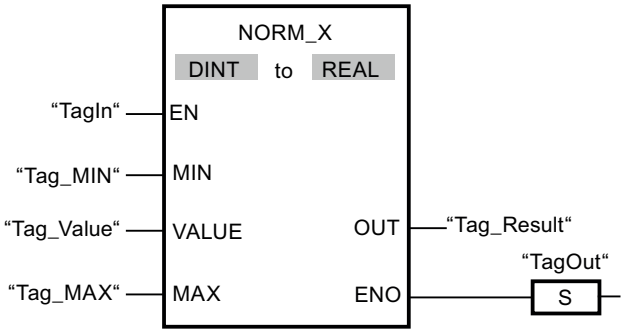
Note

For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the instruction "Normalize":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
MIN [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Low limit of the value range
VALUE [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be normalized.
MAX [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	High limit of the value range
OUT	Output	Floating-point numbers	I, Q, M, D, L	I, Q, M, D, L	Result of the normalization
[1)] If you use constants in these three parameters, you only need to declare one of them.					



You can select the data types of the instruction from the "???" drop-down lists of the instruction box.

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
MIN	Tag_MIN	10
VALUE	Tag_Value	20
MAX	Tag_MAX	30
OUT	Tag_Result	0.5

If the "TagIn" operand has signal state "1", the instruction is executed. The value at input "Tag_Value" is assigned to the range of values defined by the values at inputs "Tag_MIN" and "Tag_MAX". The tag value at input "Tag_Value" is normalized corresponding to the defined value range. The result is stored as a floating-point number at output "Tag_Result". If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Legacy (S7-1500)

SCALE: Scale (S7-1500)

Description

Use the "Scale" instruction to convert the integer in the IN parameter into a floating-point number, which can be scaled in physical units between a low limit value and a high limit value. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output at the OUT parameter.

The "Scale" instruction works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the constants "K1" and "K2" are determined by the signal state of the BIPOLAR parameter. The following signal states are possible in the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the constant "K2", the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

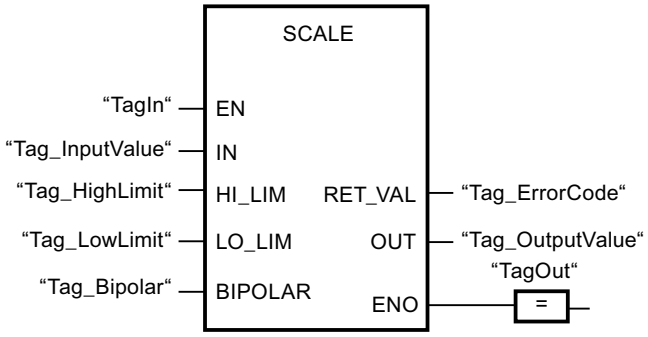
When the value at the IN parameter is less than the value of the constant "K1", the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameters

The following table shows the parameters of the "Scale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	INT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Indicates if the value at IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the "K2" constant or less than the value of the "K1" constant.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

Basic information on FBD (Page 4937)

UNSCALE: Unscale (S7-1500)

Description

You use the "Unscale" instruction to unscale the floating-point number in the IN parameter into physical units between a low limit and a high limit and convert it into an integer. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output at the OUT parameter.

The "Unscale" instruction works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the "K1" and "K2" constants are determined by the signal state at the BIPOLAR parameter. The following signal states are possible at the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

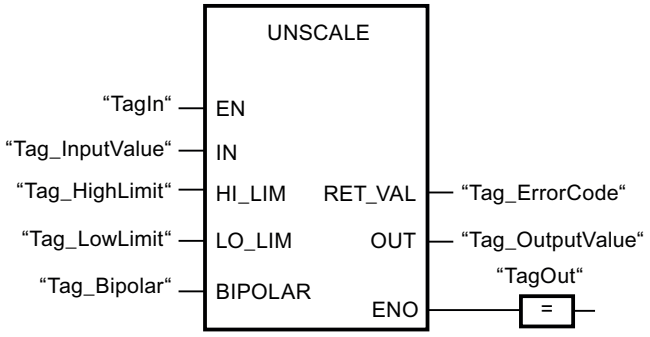
When the value at parameter IN is not within the limits defined by HI_LIM and LO_LIM, an error is output and the result is set to the nearest limit.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameters

The following table shows the parameters of the "Unscale" instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Indicates whether the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction
RET_VAL	Output	WORD	I, Q, M, D, L, P	I, Q, M, D, L, P	Error information



RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally"
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats here: AUTOHOTSPOT	

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_OutputValue	22
RET_VAL	Tag_ErrorCode	W#16#0000

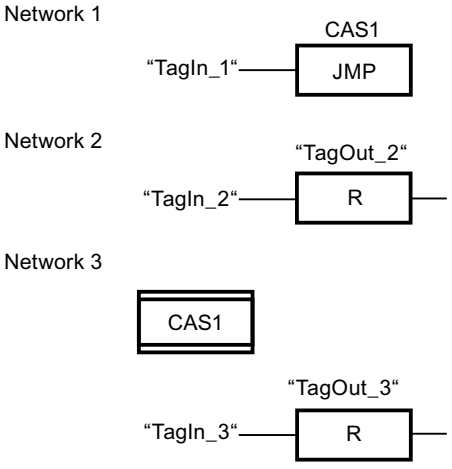
Program control operations (S7-1200, S7-1500)

JMP: Jump if RLO = 1 (S7-1200, S7-1500)

Description

You can use the "Jump if RLO = 1" instruction to interrupt the linear execution of the program and resume it in another network. The target network must be identified by a jump label (LABEL). The jump label description is entered in the placeholder above the instruction box.



The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil can occur in a network.

If the result of logic operation (RLO) at the input of the instruction is "1", the jump to the network identified by the jump label is executed. The jump direction can be towards higher or lower network numbers.

If the condition at the input of the instruction is not fulfilled (RLO = 0), execution of the program continues in the next network.

Example

The following example shows how the instruction works:

If the "TagIn_1" operand has signal state "1", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If input "TagIn_3" has the signal state "1", output "TagOut_3" is reset.

See also

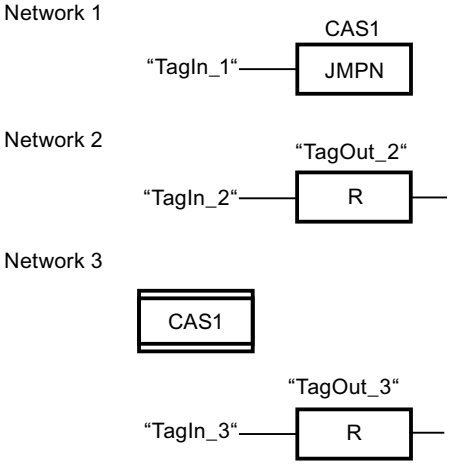
Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

JMPN: Jump if RLO = 0 (S7-1200, S7-1500)

Description

You can use the instruction "Jump if RLO = 0" to interrupt the linear execution of the program and resume it in another network, when the result of logic operation at the input of the instruction is "0". The target network must be identified by a jump label (LABEL). The jump label description is entered in the placeholder above the instruction box.



The specified jump label must be in the same block in which the instruction is executed. The name you specify can only occur once in the block. Only one jumping coil can occur in a network.

If the result of logic operation (RLO) at the input of the instruction is "0", the jump to the network identified by the jump label is executed. The jump direction can be towards higher or lower network numbers.

If the result of the logic operation RLO at the input of the instruction is "1", execution of the program continues in the next network.

Example

The following example shows how the instruction works:

If the "TagIn_1" operand has signal state "0", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If input "TagIn_3" has the signal state "1", output "TagOut_3" is reset.

See also

Overview of the valid data types (Page 2239)

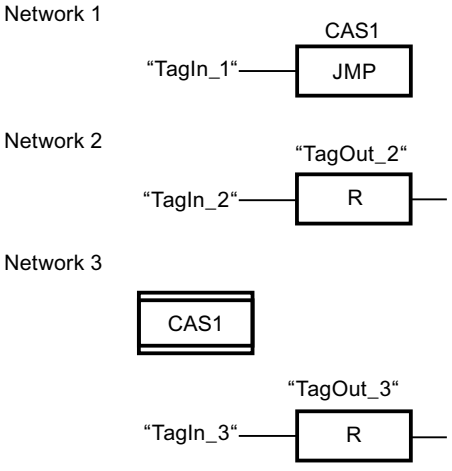
Basic information on FBD (Page 4937)

LABEL: Jump label (S7-1200, S7-1500)

Description

The jump label identifies a destination network in which the execution of the program can be resumed after the execution of a jump instruction.

The jump label and the instruction in which the jump label is specified must be located in the same block. The name of a jump label can only be assigned once in a block. You can declare up to 32 jump labels when you use a CPU S7-1200 and a maximum of 256 jump labels when you use a CPU S7-1500.



Only one jump label can be placed in a network. Each jump label can jump to several locations.

Adhere to the following grammatical rules for jump labels:

- Letters (a to z, A to Z)
- A combination of letters and numbers. Check that the order is correct, i.e. first the letters, then the numbers (a - z, A - Z, 0 - 9).
- Special characters or a combination of letters and numbers must not be used in reverse order, i.e. first the numbers and then the letters (0-9, a - z, A - Z).

Example

The following example shows how the instruction works:

If the "TagIn_1" operand has signal state "1", the instruction is executed. The linear execution of the program is interrupted and continues in Network 3, which is identified by the jump label CAS1. If the "TagIn_3" input has the signal state "1", output "TagOut_3" is reset.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

JMP_LIST: Define jump list (S7-1200, S7-1500)

Description

You can use the "Define jump list" instruction to define several conditional jumps and continue the program execution in a specific network depending on the value of the K parameter.

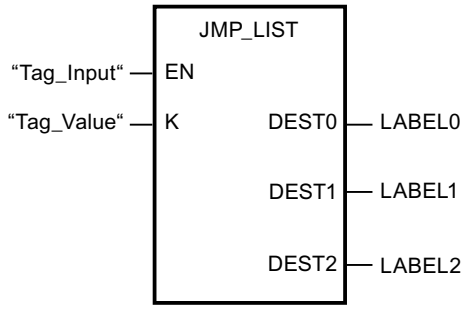
You define the jumps with jump labels (LABEL), which you specify at the outputs of the instruction box. The number of outputs can be expanded in the instruction box. You can declare up to 32 outputs when you use a CPU S7-1200 and a maximum of 256 outputs when you use a CPU S7-1500.

The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Only jump labels can be specified at the outputs of the instruction. Instructions or operands cannot be specified.

The value of the K parameter specifies the number of the output and thus the jump label where the program execution is to be resumed. If the value in the K parameter is greater than the number of available outputs, the program execution is resumed in the next network of the block.

The "Define jump list" instruction is only executed if the signal state is "1" at the EN enable input.

Parameters



The following table shows the parameters of the "Define jump list" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, L, D	Enable input
K	Input	UINT	I, Q, M, L, D or constant	Specifies the number of the output and thus the jump that is to be made.
DEST0	-	-	-	First jump label
DEST1	-	-	-	Second jump label
DESTn	-	-	-	Optional jump labels

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	1
DEST0	LABEL0	Jump to the network that is identified with the jump label "LABEL0".
DEST1	LABEL1	Jump to the network that is identified with the jump label "LABEL1".
DEST2	LABEL2	Jump to the network that is identified with the jump label "LABEL2".

If the "Tag_Input" operand has signal state "1", the instruction is executed. The execution of the program is continued according to the value of the operand "Tag_Value" in the network that is identified with the jump label "LABEL1".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

SWITCH: Jump distributor (S7-1200, S7-1500)

Description

You can use the "Jump distributor" instruction to define multiple program jumps to be executed depending on the result of one or more comparison instructions.

You specify the value to be compared in the K parameter. This value is compared with the values that are provided by the various inputs. You can select the comparison method for each individual input. The availability of the various comparison instructions depends on the data type of the instruction.

The following table shows the comparison instructions that are available depending on the selected data type:

Data type		Instruction	Syntax
S7-1200	S7-1500		
Bit strings	Bit strings	Equal	==
		Not equal	<>
Integers, floating-point numbers, TIME, DATE, TOD	Integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	Equal	==
		Not equal	<>
		Greater or equal	>=
		Less or equal	<=
		Greater than	>
		Less than	<

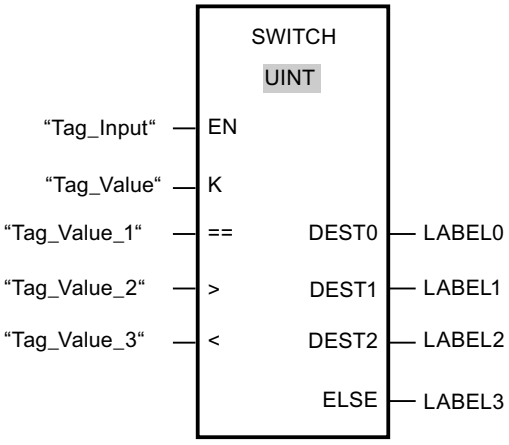
You can select the data type of the instruction from the "???" drop-down list of the instruction box. If you select a comparison instruction and the data type of the instruction is not yet defined, then the "???" drop-down list will only list those data types that are permitted for the selected comparison instruction.

Execution of the instruction begins with the first comparison and runs until a comparison condition is met. If a comparison condition is met, the subsequent comparison conditions are not considered. If none of the specified comparison conditions are fulfilled, the jump is executed at output ELSE. If not jump label is defined at output ELSE, the linear execution of the program is not interrupted but instead continued in the next network.

In its initial state the instruction box contains at least 2 outputs (DEST0 and DEST1). The number of outputs can be extended. The numbering of the outputs begins with the value "0" and is continued in ascending order with each new output. Specify jump labels (LABEL) at the outputs of the instruction. Instructions or operands cannot be specified at the outputs of the instruction.

An input is automatically inserted to each additional output. The jump programmed at an output is executed if the comparison condition of the corresponding input is fulfilled.

Parameters



The following table shows the parameters of the instruction "Jump distributor":

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
EN	Input	BOOL	BOOL	I, Q, M, D, L	Enable input
K	Input	UINT	UINT	I, Q, M, D, L or constant	Specifies the value to be compared.
<Comparison values>	Input	Bit strings, integers, floating-point numbers, TIME, DATE, TOD	Bit strings, integers, floating-point numbers, TIME, LTIME, DATE, TOD, LTOD, LDT	I, Q, M, D, L or constant	Input values with which the value of the parameter K is compared.
DEST0	-	-	-	-	First jump label
DEST1	-	-	-	-	Second jump label
DEST(n)	-	-	-	-	Optional jump labels: • S7-1200: n = 2 to 32 • S7-1500: n = 2 to 256
ELSE	-	-	-	-	Program jump which is executed if none of the comparison conditions are fulfilled.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand/jump label	Value
K	Tag_Value	23
==	Tag_Value_1	20
>	Tag_Value_2	21
<	Tag_Value_3	19
DEST0	LABEL0	Jump to jump label "LABEL0", if the value of parameter K is equal to 20.
DEST1	LABEL1	Jump to jump label "LABEL1", if the value of parameter K is greater than 21.
DEST2	LABEL2	Jump to jump label "LABEL2", if the value of parameter K is less than 19.
ELSE	LABEL3	Jump to jump label "LABEL3", if the none of the comparison conditions are fulfilled.

If the operand "Tag_Input" changes to signal state "1", the instruction is executed. The execution of the program is continued in the network that is identified with the jump label "LABEL1".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

RET: Return (S7-1200, S7-1500)

Description

You can use the "Return" instruction to stop the execution of a program block conditionally or absolutely. The signal state of the return value (operand) is mapped in the enable output ENO of the calling program block when the program block is exited.

There are three ways that the execution of a program block can be ended:

Termination of the program block	Description
Without a call of the instruction	The program block is exited after the execution of the last network. The enable output ENO of the calling program block is set to signal state "1".
Call of the instruction with preceding logic operation (see example)	If the preceding logic operation is fulfilled, the program execution in the currently called program block is ended and the program block is exited. (Conditional program block end) The program execution is continued in the calling program block (e.g. an OB) after the program block call. The enable output ENO of the calling program block corresponds to the operand.
Call of the instruction without preceding logic or the instruction is directly connected to the left power rail.	The program block is exited unconditionally. (Absolute program block end) The enable output ENO of the calling program block corresponds to the operand.

If an organization block (OB) is ended, another program block is selected by the execution level system and started or further executed.

- If the OB program cycle is ended, it is restarted.
- If an OB is ended that has interrupted another program block (e.g. an interrupt OB), then the interrupted program block (e.g. program cycle OB) is further executed.

Note

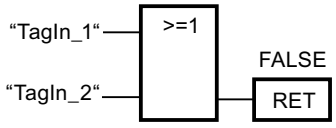
RET instruction in relation with JMP and JMPN

If a network already contains the "JMP: Jump if RLO = 1" or "JMPN: Jump if RLO = 0 instruction, the RET: Return" instruction must not be used. Only one jumping coil may be used in a network

Possible settings of the return value (operand)

The return value of the instruction can assume the following values:

- Ret (RLO, corresponds to the result of logic operation RLO. The signal state "1" is supplied to the enable output ENO of the calling program block because the RET instruction is only then executed as a conditional instruction when the condition is TRUE.)
- Ret True or Ret False (the respective value of the constant, TRUE or FALSE, is supplied to the calling program block.)
- Ret Value (the value of the Boolean tag <Operand> is supplied to the calling program block.)



To set the return value of the instruction, click the small yellow triangle of the instruction and select the desired value in the drop-down list.

The following table shows the status of the calling program block when the instruction is programmed in a network within the called program block:

RLO	Return value	ENO of the calling program block
1	RLO	1
	TRUE	1
	FALSE	0
	<Operand> Boolean tag with possible memory areas I, Q, M, D, L, T, and C	<Operand>
0	RLO	The program execution is continued in the next network of the called program block.
	TRUE	
	FALSE	
	<Operand>	

Example

The following example shows how the instruction works:

If one of the operands "TagIn_1" or "TagIn_2" have signal state "1", the instruction is executed. Program execution is ended in the called program block and continues in the calling program block. The enable output ENO of the calling program block is reset to signal state "0".

Runtime control (S7-1200, S7-1500)

ENDIS_PW: Limit and enable password legitimation (S7-1200, S7-1500)

Description

You use the "Limit and enable password legitimation" instruction to specify whether passwords configured for the CPU are legitimized or not. In this way, you can prevent legitimized connections, even if the correct password is known.

When the instruction is called and the REQ parameter has the signal state "0", the currently set state is displayed at the output parameters. If changes have been made to the input parameters, these are not transferred to the output parameters.

When the instruction is called and the REQ parameter has the signal state "1", the signal state is taken from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD).

- If signal state "0" is present, authorization via password is not allowed.
- If signal state "1" is present, the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Passwords that are not configured must have the signal state TRUE at the input and return the signal state TRUE at the output. The fail-safe password can only be configured for an F-CPU and must therefore always be interconnected with the signal state TRUE in a standard CPU. If the instruction returns an error, the call has no effect and the previous lock is still in effect.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.
- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".
- Set the mode selector to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Plugging an empty memory card (transfer module or program card) into an S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called once again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access from HMI systems if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing unintentional lockout on an S7-1500 CPU

The settings can be made on the front panel of the CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode selector to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing unintentional lockout on an S7-1200 CPU

Because the S7-1200 CPU does not have a mode switch, protection is disabled with POWER OFF - POWER ON. This means that it is possible and advisable to prevent accidental lockout with the help of specific program sequences within your program.

To do so, program a time control either by means of a cyclic interrupt OB or a timer in the Main OB (OB 1). This gives you the option of calling the "Limit and enable password legitimation" instruction in the respective OB (e.g., OB 1 or OB 35) relatively quickly after a transition from POWER OFF to POWER ON and the associated disabling of the protection. Call the instruction in the startup OB (OB 100) to keep the time window in which the instruction is inactive and there are no limitations for password legitimation relatively small. This procedure will give you the best possible protection from unauthorized access.

If there has been an accidental lockout, you can skip the call in the startup OB (by querying an input parameter, for example) and you have the set time (for example, 10 seconds up to 1 minute) to establish a connection to the CPU before the lock becomes active once again.

If there is no timer in your program code and a lockout has occurred, insert an empty transfer card or an empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then download the user program once again from STEP 7 to the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

⚠ WARNING

Inserting an empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Once you have pulled the transfer card, the content of the transfer card is available in the internal load memory. Make sure that the card does not include a program at this point.

⚠ WARNING

Inserting an empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. Once you have pulled the previously empty program card, the internal load memory is empty.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200 CPU: The lock is disabled and the instruction must be called once again in the program (e.g., in the startup OB). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Parameters

The following table shows the parameters of the "Limit and enable password legitimation" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L or constant	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password

Parameters	Declaration	Data type	Memory area	Description
FULL_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password
R_PWD	Input	BOOL	I, Q, M, D, L or constant	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password
HMI_PWD	Input	BOOL	I, Q, M, D, L or constant	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
RET_VAL	Output	WORD	I, Q, M, D, L	Error information

You can find additional information on valid data types under "See also".

Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. The signal state must be TRUE for standard CPUs.
80D1	The read/write access is not configured
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

PC systems (S7-1200, S7-1500)

SHUT_DOWN: Shut down target system (S7-1200, S7-1500)

Description

You can use the instruction "SHUT_DOWN: Shutdown target system" to shut down the PC-based automation system and restart the S7 software controller CPU 150xS or Windows on the PC-based automation system.

The instruction is available in the "Instructions" task card under Basic instructions > Program control > Runtime control.

A restart is, for example, advisable in the following situations:

- An industrial UPS (uninterruptible power supply) reports a power failure via a digital input.
- Windows stops responding or shows a "blue screen".
- Too many error OBs are called in the user program.

Parameter

The following table shows the parameters of the "Shutdown target system" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	MODE = 1: Shut down CPU 150xS and Windows The CPU goes to STOP and saves the retentive data. Then the CPU and Windows are shut down. The system must be restarted manually. MODE = 2: Restart CPU 150xS The CPU goes to STOP and saves the retentive data. Then the CPU is shut down and restarted. MODE = 3: Restart Windows The CPU remains in RUN. Windows is restarted (as of TIA Portal V14, MODE 3 is only retained for backward compatibility. We recommend using MODE 4 or MODE 5). MODE = 4: Windows is shut down and restarted correctly. The CPU remains in RUN. MODE = 5: Restart Windows (Comparable with MODE 3; Exception: MODE 5 should only be used if Windows has crashed).
COM-MENT	Input	STRING	I, Q, M, D, L	With Mode = 1, 3 and 4, you can specify a reason for the restart. The reason is output in the Windows Event Log.
Ret_Val	Return	WORD	Q, M, D, L	Ret_Val = 0: No faults Ret_Val = 8090: The value passed to MODE is not supported. Ret_Val = 8091: Windows does not respond to the call of the Shut_Down instruction (only valid for Mode 3 and 4). Ret_Val = 8092: Please contact SIMATIC Customer Support if this error occurs (only valid for Mode 3 and 4).

RE_TRIGR: Restart cycle monitoring time (S7-1200, S7-1500)

Description

The "Restart cycle monitoring time" instruction is used to restart the cycle monitoring time of the CPU. The cycle monitoring time then restarts with the time you have set in the CPU configuration.

If the instruction is called in a block with a higher priority, such as a hardware interrupt or diagnostic error interrupt, the instruction is not executed and the enable output ENO returns signal state "0".

The instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Calling the instruction

The following call conditions apply:

- The following applies to a CPU of the S7-1200 series:
  In firmware versions <= 2.2, you can call the instruction only in a program cycle organization block of priority 1. This corresponds to the lowest priority of all organization blocks. If the instruction is called in an organization block with a higher priority, the instruction is not executed and the result (BR bit, enable output ENO) is always "0".
  In firmware versions >= 2.2, you can call the instruction regardless of the priority in all organization blocks.
- The following applies to a CPU of the S7-1500 series:
  You can call the instruction regardless of the priority in all organization blocks.

Parameters

The instruction "Restart cycle monitoring time" has no parameters.

STP: Exit program (S7-1200, S7-1500)

Description

The instruction "Exit program" instruction is used to set the CPU to STOP mode and therefore to terminate the execution of the program. The effects of changing from RUN to STOP depend on the CPU configuration.

When the (RLO) at the input of the instruction is "1", the CPU changes to STOP mode and the execution of the program is terminated. The signal state at the output of the instruction is not evaluated.

If the RLO at the input of the instruction is "0", then the instruction will not be executed.

Parameters

The instruction "Exit program" has no parameters.

GET_ERROR: Get error locally (S7-1200, S7-1500)

Description

The "Get error locally" instruction is used to query the occurrence of errors within a program block. This normally involves programming or access errors. If the system reports an error during the execution of the program block, detailed information is stored in the operand at the ERROR output for the first error to occur during the execution of the block since the last execution of the instruction.

Only operands of the "ErrorStruct" system data type can be specified at the ERROR output. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the program block, the error information about the next error to occur is output by the instruction only after the first error that occurred has been remedied.

Note

Output ERROR

The ERROR output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO is only set if the enable input EN returns signal state "1" and error information is present. If one of these conditions does not apply, then the remaining program execution is not affected by the instruction.

Note

Activation of the local error handling

As soon as you insert the instruction in the program code of a program block, the local error handling is activated and default system reactions are ignored when errors occur.

Options for error handling

You can find an overview of the options for error handling here: AUTOHOTSPOT

For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the "Get error locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ERROR	Output	ErrorStruct	D, L	Error information

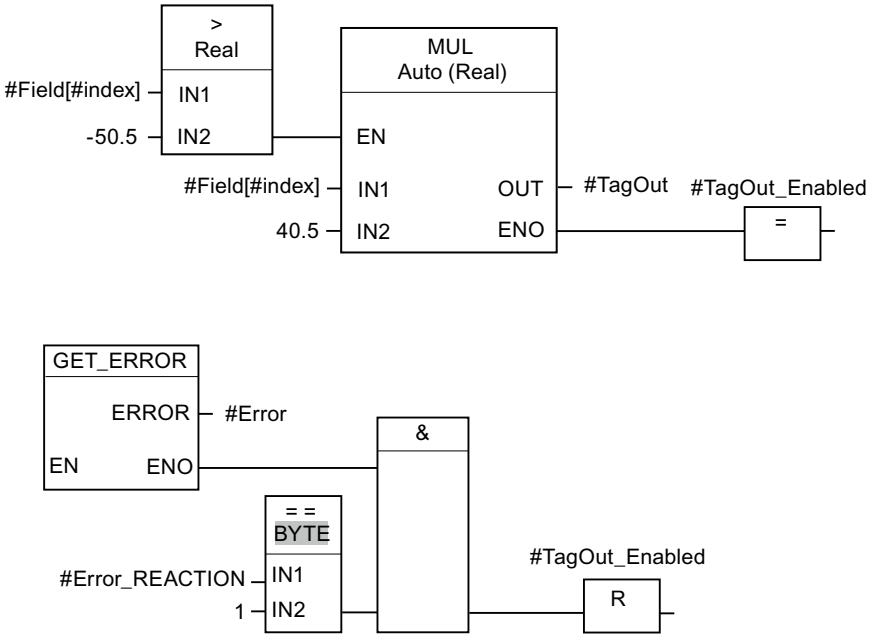
Data type "ErrorStruct"

The "ErrorStruct" data type can be inserted in a global data block or in the block interface. You can insert the data type more then once if you assign a different name for the data structure each time. The data structure and the name of individual structure elements cannot be changed. If you save the error information in a global data block, it can also be read out by other program blocks.

The following table shows the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows whether the error occurred during a program block call. 16#01: Error during a program block call 16#00: No error during a program block call
REACTION		BYTE	Default reaction: 0: Ignore (write error) 1: Continue with substitute value "0" (read error) 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of the program block
	BLOCK_TYPE	BYTE	Program block type in which the error occurred: 1: Organization block (OB) 2: Function (FC) 3: Function block (FB)
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40...16#7F, 16#86, 16#87, 16#8E, 16#8F, 16#C0...16#FF I: 16#81 Q: 16#82 M: 16#83 DB: 16#40, 16#84, 16#85, 16#8A, 16#8B PI: 16#01 PQ: 16#02 Technological objects: 16#04

Structure component		Data type	Description
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand



Structure component "ERROR_ID"

The following table shows the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".		

Example

The following example shows how the instruction works:

An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error locally" instruction is evaluated with the comparison instruction "Equal". If the "#Error.REACTION" structure component has the value "1", this involves a read/access error and the #TagOut_Enabled output is reset.

GET_ERR_ID: Get error ID locally (S7-1200, S7-1500)

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the error ID of the first error that occurred in the tag is stored at the ID output.

Only operands of the WORD data type can be specified at the ID output. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The ID output is only changed if error information is present. To set the output back to "0" after handling an error, you have the following options:

- Declare the tag in the "Temp" section of the block interface.
- Reset the tag to "0" before calling the instruction.
- Query the enable output ENO.

The enable output ENO of the instruction "Get error ID locally" instruction is set only if the enable input EN returns signal state "1" and error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Options for error handling

You can find an overview of the options for error handling here:AUTOHOTSPOT

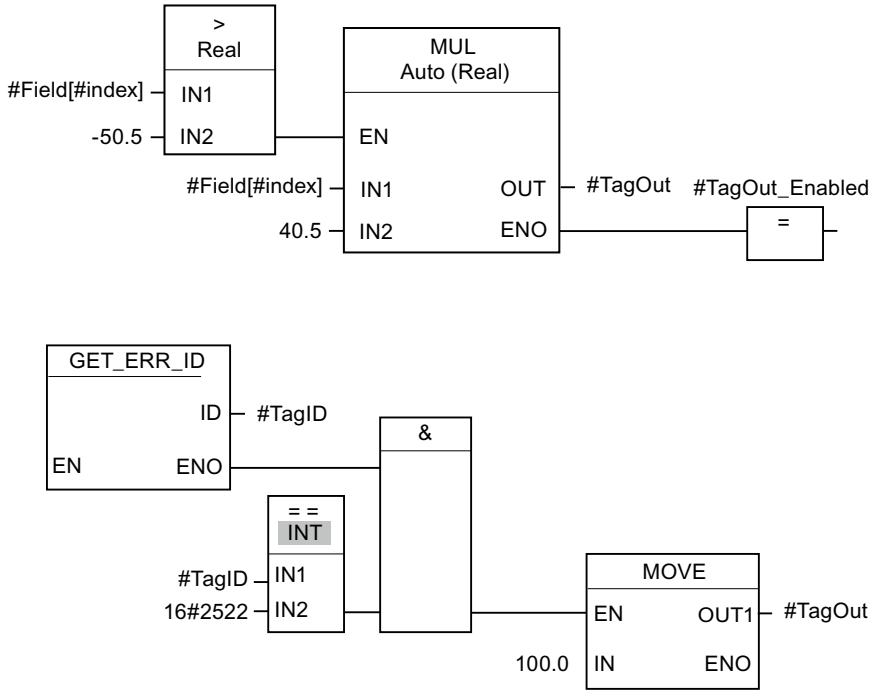
For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the "Get error ID locally" instruction:

Parameters	Declaration	Data type	Memory area	Description
ID	Output	WORD	I, Q, M, D, L	Error ID

Parameter ID



The following table shows the values that can be output at the ID parameter:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING

ID* (hexadecimal)	ID* (decimal)	Description
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
* The error codes can be displayed as integer or hexadecimal values in the program editor. You can find information on switching the display formats under "See also".		

Example

The following example shows how the instruction works:

An error occurred accessing the #Field[#index] tag. The enable output ENO of the "Multiply" instruction and the #TagOut_Enabled operand have signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, it is recommended to program the "Get error ID locally" instruction after the "Multiply" instruction to get the error. The error information supplied by the "Get error ID locally" instruction is evaluated with the comparison instruction "Equal". If the #TagID operand returns the ID 2522, this involves a read/access error and the value "100.0" is written to the #TagOut output.

INIT_RD: Initialize all retain data (S7-1500)

Description

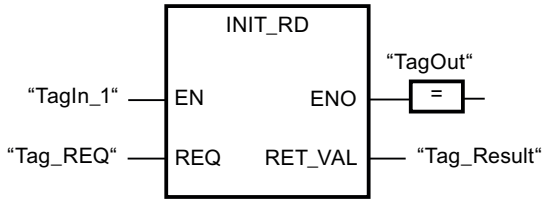
The "Initialize all retain data" instruction is used to reset the retentive data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution exceeds the program cycle duration.

Parameters

The following table shows the parameters of the "Initialize all retain data" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	If the input "REQ" has the signal state "1", all retentive data are reset.
RET_VAL	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output in the RET_VAL parameter.

For additional information on valid data types, refer to "See also".



Parameter RET_VAL

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal values in the program editor. You will find information on changing display formats in "See also".	

Example

The following example shows how the instruction works:

If the operands "TagIn_1" and "Tag_REQ" have signal state "1", the instruction is executed. All retentive data of all data blocks, bit memories and SIMATIC timers and counters are reset. If the instruction is executed without errors, the ENO enable output has the signal state "1".

Basic information on FBD (Page 4937)

WAIT: Configure time delay (S7-1500)

Description

The "Configure time delay" instruction pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to +32767 microseconds (µs). The smallest possible delay time depends on the CPU and corresponds to the execution time of the instruction.

The execution of the instruction can be interrupted by higher priority events and does not return any error information.

Note

Negative delay time

If you specify a negative delay time at parameter WT, the enable output ENO, or the RLO and the BR bit, will return the signal state FALSE. A negative delay time does not affect the CPU. The following instructions linked to enable output ENO are not executed in LAD or FBD.

Parameters

The following table shows the parameters of the "Configure time delay" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
WT	Input	INT	I, Q, M, D, L, P or constant	Time delay in microseconds (µs)

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

RUNTIME: Measure program runtime (S7-1200, S7-1500)

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and write the value to the IN-OUT parameter MEM. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

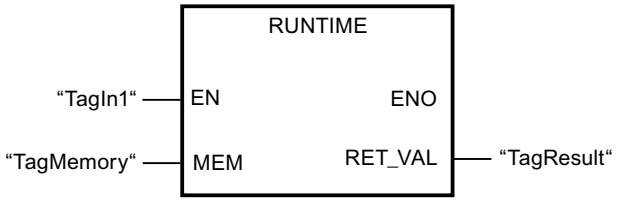
If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the IN-OUT parameter MEM as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The "Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overruns, the instruction returns values <= 0.0. This can occur up to once per minute for S7-1200 CPUs with firmware version <V4.2. Ignore these runtime values.

Note

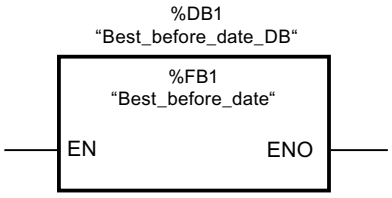
The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Parameters



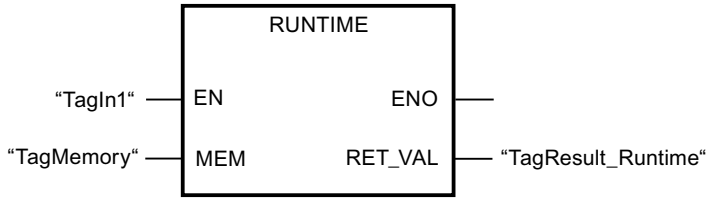
The following table lists the parameters of the "Measure program runtime" instruction:

Parameters	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
MEM	InOut	LREAL	I, Q, M, D, L	The content is for internal purposes only.
RET_VAL	Output	LREAL	I, Q, M, D, L	Returns the measured runtime in seconds



Example

The following example shows how the instruction works based on the runtime calculation of a program block:



Network 1:

Network 2:

Network 3:

When the "TagIn1" operand in network 1 has the signal state "1", the instruction is executed. The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called in network 2.

When the FB1 program block has been executed and the "TagIn1" operand has the signal state "1", the instruction in network 3 is executed. The second call of the instruction calculates the runtime of the program block and writes the result to the output RET_VAL.

You can find a more detailed example of how you can measure the total cycle time of a program in the Siemens Industry Online Support under the following entry ID: 87668055 (https://support.industry.siemens.com/cs/ww/en/view/87668055)

Word logic operations (S7-1200, S7-1500)

AND: AND logic operation (S7-1200, S7-1500)

Description

You can use the instruction "AND logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by AND logic and query the result at the output OUT.

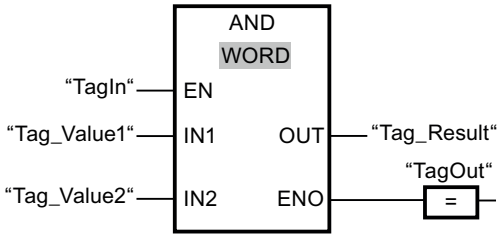
When the instruction is executed, bit 0 of the value at input IN1 is linked by AND logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified values.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by AND logic. The result is stored at output "OUT".

The result bit has the signal state "1" only when both of the bits in the logic operation also have signal state "1". If one of the two bits of the logic operation has signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "AND logic operation":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0000 0000 0000 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by AND to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

OR: OR logic operation (S7-1200, S7-1500)

Description

You can use the instruction "OR logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by OR logic and query the result at the output OUT.

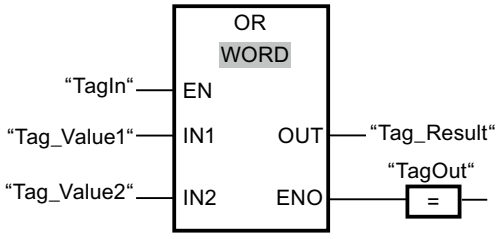
When the instruction is executed, bit 0 of the value at input IN1 is linked by OR logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all bits of the specified tags.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended in the instruction box. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by OR logic. The result is stored at output "OUT".

The result bit has the signal state "1" when at least one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "OR logic operation":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1111

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by OR to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

XOR: EXCLUSIVE OR logic operation (S7-1200, S7-1500)

Description

You can use the instruction "EXCLUSIVE OR logic operation" to link the value at input IN1 to the value at input IN2 bit-by-bit by EXCLUSIVE OR logic and query the result at the output OUT.

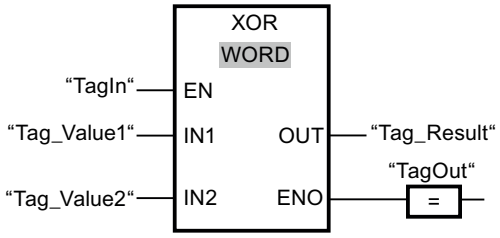
When the instruction is executed, bit 0 of the value at input IN1 is linked by EXCLUSIVE OR logic to bit 0 of the value at input IN2. The result is stored in bit 0 of output OUT. The same logic operation is executed for all other bits of the specified value.

In its initial state the instruction box contains at least 2 inputs (IN1 and IN2). The number of inputs can be extended in the instruction box. The inserted inputs are numbered in ascending order in the box. During the execution of the instruction, the values of all available input parameters are linked by EXCLUSIVE OR logic. The result is stored at output "OUT".

The result bit has the signal state "1" when one of the two bits in the logic operation has signal state "1". If both of the bits of the logic operation have signal state "1" or "0", the corresponding result bit is reset.

Parameters

The following table shows the parameters of the instruction "EXCLUSIVE OR logic operation":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN1	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First value for logic operation
IN2	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second value for logic operation
INn	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN1	Tag_Value1	0101 0101 0101 0101
IN2	Tag_Value2	0000 0000 0000 1111
OUT	Tag_Result	0101 0101 0101 1010

If the "TagIn" operand has signal state "1", the instruction is executed. The value of operand "Tag_Value1" is linked by EXCLUSIVE OR to the value of the operand "Tag_Value2". The result is mapped bit-for-bit and sent to the operand "Tag_Result". The enable output ENO and the output "TagOut" are set to signal state "1".

INVERT: Create ones complement (S7-1200, S7-1500)

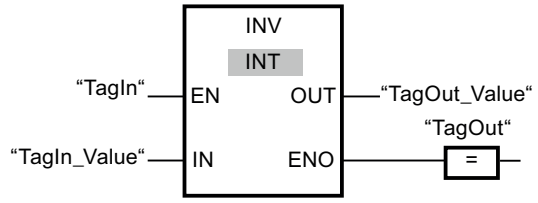
Description

You can use the instruction "Create ones complement" to invert the signal status of the bits at input IN. When the instruction is processed, the value at input IN is linked to EXCLUSIVE OR by a hexadecimal mask (W#16#FFFF for 16-bit numbers or DW#16#FFFF FFFF for 32-bit number). This inverts the signal state of the individual bits that are then stored at output OUT.

Parameters

The following table shows the parameters of the instruction "Create ones complement":

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
IN	Input	Bit strings, integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Input value
OUT	Output	Bit strings, integers	I, Q, M, D, L, P	I, Q, M, D, L, P	Ones complement of the value at input IN

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value	
IN	TagIn_Value	W#16#000F	W#16#7E
OUT	TagOut_Value	W#16#FFF0	W#16#81

If operand "TagIn" has the signal state "1", the "Create ones complement" instruction is executed. The instruction inverts the signal state of the individual bits at input "TagIn_Value" and writes the result to output "TagOut_Value". The enable output ENO and the output "TagOut" are set to signal state "1".

DECO: Decode (S7-1200, S7-1500)

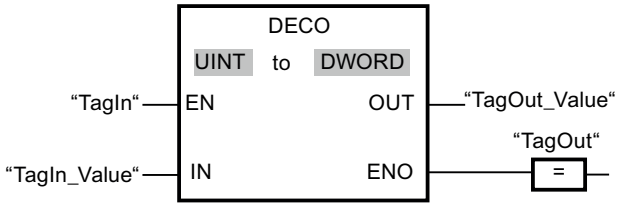
Description

You can use the "Decode" instruction to set a bit in the output value specified by the input value.

The "Decode" instruction reads the value at the IN input and sets the bit in the output value whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. If the value at input IN is greater than 31, a modulo 32 instruction is executed.

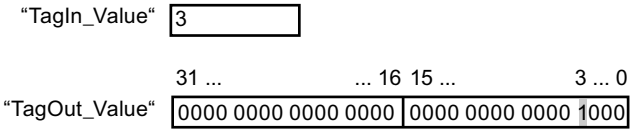
Parameters

The following table shows the parameters of the "Decode" instruction:



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	UINT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Position of the bit in the output value which is set.
OUT	Output	Bit strings	I, Q, M, D, L, P	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following figure shows how the instruction works using concrete operand values:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction reads bit number "3" from the value of the operand "TagIn_Value" and sets the third bit to the value of the operand "TagOut_Value".

If no errors occur during the execution of the instruction, the output ENO has the signal state "1" and the output "TagOut" is set.

ENCO: Encode (S7-1200, S7-1500)

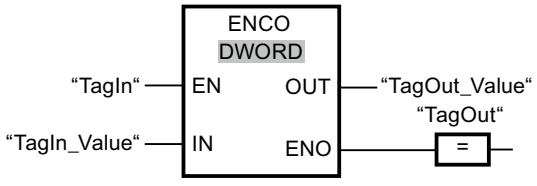
Description

The instruction "Encode" is used to read the bit number of the lowest bit in the input value and output it to the output OUT.

The instruction "Encode" selects the least significant bit of the value at the IN input and writes its bit number to the tag in the output OUT.

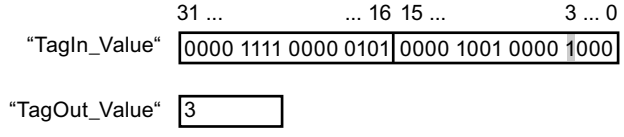
Parameters

The following table shows the parameters of the instruction "Encode":



Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
EN	Input	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Input value
OUT	Output	INT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output value

You can select the data type of the instruction from the "???" drop-down list of the instruction box.



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following figure shows how the instruction works using concrete operand values:

If the "TagIn" operand has signal state "1", the instruction is executed. The instruction selects bit position "3" as the least significant bit at input "TagIn_Value" and writes the value "3" to the tag at the output "TagOut_Value.

If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

See also

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

SEL: Select (S7-1200, S7-1500)

Description

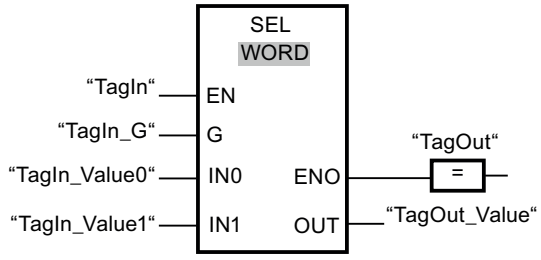
Depending on the signal state at switch (input G), the "Select" instruction selects one of the inputs IN0 or IN1 and moves its content to the output OUT. When the input G has the signal state "0", the value at the input IN0 is moved. When the input G has the signal state "1", the value at the input IN1 is moved to the output OUT.

The instruction can only be executed if the enable input EN has the signal state "1" and the tags of all parameters are of the same data type.

Parameters

The following table shows the parameters of the "Select" instruction:

Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
G	Input	BOOL	BOOL	I, Q, M, D, L or constant	I, Q, M, D, L, T, C or constant	Switch
IN0	Input	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
IN1	Input	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
OUT	Output	Bit strings, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, timers, TOD, LTOD, DATE, TDT, CHAR, WCHAR	I, Q, M, D, L, P	I, Q, M, D, L, P	Result

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value	
G	TagIn_G	0	1
IN0	TagIn_Value0	W#16#0000	W#16#4C
IN1	TagIn_Value1	W#16#FFFF	W#16#5E
OUT	TagOut_Value	W#16#0000	W#16#5E

If the "TagIn" operand has signal state "1", the instruction is executed. Based on the signal state at the input "TagIn_G", the value at input "TagIn_Value0" or "TagIn_Value1" is selected

and copied to output "TagOut_Value". If the instruction is executed without errors, the enable output ENO has the signal state "1" and the "TagOut" output is set.

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

MUX: Multiplex (S7-1200, S7-1500)

Description

You can use the instruction "Multiplex" to copy the content of a selected input to output OUT. In its initial state the instruction box contains at least 2 inputs (IN0 and IN1). The number of selectable inputs of the instruction box can be expanded. You can declare a maximum of 32 inputs.

The inputs are numbered automatically in the box. Numbering starts at IN0 and is incremented continuously with each new input. You use the K parameter to define the input whose content is to be copied to the OUT output. If the value of the parameter K is greater than the number of available inputs, the content of the parameter ELSE is copied to output OUT and enable output ENO is assigned the signal state "0".

The "Multiplex" instruction can only be executed if the tags have the same data type in all inputs and in the OUT output. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

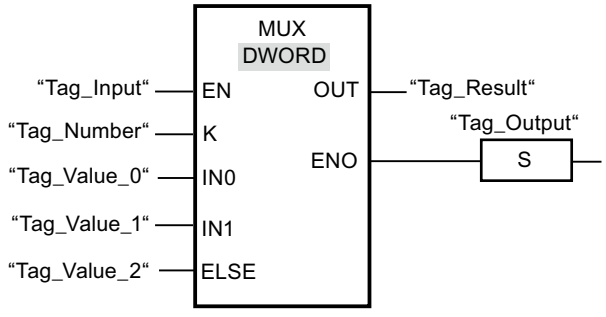
- Enable input EN has the signal state "0".
- The input at the K parameter is located outside the available inputs. This is the reaction regardless of whether the ELSE input will be used or not. The value at the OUT output remains unchanged.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the "Multiplex" instruction:

Parameters	Declaring	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

Parameters	Declaring	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
K	Input	Integers	Integers	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Specifies the input whose content is to be copied. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Second input value
INn	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Optional input values



Parameters	Declaring	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
ELSE	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P or constant	I, Q, M, D, L, P or constant	Specifies the value to be copied when K > n
OUT	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the value is to be copied

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
K	Tag_Number	1
IN0	Tag_ValueI_0	DW#16#00000000
IN1	Tag_Value_1	DW#16#003E4A7D
ELSE	Tag_Value_2	DW#16#FFFF0000
OUT	Tag_Result	DW#16#003E4A7D

If the "Tag_Input" operand has signal state "1", the instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "Tag_Value_1" is copied and assigned to the operand at output "Tag_Result". If no errors occur during the execution of the instruction, the outputs ENO and "Tag_Output" are set.

DEMUX: Demultiplex (S7-1200, S7-1500)

Description

You can use the instruction "Demultiplex" to copy the content of the input IN to a selected output. In its initial state the instruction box contains at least 2 outputs (OUT0 and OUT1). The number of selectable outputs can be extended in the instruction box. The outputs are numbered automatically in the box. Numbering starts at OUT0 and continues consecutively with each new output. You use the K parameter to define the output to which the content of the IN input is to be copied. The other outputs are not changed. If the value of the parameter K is greater than the number of available outputs, then the content of input IN is copied to the parameter ELSE and the enable output ENO is assigned the signal state "0".

The instruction "Demultiplex" can only be executed if the tags at the input IN and at all outputs are of the same data type. The K parameter is an exception, since only integers can be specified for it.

The enable output ENO is reset if one of the following conditions applies:

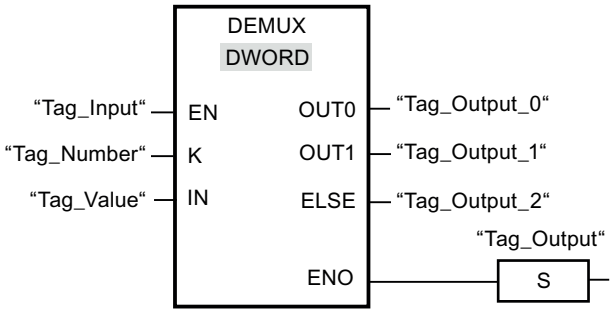
- Enable input EN has the signal state "0".
- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Parameters

The following table shows the parameters of the instruction "Demultiplex":

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
K	Input	Integers	Integers	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Specifies the output to which the input value (IN) is copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P, or constant	I, Q, M, D, L, P, or constant	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	First output
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Second output



Parameter	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Optional outputs
ELSE	Output	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, DATE	Binary numbers, integers, floating-point numbers, timers, CHAR, WCHAR, TOD, LTOD, DATE, LDT	I, Q, M, D, L, P	I, Q, M, D, L, P	Output to which the input value (IN) at K > n is copied.

You can select the data type of the instruction from the "<???>" drop-down list of the instruction box.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:

The following tables show how the instruction works using specific operand values:

Table 11-16 Input values of the "Demultiplex" instruction before network execution

Parameter	Operand	Values	
K	Tag_Number	1	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Table 11-17 Output values of the "Demultiplex" instruction after network execution

Parameter	Operand	Values	
OUT0	Tag_Output_0	Unchanged	Unchanged
OUT1	Tag_Output_1	DW#16#FFFFFFFF	Unchanged
ELSE	Tag_Output_2	Unchanged	DW#16#003E4A7D

If the "Tag_Input" input has the signal state"1", the "Demultiplex" instruction is executed. Depending on the value of the operand "Tag_Number", the value at input "IN" is copied to the corresponding output.

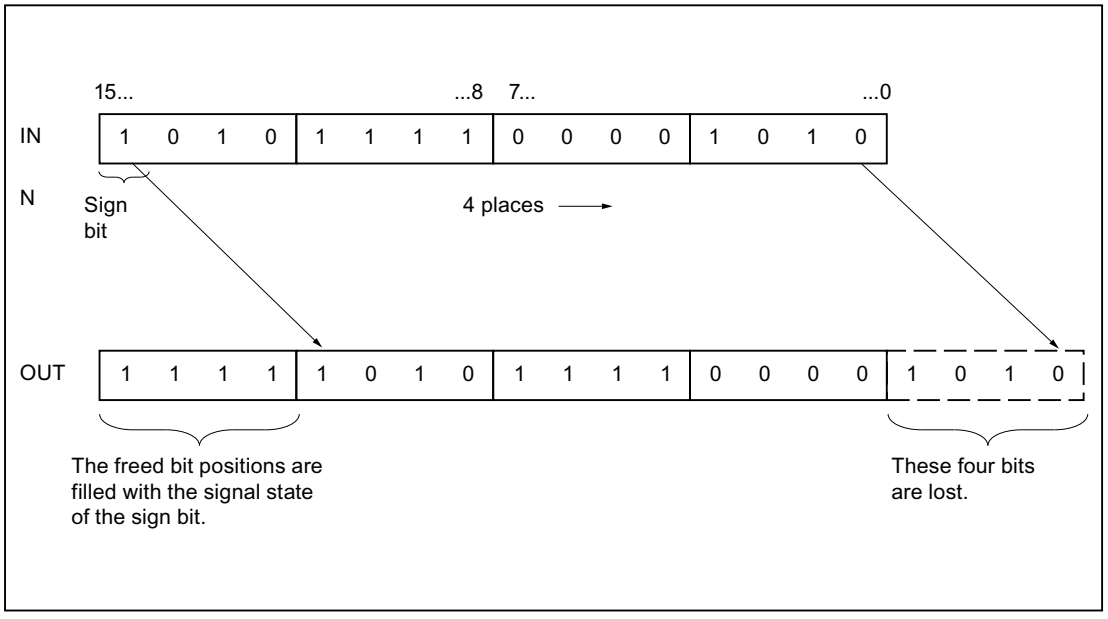
Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

Shift and Rotate (S7-1200, S7-1500)

SHR: Shift right (S7-1200, S7-1500)

Description



You can use the "Shift right" instruction to shift the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be moved.

If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

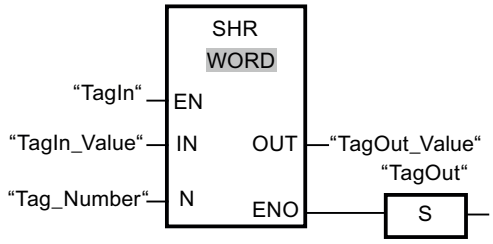
If the value at the input N is greater than the number of available bit positions, the operand value at input IN is shifted to the right by the available number of bit positions.

The freed bit positions in the left area of the operand are filled by zeroes when values without signs are shifted. If the specified value has a sign, the free bit positions are filled with the signal state of the sign bit.

The following figure show how the content of an operand of integer data type is shifted four bit positions to the right:

Parameters

The following table shows the parameters of the instruction "Shift right":



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	3
OUT	TagOut_Value	0000 0111 1111 0101

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is shifted three bit positions to the right. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

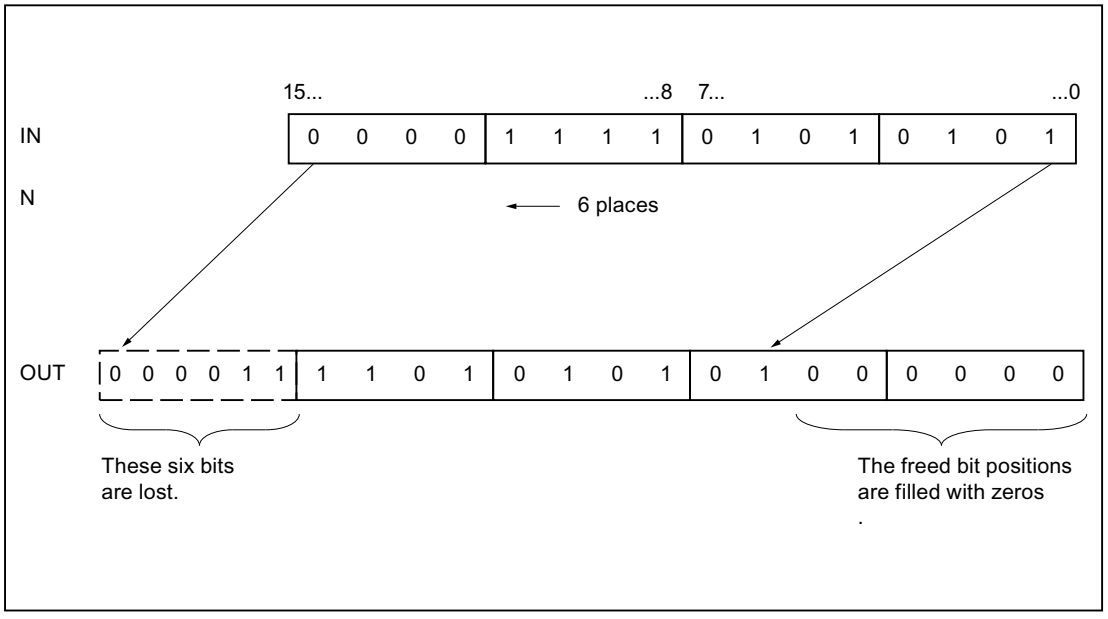
SHL: Shift left (S7-1200, S7-1500)

Description



You can use the "Shift left" instruction to shift the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be moved.

If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

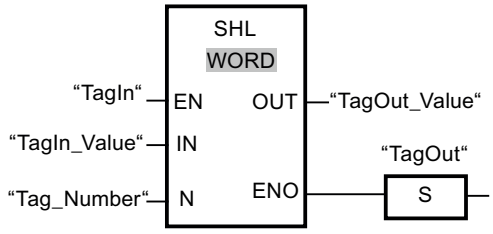
If the value at the input N is greater than the number of available bit positions, the operand value at input IN is shifted to the left by the available number of bit positions.

The bit positions in the right part of the operand freed by shifting are filled with zeros.

The following figure shows how the content of an operand of the WORD data type is shifted by six bit positions to the left:

Parameters

The following table shows the parameters of the instruction "Shift left":



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be shifted.
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is shifted.
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0011 1111 1010 1111
N	Tag_Number	4
OUT	TagOut_Value	1111 1010 1111 0000

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is shifted four bit positions to the left. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

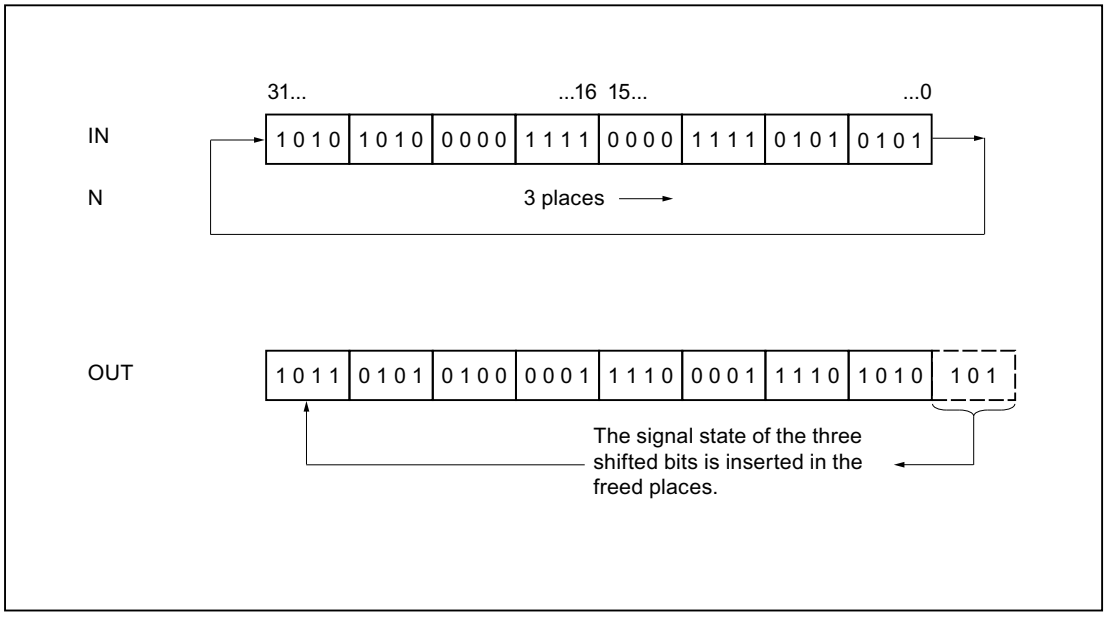
ROR: Rotate right (S7-1200, S7-1500)



Description

You can use the "Rotate right" instruction to rotate the content of the operand at the input IN bit-by-bit to the right and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating on the left-hand side are filled true-to-position with the bit positions that are pushed out from the left-hand side.

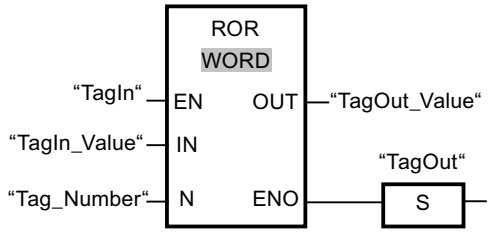
If the value at the input N is "0", the value at input IN is copied unchanged to the operand at output OUT.

If the value of the N parameter is greater than the number of available bit positions, the operand value at the IN input is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the right:

Parameters

The following table shows the parameters of the instruction "Rotate right":



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	0000 1111 1001 0101
N	Tag_Number	5
OUT	TagOut_Value	1010 1000 0111 1100

If the "TagIn" operand has signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is rotated five bit positions to the right. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

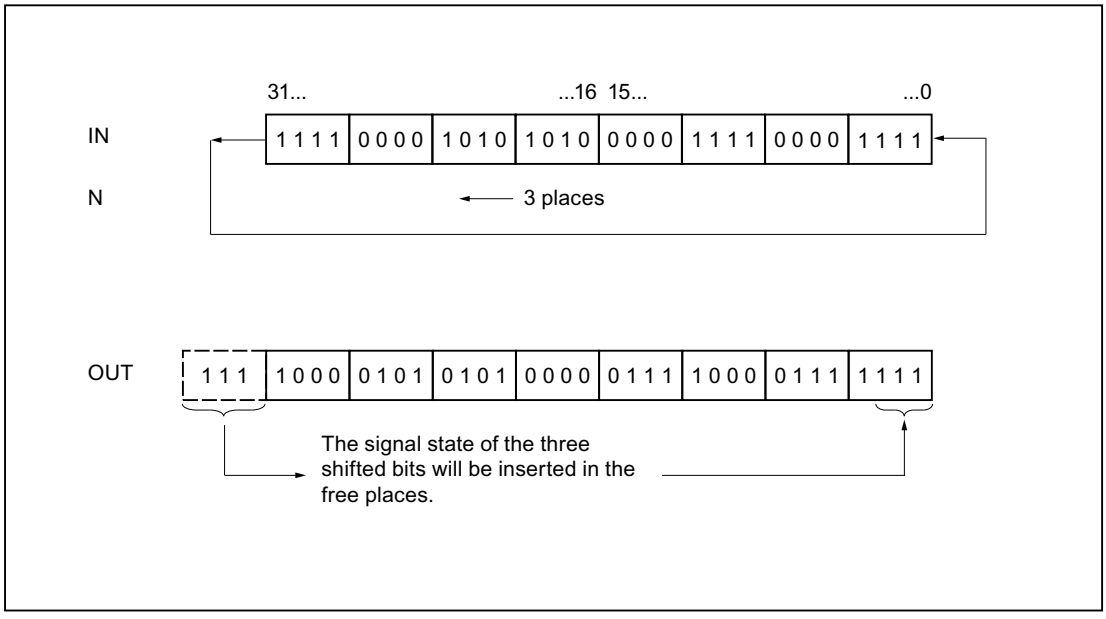
ROL: Rotate left (S7-1200, S7-1500)



Description

You can use the "Rotate left" instruction to rotate the content of the operand at the input IN bit-by-bit to the left and query the result at the OUT output. The input N is used to specify the number of bit positions by which the specified value should be rotated. The bit positions freed by rotating on the right-hand side are filled true-to-position with the bit positions that are pushed out from the left-hand side.

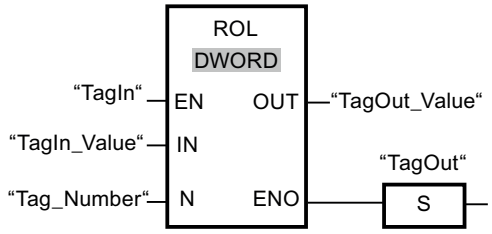
If the value at the input N is "0", the value at input IN is copied to the operand at output OUT.

If the value of the N parameter is greater than the number of available bit positions, the operand value at the IN input is nevertheless rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the left:

Parameters

The following table shows the parameters of the instruction "Rotate left":



Parameters	Declaration	Data type		Memory area		Description
		S7-1200	S7-1500	S7-1200	S7-1500	
EN	Input	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	BOOL	I, Q, M, D, L	I, Q, M, D, L	Enable output
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Value to be rotated.
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L or constant	I, Q, M, D, L or constant	Number of bit positions by which the value is rotated.
OUT	Output	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	I, Q, M, D, L	Result of the instruction

You can select the data type of the instruction from the "???" drop-down list of the instruction box.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

The following table shows how the instruction works using concrete operand values:

Parameters	Operand	Value
IN	TagIn_Value	1010 1000 1111 0110
N	Tag_Number	5
OUT	TagOut_Value	0001 1110 1101 0101

If the "TagIn" has the signal state "1", the instruction is executed. The content of the operand "TagIn_Value" is rotated five bit positions to the left. The result is output at the "TagOut_Value" output. If the instruction is executed without errors, the ENO enable output has the signal state "1" and the "TagOut" output is set.

Legacy (S7-1500)

DRUM: Implement sequencer (S7-1500)

Description

You can use the "Implement sequencer" instruction to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset when the signal state of the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a timer value, an event, or both. Steps that have an event bit and the timer value "0" advance to the next step as soon as the signal state of the event bit is "1". Steps that are programmed only with a timer value start the time immediately. Steps that are programmed with an event bit and a timer value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the Q parameter is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK) you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). When a bit of the configurable mask has a signal state of "1", the OUT_VAL value sets/resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit at the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit at the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

Parameters

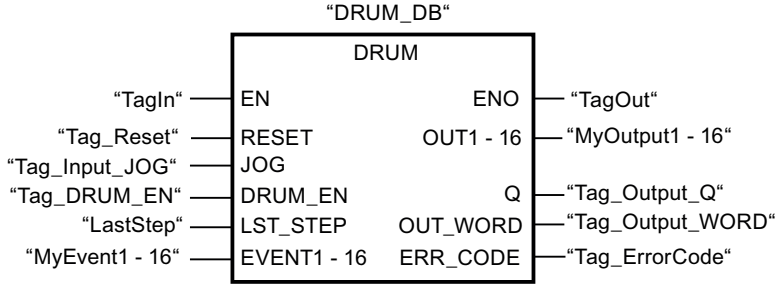
The following table shows the parameters of the "Implement sequencer" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
RESET	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates a reset condition.
JOG	Input	BOOL	I, Q, M, D, L or constant	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L or constant	The signal state "1" allows the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L or constant	Maximum step number (for example: LST_STEP = 16#08; a maximum of 8 steps is possible.)
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L or constant	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.

Parameter	Declaration	Data type	Memory area	Description
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L or constant	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L or constant	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P or constant	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P or constant	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P or constant	Current numerical value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P or constant	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L or constant	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L or constant	Preset counter value for each step [1 to 16] where one clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L or constant	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:



ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value of the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value of the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameters	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001
DCC	DBD16	DW#16#0000000A

Parameter	Address	Value
DTBP	DBW20	W#16#0001
S_PRESET[1]	DBW26	W#16#0064
S_PRESET[2]	DBW28	W#16#00C8
OUT_VAL[1,0]	DBX58.0	TRUE
OUT_VAL[1,1]	DBX58.1	TRUE
OUT_VAL[1,2]	DBX58.2	TRUE
OUT_VAL[1,3]	DBX58.3	TRUE
OUT_VAL[1,4]	DBX58.4	TRUE
OUT_VAL[1,5]	DBX58.5	TRUE
OUT_VAL[1,6]	DBX58.6	TRUE
OUT_VAL[1,7]	DBX58.7	TRUE
OUT_VAL[1,8]	DBX59.0	TRUE
OUT_VAL[1,9]	DBX59.1	TRUE
OUT_VAL[1,10]	DBX59.2	TRUE
OUT_VAL[1,11]	DBX59.3	TRUE
OUT_VAL[1,12]	DBX59.4	TRUE
OUT_VAL[1,13]	DBX59.5	TRUE
OUT_VAL[1,14]	DBX59.6	TRUE
OUT_VAL[1,15]	DBX59.7	TRUE
OUT_VAL[2,0]	DBX60.0	FALSE
OUT_VAL[2,1]	DBX60.1	FALSE
OUT_VAL[2,2]	DBX60.2	FALSE
OUT_VAL[2,3]	DBX60.3	FALSE
OUT_VAL[2,4]	DBX60.4	FALSE
OUT_VAL[2,5]	DBX60.5	FALSE
OUT_VAL[2,6]	DBX60.6	FALSE
OUT_VAL[2,7]	DBX60.7	FALSE
OUT_VAL[2,8]	DBX61.0	FALSE
OUT_VAL[2,9]	DBX61.1	FALSE
OUT_VAL[2,10]	DBX61.2	FALSE
OUT_VAL[2,11]	DBX61.3	FALSE
OUT_VAL[2,12]	DBX61.4	FALSE
OUT_VAL[2,13]	DBX61.5	FALSE
OUT_VAL[2,14]	DBX61.6	FALSE
OUT_VAL[2,15]	DBX61.7	FALSE
S_MASK[2,0]	DBX92.0	FALSE
S_MASK[2,1]	DBX92.1	TRUE
S_MASK[2,2]	DBX92.2	TRUE
S_MASK[2,3]	DBX92.3	TRUE
S_MASK[2,4]	DBX92.4	TRUE
S_MASK[2,5]	DBX92.5	FALSE
S_MASK[2,6]	DBX92.6	TRUE
S_MASK[2,7]	DBX92.7	TRUE

Parameter	Address	Value
S_MASK[2,8]	DBX93.0	FALSE
S_MASK[2,9]	DBX93.1	FALSE
S_MASK[2,10]	DBX93.2	TRUE
S_MASK[2,11]	DBX93.3	TRUE
S_MASK[2,12]	DBX93.4	TRUE
S_MASK[2,13]	DBX93.5	TRUE
S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameter	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE

Parameter	Operand	Address	Value
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameter	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

Basic information on FBD (Page 4937)

DCAT: Discrete control-timer alarm (S7-1500)

Description

You can use the "Discrete control-timer alarm" to count the time from the point at which the CMD parameter issues the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state of the command input changes before the preset time, the time is restarted.

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

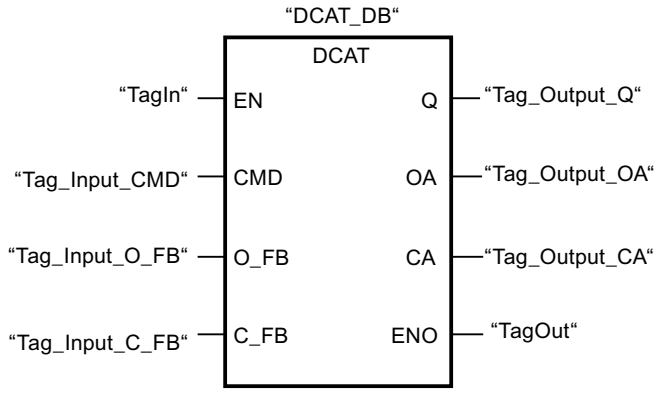
- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET is < PT) OA and CA are influenced as follows:
  - The Q and CMD_HIS parameters are set to "1".
  - The ET, OA, and CA parameters are reset to "0".
- When the signal state of the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".
- When the signal state of the CMD and CMD_HIS parameters is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the ET parameter exceeds the value of the PT parameter, the signal state at the OA parameter is set to "1". If the value of the ET parameter does not exceed the value of the PT parameter, the signal state of the OA parameter is reset to "0". The value at the parameter CMD_HIS is reset to the value of the parameter CMD.
- If the signal state of the CMD, CMD_HIS and O_FB parameters are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the O_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the CMD, CMD_HIS and C_FB parameters return signal state "0", the time difference (ms) since the last execution of the instruction is added to the value of the ET parameter. If the value of the ET parameter exceeds the value of the PT parameter, the signal state of the parameter CA is reset to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the C_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction has no error information.

Parameters

The following table shows the parameters of the "Discrete control-timer alarm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output



Parameter	Declaration	Data type	Memory area	Description
CMD	Input	BOOL	I, Q, M, D, L or constant	A signal state of "0" indicates a "close" command. A signal state of "1" indicates an "open" command.
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L or constant	Currently elapsed time, where one count = 1 ms.
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms.
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
CMD_HIS	Static	BOOL	D, L or constant	CMD history bit

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The CMD_HIS parameter of the instance data block is set to the signal state "1" and the ET parameter is reset to "0".

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameter	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameter	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameter	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

MCAT: Motor control-timer alarm (S7-1500)

Description

The "Motor control-timer alarm" instruction is used to accumulate the time from the point at which one of the command inputs (opening or closing) is switched on. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

The "Motor control-timer alarm" instruction returns no error information.

Parameters

The following table shows the parameters of the "Motor control-timer alarm" instruction:

Parameters	Declaration	Data type	Memory space	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
O_CMD	Input	BOOL	I, Q, M, D, L or constant	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L or constant	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L or constant	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L or constant	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	A signal state of "0" indicates an error condition.
ET	Static	DINT	D, L or constant	Currently elapsed time, where one count = 1 ms
PT	Static	DINT	D, L or constant	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L or constant	Previous system time
O_HIS	Static	BOOL	D, L or constant	"Open" history bit
C_HIS	Static	BOOL	D, L or constant	"Close" history bit

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the "Motor control-timer alarm" instruction to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	Status
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped

Legend:	
INC	Add the time difference (ms) since the last processing of the FB to ET
PT	PT is set to the same value as ET
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT

If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to signal state "0". In this case, the last row in the table (X) mentioned above is valid. Because it is therefore no longer possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case:

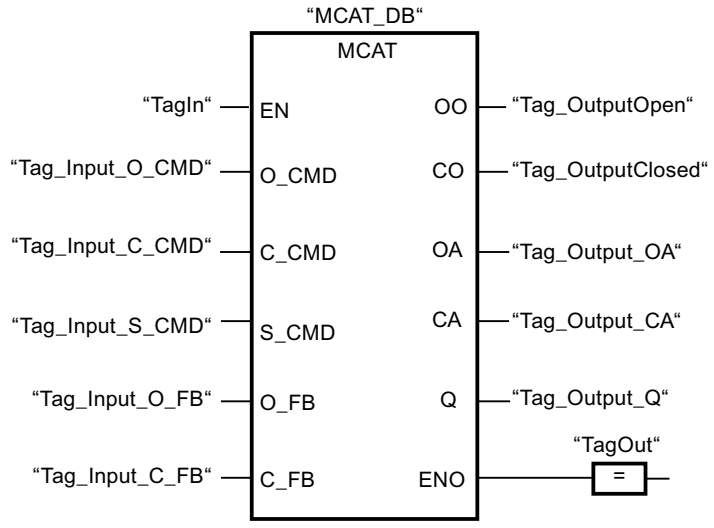
OO = FALSE

CO = FALSE

OA = FALSE

CA = FALSE

ET = PT



Q = TRUE

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameters	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE

Parameters	Operand	Value
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

IMC: Compare input bits with the bits of a mask (S7-1500)

Description

You can use the "Compare input bits with the bits of a mask" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. In the CMP_STEP parameter, you specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise the OUT parameter is set to "0".

If the value of the CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

Parameters

The following table shows the parameters of the "Compare input bits with the bits of a mask" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P or constant	The step number of the mask used for the comparison.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

SMC: Compare scan matrix (S7-1500)

Description

You can use the "Compare scan matrix" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bit of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found, the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written to the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have the default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value at the LAST parameter.

Parameters

The following table shows the parameters of the "Compare scan matrix" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN_BIT0	Input	BOOL	I, Q, M, D, L or constant	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L or constant	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L or constant	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L or constant	Input bit 3 is compared with bit 3 of the mask.

Parameter	Declaration	Data type	Memory area	Description
IN_BIT4	Input	BOOL	I, Q, M, D, L or constant	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L or constant	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L or constant	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L or constant	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L or constant	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L or constant	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L or constant	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L or constant	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L or constant	Input bit 12 is compared with bit 12 of the mask.
IN_BIT13	Input	BOOL	I, Q, M, D, L or constant	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L or constant	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L or constant	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask, or the step number which is greater by "1" than the value at the LAST parameter, provided no match is found.
LAST	Static	BYTE	I, Q, M, D, L, P or constant	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L or constant	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

Overview of the valid data types (Page 2239)

Basic information on FBD (Page 4937)

LEAD_LAG: Lead and lag algorithm (S7-1500)

Description

You can use the "Lead and lag algorithm" instruction to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the instruction "Lead and lag algorithm" is calculated using the following equation:

$$OUT = \left[\frac{LG_TIME}{LG_TIME + SAMPLE_T}\right] PREV_OUT + GAIN \left[\frac{LD_TIME + SAMPLE_T}{LG_TIME + SAMPLE_T}\right] IN - GAIN \left[\frac{LD_TIME}{LG_TIME + SAMPLE_T}\right] * PREV_IN$$

The "Lead and lag algorithm" instruction supplies plausible results only when processing is in fixed program cycles. The same units must be specified for the LD_TIME, LG_TIME, and SAMPLE_T parameters. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output on the ERR_CODE parameter.

You can use the instruction "Lead and lag algorithm" in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The "Lead" operation shifts the phase of the OUT output so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two instructions together (Lead and Lag) result in the output phase lagging behind the the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

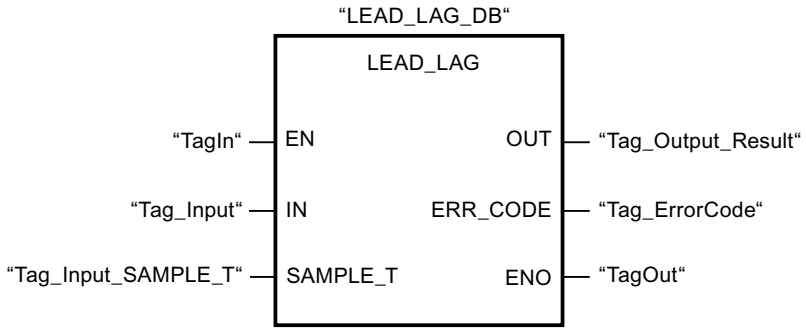
Parameters

The following table shows the parameters of the "Lead and lag algorithm" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	REAL	I, Q, M, D, L, P or constant	The input value of the current sample time (cycle time) to be processed.
SAMPLE_T	Input	INT	I, Q, M, D, L, P or constant	Sample time
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
LD_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P or constant	Lag time in the same unit as sample time
GAIN	Static	REAL	I, Q, M, D, L, P or constant	Gain as % / % (the ratio of the change in output to a change in input as a steady state).
PREV_IN	Static	REAL	I, Q, M, D, L, P or constant	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P or constant	Previous output

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:



Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input parameters:

Parameters	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_InputSampleTime	10

The following values are saved in the "LEAD_LAG_DB" instance data block of the instruction:

Parameters	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameters	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

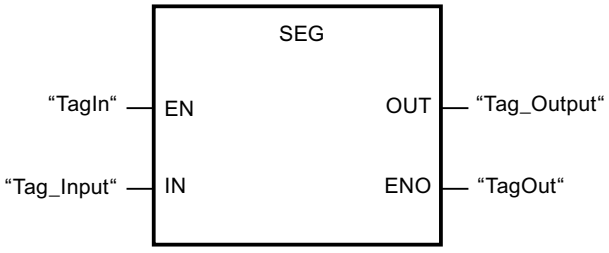
SEG: Create bit pattern for seven-segment display (S7-1500)

Description

The instruction "Create bit pattern for seven-segment display" is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a seven-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	**Assignment of the segments - g f e d c b a**	**Display** (Hexadecimal)	**Seven-segment display**
0000	00111111	0	
0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	



Parameters

The following table shows the parameters of the "Create bit pattern for seven-segment display" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output
IN	Input	WORD	I, Q, M, D, L, P or constant	Source word with four hexa-decimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display

Example

The following example shows how the instruction works:

The following table shows how the instruction functions using specific values:

Parameters	Operand	Value	
Hexadecimal	Binary		
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW#16065B4F66	00000110 01011011 01001111 01100110 Display: 1234

BCDCPL: Create tens complement (S7-1500)

Description

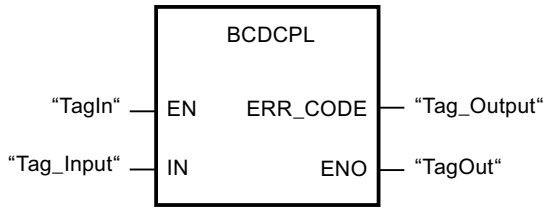
You can use the "Create tens complement" instruction to create the tens complement of a seven-digit BCD number specified in the IN parameter. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)

Parameters



The following table shows the parameters of the "Create tens complement" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P or constant	7-digit BCD number
ERR_CODE	Output	DWORD	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:

The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#01234567
ERR_CODE	Tag_Output	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

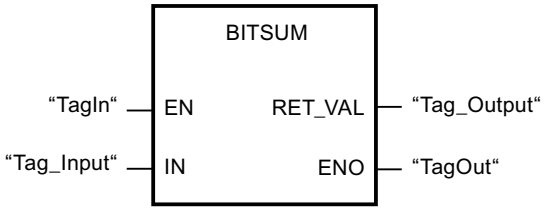
BITSUM: Count number of set bits (S7-1500)

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that is set to the signal state "1". The operand whose bits are to be counted is specified on the IN parameter. The result of the instruction is output at the RET_VAL parameter.

Parameters



The following table shows the parameters of the "Count number of set bits" instruction:

Parameter	Declaration	Data type	Memory area	Description
EN	Input	BOOL	I, Q, M, D, L, T, C	Enable input
ENO	Output	BOOL	I, Q, M, D, L	Enable output

Parameter	Declaration	Data type	Memory area	Description
IN	Input	DWORD	I, Q, M, D, L, P or constant	Operand whose set bits are counted.
RET_VAL	Output	INT	I, Q, M, D, L, P	Number of bits to be set

Example

The following example shows how the instruction works:

The following table shows how the instruction functions using specific values:

Parameter	Operand	Value*
IN	Tag_Input	DW#16#12345678
RET_VAL	Tag_Output	W#16#000D (13 Bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats under "See also".

11.4.3.3 SCL (S7-1200, S7-1500)

Bit logic operations (S7-1200, S7-1500)

R_TRIG: Detect positive signal edge (S7-1200, S7-1500)

Description

With the "Detect positive signal edge" instruction, you can detect a state change from "0" to "1" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "0" to "1", a positive signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Incoming signal, the edge of which is to be queried
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

```
SCL
"R_TRIG_DB"(CLK := "TagIn",
            Q => "TagOut");
```

The previous state of the tag at the CLK input is stored in the "R_TRIG_DB" tag. If a change is the signal state from "0" to "1" is detected in the "TagIn_1" and "TagIn_2" operands or in the "TagIn_3" operand, the "TagOut_Q" output has signal state "1" for one cycle.

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

F_TRIG: Detect negative signal edge (S7-1200, S7-1500)

Description

With the "Detect negative signal edge" instruction, you can detect a state change from "1" to "0" at the CLK input. The instruction compares the current value at the CLK input with the state of the previous query (edge memory bit) that is saved in the specified instance. If the instruction detects a state change at the CLK input from "1" to "0", a negative signal edge is generated at the Q output, i.e., the output has the value TRUE or "1" for exactly one cycle.

In all other cases, the signal state at the output of the instruction is "0".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CLK	Input	BOOL	I, Q, M, D, L	Incoming signal, the edge of which is to be queried
Q	Output	BOOL	I, Q, M, D, L	Result of edge evaluation

Example

The following example shows how the instruction works:

SCL

```
"F_TRIG_DB"(CLK := "TagIn",
            Q => "TagOut");
```

The previous state of the tag at the CLK input is stored in the "F_TRIG_DB" tag. If a change in the signal state from "1" to "0" is detected in the "TagIn" operand, the "TagOut" output has signal state "1" for one cycle.

Timer operations (S7-1200, S7-1500)

Calling IEC timers (S7-1200, S7-1500)

Description

You have the option of declaring the IEC timer as single or multiple instance and calling it in the program code.

The following syntax options are available for the declaration of an IEC timer as multi-instance within a structure in the block interface:

IEC timer as ARRAY element

Declaration in the block interface:

	Static	
	MyARRAY	Array[0..1] of IEC_TIMER
	MyARRAY[0]	IEC_TIMER
	MyARRAY[1]	IEC_TIMER

Program code:

SCL

```
#MyARRAY[1].TOF(IN := <Operand>, PT := <Operand>)
```

Declaration in the block interface:

	Static	
	MyARRAY	Array[0..1] of TON_TIME
	MyARRAY[0]	TON_TIME
	MyARRAY[1]	TON_TIME

Program code:

SCL

```
#MyARRAY[#index](IN := <Operand>, PT := <Operand>)
```

IEC timer within an anonymous structure

Declaration in the block interface:

Static	
MyStruct	Struct
FirstTime	IEC_TIMER
PT	Time
ET	Time
IN	Bool
Q	Bool

Program code:

SCL

```
#MyStruct.FirstTime.TOF(IN := <Operand>, PT := <Operand>)
```

Declaration in the block interface:

Static	
MyStruct	Struct
FirstTime	TON_TIME
PT	Time
ET	Time
IN	Bool
Q	Bool

Program code:

SCL

```
#MyStruct.FirstTime(IN := <Operand>, PT := <Operand>)
```

IEC timer in the global data block

Declaration in the data block:

MyGlobalDB

	Name	Datentyp
1	Static	
2	Timer	"MyUDT"
3	FirstTime	IEC_TIMER
4	PT	Time
5	ET	Time
6	IN	Bool
7	Q	Bool

Program code:

SCL

```
"MyGlobalDB".Timer.FirstTime.TOF(IN := <Operand>, PT := <Operand>)
```

Declaration in the data block:

MyGlobalDB

	Name	Datentyp
1	Static	
2	Timer	"MyUDT"
3	FirstTime	IEC_TIMER
4	SecondTime	TON_TIME
5	PT	Time
6	ET	Time
7	IN	Bool
8	Q	Bool

Program code:

SCL

```
"MyGlobalDB".Timer.SecondTime(IN := <Operand>, PT := <Operand>)
```

IEC timer as elements in the block interface

Declaration in the block interface:

Static	
Timer	"MyUDT"
FirstTime	IEC_TIMER
PT	Time
ET	Time
IN	Bool
Q	Bool

Program code:

SCL

```
#Timer.FirstTime.TOF(IN := <Operand>, PT := <Operand>)
```

Declaration in the block interface:

Static	
Timer	"MyUDT"
FirstTime	IEC_TIMER
SecondTime	TON_TIME
PT	Time
ET	Time
IN	Bool
Q	Bool

Program code:

SCL

```
#Timer.SecondTime(IN := <Operand>, PT := <Operand>)
```

IEC timer within an ARRAY DB

Declaration in the ARRAY DB:

MyARRAYDB

		Name	Datentyp
1		MyARRAYDB	Array[0..1] of "MyUDT"
2		MyARRAYDB[0]	"MyUDT"
3		FirstTime	IEC_TIMER
4		PT	Time
5		ET	Time
6		IN	Bool
7		Q	Bool

Program code:

SCL

```
"MyARRAYDB"."THIS"[0].FirstTime.TOF(IN := <Operand>, PT := <Operand>)
```

Declaration in the ARRAY DB:

MyARRAYDB

		Name	Datentyp
1		MyARRAYDB	Array[0..1] of "MyUDT"
2		MyARRAYDB[0]	"MyUDT"
3		FirstTime	IEC_TIMER
4		SecondTime	TON_TIME
5		PT	Time
6		ET	Time
7		IN	Bool
8		Q	Bool

Program code:

SCL

```
"MyARRAYDB"."THIS"[0].SecondTime(IN := <Operand>, PT := <Operand>)
```

TP: Generate pulse (S7-1200, S7-1500)

Description

You can use the "Generate pulse" instruction to set the parameter Q for a programmed duration. The instruction is started when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. The Q parameter is set for the time PT, regardless of the subsequent changes in the input signal. Even when a new positive signal edge is detected, the signal state of the Q parameter is not affected as long as the time duration PT is active.

You can query the current time value set in the ET parameter. The timer value starts at T#0s and ends when the value of the time duration PT is reached. When the time duration PT is reached and the signal state at the IN parameter is "0", the ET parameter is reset.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate pulse" instruction must be assigned to an IEC timer in which the instruction data is stored.

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

For information on calling IEC timers within structures (multi-instance), please refer to: Calling IEC timers (Page 3221)

For CPUs of the S7-1200 series

An IEC timer is a structure of the data type IEC_TIMER or TP_TIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TP_TIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

For CPUs of the S7-1500 series

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TP_TIME or TP_LTIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_LTIMER_DB")
- Declaration as local tag of the data type TP_TIME or TP_LTIME in the "Static" section of a program block (for example, #MyIEC_LTIMER_Instance)

IEC timer as instance data block of system data type IEC_<Timer> (Shared DB)

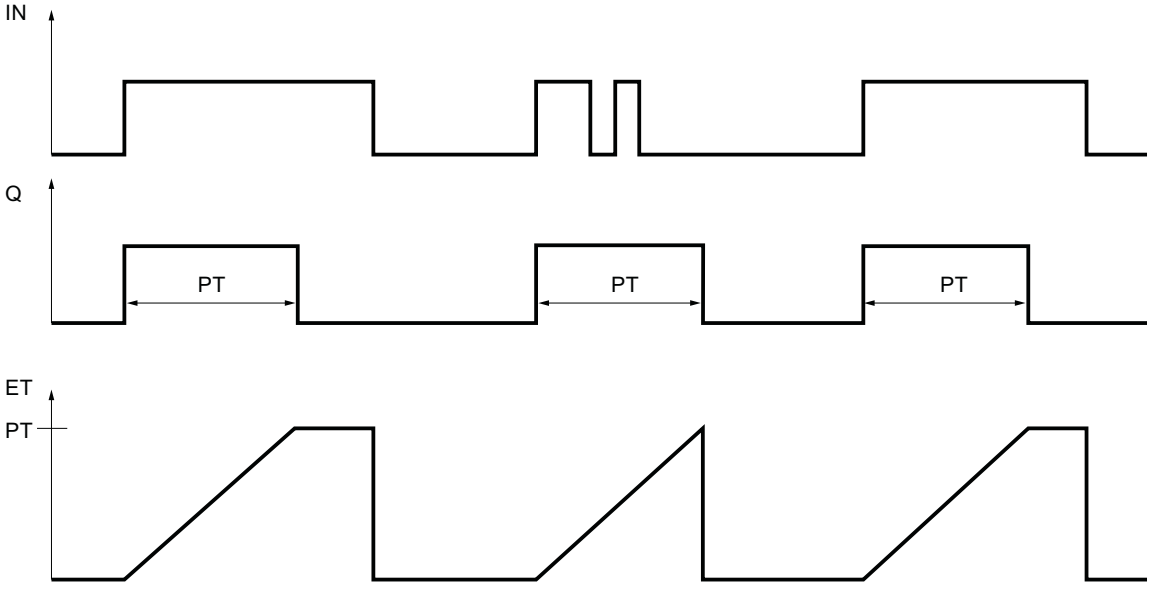
You can declare the IEC timer as a data block as follows:

<IEC_Timer_DB>.TP();

IEC timer as local tag from the block interface (multi-instance)

You can declare the IEC timer as a local tag as follows:

#myLocal_Timer();



Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the pulse. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is set for the PT duration.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current timer value

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate pulse" instruction:

Example

The following example shows how the instruction works:

```
SCL
"TP_DB".TP(IN := "Tag_Start",
           PT := "Tag_PresetTime",
           Q => "Tag_Status",
           ET => "Tag_ElapsedTime");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started and the "Tag_Status" operand is set to "1". The current time value is stored in the "Tag_ElapsedTime" operand.

Basics of SCL (Page 4991)

TON: Generate on-delay (S7-1200, S7-1500)

Description

You can use the "Generate on-delay" instruction to delay the setting of the Q parameter for the programmed duration PT. The instruction is started when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). The programmed time PT begins when the instruction starts. When the PT duration has expired, the Q parameter returns signal state "1". The Q parameter remains set as long as the start input is still "1". If the signal state of the IN parameter changes from "1" to "0", the parameter Q will be reset. The timer function is restarted when a new positive signal edge is detected at the IN parameter.

The current time value can be queried in the ET parameter. The time value starts at T#0s and ends when the value of the time duration PT is reached. The ET parameter is reset as soon as the signal state of the IN parameter changes to "0".

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate on-delay" instruction must be assigned to an IEC timer in which the instruction data is stored.

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

For information on calling IEC timers within structures (multi-instance), please refer to: Calling IEC timers (Page 3221)

For CPUs of the S7-1200 series

An IEC timer is a structure of the data type IEC_TIMER or TON_TIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TON_TIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

For CPUs of the S7-1500 series

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TON_TIME or TON_LTIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TON_TIME or TON_LTIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

IEC timer as instance data block of system data type IEC_<Timer> (Shared DB)

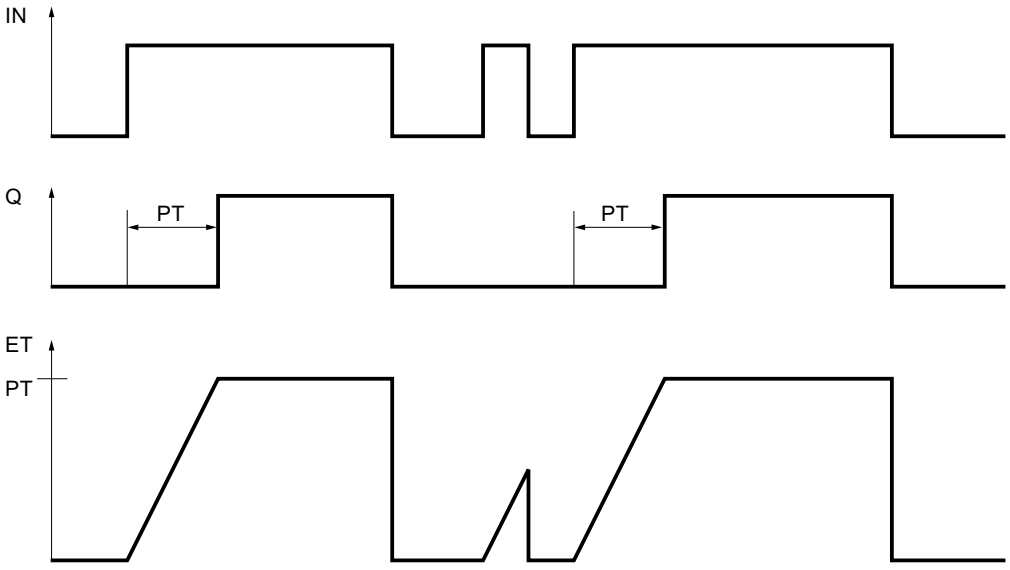
You can declare the IEC timer as a data block as follows:

<IEC_Timer_DB>.TON();

IEC timer as local tag from the block interface (multi-instance)

You can declare the IEC timer as a local tag as follows:

#myLocal_Timer();



Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the on delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is set when the timer PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current timer value

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Generate on-delay" instruction:

Example

The following example shows how the instruction works:

```
SCL
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. When the time duration expires, the "Tag_Status" operand is set to the signal state "1". The Tag_Status operand remains set to "1" as long as the Tag_Start operand has signal state "1". The current time value is stored in the "Tag_ElapsedTime" operand. When the signal state at the operand "Tag_Start" changes from "1" to "0", the "Tag_Status" operand is reset.

Basics of SCL (Page 4991)

TOF: Generate off-delay (S7-1200, S7-1500)

Description

You can use the "Generate off-delay" instruction to delay the resetting of the Q parameter for the programmed duration PT. The Q parameter is set when the result of logic operation (RLO) of the IN parameter changes from "0" to "1" (positive signal edge). When the signal state at the IN parameter changes back to "0", the programmed time PT starts. The Q parameter remains set as long as time PT is running. When the time PT expires, the Q parameter is reset. If the signal state of the IN parameter changes to "1" before time PT expires, the timer is reset. The signal state of the Q parameter remains set to "1".

The current time value can be queried in the ET parameter. The timer value starts at T#0s and ends when the value of the time duration PT is reached. When the time duration PT expires, the ET parameter remains set to the current value until the IN parameter changes back to "1". If the IN parameter changes to "1" before the time PT has expired, the ET parameter is reset to the value T#0s.

Note

If the timer is not called in the program because it is skipped, for example, output ET returns a constant value as soon as the timer has expired.

Each call of the "Generate off-delay" instruction must be assigned to an IEC Timer in which the instruction data is stored.

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

For information on calling IEC timers within structures (multi-instance), please refer to: Calling IEC timers (Page 3221)

For CPUs of the S7-1200 series

An IEC timer is a structure of the data type IEC_TIMER or TOF_TIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TOF_TIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

For CPUs of the S7-1500 series

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TOF_TIME or TOF_LTIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TOF_TIME or TOF_LTIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

IEC timer as instance data block of system data type IEC_<Timer> (Shared DB)

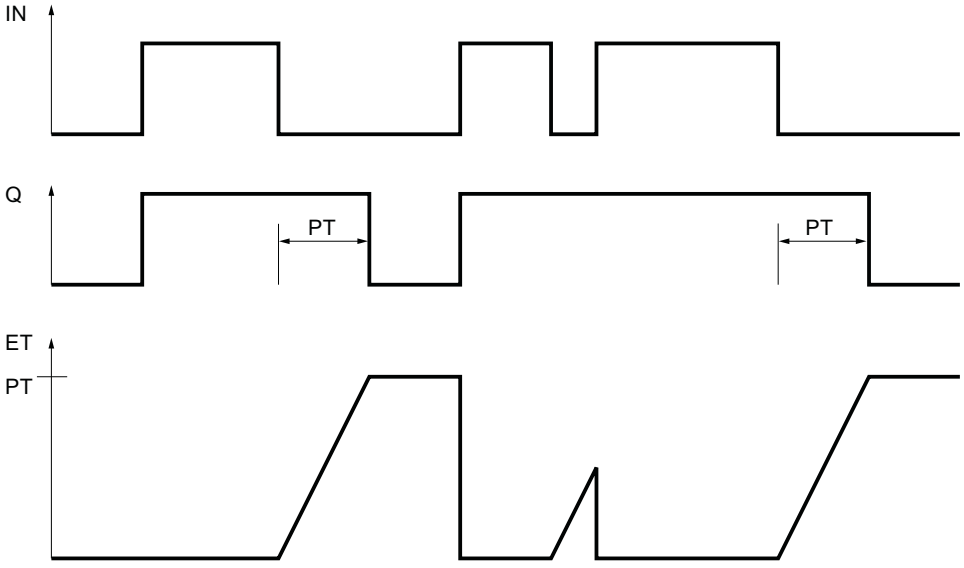
You can declare the IEC timer as a data block as follows:

<IEC_Timer_DB>.TOF();

IEC timer as local tag from the block interface (multi-instance)

You can declare the IEC timer as a local tag as follows:

#myLocal_Timer();



Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Duration of the off delay. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that is reset when the time PT expires.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Current timer value

Pulse timing diagram

The following figure shows the pulse diagram of the "Generate off-delay" instruction:

Example

The following example shows how the instruction works:

```
SCL
"TOF_DB".TOF(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
```

With a change in the signal state of the "Tag_Start" operand from "0" to "1", the "Tag_Status" operand is set. When the signal state of the "Tag_Start" operand changes from "1" to "0", the time programmed for the PT parameter is started. As long as the time is running, the "Tag_Status" operand remains set. When the time has expired, the "Tag_Status" operand is reset. The current time value is stored in the "Tag_ElapsedTime" operand.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

TONR: Time accumulator (S7-1200, S7-1500)

Description

The instruction "Time accumulator" is used to accumulate time values within a period set by the parameter PT. When the signal state of the IN parameter changes to "1", the instruction executes and the time duration PT starts. While the time duration PT is running, the time values that are recorded when the IN parameter has signal state "1" are accumulated. The accumulated time is output in the ET parameter and can be queried there. When the time duration PT is reached, the Q parameter has signal state "1". The Q parameter remains set to "1", even when the signal state at the IN parameter changes to "0".

The R parameter resets the ET and Q parameters regardless of the signal state at the IN parameter.

Each call of the "Time accumulator" instruction must be assigned an IEC timer in which the instruction data is stored.

The instruction data is updated in the following cases:

- When the instruction is called, if the ET or Q outputs are interconnected. If the outputs are not interconnected, the current time value at output ET is not updated.
- At an access to the Q or ET outputs.

For information on calling IEC timers within structures (multi-instance), please refer to: Calling IEC timers (Page 3221)

For CPUs of the S7-1200 series

An IEC Timer is a structure of the data type IEC_TIMER or TONR_TIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TONR_TIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

For CPUs of the S7-1500 series

An IEC Timer is a structure of the data type IEC_TIMER, IEC_LTIMER, TONR_TIME or TONR_LTIME that you can declare as follows:

- Declaration of an instance data block of system data type IEC_TIMER or IEC_LTIMER (for example, "MyIEC_TIMER_DB")
- Declaration as local tag of the data type TONR_TIME or TONR_LTIME in the "Static" section of a program block (for example, #MyIEC_TIMER_Instance)

IEC timer as instance data block of system data type IEC_<Timer> (Shared DB)

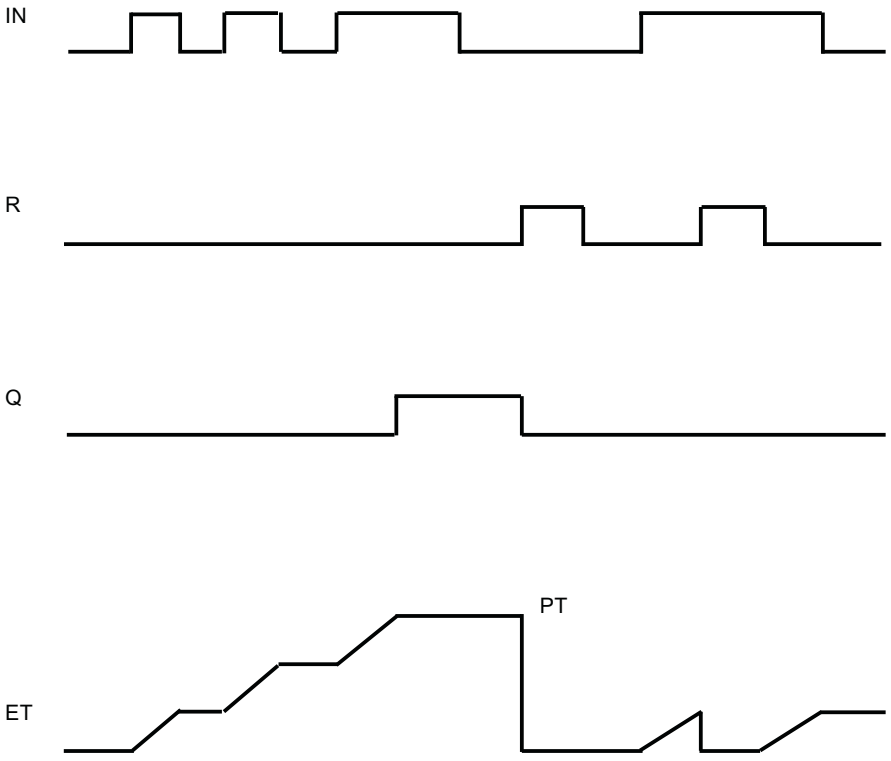
You can declare the IEC timer as a data block as follows:

<IEC_Timer_DB>.TONR();

IEC timer as local tag from the block interface (multi-instance)

You can declare the IEC timer as a local tag as follows:

#myLocal_Timer();



Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	BOOL	BOOL	I, Q, M, D, L, P	Start input
R	Input	BOOL	BOOL	I, Q, M, D, L, P	Reset of the ET and Q parameters
PT	Input	TIME	TIME, LTIME	I, Q, M, D, L, P	Maximum duration of time recording. The value of the PT parameter must be positive.
Q	Output	BOOL	BOOL	I, Q, M, D, L, P	Operand that remains set when the timer PT has expired.
ET	Output	TIME	TIME, LTIME	I, Q, M, D, L, P	Accumulated time

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Time accumulator" instruction:

Example

The following example shows how the instruction works:

```
SCL
"TONR_DB".TONR(IN := "Tag_Start",
               R := "Tag_Reset",
               PT := "Tag_PresetTime",
               Q => "Tag_Status",
               ET => "Tag_Time");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the time programmed for the PT parameter is started. While the time is running, the time values are accumulated that are recorded when the "Tag_Start" operand has signal state "1". The accumulated time is stored in the "Tag_Time" operand. When the time value specified for the PT parameter is reached, the "Tag_Status" operand is set to the signal state "1". The current time value is stored in the "Tag_Time" operand.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

RESET_TIMER: Reset timer (S7-1200, S7-1500)

Description

You can use the "Reset timer" instruction to reset an IEC timer to "0". The structure components of the timer in the specified data block are reset to "0".

The instruction does not influence the RLO. At the TIMER parameter, the "Reset timer" instruction is assigned an IEC timer declared in the program. The instruction must be programmed in an IF instruction. The instruction data is updated only when the instruction is called and not each time the assigned IEC timer is accessed. Querying the data is only identical from the call of the instruction to the next call of the instruction.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer that is reset

Example

The following example shows how the instruction works:

SCL

```
IF #started = false THEN
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
#started := true;
END_IF;

IF "TON_DB".ET < T#25s THEN
```

SCL

```
"RESET_TIMER".(TIMER := "TON_DB"),
#started := false;
END_IF;
```

When the tag #started has the signal state "0", the instruction "Generate on-delay" is executed when there is positive signal edge on the operand "Tag_Start". The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PresetTime". The operand "Tag_Status" is set if the time duration specified by the operand "Tag_PresetTime" has expired. The parameter Q remains set as long as the operand "Tag_Start" still has the signal state "1". When the signal state of the start input changes from "1" to "0", the operand on the Q parameter is reset.

If the expired time of the IEC timer "TON_DB" is less than 25s, the "Reset timer" instruction is executed and the timer stored in the "TON_DB" instance data block is reset.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

PRESET_TIMER: Load time duration (S7-1200, S7-1500)

Description

You can use the "Load time duration" instruction to set the time for an IEC timer. The instruction is executed in every cycle when the result of logic operation (RLO) at the input of the instruction has the signal state "1". The instruction writes the specified time to the structure of the specified IEC timer.

Note

If the specified IEC timer is running while the instruction executes, the instruction overwrites the current time of the specified IEC timer. This can change the timer status of the IEC timer.

You assign an IEC timer declared in the program to the "Load time duration" instruction.

The instruction data is updated only when the instruction is called and each time the assigned IEC timer is accessed. The query on Q or ET (for example, "MyTimer".Q or "MyTimer".ET) updates the IEC_TIMER structure.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Time duration>	Input	TIME	TIME, LTIME	I, Q, M, D, L	Duration with which the IEC timer runs.
<IEC timer>	Output	IEC_TIMER, TP_TIME, TON_TIME, TOF_TIME, TONR_TIME	IEC_TIMER, IEC_LTIMER, TP_TIME, TP_LTIME, TON_TIME, TON_LTIME, TOF_TIME, TOF_LTIME, TONR_TIME, TONR_LTIME	D, L	IEC timer whose duration of which is set.

Example

The following example shows how the instruction works:

SCL

```
IF #started = false THEN
"TON_DB".TON(IN := "Tag_Start",
             PT := "Tag_PresetTime",
             Q => "Tag_Status",
             ET => "Tag_ElapsedTime");
#started := true;
#preset = true
END_IF;

IF "TON_DB".ET < T#10s AND #preset = true THEN
PRESET_TIMER(PT := T#25s,
             TIMER := "TON_DB");
#preset := false;
END_IF;
```

When the tag #started has the signal state "0" and the operand "Tag_Start" has a positive signal edge, the instruction "Generate on-delay" is executed. The IEC timer stored in the instance data block "TON_DB" is started with the time duration that is specified by the operand "Tag_PresetTime". The operand "Tag_Status" is set if the time duration PT specified by the operand "Tag_PresetTime" has expired. The parameter Q remains set as long as the operand

"Tag_Start" still has the signal state "1". When the signal state of the start input changes from "1" to "0", the operand on the Q parameter is reset.

The instruction "Load time duration" is executed when the expired time of the IEC timer "TON_DB" is less than 10s and the tag #preset has the signal state "1". The instruction writes the time duration that is specified at the parameter PT in the instance data block "TON_DB", thereby overwriting the time value of the operand "Tag_PresetTime" within the instance data block. The signal state of the timer status may therefore change at the next query or when "TON_DB".Q or "TON_DB".ET are accessed.

Basics of SCL (Page 4991)

Legacy (S7-1500)

S_PULSE: Assign pulse timer parameters and start (S7-1500)

Description

The "Assign pulse timer parameters and start" instruction starts the time programmed in the T_NO parameter when a change from "0" to "1" (positive signal edge) is detected in the result of logic operation (RLO) of the S parameter. The timer runs for the programmed time (TV) as long as the signal state of the S parameter is "1".

When the signal state of the S parameter changes to "0" before the programmed time has expired, the timer is stopped and the Q parameter is reset to "0".

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the timer is running and the signal state at input R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running, the signal state "1" at the R input has no effect.

Parameter Q returns signal state "1" as long as the timer is running and the signal state at parameter S is "1". When the signal state of the S parameter changes to "0" before the programmed time has expired, the Q parameter returns signal state "0". If the timer is reset by parameter R or if the timer has expired then parameter Q also returns signal state "0".

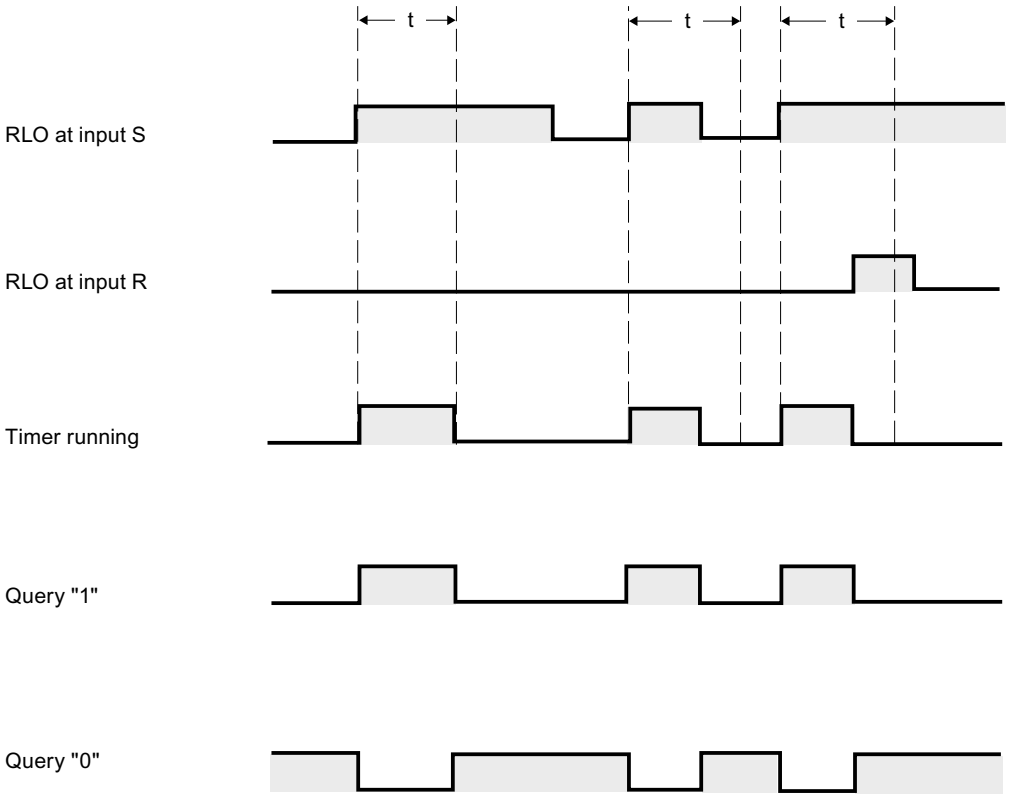
The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters



The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current timer value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign pulse timer parameters and start" instruction:

t = programmed time

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_PULSE(T_NO := "Timer_1",
                        S := "Tag_1",
                        TV := "Tag_Number",
                        R := "Tag_Reset",
                        Q => "Tag_Status",
                        BI => "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer counts down with the time value of the operand "Tag_Number" until operand "Tag_1" returns signal state "1".

If the signal state at the S parameter changes to "0" before the programmed time has elapsed, the "Tag_Status" operand is reset to "0". If the timer is reset by the R parameter or if the timer has expired, the "Tag_Status" operand also returns signal state "0".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

S_PEXT: Assign extended pulse timer parameters and start (S7-1500)

Description

The "Assign extended pulse timer parameters and start" instruction starts a programmed timer when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) even if the signal state at the S parameter changes to "0". As long as the timer runs, parameter Q returns the signal state "1".

When the timer has expired, parameter Q is reset to "0". If the signal state at the S parameter changes from "0" to "1" while the timer is running, the timer is restarted with the time programmed in the TV parameter.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the timer is running and the signal state at parameter R changes to "1" then the current time value and the time base are also set to zero. If the timer is not running then signal state "1" at parameter R has no effect.

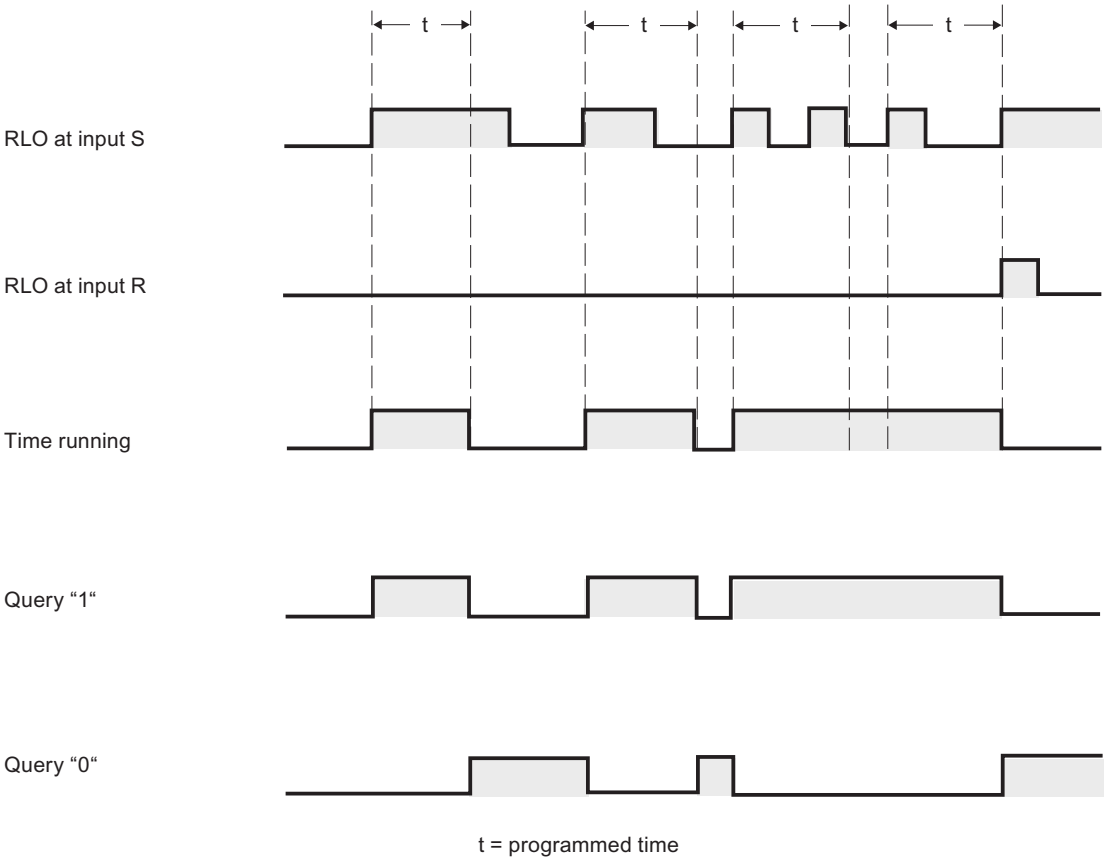
The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters



The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current timer value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign extended pulse timer parameters and start" instruction:

t = programmed time

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_PEXT(T_NO := "Timer_1",
                       S := "Tag_1",
                       TV := "Tag_Number",
                       R := "Tag_Reset",
                       Q => "Tag_Status",
                       BI => "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". As long as the timer runs, operand "Tag_Status" returns the signal state "1". When the timer has expired, operand "Tag_Status" is reset to "0". If the signal state at the S input changes from "0" to "1" while the timer is running, the timer is restarted with the time "Tag_Number".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

S_ODT: Assign on-delay timer parameters and start (S7-1500)

Description

The "Assign on-delay timer parameters and start" instruction starts a programmed timer as on-delay when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) as long as the signal state of the S parameter is "1".

If the timer expires correctly and parameter S still has signal state "1" then parameter Q returns signal state "1". If the signal state at the S parameter changes from "1" to "0" while the timer is running, the timer is stopped. In this case, output Q is reset to signal state "0".

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

If the time is running and the signal state at input R changes from "0" to "1" then the current time value and the time base are also set to zero. In this case, the signal state at parameter Q is "0". The timer is reset if the signal state at the R parameter is "1", even if the timer is not running and the result of logic operation (RLO) at the S parameter is "1".

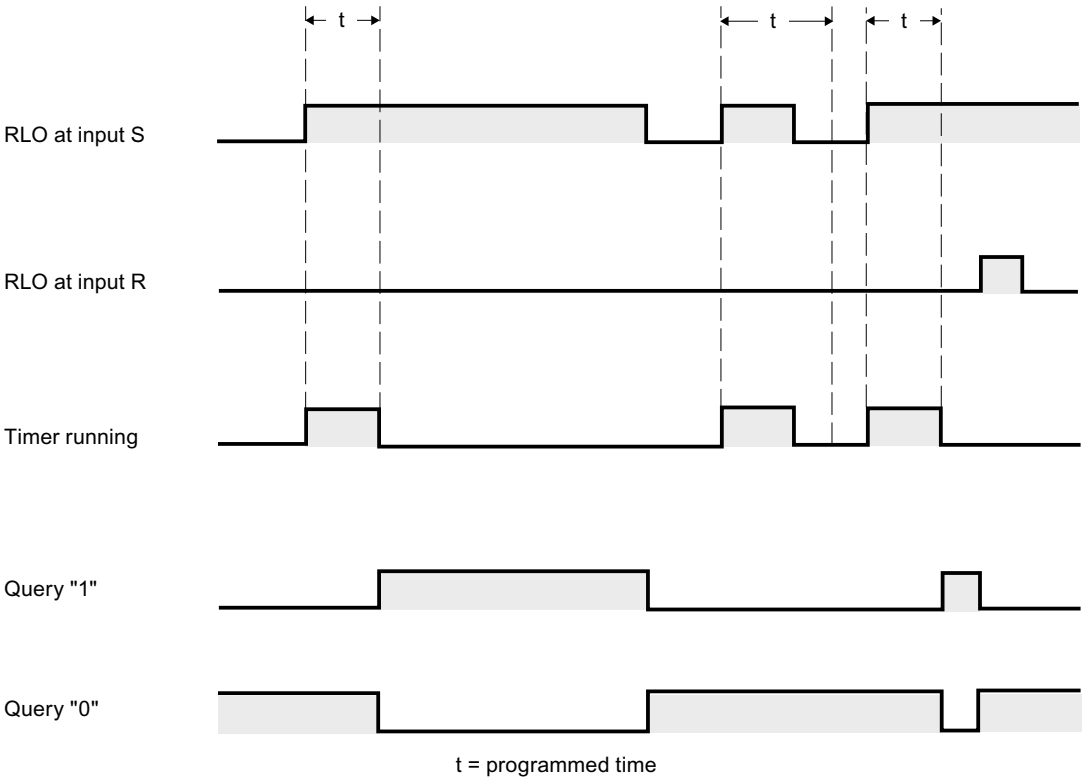
The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters



The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current timer value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign on-delay timer parameters and start" instruction:

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_ODT(T_NO := "Timer_1",
                      S := "Tag_1",
                      TV := "Tag_Number",
                      R := "Tag_Reset",
                      Q => "Tag_Status",
                      BI => "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer runs for the duration "Tag_Number" as long as the signal state of operand "Tag_1" is "1".

If the timer expires correctly and operand "Tag_Status" has signal state "1" then operand "Tag_Status" is reset to "1". If the signal state of the "Tag_1" operand changes from "1" to "0" while the timer is running, the timer is stopped. In this case, operand "Tag_Status" returns signal state "0".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

S_ODTS: Assign retentive on-delay timer parameters and start (S7-1500)

Description

The "Assign retentive on-delay timer parameters and start" instruction starts a programmed timer when a positive signal edge is detected at the S parameter. The timer runs for the programmed time (TV) even if the signal state at the S parameter changes to "0".

When the timer expires, the "Q" parameter returns signal state "1" regardless of the signal state of the "S" parameter. If the signal state at the S parameter changes from "0" to "1" while the timer is running, the timer is restarted with the programmed time TV.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

Signal state "1" at parameter R resets the current time value and time base to "0", independent of the signal state at parameter S. In this case, the signal state at parameter Q is "0".

The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

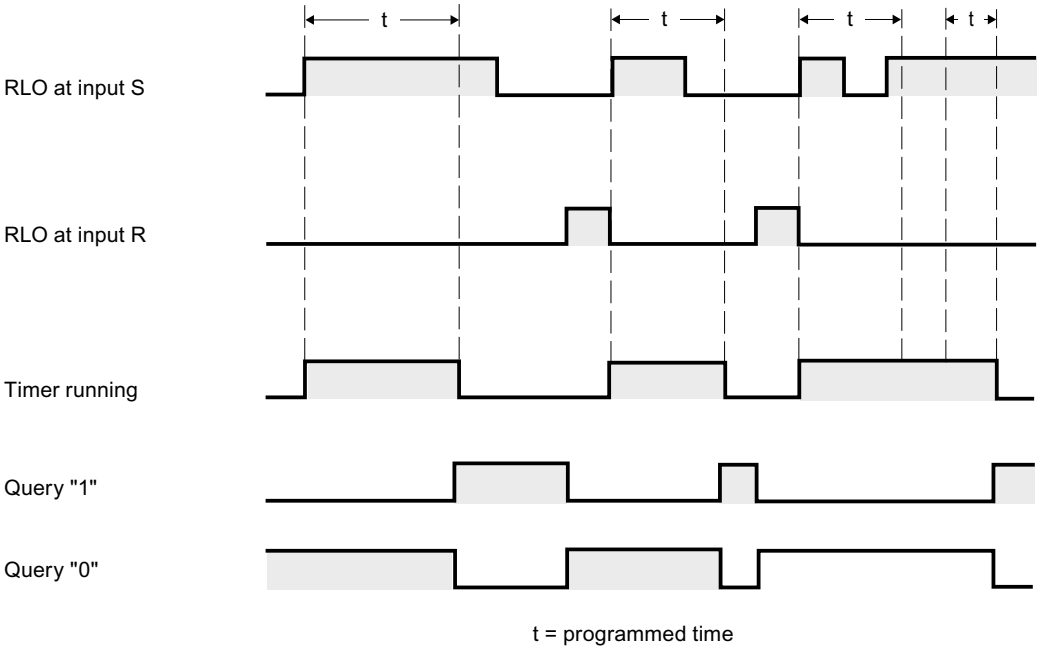
Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters

The following table shows the parameters of the instruction:



Parameters	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input

Parameters	Declaration	Data type	Memory area	Description
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current timer value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign retentive on-delay timer parameters and start" instruction:

t = programmed time

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_ODTS(T_NO := "Timer_1",
                       S := "Tag_1",
                       TV := "Tag_Number",
                       R := "Tag_Reset",
                       Q => "Tag_Status",
                       BI => "Tag_Value");
```

"Timer_1" starts when the signal state of the "Tag_1" operand changes from "0" to "1". The timer runs for the duration "Tag_Number".

If the timer expires, operand "Tag_Status" returns signal state "1" independent of the signal state of operand "Tag_1". If the signal state of the "Tag_1" operand changes from "0" to "1" while the timer is running, the timer is restarted with the time "Tag_Number".

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

S_OFFDT: Assign off-delay timer parameters and start (S7-1500)

Description

The "Assign off-delay timer parameters and start" instruction starts a programmed timer when a negative signal edge is detected at the S parameter. The timer runs for the programmed time (TV). As long as the timer is running or parameter S returns signal state "1", then parameter Q has signal state "1".

If the timer expires and the signal state is "0" then parameter Q is reset to signal state "0". If the signal state at parameter S changes from "0" to "1" while the timer is running, the timer is stopped. The timer is only restarted after a falling signal edge is detected at parameter S.

Internally, the time is made up of a time value and a time base and is programmed in the TV parameter. When the instruction starts, the programmed time value counts down to zero. The time base specifies the time increment by which the time value changes. The current time value is provided at the parameter BI.

Signal state "1" at parameter R resets the current time value and time base to "0". In this case, the signal state at parameter Q is "0".

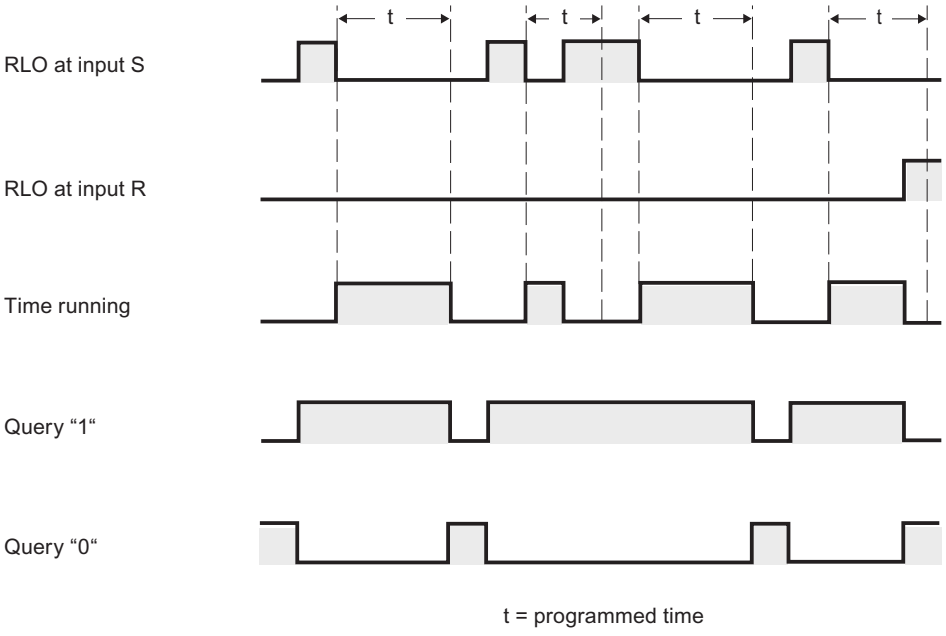
The instruction data is updated with each access. It is therefore possible that the query of the data at the start of the cycle returns different values from those at the end of the cycle.

Note

In the time cell, the operating system reduces the time value in an interval specified by the time base by one unit until the value equals "0". The decrementation is performed asynchronously to the user program. The resulting timer is therefore at maximum up to one time interval shorter than the desired time base.

You can find an example of how a time cell can be formed under: See also "L: Load timer value".

Parameters



The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
T_NO	Input	TIMER, INT	T	The timer that is started. The number of timers depends on the CPU.
S	Input	BOOL	I, Q, M, D, L	Start input
TV	Input	S5TIME, WORD	I, Q, M, D, L	Preset time value
R	Input	BOOL	I, Q, M, D, L, P	Reset input
Q	Output	BOOL	I, Q, M, D, L, P	Status of the timer
BI	Output	WORD	I, Q, M, D, L, P	Current dual-coded timer value
Function value		S5TIME	I, Q, M, D, L	Current timer value

For additional information on valid data types, refer to "See also".

Pulse timing diagram

The following figure shows the pulse timing diagram of the "Assign off-delay timer parameters and start" instruction:

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := S_OFFDT(T_NO := "Timer_1",
                        S := "Tag_1",
                        TV := "Tag_Number",
                        R := "Tag_Reset",
                        Q => "Tag_Status",
                        BI => "Tag_Value");
```

The timer "Timer_1" is started when the signal state of the operand "Tag_1" changes from "1" to "0". The timer runs for the duration "Tag_Number". As long as the timer is running or operand "Tag_1" returns signal state "1", then operand "Tag_Status" has signal state "1".

If the timer expires and the signal state of operand "Tag_1" is "0" then operand "Tag_Status" is reset to signal state "0". If the signal state of the "Tag_1" operand changes from "0" to "1" while the timer is running, the timer is reset. The timer is only restarted after a falling edge is detected at parameter S.

The current time value is stored both dual-coded at the "Tag_Value" operand and returned as a function value.

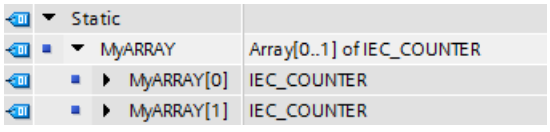
Basics of SCL (Page 4991)

Counter operations (S7-1200, S7-1500)

Calling IEC counters (S7-1200, S7-1500)



Description

You have the option of declaring the IEC counter as single or multiple instance and calling it in the program code.

The following syntax options are available for the declaration of an IEC counter as multi-instance within a structure in the block interface:

IEC counter as ARRAY element

Declaration in the block interface:

Program code:

SCL

```
#MyARRAY[1].CTU(CU := <Operand>, PV := <Operand>)
```

Declaration in the block interface:

	Static	
	MyARRAY	Array[0..1] of CTU_INT
	MyARRAY[0]	CTU_INT
	MyARRAY[1]	CTU_INT

Program code:

SCL

```
#MyARRAY[#index](CU := <Operand>, PV := <Operand>)
```

IEC counter within an anonymous structure

Declaration in the block interface:

	Static	
	MyStruct	Struct
	FirstTime	IEC_COUNTER
	CU	Bool
	CD	Bool
	R	Bool
	LD	Bool
	QU	Bool
	QD	Bool
	PV	Int
	CV	Int

Program code:

SCL

```
#MyStruct.FirstTime.CTU(CU := <Operand>, PV := <Operand>)
```

Declaration in the block interface:

	Static	
	MyStruct	Struct
	FirstTime	CTU_INT
	CU	Bool
	CD	Bool
	R	Bool
	LD	Bool
	QU	Bool
	QD	Bool
	PV	Int
	CV	Int

Program code:

SCL

```
#MyStruct.FirstTime(CU := <Operand>, PV := <Operand>)
```

IEC counter in the global data block

Declaration in the data block:

MyGlobalDB

	Name	Datentyp
1	Static	
2	Counter	"MyUDT"
3	FirstCount	IEC_COUNTER
4	CU	Bool
5	CD	Bool
6	R	Bool
7	LD	Bool
8	QU	Bool
9	QD	Bool
10	PV	Int
11	CV	Int

Program code:

SCL

```
"MyGlobalDB".Counter.FirstCount.CTU(CU := <Operand>, PV := <Operand>)
```

Declaration in the data block:

MyGlobalDB

	Name	Datentyp
1	Static	
2	Counter	"MyUDT"
3	FirstCount	IEC_COUNTER
4	SecondCount	CTU_INT
5	CU	Bool
6	CD	Bool
7	R	Bool
8	LD	Bool
9	QU	Bool
10	QD	Bool
11	PV	Int
12	CV	Int

Program code:

SCL

```
"MyGlobalDB".Counter.SecondCount(CU := <Operand>, PV := <Operand>)
```

IEC counter as element in the block interface

Declaration in the block interface:

Static		
Counter	"MyUDT"	
FirstCount	IEC_COUNTER	
CU	Bool	
CD	Bool	
R	Bool	
LD	Bool	
QU	Bool	
QD	Bool	
PV	Int	
CV	Int	

Program code:

SCL

```
#Counter.FirstCount.CTU(CU := <Operand>, PV := <Operand>)
```

Declaration in the block interface:

Static		
Counter	"MyUDT"	
FirstCount	IEC_COUNTER	
SecondCount	CTU_INT	
CU	Bool	
CD	Bool	
R	Bool	
LD	Bool	
QU	Bool	
QD	Bool	
PV	Int	
CV	Int	

Program code:

SCL

```
#Counter.SecondCount(CU := <Operand>, PV := <Operand>)
```

IEC counter within an ARRAY DB

Declaration in the ARRAY DB:

MyARRAYDB

	Name	Datentyp
1	MyARRAYDB	Array[0..1] of "MyUDT"
2	MyARRAYDB[0]	"MyUDT"
3	FirstCount	IEC_COUNTER
4	CU	Bool
5	CD	Bool
6	R	Bool
7	LD	Bool
8	QU	Bool
9	QD	Bool
10	PV	Int
11	CV	Int

Program code:

SCL

```
"MyARRAYDB"."THIS"[0].FirstCount.CTU(CU := <Operand>, PV := <Operand>)
```

Declaration in the ARRAY DB:

MyARRAYDB

	Name	Datentyp
1	MyARRAYDB	Array[0..1] of "MyUDT"
2	MyARRAYDB[0]	"MyUDT"
3	FirstCount	IEC_COUNTER
4	SecondCount	CTU_INT
5	CU	Bool
6	CD	Bool
7	R	Bool
8	LD	Bool
9	QU	Bool
10	QD	Bool
11	PV	Int
12	CV	Int

Program code:

SCL

```
"MyARRAYDB"."THIS"[0].SecondCount(CU := <Operand>, PV := <Operand>)
```

CTU: Count up (S7-1200, S7-1500)

Description

You can use the "Count up" instruction to increment the value at the CV parameter. When the signal state of the parameter CU changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value of the parameter CV is incremented by one. The counter value is incremented each time a positive signal edge is detected, until it reaches the high limit of the data type specified at the CV parameter. When the high limit is reached, the signal state of the CU parameter no longer has an effect on the instruction.

You can query the count status of the Q parameter. The signal state of the Q parameter is determined by the PV parameter. When the current counter value is greater than or equal to the value of the PV parameter, the Q parameter is set to signal state "1". In all other cases, the signal state of the Q parameter is "0". You can also specify a constant for the PV parameter.

The value of the CV parameter is reset to zero when the signal state at the R parameter changes to "1". As long as the signal state of the R parameter is "1", the signal state of the CU parameter has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For CPUs of the S7-1200 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTU_SINT / CTU_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTU_INT / CTU_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_DINT / CTU_UDINT

For CPUs of the S7-1500 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTU_SINT / CTU_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTU_INT / CTU_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTU_DINT / CTU_UDINT
• IEC_LCOUNTER / IEC_ULCOUNTER	• CTU_LINT / CTU_ULINT

You can declare an IEC counter as follows:

- Declaration of an instance data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER_DB")
- Declaration as local tag of the data type CTUD_<DatenType> in the "Static" section of a program block (for example, #MyIEC_COUNTER_Instance)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive.

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

IEC counter as data block of system data type IEC_<Counter> (Shared DB)

You can declare the IEC counter as a data block as follows:

<IEC_Counter_DB>.CTU();

IEC counter as local tag from the block interface (multi-instance)

You can declare the IEC counter as a local tag as follows:

#myLocal_Counter();

For information on calling IEC counters within structures (multi-instance), please refer to: Calling IEC counters (Page 3252)

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CU	Input	BOOL	I, Q, M, D, L	Count input
R	Input	BOOL	I, Q, M, D, L, P	Reset input
PV	Input	Integers	I, Q, M, D, L, P	Value at which the Q output is set
Q	Output	BOOL	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

Example

The following example shows how the instruction works:

```
SCL
"IEC_COUNTER_DB".CTU(CU := "Tag_Start",
                     R := "Tag_Reset",
                     PV := "Tag_PresetValue",
                     Q => "Tag_Status",
                     CV => "Tag_CounterValue");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the "Count up" instruction is executed and the current counter value of the "Tag_CounterValue" operand is incremented by one. With each additional positive signal edge, the counter value is incremented until the high limit of the specified data type (INT = 32767) is reached.

The "Tag_Status" output has signal state "1" as long as the current counter value is greater than or equal to the value of the "Tag_PresetValue" operand. In all other cases, the "Tag_Status" output has signal state "0". The current counter value is stored in the "Tag_CounterValue" operand.

CTD: Count down (S7-1200, S7-1500)

Description

The "Count down" instruction is used to decrement the value at the parameter CV. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the instruction is executed and the current counter value of the CV parameter is decremented by one. Each time a positive signal edge is detected, the counter value is decremented until it reaches the low limit of the specified data type. When the low limit is reached, the signal state of the CD parameter no longer has an effect on the instruction.

You can query the count status of the Q parameter. If the current counter value is less than or equal to zero, the Q parameter is set to signal state "1". In all other cases, the signal state of the Q parameter is "0". You can also specify a constant for the PV parameter.

The value of the CV parameter is set to the value of the PV parameter when the signal state of the LD parameter changes to "1". As long as the signal state of the LD parameter is "1", the signal state of the CD parameter has no effect on the instruction.

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For CPUs of the S7-1200 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT

For CPUs of the S7-1500 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER • IEC_COUNTER / IEC_UCOUNTER • IEC_DCOUNTER / IEC_UDCOUNTER • IEC_LCOUNTER / IEC_ULCOUNTER	• CTD_SINT / CTD_USINT • CTD_INT / CTD_UINT • CTD_DINT / CTD_UDINT • CTD_LINT / CTD_ULINT

You can declare an IEC counter as follows:

- Declaration of an instance data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER_DB")
- Declaration as local tag of the data type CTD_<DatenType> in the "Static" section of a program block (for example, #MyIEC_COUNTER_Instance)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive.

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

IEC counter as data block of system data type IEC_<Counter> (Shared DB)

You can declare the IEC counter as a data block as follows:

<IEC_Counter_DB>.CTD();

IEC counter as local tag from the block interface (multi-instance)

You can declare the IEC counter as a local tag as follows:

#myLocal_Counter();

For information on calling IEC counters within structures (multi-instance), please refer to: Calling IEC counters (Page 3252)

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CD	Input	BOOL	I, Q, M, D, L	Count input
LD	Input	BOOL	I, Q, M, D, L, P	Load input
PV	Input	Integers	I, Q, M, D, L, P	Value to which the CV output is set with LD = 1.
Q	Output	BOOL	I, Q, M, D, L	Counter status
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

Example

The following example shows how the instruction works:

```
SCL
"IEC_SCOUNTER_DB".CTD(CD := "Tag_Start",
                      LD := "Tag_Load",
                      PV := "Tag_PresetValue",
                      Q => "Tag_Status",
                      CV => "Tag_CounterValue");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1", the instruction is executed and the value of the "Tag_CounterValue" operand is decremented by one. With each additional positive signal edge, the counter value is decremented until it reaches the low limit of the specified data type (-128).

The operand "Tag_Status" has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "Tag_Status" output has signal state "0". The current counter value is stored in the "Tag_CounterValue" operand.

Basics of SCL (Page 4991)

CTUD: Count up and down (S7-1200, S7-1500)

Description

Use the "Count up and down" instruction to increment or decrement the counter value at the CV parameter. When the signal state of the CU parameter changes from "0" to "1" (positive signal edge), the current counter value of the CV parameter is incremented by one. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the counter value of the CV parameter is decremented by one. If there is a positive signal edge at the CU and CD inputs in a program cycle, the current counter value of the CV parameter remains unchanged.

The counter value can be incremented until it reaches the high limit of the data type specified at the CV parameter. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. The counter value is no longer decremented once the low limit of the specified data type has been reached.

When the signal state of the LD parameter changes to "1", the counter value of the CV parameter is set to the value of the PV parameter. As long as the LD parameter has signal state "1", the signal state of the CU and CD parameters has no effect on the instruction.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the R parameter has signal state "1", a change in the signal state of the CU, CD and LD parameters has no effect on the "Count up and down" instruction.

You can query the status of the up counter at the QU parameter. When the current counter value is greater than or equal to the value of the PV parameter, the QU parameter is set to

signal state "1". In all other cases, the signal state of the QU parameter is "0". You can also specify a constant for the PV parameter.

You can query the status of the down counter at the QD parameter. If the current counter value is less than or equal to zero, the QD parameter is set to signal state "1". In all other cases, the signal state of the QD parameter is "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Each call of the "Count up and down" instruction must be assigned an IEC counter in which the instruction data is stored. An IEC counter is a structure with one of the following data types:

For CPUs of the S7-1200 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTUD_SINT / CTUD_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTUD_INT / CTUD_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_DINT / CTUD_UDINT

For CPUs of the S7-1500 series

Data block of system data type IEC_<Counter> (Shared DB)	Local tag
• IEC_SCOUNTER / IEC_USCOUNTER	• CTUD_SINT / CTUD_USINT
• IEC_COUNTER / IEC_UCOUNTER	• CTUD_INT / CTUD_UINT
• IEC_DCOUNTER / IEC_UDCOUNTER	• CTUD_DINT / CTUD_UDINT
• IEC_LCOUNTER / IEC_ULCOUNTER	• CTUD_LINT / CTUD_ULINT

You can declare an IEC counter as follows:

- Declaration of an instance data block of system data type IEC_<Counter> (for example, "MyIEC_COUNTER_DB")
- Declaration as local tag of the data type CTUD_<DatenType> in the "Static" section of a program block (for example, #MyCTUD_COUNTER_Instance)

When you set up the IEC counter in a separate data block (single instance), the instance data block is created by default with "optimized block access" and the individual tags are defined as retentive.

When you set up the IEC counter as local tag (multi-instance) in a function block with "optimized block access", it is defined as retentive in the block interface.

IEC counter as data block of system data type IEC_<Counter> (Shared DB)

You can declare the IEC counter as a data block as follows:

<IEC_Counter_DB>.CTUD();

IEC counter as local tag from the block interface (multi-instance)

You can declare the IEC counter as a local tag as follows:

#myLocal_Counter();

For information on calling IEC counters within structures (multi-instance), please refer to: Calling IEC counters (Page 3252)

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L	Count down input
R	Input	BOOL	I, Q, M, D, L, P	Reset input
LD	Input	BOOL	I, Q, M, D, L, P	Load input
PV	Input	Integers	I, Q, M, D, L, P	Value at which the QU output is set / value to which the CV output is set when LD = 1.
QU	Output	BOOL	I, Q, M, D, L	Status of the up counter
QD	Output	BOOL	I, Q, M, D, L	Status of the down counter
CV	Output	Integers, CHAR, WCHAR, DATE	I, Q, M, D, L, P	Current counter value

Example

The following example shows how the instruction works:

```
SCL
"IEC_COUNTER_DB".CTUD(CU := "Tag_Start1",
                      CD := "Tag_Start2",
                      LD := "Tag_Load",
                      R := "Tag_Reset",
                      PV := "Tag_PresetValue",
                      QU => "Tag_CU_Status",
                      QD => "Tag_CD_Status",
                      CV => "Tag_CounterValue");
```

If the "Tag_Start1" operand has a positive signal edge in the signal state, the current counter value is incremented by one and stored in the "Tag_CounterValue" operand. If the "Tag_Start2" operand has a positive signal edge in the signal state, the counter value is decremented by one and is also stored in the "Tag_CounterValue" operand. The counter value is incremented on the positive signal edge of the CU parameter until it reaches the high limit of the specified data type (INT). If the CD parameter has a positive signal edge, the counter value is decremented until it reaches the low limit of the specified data type (INT).

The operand "Tag_CU_Status" has signal state "1" as long as the current counter value is greater than or equal to the value of the operand "Tag_PresetValue". In all other cases, the "Tag_CU_Status" output has signal state "0".

The operand "Tag_CD_Status" has signal state "1" as long as the current counter value is less than or equal to zero. In all other cases, the "Tag_CD_Status" output has signal state "0".

Legacy (S7-1500)

S_CU: Assign parameters and count up (S7-1500)

Description

You can use the "Assign parameters and count up" instruction to increment the value of a counter. When the signal state of the CU parameter changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. The current counter value is provided at the parameter CV. The counter value is incremented until the limit of "999" is reached. When the limit value is reached, the counter value is no longer incremented on a positive signal edge.

When the signal state of the S parameter changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if the result of logic operation (RLO) at the CU input is "1", the counter counts once in the next cycle, even when no signal edge change is detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the R parameter has the signal state "1", a change in the signal state of the parameters CU and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counter operations The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter

Parameters	Declaration	Data type	Memory area	Description
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD	I, Q, M, D, L	Current counter value
Function value		WORD	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_CU(C_NO := "Counter_1",
                     CU := "Tag_Start",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

If the signal state of the "Tag_Start" parameter changes from "0" to "1" (positive signal edge) and the current counter value is less than "999", the counter value is incremented by one. If the signal state of the "Tag_1" input changes from "0" to "1", the counter value in BCD format is set to the value of the "Tag_PresetValue" operand. The counter value is reset to "0" when the "Tag_Reset" operand has signal state "1".

The current counter value is stored in hexadecimal form in the operand "Tag_Value".

The "Tag_Status" output has the signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

Basics of SCL (Page 4991)

S_CD: Assign parameters and count down (S7-1500)

Description

You can use the "Assign parameters and count down" instruction to decrement the value of a counter. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the current counter value is decreased by one. The current counter value is provided at the parameter CV. The counter value is decreased until the low limit of "0" is reached. When the low limit is reached, the counter value is no longer decreased on a positive signal edge.

When the signal state of the S parameter changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if the result of logic operation (RLO) at the CD parameter is "1", the counter counts once in the next cycle, even when no signal edge change is detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the R parameter has the signal state "1", a change in the signal state of the parameters CD and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counter operations The number of counters depends on the CPU.
CD	Input	BOOL	I, Q, M, D, L	Count down input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD	I, Q, M, D, L	Current counter value
Function value		WORD	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_CD(C_NO := "Counter_1",
                     CD := "Tag_Start",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

When the signal state of the "Tag_Start" operand changes from "0" to "1" (positive signal edge) and the current counter value is greater than "0", the counter value is decreased by one. If the signal state of the "Tag_1" operand changes from "0" to "1", the counter value in BCD format is set to the value of the "Tag_PresetValue" operand. The counter value is reset to "0" when the "Tag_Reset" operand has signal state "1".

The current counter value is stored in the "Tag_Value" operand.

The "Tag_Status" operand returns signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

S_CUD: Assign parameters and count up / down (S7-1500)

Description

You can use the "Assign parameters and count up / down" instruction to increment and decrement the value of a counter. When the signal state of the CU parameter changes from "0" to "1" (positive signal edge), the current counter value is incremented by one. When the signal state of the CD parameter changes from "0" to "1" (positive signal edge), the counter value is decreased by one. The current counter value is provided at the parameter CV. If there is a positive signal edge at the parameters CU and CD in one program cycle, the counter value remains unchanged.

The counter value is incremented until the high limit of "999" is reached. When the high limit is reached, the counter value is no longer incremented on a positive signal edge. When the low limit "0" is reached, the counter value is not decremented any further.

When the signal state of the S parameter changes from "0" to "1", the counter value is set to the value of the PV parameter. If the counter is set and if the result of logic operation (RLO) of the CU and CD parameters is "1", the counter will count once in the next cycle, even if no signal edge change was detected.

The counter value is set to zero when the signal state of the R parameter changes to "1". As long as the parameter R has the signal state "1", processing of the signal state of the parameters CU, CD and S has no effect on the counter value.

The signal state at parameter Q is "1" if the counter value is greater than zero. When the counter value equals zero, parameter Q returns signal state "0".

Note

Only use a counter at a single point in the program to avoid the risk of counting errors.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
C_NO	Input	COUNTER, INT	C	Counter operations The number of counters depends on the CPU.
CU	Input	BOOL	I, Q, M, D, L	Count up input
CD	Input	BOOL	I, Q, M, D, L	Count down input
S	Input	BOOL	I, Q, M, D, L	Input for presetting the counter
PV	Input	WORD	I, Q, M, D, L	Preset counter value (C#0 to C#999) in BCD format
R	Input	BOOL	I, Q, M, D, L	Reset input
Q	Output	BOOL	I, Q, M, D, L	Status of the counter
CV	Output	WORD	I, Q, M, D, L	Current counter value (hexadecimal)
Function value		WORD	I, Q, M, D, L	Current counter value in BCD format

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := S_CD(C_NO := "Counter_1",
                     CU := "Tag_CU",
                     CD := "Tag_CD",
                     S := "Tag_1",
                     PV := "Tag_PresetValue",
                     R := "Tag_Reset",
                     Q => "Tag_Status",
                     CV => "Tag_Value");
```

When a positive signal edge is detected in the signal state of the "Tag_CU" operand and the current counter value is less than "999", the counter value is incremented by one. When a positive signal edge is detected in the signal state of the "Tag_CD" operand and the current counter value is greater than "0", the counter value is decremented by one.

If the signal state of the "Tag_1" operand changes from "0" to "1", the counter value in BCD format is set to the value of the "Tag_PresetValue" operand. The counter value is reset to "0" when the "Tag_Reset" operand has signal state "1".

The current counter value is stored in the "Tag_Value" operand.

The "Tag_Status" operand returns signal state "1" as long as the current counter value is not equal to "0". The current counter value is returned in the "Tag_Value" operand and as a function value.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

Comparator operations (S7-1200, S7-1500)

TypeOf: Check data type of a VARIANT tag (S7-1200, S7-1500)

Description

You can use the "Check data type of a VARIANT tag" instruction to query the data type of a tag to which a VARIANT tag is pointing. You can compare the data type of the that you have declared in the block interface either to the data type of another tag or directly with a data type to determine whether they are "Equal" or "Not equal".

The comparison operand can be an elementary data type or a PLC data type.

You can only use the "Check data type of a VARIANT tag" instruction within an IF or CASE instruction.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Binary numbers, integers, floating-point numbers, times, date and time, character strings, VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand

For additional information on valid data types, refer to "See also".

Example

The following example shows the comparison with another tag:

SCL

```
IF TypeOf(#TagVARIANT) = TypeOf("TagBYTE") THEN
...;
END_IF;
```

The following example shows the comparison with a data type:

SCL

```
IF TypeOf(#TagVARIANT) = BYTE THEN
...;
END_IF;
```

If the operand to which the VARIANT #TagVARIANT is pointing has the BYTE data type, the comparison condition has been met.

See also

Overview of the valid data types (Page 2239)

Example of programming a queue (FIFO) (Page 2320)

Basic information on VARIANT (Page 2308)

Basics of SCL (Page 4991)

TypeOfElements: Check data type of an ARRAY element of a VARIANT tag (S7-1200, S7-1500)

Description

You can use the "Check data type of an ARRAY element of a VARIANT tag" instruction to query the data type of a tag to which a VARIANT tag is pointing. You compare the data type of a tag to the data type of the tag that you have declared in the block interface to determine whether they are "Equal" or "Not equal".

The operand must have the VARIANT data type. The comparison operand can be an elementary data type or a PLC data type.

If the data type of the VARIANT tag is an ARRAY, the data type of the ARRAY elements is compared.

You can only use the instruction within an IF instruction.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	First operand

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF TypeOfElements(#Tag_VARIANT) = TypeOf("GlobalDB".Product[1]) THEN
"Tag_Result" := "GlobalDB".Product[1] * 3;
END_IF;
```

The following table shows how the instruction works using specific operand values:

Operand	Value
#Tag_VARIANT	1.5
"GlobalDB".Product[1]	4.5

If the tag to which the VARIANT points and the "GlobalDB".Product[1] operand have the REAL data type, the "GlobalDB".Product[1] operand is then multiplied by 3 and the result is written to the "Tag_Result" operand.

Basic information on VARIANT (Page 2308)

Basics of SCL (Page 4991)

IS_ARRAY: Check for ARRAY (S7-1200, S7-1500)

Description

You can use the "Check for ARRAY" instruction to query whether the VARIANT points to a tag of the ARRAY data type.

You can only use the "Check for ARRAY" instruction within an IF instruction.

Parameters

The following table shows the parameters of the "Check for ARRAY" instruction:

Parameters	Declaration	Data type	Memory area	Description
<operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Operand that is queried for ARRAY
Function value		UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF IS_ARRAY(#Tag_VARIANTToArray) THEN
"Tag_Result" := CountOfElements(#Tag_VARIANTToArray);
END_IF;
```

If the tag to which the VARIANT points is an ARRAY, the number of ARRAY elements is output.

Math functions (S7-1200, S7-1500)

ABS: Form absolute value (S7-1200, S7-1500)

Description

Use the "Form absolute value" instruction to calculate the absolute value of an input value and to save the result in the specified operands.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<expression>	Input	SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Input value
Function value		SINT, INT, DINT, floating-point numbers	SINT, INT, DINT, LINT, floating-point numbers	I, Q, M, D, L, P	Absolute value of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result1" := ABS("Tag_Value");
"Tag_Result2" := ABS("Tag_Value1"*"Tag_Value2");
```

The absolute value of the input value is returned in the format of the input value as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	-2
Tag_Result1	2
Tag_Value1	4
Tag_Value2	-1
Tag_Result2	4

Basics of SCL (Page 4991)

MIN: Get minimum (S7-1200, S7-1500)

Description

The "Get minimum" instruction compares the values of the available inputs and returns the lowest value as the result.

A minimum of two and a maximum of 32 inputs can be specified at the instruction.

The result is invalid if any of the following conditions are met:

- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get minimum" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	First input value
IN2	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Second input value
INn	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Additionally inserted inputs whose values are to be compared
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := MIN(IN1 := "Tag_Value1",
                    IN2 := "Tag_Value2",
                    IN3 := "Tag_Value3");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN1	Tag_Value1	12222
IN2	Tag_Value2	14444
IN3	Tag_Value3	13333
Function value	Tag_Result	12222

The instruction compares the values of the available inputs and copies the lowest value ("Tag_Value1") to operand "Tag_Result".

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

MAX: Get maximum (S7-1200, S7-1500)

Description

The "Get maximum" instruction compares the values of the available inputs and returns the greatest value as the result.

A minimum of two and a maximum of 32 inputs can be specified at the instruction.

The result is invalid if any of the following conditions are met:

- The implicit conversion of the data types fails during execution of the instruction.
- A floating-point number has an invalid value.

Parameters

The following table shows the parameters of the "Get maximum" instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	First input value
IN2	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Second input value
INn	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Additionally inserted inputs whose values are to be compared
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MAX(IN1 := "Tag_Value1",
                    IN2 := "Tag_Value2",
                    IN3 := "Tag_Value3");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN1	Tag_Value1	12 222
IN2	Tag_Value2	14 444
IN3	Tag_Value3	13 333
Function value	Tag_Result	14 444

The instruction compares the values of the specified operands and copies the greatest value ("Tag_Value2") to the operand "Tag_Result".

Basics of SCL (Page 4991)

LIMIT: Set limit value (S7-1200, S7-1500)

Description

The "Set limit value" instruction limits the value of the parameter IN to the values of the parameters MN and MX. The value of the parameter MN may not be greater than the value of the parameter MX.

If the value of the IN parameter fulfills the MN condition <=IN <= MX, it is returned as the result of the instruction. If the condition is not fulfilled and the IN input value is less than the MN low limit, the value of the MN parameter is returned as the result. If the high limit MX is exceeded, the value of the MX parameter is returned as the result.

If the value at the MN input is greater than at the MX input, the result is the value specified at the IN parameter and the enable output ENO is "0".

The instruction is only executed if the operands of all parameters are of the same data type.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
MN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Low limit
IN	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Input value
MX	Input	Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	High limit
Function value		Integers, floating-point numbers, TIME, TOD, DATE, DTL	Integers, floating-point numbers, TIME, LTIME, TOD, LTOD, DATE, LDT, DT, DTL	I, Q, M, D, L, P	Result of the instruction
The data types TOD, LTOD, DATE, and LDT can only be used if the IEC test is not enabled.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := LIMIT(MN := "Tag_Minimum",
                      IN := "Tag_Value",
                      MX := "Tag_Maximum");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
MN	Tag_Minimum	12 000
IN	Tag_Value	8 000
MX	Tag_Maximum	16 000
Function value	Tag_Result	12 000

The value of operand "Tag_Value" is compared with the values of operands "Tag_Minimum" and "Tag_Maximum". Because the value of the operand "Tag_Value" is less than the low limit value, the value of operand "Tag_Minimum" will be copied to operand "Tag_Result".

Basics of SCL (Page 4991)

SQR: Form square (S7-1200, S7-1500)

Description

Use the "Form square" instruction to square the input value and save the result in the specified operand.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Square of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := SQR("Tag_Value");
"Tag_Result2" := SQR((SQR("Tag_Value1"))*"Tag_Value2");
```

The square of the input value is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	2.5
Tag_Result1	6.25
Tag_Value1	6.0
Tag_Value2	2.0
Tag_Result2	5184.0

SQRT: Form square root (S7-1200, S7-1500)

Description

Use the "Form square root" instruction to calculate the square root of the input value and save the result in the specified operand. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, the instruction returns an invalid floating-point number. If the input value is "0", the result is also "0".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Square root of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := SQRT("Tag_Value");
"Tag_Result2" := SQRT((SQR("Tag_Value1"))+"Tag_Value2");
```

The square root of the input value is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	4.0
Tag_Result1	2.0
Tag_Value1	3.0
Tag_Value2	16.0
Tag_Result2	5.0

See also

Basics of SCL (Page 4991)

LN: Form natural logarithm (S7-1200, S7-1500)

Description

You can use the "Form natural logarithm" instruction to calculate the natural logarithm to base e (e=2.718282) from the input value. The instruction has a positive result if the input value is greater than zero. If input values are less than zero, the instruction returns an invalid floating-point number.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expres-sion>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Natural logarithm of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := LN("Tag_Value");
"Tag_Result2" := LN("Tag_Value1"+"Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	2.5
Tag_Result1	0.916
Tag_Value1	1.5
Tag_Value2	3.2
Tag_Result2	1.548

Basics of SCL (Page 4991)

EXP: Form exponential value (S7-1200, S7-1500)

Description

The "Form exponential value" instruction calculates the exponent from the base e (e = 2.718282) and the input value and saves the result in the specified operand.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
Function value		Floating-point numbers	I, Q, M, D, L, P	Exponential value of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := EXP("Tag_Value");
"Tag_Result2" := EXP("Tag_Value1"/"Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	20.5
Tag_Result1	799 902 200

Operand	Value
Tag_Value1	15.5
Tag_Value2	30.2
Tag_Result2	1.671

SIN: Form sine value (S7-1200, S7-1500)

Description

Use the "Form sine value" instruction to calculate the sine of the input value. The input value must be given in radians.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SIN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+1.570796 (π/2)
Tag_Result	1.0

COS: Form cosine value (S7-1200, S7-1500)

Description

Use the "Form cosine value" instruction to calculate the cosine of the input value. The input value must be given in radians.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := COS("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+1.570796 (π/2)
Tag_Result	0

TAN: Form tangent value (S7-1200, S7-1500)

Description

Use the "Form tangent value" instruction to calculate the sine of the input value. The input value must be given in radians.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expres-sion>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value (size of an angle in radians)
Function value		Floating-point numbers	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := TAN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	+3.141593 (π)
Tag_Result	0

ASIN: Form arcsine value (S7-1200, S7-1500)

Description

You can use the "Form arcsine value" instruction to calculate the size of the angle from a sine value, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified as input values. The calculated angle size is given in radians and can range in value from -π/2 to +π/2.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expres-sion>	Input	Floating-point numbers	I, Q, M, D, L, P	Sine value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ASIN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	1.0
Tag_Result	+1.570796 (π/2)

ACOS: Form arccosine value (S7-1200, S7-1500)

Description

You can use the "Form arccosine value" instruction to calculate the size of the angle from a cosine value, which corresponds to this value. Only valid floating-point numbers within the range -1 to +1 can be specified as input values. The calculated angle size is given in radians and can range in value from 0 to +π.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expres-sion>	Input	Floating-point numbers	I, Q, M, D, L, P	Cosine value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ACOS("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	0
Tag_Result	+1.570796 (π/2)

Basics of SCL (Page 4991)

ATAN: Form arctangent value (S7-1200, S7-1500)

Description

You can use the "Form arctangent value" instruction to calculate the size of the angle from a tangent value, which corresponds to this value. It is only permitted to specify valid floating-point numbers (or -NaN/+NaN) as input value. The calculated angle size is given in radians and can range in value from -π/2 to +π/2.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expres-sion>	Input	Floating-point numbers	I, Q, M, D, L, P	Tangent value
Function value		Floating-point numbers	I, Q, M, D, L, P	Size of angle in radians

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ATAN("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	1.0
Tag_Result	+0.785398 (π/4)

FRAC: Return fraction (S7-1200, S7-1500)

Description

The result of the instruction "Return fraction" returns the decimal places of a value. Input value 123.4567, for example, returns the value 0.4567.

Use the following syntax to change the data type of the instruction:

FRAC_<data type>();

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Floating-point numbers Default: REAL	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Floating-point numbers	I, Q, M, D, L, P	Decimal places of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := FRAC("Tag_Value");
"Tag_Result2" := FRAC_LREAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	2.555	-1.4421
Tag_Result1	0.555	-0.4421

Invalid floating-point numbers (Page 2259)

Basics of SCL (Page 4991)

Move operations (S7-1200, S7-1500)

Deserialize: Deserialize (S7-1200, S7-1500)

Description

You can use the "Deserialize" instruction to convert back the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> and to fill its entire contents.

The memory area in which the sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type> is located must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized memory areas also permitted as of version 2.0. The capacity of the standard memory area is 64 KB. Make sure that there is enough memory space prior to the conversion. If the memory area is filled using the instruction "Serialize" and it is possible that fill bytes were inserted, their conversion is not taken into account.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The instruction enables you to convert multiple sequential representations of converted data back to their original state step-by-step.

If you only want to convert back a single sequential representation of a PLC data type (UDT), STRUCT or ARRAY of <data type>, you can also directly use the instruction "TRCV: Receive data via communication connection".

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To deserialize larger structures, you can declare the memory area for sequential representation with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The content of the sequential representation remains unchanged, as for a standard memory area. Only symbolic access to the bytes in the ARRAY is possible.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
SRC_ARRAY	Input	VARIANT ARRAY[*] of BYTE [1]	D, block interface of an FB (The sections Input, Output, Static and Temp are possible.)	Tag of ARRAY of BYTE data type in which the generate data flow is stored
DEST_VARIABLE	InOut	VARIANT	D, block interface of an FB	Tag in which the reconverted PLC data type (UDT), STRUCT, ARRAY of <data type> is stored
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the number of bytes occupied by the converted customer data. The POS parameter is calculated zero-based.
Function value		INT	I, Q, M, D, L	Error information
[1] Possible for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.				

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_ARRAY and DEST_VARIABLE parameters overlap.
8136	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8150	The VARIANT data type at the SRC_ARRAY parameter contains a ZERO pointer.
8151	No valid reference at the SRC_ARRAY parameter
8153	There is not enough free memory available at the SRC_ARRAY parameter.
8154	Invalid data type at the SRC_ARRAY parameter
8250	The VARIANT data type at the DEST_VARIABLE parameter contains a ZERO pointer.
8251	No valid reference at the DEST_VARIABLE parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

Error code* (W#16#...)	Explanation
8136	Access to the memory area at the SRC_ARRAY parameter is invalid.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface of an FB or FC.
BufferPos	DINT	In the "Temp" section of the block interface of an FB or FC.
Error	INT	
Label	STRING[4]	

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Target	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
	Bill	Array[0..10] of INT
Buffer	Field	Array[0..294] of BYTE

The following example shows how the instruction works:

SCL

```
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := "Target".Client,
                           POS := #BufferPos);

#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := #Label,
                           POS := #BufferPos);
```

SCL

```
IF #Label = 'arti' THEN
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := "Target".Article[#DeliverPos],
                           POS := #BufferPos);
ELSIF #Label = 'Bill' THEN
#Tag_RetVal := Deserialize(SRC_ARRAY := "Buffer".Field,
                           DEST_VARIABLE := "Target".Bill[#DeliverPos],
                           POS := #BufferPos);
;
ELSE
;
END_IF;
```

The "Deserialize" instruction deserializes the sequential representation of the customer data from the "Buffer" tag and writes it to the "Target" tag. The #BufferPos operand stores the index of the first byte based on the number of bytes occupied by the converted customer data.

The "Deserialize" instruction deserializes the sequential representation of the separator sheet, which was stored in the sequential representation after the customer data, from the "Buffer" tag and writes the characters to the #Label operand. The characters are compared using comparison instructions "arti" and "Bill". If the comparison for "arti" = TRUE, these are article data that have been deserialized and written to the "Target" tag. If the comparison for "Bill" = TRUE, these are billing data that have been deserialized and written to the "Target" tag.

Structure of a STRING tag (Page 2272)

Basics of SCL (Page 4991)

Serialize: Serialize (S7-1200, S7-1500)

Description

You can use the "Serialize" instruction to convert several PLC data types (UDT), STRUCT or ARRAY of <data type> to a sequential representation without losing parts of their structure.

You use the instruction to temporarily save multiple structured data items from your program in a buffer, which should preferably be in a global data block, and send them to another CPU. The memory area in which the converted data are stored must have the ARRAY of BYTE data type and be declared with standard access in version 1.0. Optimized data are also permitted as of version 2.0. Fill bytes or fill bits of a data area (e.g. ARRAY, STRUCT or PLC data type

(UDT)) as well as the characters of a string currently not in use are undefined in the destination ARRAY.

The capacity of the standard memory area is 64 KB. Structures that are larger than 64 KB in accordance with the rules for standard memory areas cannot be serialized if the operand at the DEST_ARRAY parameter is located in a standard memory area.

It is recommended to define the low limit of the ARRAY with "0", because then the index within ARRAY corresponds to the value of the POS parameter, e.g. ARRAY[0] = POS 0. The description and example below have been formed based on this.

The operand at the POS parameter contains information about the number of bytes used by the converted data.

If you want to send a single PLC data type (UDT), STRUCT or ARRAY of <data type>, you can directly call the instruction "TSEND: Send data via communication connection".

Note

Comparison of structures

To compare structures, they have to be serialized first. Use a comparison expression instead.

You can find additional information here: Relational expressions (Page 4995)

Size of the memory area

The alignment rules mean that simple structures in the optimized memory area do not contain filling bytes. This results in a structure in the optimized memory area being smaller than in the standard memory area. ARRAYs of structures and structures in which other structures are located contain filling bytes. There is no general rule as to the memory area in which a composed structure requires more space.

Applies to CPUs of the S7-1500 series:

For a block with the block property "Optimized block access", the BOOL has a length of 1 byte. A structure that consists largely of the data type BOOL can therefore be larger in the optimized memory area than in the standard memory area. Composed structures with a low proportion of BOOL data types are smaller in the optimized memory area than in the standard memory area.

Optimized memory area

To serialize larger structures, you can declare the memory area with optimized access for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0. The sequential representation remains unchanged, as for a standard memory area.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
SRC_VARIABLE	Input	VARIANT	D, block interface of an FB	PLC data type (UDT), STRUCT or ARRAY of <data type> that is converted to sequential representation.
DEST_ARRAY	InOut	VARIANT	D, block interface of an FB (The sections Input, Output, Static and Temp are possible.)	Data block in which the generated data stream is stored.
POS	InOut	DINT	I, Q, M, D, L	The operand at the POS parameter stores the index of the first byte based on the total number of bytes that the converted customer data has occupied. The POS parameter is calculated zero-based.
Function value		INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B0	The memory areas for the SRC_VARIABLE and DEST_ARRAY parameters overlap.
8150	The VARIANT data type at the SRC_VARIABLE parameter contains a ZERO pointer.
8151	No valid reference at the SRC_VARIABLE parameter
8236	The tag at the SRC_ARRAY parameter is not in a block with standard access.
8250	The VARIANT data type at the DEST_ARRAY parameter contains a ZERO pointer.
8251	No valid reference at the DEST_ARRAY parameter
8253	There is not enough free memory available at the DEST_ARRAY parameter.
8254	Invalid data type at the DEST_ARRAY parameter
8382	The value at the POS parameter is outside the limits of the array.
9512	For a CPU of the S7-1200 module and a block with the block property "Optimized block access": The BOOL data type is used at the DEST_VARIABLE parameter. This makes the object smaller than a full byte.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

For a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0, the following error code has a different meaning:

Error code* (W#16#...)	Explanation
8236	Access to the memory area at the DEST_ARRAY parameter is invalid.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
#Tag_RetVal := Serialize(SRC_VARIABLE := "Source".Client,
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);

#Label := STRING_TO_WSTRING('arti');

#Tag_RetVal := Serialize(SRC_VARIABLE := #Label,
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);

#Tag_RetVal := Serialize(SRC_VARIABLE := "Source".Article[#DeliverPos],
                         DEST_ARRAY := "Buffer".Field,
                         POS := #BufferPos);
```

The "Serialize" instruction serializes the customer data from the "Source" tag and writes the sequential representation to the "Buffer" tag. The index of the next unwritten byte of the "Buffer".Field operand is saved in the #BufferPos operand.

A kind of separator sheet is inserted now to make it easier to deserialize the sequential representation later. The "Move character string" instruction moves the "arti" characters to the #Label operand. The "Serialize" instruction writes these characters after the customer data to the "Buffer" tag. The value of the #BufferPos operand is incremented accordingly.

The "Serialize" instruction serializes the data of a specific article, which is calculated in runtime, from the "Source" tag and writes them in sequential representation to the "Buffer" tag after the "arti" characters.

The following table shows the declaration of the operands:

Operand	Data type	Declaration
DeliverPos	INT	In the "Input" section of the block interface
BufferPos	DINT	In the "Temp" section of the block interface

Operand	Data type	Declaration
Error	INT	In the "Temp" section of the block interface
Label	STRING[4]	In the "Temp" section of the block interface

The following table shows the declarations of the PLC data types:

Name of the PLC data types	Name	Data type
Article	Number	DINT
	Declaration	STRING
	Colli	INT
Client	Title	INT
	First name	STRING[10]
	Surname	STRING[10]

The following table shows the declaration of the data blocks:

Name of the data blocks	Name	Data type
Source	Client	"Client" (PLC data type)
	Article	Array[0..10] of "Article" (PLC data type)
Buffer	Field	Array[0..294] of BYTE

MOVE_BLK: Move block (S7-1200, S7-1500)

Description

You can use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). The number of elements to be moved to the target range is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the first element in the source area.

The instruction can only be executed if the source range and the target range have the same data type.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at the IN parameter or OUT parameter.

Note

Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of elements to be copied from the source range to the target range
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the target range to which the contents of the source range are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
MOVE_BLK(IN := #a_array[2],
         COUNT := "Tag_Count",
         OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is ARRAY[0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is ARRAY[0..6] of INT. It consists of seven elements of data type INT.

Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element.

Note

You can find more information on the MOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Basics of SCL (Page 4991)

SCATTER: Parse the bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse the bit sequence into individual bits" disassembles a tag of the BYTE, WORD, DWORD or LWORD data type into individual bits and saves them in an ARRAY of BOOL.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse a status word, and read and change the status of the individual bits using the index. Using GATHER, you can merge the bits once again into a bit sequence.

The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- If the ARRAY does not provide enough BOOL elements.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Bit sequence that is parsed
OUT	Output	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY in which the individual bits are saved

You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
SourceWord	Input	WORD
DestinationArray	Output	ARRAY[0..15] of BOOL

The following example shows how the instruction works:

SCL

```
SCATTER(IN := #SourceWord,
        OUT => #DestinationArray);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceWord	WORD (16 bits)
OUT	DestinationArray	The operand "DestinationArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD that is to be parsed.

The operand #SourceWord of the data type WORD is parsed into its individual bits (16) and assigned to the individual elements of the #DestinationArray operand.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

SCATTER_BLK: Parse elements of an ARRAY of bit sequence into individual bits (S7-1200, S7-1500)

Description

The instruction "Parse elements of an ARRAY of bit sequence into individual bits" parses one or more elements of an ARRAY of BYTE, WORD, DWORD or LWORD into individual bits and saves them in an ARRAY of BOOL. At the COUNT_IN parameter you specify how many elements of the source ARRAY are going to be disassembled. The source ARRAY at the IN parameter may have more elements than specified at the COUNT_IN parameter. The ARRAY of BOOL must have sufficient elements to save the bits of the disassembled bit strings. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n(number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note
Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

This way you can, for example, parse status words, and read and change the status of the individual bits using the index. Using GATHER, you can combine the bits once again into a bit string.

The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The source ARRAY has fewer elements than specified at the COUNT_IN parameter.
- The index of the destination ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of BOOL.
- The ARRAY[*] of BOOL does not provide the required number of elements. In this case as many bit strings as possible are parsed and written to the ARRAY of BOOL. The remaining bit strings are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> that is disassembled
COUNT_IN	Input	UDINT	I, Q, M, D, L	Counter for the number of elements of the source ARRAY that are going to be disassembled
OUT	Output	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY in which the individual bits are saved

You can find additional information on valid data types under "See also".

Example of a destination ARRAY wit the low limit "0"

Create the following tags in the block interface:

Tag	Section	Data type
SourceArrayWord	Input	ARRAY[0..5] of WORD
CounterInput		UDINT
DestinationArrayBool	Output	ARRAY[0..95] of BOOL

The following example shows how the instruction works:

SCL

```
SCATTER_BLK(IN := #SourceArrayWord[2],
            COUNT_IN := #CounterInput,
```

SCL

```
OUT => #DestinationArrayBool[0]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be disassembled.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[0]	The operand "DestinationArrayBool" is of the data type ARRAY[0..95] of BOOL. This means it provides 96 BOOL elements.

The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the first element assigned to the individual elements of the #DestinationArrayBool operand.

Example of a destination ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
SourceArrayWord	Input	ARRAY[0..5] of WORD
CounterInput		UDINT
DestinationArrayBool	Output	ARRAY[-2..93] of BOOL

The following example shows how the instruction works:

SCL

```
SCATTER_BLK(IN := #SourceArrayWord[2],
            COUNT_IN := #CounterInput,
            OUT => #DestinationArrayBool[14]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayWord[2]	ARRAY[0..5] of WORD (96 bits can be disassembled.)
COUNT_IN	CounterInput = 3	UDINT3 (3 WORDs or 48 bits are to be parsed. This means at least 48 bits must be available in the destination ARRAY.)
OUT	DestinationArrayBool[14]	The operand "DestinationArrayBool" is of the data type ARRAY[-2..93] of BOOL. This means it provides 96 BOOL elements.

The 3rd, 4th and 5th WORD of the operand #SourceArrayWord is parsed into its individual bits (48) and as of the 16th element assigned to the individual elements of the #DestinationArrayBool operand.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

GATHER: Merge individual bits into a bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into a bit sequence" combines the bits from an ARRAY of BOOL into a bit sequence. The bit sequence is saved in a tag of the data type BYTE, WORD, DWORD or LWORD.

Note

Length of the ARRAY

The ARRAY of BOOL must have exactly the number of elements that is specified by the bit sequence.

This means for the data type BYTE, for example, the ARRAY must have exactly 8 elements (WORD = 16, DWORD = 32 and LWORD = 64).

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- If the ARRAY has fewer or more BOOL elements than specified by the bit sequence, they are not transferred and the ENO returns signal state "0". The ENO also returns "0" if fewer than the necessary number of bits is available.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	ARRAY[*] of BOOL *: 8, 16, 32 or 64 elements	I, Q, M, D, L	ARRAY whose bits are combined into a bit sequence
OUT	Output	BYTE, WORD, DWORD, LWORD	I, Q, M, D, L	Combined bit sequence, saved in a tag

You can find additional information on valid data types under "See also".

Example

Create the following tags in the block interface:

Tag	Section	Data type
SourceArray	Input	ARRAY[0..15] of BOOL
DestinationWord	Output	WORD

The following example shows how the instruction works:

SCL

```
GATHER(IN := #SourceArray,
       OUT => #DestinationWord);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArray	The operand "SourceArray" is of the data type ARRAY[0..15] of BOOL. It consists of 16 elements and is therefore just as large as the WORD in which the bits are to be combined.
OUT	DestinationWord	WORD (16 bits)

The bits of the operand #SourceArray are combined into a WORD.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

GATHER_BLK: Merge individual bits into multiple elements of an ARRAY of bit sequence (S7-1200, S7-1500)

Description

The instruction "Merge individual bits into multiple elements of an ARRAY of bit sequence" combines the bits from an ARRAY of BOOL into one or multiple elements of an ARRAY of <bit string>. At the COUNT_OUT parameter you specify how many elements of the destination ARRAY are going to be written. With this step you also implicitly specify how many elements of the ARRAY of BOOL are required. The destination ARRAY at the OUT parameter may have more elements than specified at the COUNT_OUT parameter. The ARRAY of <bit string> must have sufficient elements to save the bits that are going to be combined. However, the destination ARRAY may also be larger.

Note

If the low ARRAY limit of the target ARRAY is not "0", note the following:

For performance reasons the index must always start at a BYTE, WORD, DWORD or LWORD limit. This means the index must be calculated starting at the low limit of the ARRAY. The following formula is used as basis for this calculation:

Valid indices = Low ARRAY limit + n(number of bit strings) × number of bits of the desired bit string

For an ARRAY[-2..45] of BOOL and the bit string WORD the calculation looks as follows:

- Valid index (-2) = -2 + 0 × 16
- Valid index (14) = -2 + 1 × 16
- Valid index (30) = -2 + 2 × 16

You can find an example described below.

Note

Availability of instruction on a S7-1500 CPU

The instruction can be used with a CPU of the S7-1200 series as of firmware version 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.1.

The enable output ENO returns signal state "0" if one of the following conditions applies:

- Enable input EN has signal state "0".
- The index of the source ARRAY does not start at a BYTE, WORD, DWORD or LWORD limit. In this case, no result is written to the ARRAY of <bit string>.
- The ARRAY[*] of <bit string> does not provide the required number of elements. In this case as many bit strings as possible are combined and written to the ARRAY of <bit string>. The remaining bits are no longer taken into account.

Parameter

The following table shows the parameters of the instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	Element of an ARRAY[*] of BOOL	I, Q, M, D, L	ARRAY of BOOL whose bits are combined (source ARRAY)
COUNT_OUT	Input	UDINT	I, Q, M, D, L	Counter of the number of elements of the destination ARRAY that are going to be written
OUT	Output	Element of an ARRAY[*] of <bit string>	I, Q, M, D, L	ARRAY of <bit string> to which the bits are saved (destination ARRAY)

You can select the required bit string from the "???" drop-down list of the instruction box.

You can find additional information on valid data types under "See also".

Example of a source ARRAY wit the low limit "0"

Create the following tags in the block interface:

Tag	Section	Data type
SourceArrayBool	Input	ARRAY[0..95] of BOOL
CounterOutput		UDINT
DestinationArrayWord	Output	ARRAY[0..5] of WORD

The following example shows how the instruction works:

SCL

```
GATHER_BLK(IN := #SourceArrayBool[0],
           COUNT_OUT := #CounterOutput,
           OUT => #DestinationArrayWord[2]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[0]	The operand "SourceArrayBool" is of the data type ARRAY[0..95] of BOOL. This means it provides 96 BOOL elements that can combined into words once again.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 1st element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits are written to the 3rd word, the second 16 bits to the 4th word, and the third 16 bits to the 5th word of the destination ARRAY. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Example of a source ARRAY wit the low limit "-2"

Create the following tags in the block interface:

Tag	Section	Data type
SourceArrayBool	Input	ARRAY[-2..93] of BOOL
CounterOutput		UDINT
DestinationArrayWord	Output	ARRAY[0..5] of WORD

The following example shows how the instruction works:

SCL

```
GATHER_BLK(IN := #SourceArrayBool[14],
           COUNT_OUT := #CounterOutput,
           OUT => #DestinationArrayWord[2]);
```

The following table shows how the instruction works using specific operand values:

Parameter	Operand	Data type
IN	SourceArrayBool[14]	The operand "SourceArrayBool" is of the data type ARRAY[-2..93] of BOOL. Because the starting point is the 14th element, only 80 BOOL elements that can be combined into words again are available.
COUNT_OUT	CounterOutput = 3	UDINT3 (3 words are to be written. This means 48 bits must be available in the source ARRAY.)
OUT	DestinationArrayWord[2]	The operand "DestinationArrayWord" is of the data type ARRAY[0..5] of WORD. This means 6 WORD elements are available.

If the operand #Enable returns the signal state "1" at the enable input EN, the instruction is executed. Starting with the 14th element of the operand #SourceArrayBool, 48 bits are combined in the operand #DestinationArrayWord. The starting point in the destination ARRAY is the 3rd element. This means the first 16 bits of the source ARRAY are ignored. The second 16 bits are written to the 3rd word, the third 16 bits to the 4th word, and the fourth 16 bits to the 5th word of the destination ARRAY. The remaining 64 bits of the source ARRAY are not taken into account either. If an error occurs during the execution of the instruction, the operand #EnableOut returns the signal state "0" at the enable output ENO.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

MOVE_BLK_VARIANT: Move block (S7-1200, S7-1500)

Description

You can use the "Move block" instruction to move the content of a memory area (source range) to another memory area (target range). You can copy a complete ARRAY or elements of an ARRAY to another ARRAY of the same data type. The size (number of elements) of source and destination ARRAY may be different. You can copy multiple or single elements within an ARRAY.

The number of elements that are to be copied must not exceed the selected source range or target range.

If you use the instruction at the time the block is being created, the ARRAY does not yet have to be known, as the source and the target are transferred per VARIANT.

Counting at the parameters SRC_INDEX and DEST_INDEX always begins with the low limit "0", regardless of the later declaration of the ARRAY.

The instruction is not executed if more data is copied than is made available.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
SRC	Input [2)]	VARIANT (which points to an ARRAY or an individual ARRAY element), ARRAY of <Data_type>	L (A declaration in the "Temp" section of the block interface is not possible.)	Source block from which to copy
COUNT	Input	UDINT	I, Q, M, D, L	Number of elements which are copied Assign the value "1" to the parameter COUNT, if no ARRAY is specified at parameter SRC or at parameter DEST.
SRC_INDEX	Input	DINT	I, Q, M, D, L	Defines the first element to be copied: • The SRC_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter SRC, the integer at parameter SRC_INDEX specifies the first element within the source area from which it is to be copied. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter SRC or only one single element of an ARRAY is specified, then assign the value "0" at parameter SRC_INDEX.

Parameters	Declaration	Data type	Memory area	Description
DEST_INDEX	Input	DINT	I, Q, M, D, L	Defines the start of the destination memory area: • The DEST_INDEX parameter is calculated zero-based. If an ARRAY is specified at parameter DEST, the integer at parameter DEST_INDEX specifies the first element within the target range that is to be copied into. Independent of the declared ARRAY limits. • If no ARRAY is specified at parameter DEST, then assign the value "0" at parameter DEST_INDEX.
DEST	Output [1]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Destination area into which the contents of the source block are copied.
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information
1) The DEST parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface. 2) With the SRC parameter, the data types BOOL and ARRAY of BOOL are not permitted.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data types do not correspond. Instead of an ARRAY of <Struct>, use an ARRAY of <PLC data type (UDT)>.
8151	Access to the SRC parameter is not possible.
8152	The operand at the SRC parameter is not typed.
8153	Code generation error at the SRC parameter
8154	The operand at the SRC parameter has the data type BOOL.
8281	The COUNT parameter has an invalid value
8382	The value at the SRC_INDEX parameter is outside the limits of the VARIANT.
8383	The value at the SRC_INDEX is outside the high limit of the ARRAY.
8482	The value at the DEST_INDEX parameter is outside the limits of the VARIANT.
8483	The value at the DEST_INDEX is outside the high limit of the ARRAY.

Error code* (W#16#...)	Explanation
8534	The DEST parameter is write protected
8551	Access to the DEST parameter is not possible.
8552	The operand at the DEST parameter is not typed.
8553	Code generation error at the DEST parameter
8554	The operand at the DEST parameter has the data type BOOL.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MOVE_BLK_VARIANT(SRC := #SrcField,
                                 COUNT := "Tag_Count",
                                 SRC_INDEX := "Tag_Src_Index",
                                 DEST_INDEX := "Tag_Dest_Index",
                                 DEST => #DestField);
```

The following table shows how the instruction works using specific operand values:

Parameters	Declaration in the block interface	Operand	Value
SRC	Input	#SrcField	The local operand #SrcField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[0..10] of "MOVE_UDT")
COUNT	Input	Tag_Count	2
SRC_INDEX	Input	Tag_Src_Index	3
DEST_INDEX	Input	Tag_Dest_Index	3
DEST	InOut	#DestField	The local operand #DestField uses a PLC data type that was still unknown at the time when the block was programmed. (ARRAY[10..20] of "MOVE_UDT")

Two elements are moved from the source range, starting from the fourth element of the ARRAY [0..10] of MOVE_UDT, to the target range. The copies are pasted in the ARRAY [10..20] of MOVE_UDT starting from the fourth element.

Note

You can find more information on the MOVE_BLK_VARIANT instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Basics of SCL (Page 4991)

UMOVE_BLK: Move block uninterruptible (S7-1200, S7-1500)

Description

You use the "Move block uninterruptible" instruction to move the content of a memory area (source range) to another memory area (target range). The instruction cannot be interrupted. The number of elements to be moved to the target range is specified with the COUNT parameter. The width of the elements to be moved is defined by the width of the first element in the source area.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the interrupt reaction times of the CPU increase during the execution of the "Move block uninterruptible" instruction.

The value of the OUT output is invalid if the following condition is met:

- More data is moved than is made available at the IN parameter or OUT parameter.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Note

Use of ARRAYs

The instruction copies the contents from the defined element n elements (n = depending on the value at the parameter COUNT) from the source range to the target range, starting at the specified index.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN [1]	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the source area that is being copied
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of elements to be copied from the source range to the target range
OUT [1]	Output	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	The first element of the target range to which the contents of the source range are being copied
[1] The specified data types can only be used as elements of an ARRAY structure.					

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
UMOVE_BLK(IN := #a_array[2],
          COUNT := "Tag_Count",
          OUT => #b_array[1]);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	a_array[2]	The data type of the "a_array" operand is ARRAY[0..5] of INT. It consists of six elements of data type INT.
COUNT	Tag_Count	3
OUT	b_array[1]	The data type of the "b_array" operand is ARRAY[0..6] of INT. It consists of seven elements of data type INT.

Starting from the third element, the instruction selects three INT elements from the #a_array tag and copies their contents to the #b_array output tag, beginning with the second element. The move operation cannot be interrupted by other operating system activities.

Note

You can find more information on the UMOVE_BLK instruction in the following article in the Siemens Industry Online Support:

In STEP 7 (TIA Portal) how do you copy memory areas and structured data from one data block to another?

https://support.industry.siemens.com/cs/ww/en/view/42603881 (https://support.industry.siemens.com/cs/ww/en/view/42603881)

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

FILL_BLK: Fill block (S7-1200, S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (target range) with the value of the IN input. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

Note

Use of ARRAYs

The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P	Element used to fill the target range
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in target range from which filling starts

For additional information on valid data types, refer to "See also".

Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

SCL

```
FILL_BLK(IN := #FillValue,
         COUNT := "Tag_Count",
         OUT => #TargetArea[1]);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element.

Examples with a structure

The following examples show how the instruction works when you want to fill a structure:

Create a global data block with the following elements:

Data_block_1		Data type
MyStruct1		STRUCT
	Member_1	INT
	Member_2	INT
	Member_3	INT
	Member_4	INT
MyStruct2		STRUCT

Data_block_1					Data type
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

SCL

```
FILL_BLK(IN := 10,
         COUNT := 2,
         OUT => "Data_block_1".MyStruct1.Member_2);
```

Generate the following program code to address the MyStruct2 tag:

SCL

```
FILL_BLK(IN := 10,
         COUNT := 2,
        OUT => "Data_block_1".MyStruct2.SubArray[1].NestedStruct.Member_2);
```

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and Member_4, are not changed.

Basics of SCL (Page 4991)

UFILL_BLK: Fill block uninterruptible (S7-1200, S7-1500)

Description

You can use the "Fill block uninterruptible" instruction to fill a memory area (target range) with the value of the IN input. The instruction cannot be interrupted. The target range is filled beginning with the address specified at the OUT output. The number of repeated copy operations is specified with the COUNT parameter. When the instruction is executed, the value at the input IN is moved to the target range as often as specified by the value of the COUNT parameter.

The instruction can only be executed if the source range and the target range have the same data type.

Note

The move operation cannot be interrupted by other operating system activities. This is why the alarm reaction times of the CPU increase during the execution of the "Fill block uninterruptible" instruction.

The maximum number of elements changed is the number of elements in the ARRAY or structure. If you copy more data than there are elements at the OUT output, you will get an unintended result.

Note

Use of ARRAYs

The instruction reads the content from the selected element from the source range and copies this content n-times (n = depending on the value at the parameter COUNT) to the destination, starting at the specified index.

You use the "Fill block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Filling structures

As well as the elements of an ARRAY, you can also fill multiple elements of a structure (STRUCT, PLC data type) with the same value. The structure whose elements you want to fill must only contain individual elements of the same elementary data type. The structure itself can, however, be embedded in another structure.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	I, Q, M, D, L, P	Element used to fill the target range
COUNT	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L, P	Number of repeated move operations
OUT	Output	Binary numbers, integers, floating-point numbers, timers, TOD, DATE, CHAR, WCHAR	Binary numbers, integers, floating-point numbers, timers, DATE, CHAR, WCHAR, TOD, LTOD	D, L	Address in target range from which filling starts

For additional information on valid data types, refer to "See also".

Example with an ARRAY

The following example shows how the instruction works when you want to fill an ARRAY:

SCL

```
UFILL_BLK(IN := #FillValue,
          COUNT := "Tag_Count",
          OUT => #TargetArea[1]);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	FillValue	The data type of the operand is INT.
COUNT	Tag_Count	3
OUT	TargetArea	The data type of the operand TargetArea is ARRAY[1..5] of INT. It consists of five elements of data type INT.

The instruction copies the value of the operand #FillValue to the #TargetArea output tag three times, starting with the first element. The move operation cannot be interrupted by other operating system activities.

Examples with a structure

The following examples show how the instruction works when you want to fill a structure:

Create a global data block with the following elements:

Data_block_1					Data type
MyStruct1					STRUCT
	Member_1				INT
	Member_2				INT
	Member_3				INT
	Member_4				INT
MyStruct2					STRUCT
	SubArray				ARRAY[1..2] of STRUCT
		SubArray[1]			STRUCT
			NestedStruct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT
		SubArray[2]			STRUCT
			Nested-Struct		STRUCT
				Member_1	INT
				Member_2	INT
				Member_3	INT
				Member_4	INT

Generate the following program code to address the MyStruct1 tag:

SCL

```
UFILL_BLK(IN := 10,
          COUNT := 2,
          OUT => "Data_block_1".MyStruct1.Member_2);
```

Generate the following program code to address the MyStruct2 tag:

SCL

```
UFILL_BLK(IN := 10,
          COUNT := 2,
          OUT => "Data_block_1".MyStruct2.SubArray[1].NestedStruct.Member_2);
```

In each of the two examples, the value 10 of the IN parameter is copied twice to the operand at the OUT parameter, starting with the element Member_2. This means that the value 10 is copied to the elements Member_2 and Member_3. The other two elements, Member_1 and Member_4, are not changed.

SWAP: Swap (S7-1200, S7-1500)

Description

You can use the "Swap" instruction to change the arrangement of the bytes of an input value and save the result in the specified operand.

The following figure shows how the bytes of an operand of the DWORD data type are swapped using the "Swap" instruction:

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
<Expression>	Input	WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Input value
Function value		WORD, DWORD	WORD, DWORD, LWORD	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SWAP("Tag_Value");
```

The result of the instruction is returned as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value	0000 1111 0101 0101
Tag_Result	0101 0101 0000 1111

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

ARRAY DB (S7-1500)

ReadFromArrayDB: Read from array data block (S7-1500)

Description

The instruction "Read from ARRAY data block" is used to read the element from a data block of the ARRAY DB block type to which the index references, and write the value of the element to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
DB	Input	DB_ANY	I, Q, M, D, L	Data block that is read
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.
VALUE	Output [1)]	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value that is read and output

Parameters	Declaration	Data type	Memory area	Description
Function value (RET_VAL)		INT	I, Q, M, D, L	Result of the instruction
1) The VALUE parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, write protected, or is located in load memory.
8135	The ARRAY data block contains invalid values.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8452	Code generation error
8453	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"TagResult" := ReadFromArrayDB(DB := "ArrayDB",
                               INDEX := 2,
                               VALUE => "TargetField");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.

The 2nd element is read from "ArrayDB" and written to the "TargetField" operand.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

WriteToArrayDB: Write to array data block (S7-1500)

Description

The instruction "Write to ARRAY data block" is used to write the element to which the index references to a data block of the ARRAY DB block type.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
DB	Input	DB_ANY	I, Q, M, D, L	Data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Value to be written
Function value (RET_VAL)		INT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
80B5	The copying was interrupted.
8132	The data block does not exist, is too short, or is located in load memory.
8134	The data block is write protected.
8135	The data block is not an ARRAY data block.
8154	The data block has the incorrect data type.
8282	The value at the INDEX parameter is outside the limits of the ARRAY.
8350	The data type VARIANT at parameter VALUE provides the value "0".
8352	Code generation error
8353	There are two possible causes of the error: • The size of the VALUE parameter does not match the element length in the ARRAY data block. • The two tags are not in a memory area with optimized access. For additional information on the memory area access types, refer to: AUTOHOTSPOT
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"TagResult" := WriteToArrayDB(DB := "ArrayDB",
                              INDEX := 2,
                              VALUE := "SourceField");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type Array [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.

The value of the "SourceField" operand is written to the 2nd element of the ARRAY DB.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

ReadFromArrayDBL: Read from array data block in load memory (S7-1500)

Description

The instruction "Read from ARRAY data block in load memory" is used to read the element ti which the index references from a data block of the ARRAY DB block type in the load memory and write it to the target range.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". The instruction is terminated if a negative signal edge is detected at the BUSY parameter. The DONE parameter has the signal state "1" for one program cycle and the read value is output at the VALUE parameter within this cycle. With all other program cycles, the value at the VALUE parameter is not changed.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	REQ = "1": Begin with the reading of the ARRAY DB
DB [1)]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block that is read.
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB that is read. The specification can be a constant, a global tag or an indexed value.
VALUE [1)]	InOut	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being read
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully

Parameters	Declaration	Data type	Memory area	Description
ERROR	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8750	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

SCL

```
"ReadFromArrayDBL_DB"(REQ := "TagReg",
                      DB := "ArrayDB",
                      INDEX := 2,
                      VALUE := "TargetField",
                      BUSY => "TagBusy",
                      DONE => "TagDone",
                      ERROR => "TagError");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	TargetField	The "TargetField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

The instruction is executed when a positive signal edge is detected at the "TagReq" operand. The 2nd element is read from "ArrayDB" and output at the VALUE parameter. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is no longer changed. After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

Basics of SCL (Page 4991)

WriteToArrayDBL: Write to array data block in load memory (S7-1500)

Description

The instruction "Write to ARRAY data block in load memory" is used to write the element to which the index references to a data block of the ARRAY DB block type in load memory.

An ARRAY data block is a data block that consists of exactly one ARRAY of <Data type>. The elements of the ARRAY can be of PLC data type or any other elementary data type. Counting of the ARRAY always begins with the low limit "0".

If the ARRAY data block has been designated with the block attribute "Only store in load memory", it will only be stored in the load memory.

The instruction is executed when a positive signal edge is detected at the REQ parameter. The BUSY parameter then has the signal state "1". If a negative signal edge is detected at the BUSY parameter, the instruction is terminated and the value at the VALUE parameter is written to the data block. The DONE parameter then has the signal state "1" for one program cycle.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L	REQ = "1": Start writing to the array DB
DB [1]	Input	DB_ANY	I, Q, M, D, L	ARRAY data block to which data is written
INDEX	Input	DINT	I, Q, M, D, L, P	Element in the DB to which data is written. The specification can be a constant, a global tag or an indexed value.
VALUE [1]	Input	VARIANT	D (element of a global data block) L (A declaration in the "Temp" section of the block interface is not possible.)	Pointer to the DB in the work memory that is to be read and the value of which is to be written. No local constants or tags from the TEMP section must be used.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = "1": The array DB is still being written
DONE	Output	BOOL	I, Q, M, D, L	DONE = "1": The instruction was executed successfully
ERROR	Output	INT	I, Q, M, D, L	Error information: If an error occurs during execution of the instruction, an error code is output at the ERROR parameter.
[1] The data blocks must be created with the "Optimized" block property.				

ERROR parameter

The following table shows the meaning of the values of the ERROR parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8230	The data block number is incorrect.
8231	The data block does not exist.
8232	The data block is too short, or is not located in load memory.
8234	The data block is write protected.
8235	The data block is not an ARRAY DB.
8254	The data block has the incorrect data type.
8382	The value at the INDEX parameter is outside the limits of the ARRAY.
8450	The data type VARIANT at parameter VALUE provides the value "0".
8751	Code generation error

Error code* (W#16#...)	Explanation
8752	Code generation error
8753	The size of the VALUE parameter does not match the element length in the ARRAY data block.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

You can find descriptions of the error codes triggered by the instructions "READ_DBL" and "WRIT_DBL" in the corresponding descriptions of the instructions.

Example

The following example shows how the instruction works:

SCL

```
"WriteToArrayDBL_DB"(REQ := "TagReg",
                     DB := "ArrayDB",
                     INDEX := 2,
                     VALUE := "SourceField",
                     BUSY => "TagBusy",
                     DONE => "TagDone",
                     ERROR => "TagError");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
REQ	TagReq	BOOL
DB	ArrayDB	The "ArrayDB" operand is an ARRAY DB of the data type ARRAY [0 to 10] of INT.
INDEX	2	2nd element of the "ArrayDB"
VALUE	SourceField	The "SourceField" operand is a global tag of the data type INT.
BUSY	TagBusy	BOOL
DONE	TagDone	BOOL

The instruction is executed when a positive signal edge is detected at the "TagReq" operand. As soon as a negative signal edge is detected at the "TagBusy" operand, the instruction is terminated and the value at the VALUE parameter is written to the 2nd element of the "ArrayDB". After the instruction has been processed, the "TagDone" operand has the signal state TRUE.

Overview of the valid data types (Page 2239)

READ_DBL: Read from data block in the load memory (Page 4050)

WRIT_DBL: Write to data block in the load memory (Page 4054)

Difference between synchronous and asynchronous instructions (Page 2571)

Basics of SCL (Page 4991)

Read/write access (S7-1200, S7-1500)

PEEK: Read memory address (S7-1200, S7-1500)

Description

The "Read memory address" instruction is used to read a memory address from a standard memory area without specifying a data type.

Use the following syntax to change the data type of the instruction:

PEEK_<data type>();

Use of memory area 16#84: DB

If you use a data block as memory area and this is not yet known during the creation of the program code you have the option of using the EN/ENO mechanism to recognize possible access errors:

SCL

```
#Peeker := PEEK(AREA := 16#84,
                DBNUMBER := 1,
                BYTEOFFSET := 2,
                ENO => ENO);
IF NOT ENO THEN;
     #Peeker := 16#ffff;
END_IF;
```

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#1: Peripheral input (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"

Parameters	Declaration	Data type	Memory area	Description
BYTEOFF-SET	Input	DINT	I, Q, M, D	Address to read from Only the 16 least significant bits are used.
_<data type>		Bit strings default: BYTE	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Bit strings	I, Q, M, D	Result of the instruction

Note

If you read the memory address from the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := PEEK(AREA := "Tag_Area",
                      DBNUMBER := "Tag_DBNumber",
                      BYTEOFFSET := "Tag_Byte");
```

SCL

```
"Tag_Result2" := PEEK_WORD(AREA := "Tag_Area",
                           DBNUMBER := "Tag_DBNumber",
                           BYTEOFFSET := "Tag_Byte");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
Function value	Tag_Result1	Byte value "20"
Function value	Tag_Result2	Word value "20"

The instruction reads the value of address "20" from the "Tag_Byte" operand at data block "5" and returns the result as a function value at the "Tag_Result" operand.

PEEK_BOOL: Read memory bit (S7-1200, S7-1500)

Description

The "Read memory bit" instruction is used to read a memory bit from a standard memory area without specifying a data type.

Use of memory area 16#84: DB

If you use a data block as memory area and this is not yet known during the creation of the program code you have the option of using the EN/ENO mechanism to recognize possible access errors:

SCL

```
#Peeker_BOOL := PEEK_BOOL(AREA := 16#84,
                          DBNUMBER := 1,
                          BYTEOFFSET := 2,
                          BITOFFSET := 1,
                          ENO => ENO);
IF NOT ENO THEN;
     #Peeker_BOOL := 0;
END_IF;
```

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#1: Peripheral input (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D	Address to read from Only the 16 least significant bits are used.

Parameters	Declaration	Data type	Memory area	Description
BITOFFSET	Input	INT	I, Q, M, D	Bit to be read from
Function value		BOOL	I, Q, M, D	Result of the instruction

Note

If you read the memory bit from the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := PEEK_BOOL(AREA := "Tag_Area",
                          DBNUMBER := "Tag_DBNumber",
                          BYTEOFFSET := "Tag_Byte",
                          BITOFFSET := "Tag_Bit");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
BITOFFSET	Tag_Bit	3
Function value	Tag_Result	3

The instruction reads the value of memory bit "3" from the "Tag_Bit" operand at byte "20" of data block "5" and returns the result at the "Tag_Result" operand as function value.

POKE: Write memory address (S7-1200, S7-1500)

Description

The "Write memory address" instruction is used to write a memory address to a standard memory area without specifying a data type.

Use of memory area 16#84: DB

If you use a data block as memory area and this is not yet known during the creation of the program code you have the option of using the EN/ENO mechanism to recognize possible access errors:

SCL

```
POKE(AREA := 16#84,
     DBNUMBER := 1,
     BYTEOFFSET := 2,
     VALUE := BYTE#7,
     ENO => ENO);
```

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#2: Peripheral output (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D	Address to be written Only the 16 least significant bits are used.
VALUE	Input	Bit strings	I, Q, M, D	Value to be written

Note

If you write the memory address to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
POKE(AREA := "Tag_Area",
     DBNUMBER := "Tag_DBNumber",
     BYTEOFFSET := "Tag_Byte");
     VALUE := "Tag_Value",
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
VALUE	Tag_Value	16#11

The instruction overwrites the memory address "20" in the data block "5" with value "16#11".

POKE_BOOL: Write memory bit (S7-1200, S7-1500)

Description

The "Write memory bit" instruction is used to write a memory bit to a standard memory area without specifying a data type.

Use of memory area 16#84: DB

If you use a data block as memory area and this is not yet known during the creation of the program code you have the option of using the EN/ENO mechanism to recognize possible access errors:

SCL

```
POKE(AREA := 16#84,
     DBNUMBER := 1,
     BYTEOFFSET := 2,
     BITOFFSET := 4,
     VALUE := TRUE,
     ENO => ENO);
```

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
AREA	Input	BYTE	I, Q, M, D	The following areas can be selected: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB • 16#2: Peripheral output (S7-1500 only)
DBNUM-BER	Input	DINT, DB_ANY	D	Number of the data block if AREA = DB, otherwise "0"
BYTEOFF-SET	Input	DINT	I, Q, M, D	Address to be written Only the 16 least significant bits are used.
BITOFFSET	Input	INT	I, Q, M, D	Bit to be written
VALUE	Input	BOOL	I, Q, M, D	Value to be written

Note

If you write the memory bit to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
POKE_BOOL(AREA := "Tag_Area",
          DBNUMBER := "Tag_DBNumber",
          BYTEOFFSET := "Tag_Byte",
          BITOFFSET := "Tag_Bit",
          VALUE := "Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
AREA	Tag_Area	16#84
DBNUMBER	Tag_DBNumber	5
BYTEOFFSET	Tag_Byte	20
BITOFFSET	Tag_Bit	3
VALUE	Tag_Value	M0.0

The instruction overwrites the memory bit "3" in data block "5" in byte "20" with the value "M0.0".

POKE_BLK: Write memory area (S7-1200, S7-1500)

Description

The "Write memory area" instruction is used to write a memory area to a different standard memory area without specifying a data type.

Use of memory area 16#84: DB

If you use a data block as memory area and this is not yet known during the creation of the program code you have the option of using the EN/ENO mechanism to recognize possible access errors:

SCL

```
POKE_BLK(AREA_SRC := 16#84,
         DBNUMBER_SRC := 1,
         BYTEOFFSET_SRC := 2,
         AREA_DEST := 16#84,
         DBNUMBER_DEST := 11,
         BYTEOFFSET_DEST := 22,
         COUNT := 3,
         ENO => ENO);
```

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
AREA_SRC	Input	BYTE	I, Q, M, D	The following areas can be selected in the source memory area: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB
DBNUMBER_SRC	Input	DINT, DB_ANY [1]	D	Number of the data block in the source memory area, if AREA = DB, otherwise "0"
BYTEOFF-SET_SRC	Input	DINT	I, Q, M, D	Address in the source memory area to be written Only the 16 least significant bits are used.

Parameters	Declaration	Data type	Memory area	Description
AREA_DEST	Input	BYTE	I, Q, M, D	The following areas can be selected in the destination memory area: • 16#81: Input • 16#82: Output • 16#83: Bit memory • 16#84: DB
DBNUMBER_DEST	Input	DINT, DB_ANY [1]	D	Number of the data block in the destination memory area, if AREA = DB, otherwise "0"
BYTEOFFSET_DEST	Input	DINT	I, Q, M, D	Address in the destination memory area to be written Only the 16 least significant bits are used.
COUNT	Input	DINT	I, Q, M, D	Number of bytes which are copied
[1] The data types of the parameters DBNUMBER_SRC and DBNUMBER_DEST must have the same data type. In other words, both tags must be either data type DINT or data type DB_ANY.				

Note

If you write the memory address to the input, output or bit memory areas, you must assign the DBNUMBER parameter the value "0", as the instruction is invalid otherwise.

Example

The following example shows how the instruction works:

SCL

```
POKE_BLK(AREA_SRC := "Tag_Source_Area",
         DBNUMBER_SRC := "Tag_Source_DBNumber",
         BYTEOFFSET_SRC := "Tag_Source_Byte");
         AREA_DEST := "Tag_Destination_Area",
         DBNUMBER_DEST := "Tag_Destination_DBNumber",
         BYTEOFFSET_DEST := "Tag_Destination_Byte",
         COUNT := "Tag_Count");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
AREA_SRC	Tag_Source_Area	16#84
DBNUMBER_SRC	Tag_Source_DBNumber	5
BYTEOFFSET_SRC	Tag_Source_Byte	20
AREA_DEST	Tag_Destination_Area	16#83
DBNUMBER_DEST	Tag_Destination_DBNumber	0
BYTEOFFSET_DEST	Tag_Destination_Byte	30
COUNT	Tag_Count	100

The instruction writes 100 byte from data block "5" starting with address "20" in the memory area of the bit memory starting at address "30".

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

READ_LITTLE: Read data in little endian format (S7-1200, S7-1500)

Description

The instruction "Read data in little endian format" is used to read data from a memory area and to write this to a single tag in the little endian byte sequence. With the little endian format, the byte with the least significant bits is saved first, which means at the lowest memory address.

The parameters SRC_ARRAY and DEST_VARIABLE are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at parameter DEST_VARIABLE has to be an elementary data type. The VARIANT at the SRC_ARRAY parameter points to the memory area to be read from, and this must be an ARRAY of BYTE.

You can also use an actual parameter with variable ARRAY index for the parameters SRC_ARRAY and DEST_VARIABLE.

The operand at the POS parameter determines the position in the memory area at which reading starts.

Note

Reading tag of data type VARIANT or BOOL

If you want to read a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to read a tag of the data type BOOL, use a "Slice access".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200 V4.0 and higher	S7-1500		
SRC_ARRAY	Input	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to be read from
DEST_VARIABLE	Output	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Read value

Parameters	Declaration	Data type		Memory area	Description
		S7-1200 V4.0 and higher	S7-1500		
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the reading starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := READ_LITTLE(SRC_ARRAY := #SourceField,
                          DEST_VARIABLE => #DINTVariable,
                          POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
SRC_ARRAY	#SourceField	ARRAY[0..3] of BYTE := 16#1A, 16#2B, 16#3C, 16#4D
DEST_VARIABLE	#DINTVariable	1295788826 16#4D3C2B1A
POS	#TagPos	0 => 4

The instruction reads the integer 1_295_788_826 from the #SourceField memory area and writes it to the #DINTVariable operand in little endian format. The data type at the DEST_VARIABLE parameter specifies how many bytes are read. The quantity 4 is stored in the #TagPos operand.

Serialize: Serialize (Page 3293)

Basics of SCL (Page 4991)

WRITE_LITTLE: Write data in little endian format (S7-1200, S7-1500)

Description

You use the "Write data in little endian format" instruction to write the data of a single tag in the little endian byte sequence to a memory area. With the little endian format, the byte with the least significant bits is saved first, which means at the lowest memory address.

The parameters SRC_VARIABLE and DEST_ARRAY are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the SRC_VARIABLE parameter must point to an elementary data type. The VARIANT at the DEST_ARRAY parameter points to the memory area to which the data is written, and this must be an ARRAY of BYTE.

You can also use an actual parameter with variable ARRAY index for the parameters SRC_ARRAY and DEST_VARIABLE.

The operand at the POS parameter determines the position in the memory area at which writing starts.

Note

Writing tag of data type VARIANT or BOOL

If you want to write a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to write a tag of the data type BOOL, use a "Slice access".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200 V4.0 and higher	S7-1500		
SRC_VARIABLE	Input	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Tag whose data are written
DEST_ARRAY	InOut	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to which the data are written
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the writing starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := WRITE_LITTLE(SRC_VARIABLE := #DINTVariable,
                           DEST_ARRAY := #TargetField,
                           POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
SRC_VARIABLE	#DINTVariable	1295788826 16#4D3C2B1A
DEST_ARRAY	#TargetField	ARRAY[0..10] of BYTE = 16#1A, 16#2B, 16#3C, 16#4D
POS	#TagPos	0 => 4

The instruction writes the integer 1_295_788_826 from the #DINTVariable operand to the #TargetField memory area in little endian format. The data type at the SRC_VARIABLE parameter specifies how many bytes are written. The quantity 4 is stored in the #TagPos operand.

Serialize: Serialize (Page 3293)

Basics of SCL (Page 4991)

READ_BIG: Read data in big endian format (S7-1200, S7-1500)

Description

The instruction "Read data in little endian format" is used to read data from a memory area and to write this to a single tag in the big endian byte sequence. With the big endian format, the byte with the most significant bits is saved first, which means at the lowest memory address.

The parameters SRC_ARRAY and DEST_VARIABLE are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at parameter DEST_VARIABLE has to be an elementary data type. The VARIANT at the SRC_ARRAY parameter points to the memory area to be read from, and this must be an ARRAY of BYTE.

You can also use an actual parameter with variable ARRAY index for the parameters SRC_ARRAY and DEST_VARIABLE.

The operand at the POS parameter determines the position in the memory area at which reading starts.

Note

Reading tag of data type VARIANT or BOOL

If you want to read a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to read a tag of the data type BOOL, use a "Slice access".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200 V4.0 and higher	S7-1500		
SRC_ARRAY	Input	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to be read from
DEST_VARIABLE	Output	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Read value
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the reading starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := READ_BIG(SRC_ARRAY := #SourceField,
                       DEST_VARIABLE => #DINTVariable,
                       POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
SRC_ARRAY	#SourceField	ARRAY[0..10] of BYTE := 16#1A, 16#2B, 16#3C, 16#4D
DEST_VARIABLE	#DINTVariable	439041101 16#1A2B3C4D
POS	#TagPos	0 => 4

The instruction reads the integer 439_041_101 from the #SourceField memory area and writes it to the #DINTVariable operand in big endian format. The data type at the DEST_VARIABLE parameter specifies how many bytes are read. The quantity 4 is stored in the #TagPos operand.

Basics of SCL (Page 4991)

WRITE_BIG: Write data in big endian format (S7-1200, S7-1500)

Description

You use the "Write data in big endian format" instruction to write the data of a single tag in the big endian byte sequence to a memory area. With the big endian format, the byte with the most significant bits is saved first, which means at the lowest memory address.

The parameters SRC_VARIABLE and DEST_ARRAY are of data type VARIANT. However, there are a few restrictions regarding the data type with which the parameters can be interconnected. The VARIANT at the SRC_VARIABLE parameter must point to an elementary data type. The VARIANT at the DEST_ARRAY parameter points to the memory area to which the data is written, and this must be an ARRAY of BYTE.

You can also use an actual parameter with variable ARRAY index for the parameters SRC_ARRAY and DEST_VARIABLE.

The operand at the POS parameter determines the position in the memory area at which writing starts.

Note

Writing tag of data type VARIANT or BOOL

If you want to write a tag to which a VARIANT points, use the "Serialize" or "Deserialize" instructions.

If you want to write a tag of the data type BOOL, use a "Slice access".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200 V4.0 and higher	S7-1500		
SRC_VARIABLE	Input	Bit strings, integers, floating-point numbers, TOD, DATE, CHAR, WCHAR	Bit strings, integers, floating-point numbers, LDT, TOD, LTOD, DATE, CHAR, WCHAR	I, Q, M, D, L	Tag whose data are written
DEST_ARRAY	InOut	ARRAY of BYTE	ARRAY of BYTE	I, Q, M, D, L	Memory area to which the data are written
POS	InOut	DINT	DINT	I, Q, M, D, L	Determines the position at which the writing starts. The POS parameter is calculated zero-based.
Function value (RET_VAL)		INT	INT	I, Q, M, D, L	Error information

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B4	The data type at the SRC_ARRAY parameter is not ARRAY of BYTE.
8382	The value at the POS parameter is outside the limits of the ARRAY.
8383	The value at the POS parameter is within the limits of the ARRAY but the size of the memory area exceeds the high limit of the ARRAY.

Example

The following example shows how the instruction works:

SCL

```
#TagResult := WRITE_BIG(SRC_VARIABLE := #DINTVariable,
                        DEST_ARRAY := #TargetField,
                        POS := #TagPos);
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
SRC_VARIABLE	#DINTVariable	439041101 16#1A2B3C4D
DEST_ARRAY	#TargetField	ARRAY[0..10] of BYTE = 16#1A, 16#2B, 16#3C, 16#4D
POS	#TagPos	0 => 4

The instruction writes the integer 439_041_101 from the #DINTVariable operand to the #TargetField memory area in big endian format. The data type at the SRC_VARIABLE parameter specifies how many bytes are written. The quantity 4 is stored in the #TagPos operand.

Basics of SCL (Page 4991)

VARIANT (S7-1200, S7-1500)

VariantGet: Read out VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Read out VARIANT tag value" instruction to read the value of the tag to which the VARIANT at the SRC parameter points and write it in the tag at the DST parameter.

The SRC parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the DST parameter.

The data type of the tag specified at the DST parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT instruction: Move block" instruction. For additional information, refer to "See also".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
SRC	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be read
DST	Output	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
VariantGet(SRC := #TagIn_Source,
           DST => "TagOut_Dest");
```

The value of the tag to which the VARIANT at the "#TagIn_Source" operand points, is read and written to the "TagOut_Dest" operand.

See also

Overview of the valid data types (Page 2239)

MOVE_BLK_VARIANT: Move block (Page 3309)

Basics of SCL (Page 4991)

VariantPut: Write VARIANT tag value (S7-1200, S7-1500)

Description

You can use the "Write VARIANT tag value" instruction to write the value of the tag at the SRC parameter to the memory at the DST parameter to which the VARIANT points.

The DST parameter has the VARIANT data type. Any data type except for VARIANT can be specified at the SRC parameter.

The data type of the tag at the SRC parameter must match the data type to which the VARIANT points.

Note

To copy structures and ARRAYs, you can use the "MOVE_BLK_VARIANT instruction: Move block" instruction. For additional information, refer to "See also".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area		Description
			S7-1200	S7-1500	
SRC	Input	Bit strings, integers, floating-point numbers, timers, date and time, character strings, ARRAY elements, PLC data types	I, Q, M, D, L	I, Q, M, D, L, P	Tag to be read
DST	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	L (A declaration in the "Temp" section of the block interface is not possible.)	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
VariantPut(SRC := "TagIn_Source",
           DST := #TagIn_Dest);
```

The value of the "TagIn_Source" operand is written to the tag to which the VARIANT at the #TagIn_Dest operand points.

See also

Overview of the valid data types (Page 2239)

MOVE_BLK_VARIANT: Move block (Page 3309)

Basics of SCL (Page 4991)

CountOfElements: Get number of ARRAY elements (S7-1200, S7-1500)

Description

You use the "Get number of ARRAY elements" instruction to query how many ARRAY elements a tag to which VARIANT points has.

If it is a multi-dimensional ARRAY, the number of ARRAY elements is output as the result. (The difference between the high and low limit +1). If it is a multi-dimensional ARRAY, the number of all dimensions is output as the result.

Note

Instances

The VARIANT pointer can point to no instance and therefore also to no multi-instance or an ARRAY of multi-instances.

Note

ARRAY within a data block

If you want to query the number of the elements of an ARRAY which is located in a data block, the block attribute "Data block write-protected in the device" must not be activated in this block. Otherwise, the RET_VAL parameter returns the result "0", irrespective of how many elements the ARRAY contains.

The result is also "0" if the VARIANT tag is not an ARRAY.

If the VARIANT points to an ARRAY of BOOL, the fill elements are included in the count. (For example, 8 is returned for an ARRAY[0..1] of BOOL).

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be queried
Function value		UDINT	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
IF IS_ARRAY(#Tag_VARIANTToArray) THEN
"Tag_Result" := CountOfElements(#Tag_VARIANTToArray);
```

SCL

```
END_IF;
```

If the tag to which the VARIANT points is an ARRAY, the number of ARRAY elements is output.

Basics of SCL (Page 4991)

ARRAY[*] (S7-1200, S7-1500)

LOWER_BOUND: Read out low ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

The "Read out ARRAY low limit" instruction is used to read out the variable low limit of the ARRAY.

Note

Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable low limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable low limit is to be read.
Function value		DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

SCL

```
"Result" := LOWER_BOUND(ARR := #ARRAY_A,
                        DIM := 2);
```

The instruction reads out the variable low limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Result".

See also

Overview of the valid data types (Page 2239)

Basic information on ARRAY (Page 2286)

Basics of SCL (Page 4991)

UPPER_BOUND: Read out high ARRAY limit (S7-1200, S7-1500)

Description

You can declare tags of the data type ARRAY[*] in the block interface of a function block or function. For these local tags, you can read out the limits of the ARRAY. You will need to specify the required dimension at the DIM parameter.

The instruction "Read out ARRAY high limit" is used to read out the variable high limit of the ARRAY.

Note

Availability of the instruction

The instruction is available for a CPU of the S7-1200 series as of firmware version >= 4.2, and for a CPU of the S7-1500 series as of firmware version >= 2.0.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
ARR	Input	ARRAY[*]	FB => Section In-Out FC => Sections Input and InOut	ARRAY of which the variable high limit is to be read.
DIM	Input	UDINT	I, Q, M, D, L, P or constant	Dimension of the ARRAY of which the variable high limit is to be read.
Function value		DINT	I, Q, M, D, L, P	Result

Example

The following example shows how the instruction works:

SCL

```
"Result" := UPPER_BOUND(ARR := #ARRAY_A,
                        DIM := 2);
```

The instruction reads out the variable high limit of the ARRAY #ARRAY_A from the second dimension. If the instruction is executed without errors, the result is written to operand "Result".

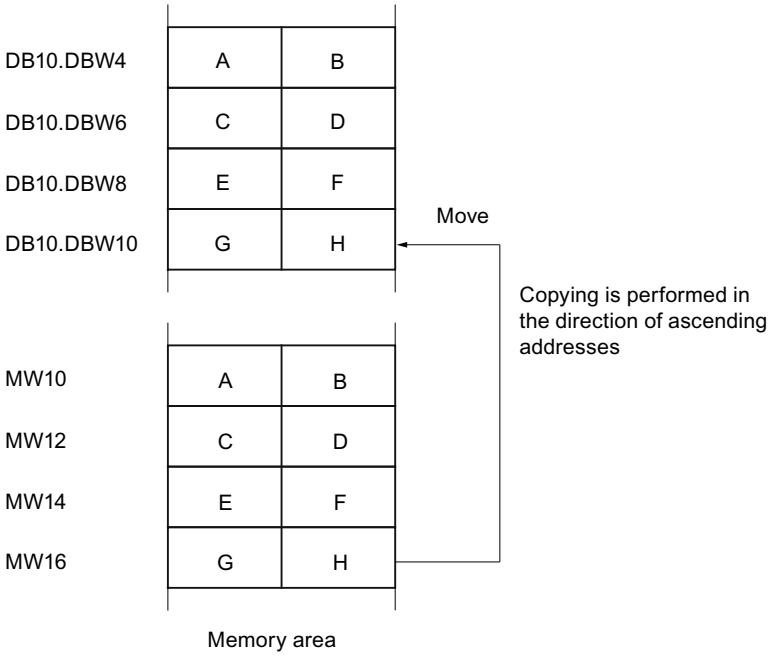
Legacy (S7-1500)

BLKMOV: Move block (S7-1500)

Description



You can use the "Move block" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can also use this tag in memory areas "with optimized block access".

The following figure shows the principle of the move operation:

Consistency of source and destination data

Note that while the instruction "Move block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Interruptibility

There is no limit to the nesting depth.

Memory areas

You can use the "Move block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the source and destination areas have different lengths, only the length of the smaller area will be moved.

If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

Rules for moving character strings

You can use the "Move block" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length is also written to the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved.

If you want to move the information on the maximum and actual length of a character string, specify the areas in bytes in the SRCBLK and DSTBLK parameters.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).
DSTBLK	Output 1)	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
Function value (RET_VAL)		INT	I, Q, M, D, L, P	Error information
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8092	The source or target area is only available in the load memory.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported for the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported for the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := BLKMOV(SRCBLK := P#M100.0 BYTE 10,
                       DSTBLK => P#DB1.DBX0.0 BYTE 10);
```

The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

Overview of the valid data types (Page 2239)

GET_ERR_ID: Get error ID locally (Page 3409)

Basics of SCL (Page 4991)

UBLKMOV: Move block uninterruptible (S7-1500)

Description

You can use the "Move block uninterruptible" instruction to move the content of a memory area (source area) to another memory area (destination area). The move operation takes place in the direction of ascending addresses. You use VARIANT to define the source and destination areas.

The move operation cannot be interrupted by other operating system activities. As a result, the interrupt reaction time of the CPU can increase during the execution of the "Move block uninterruptible" instruction.

Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can also use this tag in memory areas "with optimized block access".

Memory areas

You can use the "Move block uninterruptible" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination area must not overlap during the execution of the "Move block uninterruptible" instruction. If the source area is smaller than the destination area, the entire source area will be written to the destination area. The remaining bytes of the destination area remain unchanged.

If the destination area is smaller than the source area, the entire destination area will be written. The remaining bytes of the source area are ignored.

If a source or destination area defined as a formal parameter is smaller than a destination or source area specified in the SRCBLK or DSTBLK parameter, no data is transferred.

If a block of data type BOOL is moved, the tag must be addressed absolutely and the specified length of the area must be divisible by 8, otherwise the instruction cannot be executed.

You can use the "Move block uninterruptible" instruction to move a maximum of 16 KB. Note the CPU-specific restrictions for this.

Rules for moving character strings

You can use the "Move block uninterruptible" instruction to also move source and destination areas of the STRING data type. If only the source area is STRING data type, the characters will be moved that are actually contained in the character string. Information on the actual and maximum length are not written in the destination area. If the source and destination area are both STRING data type, the current length of the character string in the destination area is set to the number of characters actually moved. If areas of the STRING data type are moved, specify "1" as the area length.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
SRCBLK	Input	VARIANT	I, Q, M, D, L, P	Specifies the memory area to be moved (source area).
DSTBLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specifies the memory area to which the block is to be moved (destination area).
Function value (RET_VAL)		INT	I, Q, M, D, L, P	Error information
1) The DSTBLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8091	The source or target area is only available in the load memory.

Error code (W#16#...)	Explanation
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported for the SRCBLK parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported for the DSTBLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := UBLKMOV(SRCBLK := P#M100.0 BYTE 10,
                        DSTBLK => P#DB1.DBX0.0 BYTE 10);
```

The instruction copies 10 bytes starting from MB100 and writes them to DB1. If an error occurs during the move operation, its error code is output in the "Tag_RetVal" tag.

See also

Overview of the valid data types (Page 2239)

GET_ERR_ID: Get error ID locally (Page 3409)

Basics of SCL (Page 4991)

FILL: Fill block (S7-1500)

Description

You can use the "Fill block" instruction to fill a memory area (destination area) with the content of another memory area (source area). The "Fill block" instruction moves the content of the source area to the destination area until the destination area is completely written. The move operation takes place in the direction of ascending addresses.

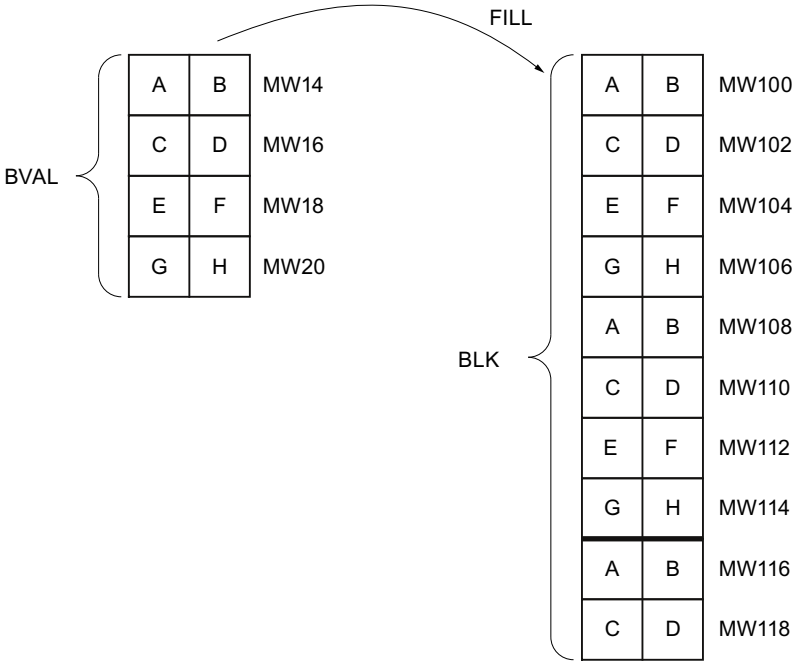
You use VARIANT to define the source and destination areas.

Note

You can also define the source and destination areas using the ANY data type

If you use the ANY data type, you must observe the following in connection with the STRING data type:

- In the case of an assignment of STRING (source area) using ANY after STRING (destination area), the content of the STRING is copied to the destination area repeatedly until it is full.
  Source area: 'STEP7-SCL-TIA-Portal'
  Destination area: 'STEP7-SCL-TIA-PortalSTEP7-SCL-TIA-PortalSTEP7-SCL'
- In the case of an assignment of WSTRING (source area) using ANY after WSTRING (destination area), the entire WSTRING including type information is copied only once to the destination area.
  Source area: WSTRING#'STEP7-SCL-TIA-Portal'
  Destination area: WSTRING#'STEP7-SCL-TIA-Portal'



Note

The tags of the instruction can only be used within memory areas in which the "Optimized block access" attribute is not activated. This applies to data blocks (DBs), organization blocks (OBs), functions (FCs), bit memory (M), inputs (I), and outputs (Q).

If a tag of the instruction has been declared with the retentivity setting "Set in IDB", however, you can also use this tag in memory areas "with optimized block access".

For blocks with the "Optimized block access" attribute, you can use the "FILL_BLK instruction: Fill block" instruction.

The following figure shows the principle of the move operation:

Example: The contents of the range MW100 to MW118 are to be preassigned with the contents of the memory words MW14 to MW20.

Consistency of source and destination data

Note that while the instruction "Fill block" is being executed, the source data remains unchanged; otherwise the consistency of the destination data cannot be guaranteed.

Memory areas

You can use the "Fill block" instruction to move the following memory areas:

- Areas of a data block
- Bit memory
- Process image input
- Process image output

General rules for moving

The source and destination areas must not overlap. If the destination area to be preset is not an integer multiple of the length of the BVAL input parameter, the destination area is nevertheless written up to the last byte.

If the destination area to be preset is smaller than the source area, the function only copies as much data as can be written to the destination area.

If the destination or source area actually present is smaller than the assigned memory area for the source or destination area (BVAL, BLK parameters), no data is transferred.

If the ANY pointer (source or destination) is of the data type BOOL, it must be addressed absolutely and the length specified must be divisible by 8; otherwise the instruction is not executed.

If the destination area is STRING data type, the instruction writes the entire string including the administration information.

Rules for moving structures

When you transfer a structure as an input parameter you must bear in mind that the length of a structure is always oriented to an even number of bytes. The structure will need one byte of additional memory space if you declare a structure with an odd number of bytes.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
BVAL	Input	VARIANT	I, Q, M, D, L, P	Specification of the memory area (source area), the content of which is used to fill the destination area at the BLK parameter.
BLK	Output [1)]	VARIANT	I, Q, M, D, L, P	Specification of the memory area that will be filled with the content of the source area.
Function value (RET_VAL)		INT	I, Q, M, D, L, P	Error information
1) The BLK parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

BVAL parameter

When you transfer a structure as an input parameter, remember that the length of a structure is always based on an even number of bytes. The structure will need one byte of additional memory space if you declare a structure with an odd number of bytes.

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
8092	The source or target area is only available in the load memory.
8152	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported for the BVAL parameter.
8352	The WSTRING, WCHAR, BOOL, and ARRAY of STRING data types are not supported at the BLK parameter.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_RetVal" := FILL(BVAL := P#M14.0 WORD 4,
                     BLK => P#M100.0 WORD 10);
```

The instruction copies the source area from MW14 to MW20 and fills the destination area from MW100 to MW118 with the content of the 4 words contained in the memory area in the BVAL parameter.

GET_ERR_ID: Get error ID locally (Page 3409)

Basics of SCL (Page 4991)

Conversion operations (S7-1200, S7-1500)

CONVERT: Convert value (S7-1200, S7-1500)

Description

Use the "Convert value" instruction to program explicit conversions. When the instruction is inserted, the "CONVERT" dialog opens. You specify the source data type and the destination data type of the conversion in this dialog. The source value is read and converted to the specified destination data type.

Conversion options for bit strings

BYTE and WORD bit strings cannot be selected in the instruction box. However, it is possible to specify an operand of data type DWORD or LWORD at a parameter of the instruction if the lengths of the input and output operands match. The operand is then interpreted by the data type of a bit string according to the data type of the input or output parameter and is implicitly converted. The data type DWORD is for example interpreted as DINT/UDINT and LWORD as LINT/ULINT. These conversion options are also available to you when "IEC check" is enabled.

Note

For CPUs of the S7-1500 series: The data types DWORD and LWORD can only be converted to or from data type REAL or LREAL.

During the conversion, the bit pattern of the source value is transferred unchanged, right-justified, to the target data type. If no errors occur during the conversion, the signal state of enable output ENO = 1; if an error occurs during processing, the signal state of the enable output ENO = 0.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Source type>	Input	Binary numbers, integers, floating-point numbers, times, date and time, character strings, BCD16, BCD32	I, Q, M, D, L, P or constant	Value to be converted.
<Destination type>	Output	Binary numbers, integers, floating-point numbers, times, date and time, character strings, BCD16, BCD32	I, Q, M, D, L, P or constant	Result of the conversion

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_INT" := REAL_TO_INT("Tag_REAL");
```

The following table shows how the instruction works using specific operand values:

Operand	Data type	Value
Tag_REAL	REAL	20.56
Tag_INT	INT	21

During the conversion, the value of the "Tag_REAL" operand will be rounded to the nearest integer and saved in the "Tag_INT" operand.

Basics of SCL (Page 4991)

ROUND: Round numerical value (S7-1200, S7-1500)

Description

The "Round numerical value" instruction is used to round the value at input IN to the nearest integer. The instruction interprets the value at input IN as a floating-point number and converts it into an integer or floating-point number. If the input value is exactly between an even and odd number, the even number is selected.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value to be rounded.
Function value		Integers, floating-point numbers	I, Q, M, D, L, P	Result of the rounding

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ROUND("Tag_Value");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	1.50000000	-1.50000000
Tag_Result	2	-2

CEIL: Generate next higher integer from floating-point number (S7-1200, S7-1500)

Description

Use the "Generate next higher integer from floating-point number" instruction to round the value to the nearest integer. The instruction interprets the input value as floating-point number and converts it to the next higher integer. The function value can be greater than or equal to the input value.

Use the following syntax to change the data type of the instruction:

CEIL_<data type>();

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Integers, floating-point numbers Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Input value rounded up

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := CEIL("Tag_Value");
"Tag_Result2" := CEIL_REAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0.5	-0.5
Tag_Result1	1	0
Tag_Result2	1.0	0.0

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

Basics of SCL (Page 4991)

FLOOR: Generate next lower integer from floating-point number (S7-1200, S7-1500)

Description

Use the "Generate next lower integer from floating-point number" instruction to round the value of a floating point number to the next lower integer. The instruction interprets the input value as floating-point number and converts it to the next lower integer. The function value can be equal or less than the input value.

Use the following syntax to change the data type of the instruction:

FLOOR_<data type>();

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L, P	Input value
_<Data type>		Integers, floating-point numbers Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Input value rounded

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := FLOOR("Tag_Value");
"Tag_Result2" := FLOOR_REAL("Tag_Value");
```

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0.5	-0.5
Tag_Result1	0	-1
Tag_Result2	0.0	-1.0

The result of the instruction is returned in the operand "Tag_Resultxy" as a function value.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

TRUNC: Truncate numerical value (S7-1200, S7-1500)

Description

The "Truncate numerical value" instruction is used to generate an integer from the input value without rounding. The instruction selects only the integer part of the input value and returns this part without decimal places as the function value.

Use the following syntax to change the data type of the instruction:

TRUNC_<data type>();

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Expression>	Input	Floating-point numbers	I, Q, M, D, L	Input value
_<Data type>		Integers, floating-point numbers Default: DINT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	I, Q, M, D, L	Integer component of the input value

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result1" := TRUNC("Tag_Value1");
"Tag_Result2" := TRUNC("Tag_Value2"+"Tag_Value3");
"Tag_Result3" := TRUNC_SINT("Tag_Value4");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Value1	-1.5
Tag_Result1	-1
Tag_Value2	2.1
Tag_Value3	3.2
Tag_Result2	5
Tag_Result3	2
Tag_Value4	2.4

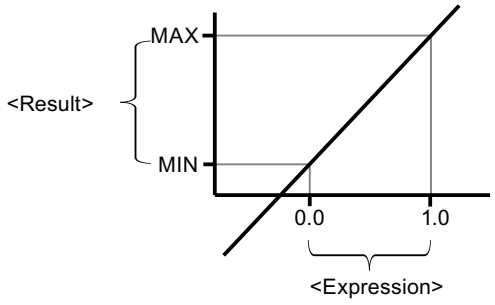
Basics of SCL (Page 4991)

SCALE_X: Scale (S7-1200, S7-1500)



Description

Use the "Scale" instruction to scale a floating-point number by mapping it to a specific value range. You specify the value range with the MIN and MAX parameters. The result of the scaling is an integer.

Use the following syntax to change the data type of the instruction:

SCALE_X_<data type>();

The following figure shows an example of how values can be scaled:

The "Scale" instruction works with the following equation:

OUT = [VALUE * (MAX – MIN)] + MIN

Note

For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
MIN	Input	Integers, floating-point numbers	I, Q, M, D, L	Low limit of the value range
VALUE	Input	Floating-point numbers	I, Q, M, D, L	Value to be scaled. If you enter a constant, you must declare it.
MAX	Input	Integers, floating-point numbers	I, Q, M, D, L	High limit of the value range
_<Data type>		Integers, floating-point numbers Default: INT	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Integers, floating-point numbers	-	Result of scaling

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := SCALE_X(MIN := "Tag_Value1",
                         VALUE := "Tag_Real",
                         MAX := "Tag_Value2");
"Tag_Result2" := SCALE_X_REAL(MIN := "Tag_Value1",
                              VALUE := "Tag_Real",
                              MAX := "Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_Real	0.5
Tag_Value1	10
Tag_Value2	30
Tag_Result1	20
Tag_Result2	20.0

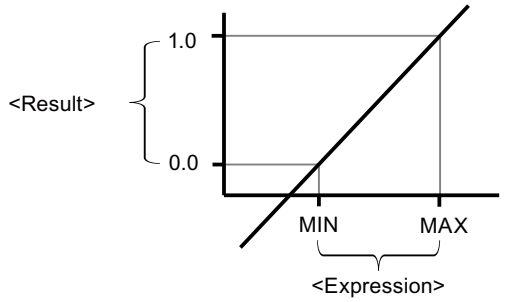
Basics of SCL (Page 4991)

NORM_X: Normalize (S7-1200, S7-1500)



Description

You can use the instruction "Normalize" to normalize the value of the tag at the VALUE input by mapping it to a linear scale. You can use the MIN and MAX parameters to define the limits of a value range that is applied to the scale. The result at the OUT output is calculated and stored as a floating-point number depending on the location of the value to be normalized within this value range. If the value to be normalized equals the value at input MIN, the instruction returns the result "0.0". If the value to be normalized equals the value at input MAX, the instruction returns the result "1.0".

Use the following syntax to change the data type of the instruction:

NORM_X_<data type>();

The following figure shows an example of how values can be normalized:

The "Normalize" instruction works with the following equation:

OUT = (VALUE – MIN) / (MAX – MIN)

Note

For more information on the conversion of analog values, refer to the respective manual.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
MIN [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L	Low limit of the value range
VALUE [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L	Value to be normalized.
MAX [1)]	Input	Integers, floating-point numbers	I, Q, M, D, L	High limit of the value range

Parameters	Declaration	Data type	Memory area	Description
_<Data type>		Floating-point numbers Default: REAL	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Floating-point numbers	I, Q, M, D, L	Result of the normalization
[1] If you use constants in these three parameters, you only need to declare one of them.				

For additional information on valid data types, refer to "See also".

For additional information on declaring constants, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result1" := NORM_X(MIN := "Tag_Value1",
                        VALUE := "Tag_InputValue",
                        MAX := "Tag_Value2");
"Tag_Result2" := NORM_X_LREAL(MIN := "Tag_Value1",
                              VALUE := "Tag_InputValue",
                              MAX := "Tag_Value2");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value
Tag_InputValue	20
Tag_Value1	10
Tag_Value2	30
Tag_Result1	0.5
Tag_Result2	0.5

Basics of SCL (Page 4991)

VARIANT (S7-1200, S7-1500)

VARIANT_TO_DB_ANY: Convert VARIANT to DB_ANY (S7-1200, S7-1500)

Description

You use the "Convert VARIANT to DB_ANY" instruction to query the data block number that the operand that is specified at the IN parameter addresses. This can be an instance data block or an ARRAY data block. The operand at the IN parameter has the data type VARIANT, which means you do not need to know the data type of the data block whose number is to be queried when the program is created. The data block number is read during runtime and written to the operand specified at the RET_VAL parameter.

Requirements

If the requirements are met, the instruction is executed. If the requirements are not met, "0" is output as data block number.

The output tag...	homed...	Conversion options
VARIANT	... a data block which is an instance data block of a PLC data type or a system data type (SDT).	The output tag can be converted to a data block number.
VARIANT	... a data block which is an ARRAY DB.	The output tag can be converted to a data block number.
VARIANT	... a tag with an elementary data type.	It is not possible to convert the output tag to a database number because a data block can never comprise only one elementary data type.
VARIANT	... a structure within a data block.	It is not possible to convert the output tags to a database number because it is only a part within the data block.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Tag to be read. (The function value of the "DB_ANY_TO_VARIANT" instruction). You can use a local or global tag at the IN parameter.
ERR	Output	INT	I, Q, M, D, L	Error information
Function value (RET_VAL)		DB_ANY	I, Q, M, D, L	Result: Number of the DB

For additional information on valid data types, refer to "See also".

ERR parameter

The following table shows the meaning of the values of the ERR parameter:

Error code* (W#16#...)	Explanation
0000	No error
252C	The VARIANT data type at the IN parameter has the value "0" and the CPU changes to STOP mode.
80B4	The element data type stored in the ARRAY data block does not match the element data type transferred in the VARIANT.
8131	The data block does not exist, is too short, or is located in load memory.
8132	The data block is too short and not an ARRAY data block.
8150	The data type VARIANT at parameter IN provides the value "0". To receive this error message, the "Handle errors within block" block property must be activated. Otherwise the CPU changes to STOP mode and sends the error code 16#252C.
8153	The VARIANT data type at the IN parameter does not point to the start of an ARRAY data block or the length of the VARIANT does not match that of the data block.
8154	The data block has the incorrect data type.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"OutputDBNumber" := VARIANT_TO_DB_ANY(IN := #tempVARIANT,
                                      ERR := "Tag_Error");
```

The following table shows how the instruction works using specific operand values:

Parameters	Declaration in the block interface	Operand	Value
IN	Input	tempVARIANT	-
<function value>	Output	OutputDBNumber	11

The number of a data block that is specified at the tempVARIANT operand is read. Because the operand has the data type VARIANT, you do not need to know the data type of the tag during program creation. The number is written to the "OutputDBNumber" tag which has the data type DB_ANY.

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

DB_ANY_TO_VARIANT: Convert DB_ANY to VARIANT (S7-1200, S7-1500)

Description

The "Convert DB_ANY to VARIANT" instruction is used to generate a VARIANT tag from a data block that meets the requirements listed below. The operand at the IN parameter has the data type DB_ANY, which means that the data block does not have to be known when the program is created. The data block number is read during runtime.

Requirements

If the requirements are met, the instruction is executed. If the requirements are not met or the data block does not exist, the value NULL is output at the RET_VAL parameter. All other accesses with the RET_VAL tag fail.

The input tag of data type ...	homed...	Conversion options
DB_ANY	...a data block which is an instance data block of a PLC data type or a system data type (SDT).	Conversion is possible
DB_ANY	...a data block which is an ARRAY DB.	Conversion is possible
DB_ANY	...a data block which is an instance data block of a function block or a global data block.	Conversion is not possible

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	DB_ANY	I, Q, M, D, L	Data block whose number is read. You can use a local or global tag at the IN parameter.
ERR	Output	INT	I, Q, M, D, L	Error information
Function value (RET_VAL) [1]		VARIANT	L (A declaration in the "Temp" section of the block interface is not possible.)	Number of the data block
1) The RET_VAL parameter is declared as Output, since the data flow into the tag. However, the tag itself must be declared as InOut in the block interface.				

For additional information on valid data types, refer to "See also".

ERR parameter

The following table shows the meaning of the values of the ERR parameter:

Error code* (W#16#...)	Explanation
0000	No error
8130	The number of the data block is "0"
8131	The data block does not exist, is too short, or is located in load memory.
8132	The data block is too short and not an ARRAY data block.
8134	The data block is write protected.
8154	The data block has the incorrect data type.
8155	The data block has an unknown data type. [1]
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

[1] The reason for the error code #8155 to be output is:

A PLC data type (UDT1) was declared and a data block (DB2) of the data type "UDT1" was created. The tag table contains a tag (3) of the data type DB_ANY. Next the instruction "DB_ANY_TO_VARIANT" was called in a program block (4) and supplied with the tag (3) at the IN parameter. During execution the instruction "DB_ANY_TO_VARIANT" returns the error code 16#8155.

Follow these steps to resolve the error code:

1. Create a function (FC5) and declare a tag of the data type VARIANT at the InOut interface.
2. Create an additional function (FC6) and call FC5 in it.
3. Create a tag (7) of the data type "UDT1" in FC6 in the Temp interface.

4. Supply the InOut interface of the FC5 with tag (7).
5. Compile and download the two blocks (FC5 and FC6) to your CPU. You do not need to call these blocks (FC5 und FC6) in the user program.

Result:

The error code 16#8155 is no longer output because the user program is now familiar with the data type.

This procedure is not necessary if you call one of the two instructions "VariantGet" or "VariantPut" after calling the instruction "DB_ANY_TO_VARIANT".

Example

The following example shows how the instruction works:

SCL

```
#tempVARIANT := DB_ANY_TO_VARIANT(IN := "InputDB",
                                  ERR := "Tag_Error");
```

The following table shows how the instruction works using specific operand values:

Parameters	Declaration in the block interface	Operand	Value
IN	Input	InputDB	11
<function value>	Temp	tempVARIANT	-

The number of any data block that is specified at the "InputDB" operand is used to generate a tag of data type VARIANT that addresses the data block. Because the operand at the IN parameter has the DB_ANY data type, the data block that will be used during runtime does not have to be known when the program is created (neither the name nor the number of the data block). Because the operand at the RET_VAL parameter has the data type VARIANT, you do not need to know the data type of the data block when the program is created.

Basics of SCL (Page 4991)

Legacy (S7-1500)

SCALE: Scale (S7-1500)

Description

Use the "Scale" instruction to convert the integer at the IN parameter into a floating-point number that can be scaled in physical units between a low limit value and a high limit value. You can use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is scaled. The result of the instruction is output at the OUT parameter.

The "Scale" instruction works with the following equation:

OUT = [((FLOAT (IN) – K1)/(K2–K1)) * (HI_LIM–LO_LIM)] + LO_LIM

The values of the "K1" and "K2" constants are determined by the signal state on the BIPOLAR parameter. The following signal states are possible at the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at the IN parameter is greater than the value of the constant "K2", the result of the instruction is set to the value of the high limit (HI_LIM) and an error is output.

When the value at the IN parameter is less than the value of the constant "K1", the result of the instruction is set to the value of the low limit value (LO_LIM) and an error is output.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled inversely proportionate to the input value.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	INT	I, Q, M, D, L, P	Input value to be scaled.
HI_LIM	Input	REAL	I, Q, M, D, L, P	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L	Indicates whether the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	REAL	I, Q, M, D, L, P	Result of the instruction
Function value (RET_VAL)		WORD	I, Q, M, D, L, P	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
0008	The value of the parameter IN is greater than 27 648 or is less than 0 (unipolar) or -27 648 (bipolar).
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_ErrorCode" := SCALE(IN := "Tag_InputValue",
                         HI_LIM := "Tag_HighLimit",
                         LO_LIM := "Tag_LowLimit",
                         BIPOLAR := "Tag_Bipolar",
                         OUT => "Tag_Result");
```

The error information is returned in the operand "Tag_ErrorCode" as a function value.

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_InputValue	22
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_Result	50.03978588
RET_VAL	Tag_ErrorCode	W#16#0000

Overview of the valid data types (Page 2239)

GET_ERR_ID: Get error ID locally (Page 3409)

Basics of SCL (Page 4991)

UNSCALE: Unscale (S7-1500)

Description

You use the "Unscale" instruction to unscale the floating-point number in the IN parameter into physical units between a low limit and a high limit and convert it into an integer. You use the LO_LIM and HI_LIM parameters to specify the low limit and high limit of the value range to which the input value is unscaled. The result of the instruction is output at the OUT parameter.

The "Unscale" instruction works with the following equation:

OUT = [((IN–LO_LIM)/(HI_LIM–LO_LIM)) * (K2–K1)] + K1

The values of the "K1" and "K2" constants are determined by the signal state at the BIPOLAR parameter. The following signal states are possible at the BIPOLAR parameter:

- Signal state "1": It is assumed that the value at the IN parameter is bipolar and in a value range between -27648 and 27648. In this case, the constant "K1" has the value -27648.0 and the constant "K2" the value +27648.0.
- Signal state "0": It is assumed that the value at the IN parameter is unipolar and in a value range between 0 and 27648. In this case, the constant "K1" has the value 0.0 and the constant "K2" the value +27648.0.

When the value at parameter IN is not within the limits defined by HI_LIM and LO_LIM, an error is output and the result is set to the nearest limit.

When the indicated low limit value is greater than the high limit value (LO_LIM > HI_LIM), the result is scaled in reverse proportion to the input value.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	REAL	I, Q, M, D, L, P	Input value to be unscaled to an integer value.
HI_LIM	Input	REAL	I, Q, M, D, L, P	High limit
LO_LIM	Input	REAL	I, Q, M, D, L, P	Low limit
BIPOLAR	Input	BOOL	I, Q, M, D, L	Indicates whether the value at the IN parameter is to be interpreted as bipolar or unipolar. The parameter can assume the following values: 1: Bipolar 0: Unipolar
OUT	Output	INT	I, Q, M, D, L, P	Result of the instruction
Function value (RET_VAL)		WORD	I, Q, M, D, L, P	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code (W#16#...)	Explanation
0000	No error
0008	The value of the IN parameter is greater than the value of the high limit (HI_LIM) or less than the value of the low limit (LO_LIM).
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. You can find information on switching the display formats here: AUTOHOTSPOT	

Example

The following example shows how the instruction works:

```
"Tag_ErrorCode" := UNSCALE(IN := "Tag_InputValue",
                           HI_LIM := "Tag_HighLimit",
                           LO_LIM := "Tag_LowLimit",
                           BIPOLAR := "Tag_Bipolar",
                           OUT => "Tag_Result");
```

The error information is returned in the operand "Tag_ErrorCode" as a function value.

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_InputValue	50.03978588
HI_LIM	Tag_HighLimit	100.0
LO_LIM	Tag_LowLimit	0.0
BIPOLAR	Tag_Bipolar	1
OUT	Tag_Result	22
RET_VAL	Tag_ErrorCode	W#16#0000

Basics of SCL (Page 4991)

Program control operations (S7-1200, S7-1500)

IF: Run conditionally (S7-1200, S7-1500)

Description

The instruction "Run conditionally" branches the program flow depending on a condition. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

Parameters

Depending on the type of branch, you can program the following forms of the instruction:

- Branch through IF:
  IF <condition> THEN <instructions>
  END_IF;

If the condition is satisfied, the instructions programmed after the THEN are executed. If the condition is not satisfied, the execution of the program continues with the next instruction after the END_IF.

- Branch through IF and ELSE:
  IF <condition> THEN <instructions1>
  ELSE <Instructions0>
  END_IF;

If the condition is satisfied, the instructions programmed after the THEN are executed. If the condition is not satisfied, the instructions programmed after the ELSE are executed. Then the execution of the program continues with the next instruction after the END_IF.

- Branch through IF, ELSIF and ELSE:
  IF <condition1> THEN <instructions1>
  ELSIF <condition2> THEN <instruction2>
  ELSE <Instructions0>
  END_IF;

If the first condition (<Condition1>) is satisfied, the instructions (<Instructions1>) after the THEN are executed. After execution of the instructions, the execution of the program continues after the END_IF.

If the first condition is not satisfied, the second condition (<Condition2>) is checked. If the second condition (<Condition2>) is fulfilled, the instructions (<Instructions2>) after the THEN are executed. After execution of the instructions, the execution of the program continues after the END_IF.

If none of the conditions are fulfilled, the instructions (<Instructions0>) after ELSE are executed followed by the execution of the program after END_IF.

You can nest as many combinations of ELSIF and THEN as you like within the IF instruction. The programming of an ELSE branch is optional.

The syntax of the IF instruction consists of the following parts:

Parameters	Data type	Memory area	Description
<Condition>	BOOL	I, Q, M, D, L	Expression to be evaluated
<Instructions>	-		Instructions to be executed with satisfied condition. An exception are instructions programmed after the ELSE. These are executed if no condition within the program loop is satisfied.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
IF "Tag_1" = 1
THEN "Tag_Value" := 10;
ELSIF "Tag_2" = 1
THEN "Tag_Value" := 20;
ELSIF "Tag_3" = 1
THEN "Tag_Value" := 30;
ELSE "Tag_Value" := 0;
END_IF;
```

The following table shows how the instruction works using specific operand values:

Operand	Value			
Tag_1	1	0	0	0
Tag_2	0	1	0	0
Tag_3	0	0	1	0
Tag_Value	10	20	30	0

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

CASE: Create multiway branch (S7-1200, S7-1500)

Description

The instruction "Create multiway branch" executes one of several instruction sequences depending on the value of a numerical expression.

The value of the expression must be an integer. When the instruction is executed, the value of the expression is compared with the values of several constants. If the value of the

expression agrees with the value of a constant, the instructions programmed directly after this constant are executed. The constants can assume the following values:

- An integer (for example, 5)
- A range of integers (for example 15...20)
- An enumeration consisting of integers and ranges (for example, 10, 11, 15...20)

You can declare the instruction as follows:

CASE <Tag> OF

<Constant1>: <Instructions1>;

<Constant2>: <Instructions2>;

<ConstantX>: <InstructionsX>; // X >= 3

ELSE <Instructions0>;

END_CASE;

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
<Tag>	Integers	I, Q, M, D, L	Value which is compared to the programmed constant values.
<Constant>	Integers	-	Constant values which form the condition for the execution of an instruction sequence. The constants can assume the following values: • An integer (for example, 5) • A range of integers (for example 15...20) • An enumeration consisting of integers and ranges (for example, 10, 11, 15...20)
<Instruction>	-	-	Any instructions which are executed if the value of the expression agrees with the value of a constant. An exception are instructions programmed after the ELSE. These instructions are executed if the values do not agree.

For additional information on valid data types, refer to "See also".

If the value of the expression agrees with the value of the first constant (<Constant1>), the instructions (<Instructions1>) which are programmed directly after the first constant are executed. Program execution subsequently resumes after the END_CASE.

If the value of the expression does not agree with the value of the first constant (<Constant1>), this value is compared to the value of the constant which is programmed next. In this way, the CASE instruction is executed until the values agree. If the value of the expression does not correspond to any of the programmed constant values, the instructions (<Instructions0>) which are programmed after the ELSE are executed. ELSE is an optional part of the syntax and can be omitted.

The CASE instruction can also be nested by replacing an instruction block with CASE. END_CASE represents the end of the CASE instruction.

Example

The following example shows how the instruction works:

```
SCL
CASE "Tag_Value" OF
     0 :
          "Tag_1" := 1;
     1,3,5 :
          "Tag_2" := 1;
     6...10 :
          "Tag_3" := 1;
     16,17,20...25 :
          "Tag_4" := 1;
     ELSE
          "Tag_5" := 1;
END_CASE;
```

The following table shows how the instruction works using specific operand values:

Operand	Values				
Tag_Value	0	1, 3 , 5	6, 7, 8, 9, 10	16, 17, 20, 21, 22, 23, 24, 25	2
Tag_1	1	-	-	-	-
Tag_2	-	1	-	-	-
Tag_3	-	-	1	-	-
Tag_4	-	-	-	1	-
Tag_5	-	-	-	-	1
1: The operand is set to the signal state "1". -: The signal state of the operand remains unaltered.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

FOR: Run in counting loop (S7-1200, S7-1500)

Description

The instruction "Run in counting loop" causes repeated execution of a program loop until a loop variable lies within a specified value range.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

Note

Information on the number of runs and the run tag

The number of runs cannot be changed while the program is running.

For performance reasons, the run tag should be declared in the block interface in the "Temp" section. In addition, the run tag should not be changed while the program is running. Otherwise the instruction may return an undefined result depending on the implementation.

Limits for FOR statements

To program "safe" FOR statements that do not run endlessly, observe the following rules and limits:

FOR <Run_tag> := <Start_value> TO <End_value> BY <Increment> DO <Instructions>;

END_FOR;

If ...	... then	Note
Start value < End value	End value < (PMAX increment)	Run tag runs in positive direction
Start value > End value AND increment < O	End value > (NMAX increment)	Run tag runs in negative direction

Limits

Different limits apply to the possible data types:

Data type	PMAX	NMAX
Run tag of type SINT	127	-128
Run tag of type INT	32767	-32768
Run tag of type DINT	2147483647	-2147483648
Run tag of type LINT	9223372036854775807	-9223372036854775808

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type		Memory area	Description
	S7-1200	S7-1500		
<Run tag>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Operand whose value is evaluated with the loop execution. The data type of the loop variable determines the data type of the other parameters.
<Start value>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression whose value is allocated at the start of the loop execution of the loop variables.

Parameters	Data type		Memory area	Description
	S7-1200	S7-1500		
<End value>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression whose value defines the last run of the program loop. The value of the loop variable is checked before each loop: • End value not reached: The instructions according to DO are executed • End value is reached: The FOR loop is executed one last time • End value exceeded: The FOR loop is completed An alteration to the end value is not permitted during execution of the instruction.
<Increment>	SINT, INT, DINT	SINT, INT, DINT, LINT	I, Q, M, D, L	Expression by whose value the loop variable is increased (positive increment) or decreased (negative increment) after each loop. Specification of the increment is optional. If no increment is given, the value of the loop variable is increased by 1 after each loop. An alteration of the increment is not permitted during execution of the instruction.
<Instructions>	-	-		Instructions which are carried out with each loop, as long as the value of the loop variable lies within the value range. The value range is defined by the start and end values.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
FOR i := 2 TO 8 BY 2
    DO "a_array[i] := "Tag_Value"*"b_array[i]";
END_FOR;
```

The operand "Tag_Value" is multiplied with the elements (2, 4, 6, 8) of the ARRAY tag "b_array". The result is read in to the elements (2, 4, 6, 8) of the ARRAY tag "a_array".

CONTINUE: Recheck loop condition (Page 3393)

EXIT: Exit loop immediately (Page 3394)

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

WHILE: Run if condition is met (S7-1200, S7-1500)

Description

The instruction "Run if condition is met" causes a program loop to be repeatedly executed until the implementation condition is satisfied. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

You can declare the instruction as follows:

WHILE <Condition> DO <Instructions>;

END_WHILE;

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
<Condition>	BOOL	I, Q, M, D, L	Expression which is evaluated before each loop.
<Instruc-tions>	-		Instructions to be executed with satisfied condition. If the condition has not been satisfied, program execution continues after END_WHILE.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
WHILE
      "Tag_Value1" <> "Tag_Value2"
      DO "Tag_Result"
      := "Tag_Input";
END_WHILE;
```

As long as the values of the operands "Tag_Value1" and "Tag_Value2" do not match, the value of the operand "Tag_Input" is allocated to the operand "Tag_Result".

See also

EXIT: Exit loop immediately (Page 3394)

CONTINUE: Recheck loop condition (Page 3393)

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

REPEAT: Run if condition is not met (S7-1200, S7-1500)

Description

The instruction "Run if condition is not met" causes a program loop to be repeatedly executed until a termination condition is met. The condition is an expression with Boolean value (TRUE or FALSE). Logical expression or comparative expressions can be stated as conditions.

When the instruction is executed, the stated expressions are evaluated. If the value of an expression is TRUE, the condition is fulfilled; if the value is FALSE, it is not fulfilled.

The instructions are executed once, even if the termination condition is fulfilled.

Program loops can also be nested. Within a program loop, you can program additional program loops with other loop variables.

The current continuous run of a program loop can be ended by the instruction "Recheck loop condition" (CONTINUE). The instruction "Exit loop immediately" (EXIT) ends the entire loop execution. For additional information on this topic, refer to "See also".

You can declare the instruction as follows:

REPEAT <instructions>;

UNTIL <condition> END_REPEAT;

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
<Instruc-tions>	-		Instructions that are executed as long as the programmed condition has the value FALSE. The instructions are executed once, even if the termination condition is fulfilled.
<Condition>	BOOL	I, Q, M, D, L	Expression which is evaluated after each loop. If the expression has the value FALSE, the program loop is executed once again. If the expression has the value TRUE, the program loop continues after END_REPEAT.

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
REPEAT "Tag_Result"
        := "Tag_Value";
UNTIL "Tag_Error"
END_REPEAT;
```

As long as the value of the operand "Tag_Error" has the signal state "0", the value of the operand "Tag_Value" is allocated to the operand "Tag_Result".

See also

CONTINUE: Recheck loop condition (Page 3393)

EXIT: Exit loop immediately (Page 3394)

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

CONTINUE: Recheck loop condition (S7-1200, S7-1500)

Description

The "Recheck loop condition" instruction ends the current program run of a FOR, WHILE or REPEAT loop.

After execution of the instruction, the conditions for the continuation of the program loop are evaluated again. The instruction affects the program loop which directly contains the instruction.

Example

The following example shows how the instruction works:

SCL

```
FOR i
     := 1 TO 15 BY 2 DO
     IF (i < 5) THEN
     CONTINUE;
END_IF;
      "DB10".Test[i] := 1;
END_FOR;
```

For additional information on valid data types, refer to "See also".

If the condition i < 5 is satisfied, the subsequent value allocation ("DB10".Test[i] := 1) will not be executed. The run variable (i) is increased by the increment of "2" and checked to see whether its current value lies in the programmed value range. If the run variable lies in the value range, the IF condition is evaluated again.

If the condition i < 5 is not satisfied, the subsequent value allocation ("DB10".Test[i] := 1) will be executed and a new loop started. In this case, the run variable is also increased by the increment "2" and checked.

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

EXIT: Exit loop immediately (S7-1200, S7-1500)

Description

The instruction "Exit loop immediately" cancels the execution of a FOR, WHILE or REPEAT loop at any point regardless of conditions. The execution of the program is continued after the end of the loop (END_FOR, END_WHILE, END_REPEAT).

The instruction affects the program loop which directly contains the instruction.

Example

The following example shows how the instruction works:

SCL

```
FOR i := 15 TO 1 BY -2 DO
IF (i < 5)
THEN EXIT;
END_IF;
"DB10".Test[i] := 1;
END_FOR;
```

For additional information on valid data types, refer to "See also".

If the condition i < 5 is satisfied, then the execution of the loop will be canceled. Program execution resumes after the END_FOR.

If the condition i < 5 is not satisfied, the subsequent value allocation ("DB10".Test[i] :=1) will be executed and a new loop started. The run tag (i) is decreased by the increment of "-2" and it is checked whether its current value lies in the programmed value range. If the (i) run variable lies within the value range, the IF condition is evaluated again.

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

GOTO: Jump (S7-1200, S7-1500)

Description

Use the instruction "Jump" to resume the execution of a program at a given point marked with a jump label.

The jump labels and the instruction "Jump" must be in the same block. The name of a jump label can only be assigned once within a block. Each jump label can be the target of several jump instructions.

A jump from the "outside" into a program loop is not permitted, but a jump from a loop to the "outside" is possible.

Adhere to the following grammatical rules for jump labels:

- Letters (a to z, A to Z)
- A combination of letters and numbers. Check that the order is correct, i.e. first the letters, then the numbers (a - z, A - Z, 0 - 9).
- Special characters or a combination of letters and numbers must not be used in reverse order, i.e. first the numbers and then the letters (0-9, a - z, A - Z).

You can declare the instruction as follows:

GOTO <jump label>;

...

<Jump label>: <Instructions>

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Description
<jump label>	-	Jump label to be jumped to
<instructions>	-	Instructions which are executed after the jump.

Example

The following example shows how the instruction works:

SCL

```
CASE "Tag_Value" OF
1 : GOTO MyLABEL1;
2 : GOTO MyLABEL2;
3 : GOTO MyLABEL3;
ELSE GOTO MyLABEL4;
END_CASE;
MyLABEL1: "Tag_1" := 1;
MyLABEL2: "Tag_2" := 1;
MyLABEL3: "Tag_3" := 1;
MyLABEL4: "Tag_4" := 1;
```

Depending on the value of the "Tag_Value" operand, the execution of the program will resume at the point identified by the corresponding jump label. If the operand "Tag_Value" has the value 2, for example, program execution will resume at the jump label "MyLABEL2". The program line identified by the jump label "MyLABEL1" will be skipped in this case.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

RETURN: Exit block (S7-1200, S7-1500)

Description

The instruction "Exit block" exits the program execution in the currently edited block and continues in the calling block.

The instruction can be omitted at the end of the block.

Example

The following example shows how the instruction works:

SCL

```
IF "Tag_Error" <>0 THEN RETURN;
END_IF;
```

If the signal state of the "Tag_Error" operand is not zero, execution of the program ends in the block currently being processed.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

(*...*): Insert a comment section (S7-1200, S7-1500)

Description

You can use the "Insert a comment section" instruction to add a comment section. The text inside the parentheses "(*...*)" is handled as a comment.

Example

The following example shows how the instruction works:

SCL

```
(*This is a comment section.*)
```

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

REGION: Structure program code (S7-1200, S7-1500)

Description

You can use the instruction "Structure program code" to structure the program code in an SCL block by dividing it into different areas.

For additional information on working with areas, please refer to:Working with regions (Page 5026)

You can declare the instruction as follows:

REGION <Name>

<Instructions>

END_REGION

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
REGION	-	-	Keyword with which the area starts
<Name>	-	-	Text designating the REGION
<Instructions>	-	-	Program code that is preceded and succeeded by the REGION
END_REGION	-	-	Keyword with which the area ends

Example

The following example shows how the instruction works:

SCL

```
REGION Feeder System
     // Structures the source code for the feeder system
   IF "Variable_1" = 0 THEN
      "Variable_2" := 10;
   END_IF;
END_REGION
```

The Feeder System area comprises the complete program code.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

Runtime control (S7-1200, S7-1500)

ENDIS_PW: Limit and enable password legitimation (S7-1200, S7-1500)

Description

You use the "Limit and enable password legitimation" instruction to specify whether passwords configured for the CPU are legitimized or not. In this way, you can prevent legitimized connections, even if the correct password is known.

When you call the instruction and the REQ parameter has the signal state "0", the currently set state is displayed at the output parameters. If changes have been made to the input parameters, these are not transferred to the output parameters.

When the instruction is called and the REQ parameter has the signal state "1", the signal state is taken from the input parameters (F_PWD, FULL_PWD, R_PWD, HMI_PWD).

- If signal state "0" is present, authorization via password is not allowed.
- If signal state "1" is present, the password can be used.

Disable or enabling of the passwords can be allowed or prohibited individually. For example, all passwords can be prohibited except the fail-safe password. You can thus limit access options to a small user group. The output parameters (F_PWD_ON, FULL_PWD_ON, R_PWD_ON, HMI_PWD_ON) always show the current status of the password use, regardless of the REQ parameter.

Passwords that are not configured must have the signal state TRUE at the input and return the signal state TRUE at the output. The fail-safe password can only be configured for an F-CPU and must therefore always be interconnected with the signal state TRUE in a standard CPU. If the instruction returns an error, the call has no effect and the previous lock is still in effect.

Disabled passwords can be enabled again under the following conditions:

- The CPU is reset to its factory settings.
- The front panel of the S7-1500 CPU supports a dialog that allows you to navigate to the appropriate menu in which the passwords can be enabled again.
- When you call the "Limit and enable password legitimation" instruction, the input parameter of the desired password has the signal state "1".
- Set the mode selector to STOP. The restriction to password legitimation is re-established as soon as the switch is set back to RUN.
- Plugging an empty memory card (transfer card or program card) into an S7-1200 CPU.
- The transition from POWER OFF to POWER ON disables the protection in the S7-1200 CPU. The "Limit and enable password legitimation" instruction must be called once again in the program (e.g. in the startup OB).

Note

The "Limit and enable password legitimation" instruction blocks access from HMI systems if the HMI password has not been enabled.

Note

Existing legitimized connections retain their access rights and you cannot use the "Limit and enable password legitimation" instruction to restrict them.

Preventing accidental lockout of an S7-1500 CPU

The settings can be made on the front panel of the CPU and the CPU saves the most recent setting.

To prevent accidental lockout, the protection can be disabled by setting the mode switch to STOP with an S7-1500 CPU. The protection is automatically enabled again by setting mode selector to RUN without having to call the "Limit and enable password legitimation" instruction again or taking additional actions on the front panel.

Preventing accidental lockout of an S7-1200 CPU

Because the S7-1200 CPU does not have a mode selector, protection is disabled with POWER OFF - POWER ON. This means that it is possible and advisable to prevent accidental lockout with the help of specific program sequences within your program.

To do so, program a time control either by means of a cyclic interrupt OB or a timer in the Main OB (OB 1). This gives you the option of calling the "Limit and enable password legitimation" instruction in the respective OB (e.g., OB 1 or OB 35) relatively quickly after a transition from POWER OFF to POWER ON and the associated disabling of the protection. Call the instruction in the startup OB (OB 100) to keep the time window in which the instruction is inactive and there are no limitations for password legitimation relatively small. This procedure will give you the best possible protection from unauthorized access.

If there has been an accidental lockout, you can skip the call in the startup OB (by querying an input parameter, for example) and you have the set time (for example, 10 seconds up to 1 minute) to establish a connection to the CPU before the lock becomes active once again.

If there is no timer in your program code and a lockout has occurred, insert an empty transfer card or an empty program card into the CPU. The empty transfer card or program card deletes the internal load memory of the CPU. You must then download the user program once again from STEP 7 to the CPU.

Procedure for lost passwords with an S7-1200 CPU

If you have lost the password for a password-protected S7-1200 CPU, delete the password-protected program with an empty transfer card or program card. The empty transfer card or program card deletes the internal load memory of the CPU. You can then load a new user program from STEP 7 Basic in the CPU.

⚠ WARNING

Inserting an empty transfer card

When you insert a transfer card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Once you have pulled the transfer card, the content of the transfer card is available in the internal load memory. Make sure that the card does not include a program at this point.

⚠ WARNING

Inserting an empty program card

When you insert a program card in a CPU during runtime, the CPU goes to STOP mode. If operating states are unstable, controllers may fail and thus cause the uncontrolled operation of the controlled devices. This leads to an unforeseen operation of the automation system which can cause deadly or serious injuries and/or damage to property.

Make sure that the program card is empty. The internal load memory is copied to the empty program card. Once you have pulled the previously empty program card, the internal load memory is empty.

You must remove the transfer card or program card before you put the CPU into RUN mode.

Effects of password use on the operating modes

The following table shows what effects the password use by means of the "Limit and enable password legitimation" instruction has on the operating modes and the corresponding user actions.

Action	Password protection by means of the instruction
Basic state after • Operating mode switch to STOP • Reset memory manually (PG, switch, change of MC (Motion Control)) • Reset to factory setting	Not activated (no restrictions)
Basic state after POWER ON	• S7-1200 CPU: The lock is disabled and the instruction must be called once again in the program (e.g., in the startup OB). • S7-1500 CPU: Enabled (if a lock was activated before POWER OFF). The option of not allowing passwords is retentive.
Operating mode transition RUN/STARTUP/HOLD -> STOP (by terminating the instruction, an error or communication) or STOP -> STARTUP/RUN/HOLD	Activated Passwords still cannot be used.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	When the REQ parameter has the signal state "0", the currently set signal state of the passwords is queried.
F_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access including fail-safe • F_PWD = "0": Do not allow password • F_PWD = "1": Allow password
FULL_PWD	Input	BOOL	I, Q, M, D, L or constant	Read/write access • FULL_PWD = "0": Do not allow password • FULL_PWD = "1": Allow password

Parameters	Declaration	Data type	Memory area	Description
R_PWD	Input	BOOL	I, Q, M, D, L or constant	Read access • R_PWD = "0": Do not allow password • R_PWD = "1": Allow password
HMI_PWD	Input	BOOL	I, Q, M, D, L or constant	HMI access • HMI_PWD = "0": Do not allow password • HMI_PWD = "1": Allow password
F_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access including fail-safe • F_PWD_ON = "0": Password not allowed • F_PWD_ON = "1": Password allowed
FULL_PWD_ON	Output	BOOL	I, Q, M, D, L	Read/write access status • FULL_PWD_ON = "0": Password not allowed • FULL_PWD_ON = "1": Password allowed
R_PWD_ON	Output	BOOL	I, Q, M, D, L	Read-access status • R_PWD_ON = "0": Password not allowed • R_PWD_ON = "1": Password allowed
HMI_PWD_ON	Output	BOOL	I, Q, M, D, L	HMI-access status • HMI_PWD_ON = "0": Password not allowed • HMI_PWD_ON = "1": Password allowed
Function value (RET_VAL)		WORD	I, Q, M, D, L	Error information

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
8090	The "Limit and enable password legitimation" instruction is not supported
80D0	The password for fail-safe is not configured. The signal state must be TRUE for standard CPUs.
80D1	The read/write access is not configured

Error code* (W#16#...)	Explanation
80D2	The read access is not configured
80D3	The HMI access is not configured
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ENDIS_PW(REQ := 0,
                         F_PWD := 0,
                         FULL_PWD := 0,
                         R_PWD := 1,
                         HMI_PWD := 0,
                         F_PWD_ON => "Status_F_PWD",
                         FULL_PWD_ON => "Status_FULL_PWD",
                         R_PWD_ON => "Status_R_PWD",
                         HMI_PWD_ON => "Status_HMI_PWD");
```

The following table shows how the instruction works using specific operand values:

Operand	Data type	Value
REQ	BOOL	0
F_PWD	BOOL	0
FULL_PWD	BOOL	0
R_PWD	BOOL	1
HMI_PWD	BOOL	0
Status_F_PWD	BOOL	0
Status_FULL_PWD	BOOL	0
Status_R_PWD	BOOL	1
Status_HMI_PWD	BOOL	0

The instruction is executed because the REQ operand has the signal state "1". The R_PWD operand has the signal state "1", which means that read access is allowed when the assigned password is entered. The R_PWD_ON status operand also has the signal state "1", thereby signaling that the R_PWD operand is activated.

PC systems (S7-1200, S7-1500)

SHUT_DOWN: Shut down target system (S7-1200, S7-1500)

Description

You can use the instruction "SHUT_DOWN: Shutdown target system" to shut down the PC-based automation system and restart the S7 software controller CPU 150xS or Windows on the PC-based automation system.

The instruction is available in the "Instructions" task card under Basic instructions > Program control > Runtime control.

A restart is, for example, advisable in the following situations:

- An industrial UPS (uninterruptible power supply) reports a power failure via a digital input.
- Windows stops responding or shows a "blue screen".
- Too many error OBs are called in the user program.

Parameter

The following table shows the parameters of the "Shutdown target system" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	UINT	I, Q, M, D, L or constant	MODE = 1: Shut down CPU 150xS and Windows The CPU goes to STOP and saves the retentive data. Then the CPU and Windows are shut down. The system must be restarted manually. MODE = 2: Restart CPU 150xS The CPU goes to STOP and saves the retentive data. Then the CPU is shut down and restarted. MODE = 3: Restart Windows The CPU remains in RUN. Windows is restarted (as of TIA Portal V14, MODE 3 is only retained for backward compatibility. We recommend using MODE 4 or MODE 5). MODE = 4: Windows is shut down and restarted correctly. The CPU remains in RUN. MODE = 5: Restart Windows (Comparable with MODE 3; Exception: MODE 5 should only be used if Windows has crashed).
COM-MENT	Input	STRING	I, Q, M, D, L	With Mode = 1, 3 and 4, you can specify a reason for the restart. The reason is output in the Windows Event Log.
Ret_Val	Return	WORD	Q, M, D, L	Ret_Val = 0: No faults Ret_Val = 8090: The value passed to MODE is not supported. Ret_Val = 8091: Windows does not respond to the call of the Shut_Down instruction (only valid for Mode 3 and 4). Ret_Val = 8092: Please contact SIMATIC Customer Support if this error occurs (only valid for Mode 3 and 4).

RE_TRIGR: Restart cycle monitoring time (S7-1200, S7-1500)

Description

The "Restart cycle monitoring time" instruction is used to restart the cycle monitoring time of the CPU. The cycle monitoring time then restarts with the time you have set in the CPU configuration.

If the instruction is called in a block with a higher priority, such as a hardware interrupt or diagnostic error interrupt, the instruction is not executed and the enable output ENO returns signal state "0".

The instruction executes completely within a time span (10 times the maximum program cycle), regardless of the number of calls. Once this time has expired, the program cycle can no longer be prolonged.

Calling the instruction

The following call conditions apply:

- The following applies to a CPU of the S7-1200 series:
  In firmware versions <= 2.2, you can call the instruction only in a program cycle organization block of priority 1. This corresponds to the lowest priority of all organization blocks. If the instruction is called in an organization block with a higher priority, the instruction is not executed and the result (BR bit, enable output ENO) is always "0".
  In firmware versions >= 2.2, you can call the instruction regardless of the priority in all organization blocks.
- The following applies to a CPU of the S7-1500 series:
  You can call the instruction regardless of the priority in all organization blocks.

Parameters

The "Restart cycle monitoring time" instruction has no parameters and supplies no error information.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

GET_ERROR: Get error locally (S7-1200, S7-1500)

Description

The "Get error locally" instruction is used to query the occurrence of errors within a program block. This normally involves programming or access errors. If the system reports an error during the execution of the program block, detailed information is output at the <Operand> on the first error to occur during the execution of the block since the last execution of the instruction.

The error information can only be saved in operands of the "ErrorStruct" system data type. The "ErrorStruct" system data type specifies the exact structure in which the information about the error is stored. Using additional instructions, you can evaluate this structure and program an appropriate response. If several errors occur in the program block, the error information about the next error to occur is output by the instruction only after the first error that occurred has been remedied.

Note

<Operand>

The <Operand> is only changed if error information is present. To set the operand back to "0" after handling the error, you have the following options:

- Declare the operand in the "Temp" section of the block interface.
- Reset the operand to "0" before calling the instruction.

Note

Activation of the local error handling

As soon as you insert the instruction in the program code of a program block, the local error handling is activated and default system reactions are ignored when errors occur.

Options for error handling

You can find an overview of the options for error handling here: AUTOHOTSPOT

For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
<Operand>	ErrorStruct	D, L	Information about errors that have occurred

Data type "ErrorStruct"

The "ErrorStruct" data type can be inserted in a global data block or in the block interface. You can insert the data type more then once if you assign a different name for the data structure each time. The data structure and the name of individual structure elements cannot be changed. If you save the error information in a global data block, it can also be read out by other program blocks.

The following table shows the structure of the "ErrorStruct" data type:

Structure component		Data type	Description
ERROR_ID		WORD	Error ID
FLAGS		BYTE	Shows whether the error occurred during a program block call. 16#01: Error during a program block call 16#00: No error during a program block call
REACTION		BYTE	Default reaction: 0: Ignore (write error) 1: Continue with substitute value "0" (read error) 2: Skip instruction (system error)
CODE_ADDRESS		CREF	Information about the address and type of the program block
	BLOCK_TYPE	BYTE	Program block type in which the error occurred: 1: Organization block (OB) 2: Function (FC) 3: Function block (FB)
	CB_NUMBER	UINT	Number of the code block
	OFFSET	UDINT	Reference to the internal memory
MODE		BYTE	Information about the address of an operand
OPERAND_NUMBER		UINT	Operand number of the machine command
POINTER_NUMBER_LOCATION		UINT	(A) Internal pointer
SLOT_NUMBER_SCOPE		UINT	(B) Storage area in internal memory
DATA_ADDRESS		NREF	Information about the address of an operand
	AREA	BYTE	(C) Memory area: L: 16#40...16#7F, 16#86, 16#87, 16#8E, 16#8F, 16#C0...16#FF I: 16#81 Q: 16#82 M: 16#83 DB: 16#40, 16#84, 16#85, 16#8A, 16#8B PI: 16#01 PQ: 16#02 Technological objects: 16#04

Structure component		Data type	Description
	DB_NUMBER	UINT	(D) Number of the data block
	OFFSET	UDINT	(E) Relative address of the operand

Structure component "ERROR_ID"

The following table shows the values that can be output at the structure component "ERROR_ID":

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:

SCL

```
LABEL: #TagOut := #Field[#index] * REAL#40.5;

GET_ERROR(#Error);

IF #Error.REACTION = 1 THEN
   GOTO LABEL;
   ;
END_IF;
```

An error occurred accessing the #Field[#index] tag. The #TagOut operand returns the signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, we recommend that you program the "Get error locally" instruction after the multiplication to get the error. The error information supplied by the "Get error locally" instruction is evaluated with a comparison. If the #Error.REACTION structure component has the value "1", there is a read/access error and the program execution begins again at the jump label LABEL.

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

GET_ERR_ID: Get error ID locally (S7-1200, S7-1500)

Description

The "Get error ID locally" instruction is used to query the occurrence of errors within a block. This is usually to access error. If the system reports during the block processing errors within the block execution since the last execution of the instruction, the instruction outputs the error ID of the first error that occurred.

The error ID can only be saved in operands of the WORD data type. If several errors occur in the block, the error ID of the next error to occur in the instruction is output only after the first error that occurred has been remedied.

Note

The <Operand> is only changed if error information is present. To set the operand back to "0" after handling the error, you have the following options:

- Declare the operand in the "Temp" section of the block interface.
- Reset the operand to "0" before calling the instruction.

The output of the "Get error ID locally" instruction is only set if error information is present. If one of these conditions is not fulfilled, the remaining program execution is not affected by the "Get error ID locally" instruction.

You can find an example of how you can implement the instruction in combination with other troubleshooting options under "See also".

Note

The "Get error ID locally" instruction enables local error handling within a block. If the "Get error ID locally" instruction is inserted in the program code of a block, any predefined system reactions are ignored if errors occur.

Options for error handling

You can find an overview of the options for error handling here: AUTOHOTSPOT

For a detailed example of local error handling that contains several error handling options, refer to: AUTOHOTSPOT

Parameters

The following table shows the parameters of the instruction:

Parameters	Data type	Memory area	Description
Function value	WORD	D, L	Error ID

Error ID

The following table shows the values that can be output:

ID* (hexadecimal)	ID* (decimal)	Description
0	0	No error
2503	9475	Invalid pointer
2520	9504	Invalid STRING
2522	9506	Read error: Operand outside the valid range
2523	9507	Write error: Operand outside the valid range
2524	9508	Read error: Invalid operand
2525	9509	Write error: Invalid operand
2528	9512	Read error: Data alignment
2529	9513	Write error: Data alignment
252C	9516	Invalid pointer
2530	9520	Write error: Data block
2533	9523	Invalid reference used
2538	9528	Access error: DB does not exist
2539	9529	Access error: Wrong DB used

ID* (hexadecimal)	ID* (decimal)	Description
253A	9530	Global data block does not exist
253C	9532	Faulty information or the function does not exist
253D	9533	System function does not exist
253E	9534	Faulty information or the function block does not exist
253F	9535	System block does not exist
2550	9552	Access error: DB does not exist
2551	9553	Access error: Wrong DB used
2575	9589	Error in the program nesting depth
2576	9590	Error in the local data distribution
2577	9591	The block property "Parameter passing via registers" is not selected.
25A0	9632	Internal error in TP
25A1	9633	Tag is write-protected
25A2	9634	Invalid numerical value of tag
2942	10562	Read error: Input
2943	10563	Write error: Output
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".		

Example

The following example shows how the instruction works:

SCL

```
#TagOut := #Field[#index] * REAL#40.5;

#TagID := GET_ERR_ID();

IF #TagID = 16#2522 THEN
   MOVE_BLK(IN := #TagArrayIn[0],
            COUNT := 1,
            OUT => #TagArrayOut[1]);
END_IF;
```

An error occurred accessing the #Field[#index] tag. The #TagOut operand returns the signal state "1" despite the read/access error and the multiplication is performed with the value "0.0". If this error scenario occurs, we recommend that you program the "Get error ID locally" instruction after the multiplication to get the error. The error ID supplied by the "Get error ID locally" instruction is evaluated with a comparison. If the #TagID operand returns ID 16#2522, there is a read/access error and the value "100.0" of the #TagArrayIn[0] operand is written to the #TagArrayOut[1] operand.

INIT_RD: Initialize all retain data (S7-1500)

Description

The "Initialize all retain data" instruction is used to reset the retentive data of all data blocks, bit memories and SIMATIC timers and counters at the same time. The instruction can only be executed within a startup OB because the execution exceeds the program cycle duration.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	BOOL	I, Q, M, D, L	If the input "REQ" has the signal state "1", all retentive data are reset.
Function value (RET_VAL)		INT	I, Q, M, D, L	Error information: If an error occurs during the execution of the instruction, an error code is output at the RET_VAL parameter.

For additional information on valid data types, refer to "See also".

RET_VAL parameter

The following table shows the meaning of the values of the RET_VAL parameter:

Error code* (W#16#...)	Explanation
0000	No error
80B5	The instruction cannot be executed because it was not programmed within a startup OB.
General error information	See also: "GET_ERR_ID: Get error ID locally"
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := INIT_RD("Tag_REQ");
```

If the operand "Tag_REQ" has the signal state "1", the instruction is executed. All retentive data of all data blocks, bit memories and SIMATIC timers and counters are reset.

GET_ERR_ID: Get error ID locally (Page 3409)

Basics of SCL (Page 4991)

WAIT: Configure time delay (S7-1500)

Description

The "Configure time delay" instruction pauses the program execution for a specific period of time. You indicate the period of time in microseconds on the WT parameter of the instruction.

You can configure time delays from -32768 up to 32767 microseconds (µs). The smallest possible delay time depends on the CPU and corresponds to the execution time of the instruction.

The execution of the instruction can be interrupted by higher priority events and does not return any error information.

Note

Negative delay time

If you specify a negative delay time at parameter WT, the enable output ENO, or the RLO and the BR bit, will return the signal state FALSE. A negative delay time does not affect the CPU. The following instructions linked to enable output ENO are not executed in LAD or FBD.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
WT	Input	INT	I, Q, M, D, L, P or constant	Time delay in microseconds (µs)

See also

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

RUNTIME: Measure program runtime (S7-1200, S7-1500)

Description

The "Measure program runtime" instruction is used to measure the runtime of the entire program, individual blocks or command sequences.

If you want to measure the runtime of your entire program, call the instruction "Measure program runtime" in OB1. Measurement of the runtime is started with the first call and the output RET_VAL returns the runtime of the program after the second call. The measured runtime includes all CPU processes that can occur during the program execution, for example, interruptions caused by higher-level events or communication. The instruction "Measure program runtime" reads an internal counter of the CPU and writes the value to the in/out parameter. The instruction calculates the current program runtime according to the internal counter frequency and writes it to output RET_VAL.

If you want to measure the runtime of individual blocks or individual command sequences, you need three separate networks. Call the instruction "Measure program runtime" in an individual network within your program. You set the starting point of the runtime measurement with this first call of the instruction. Then you call the required program block or the command sequence in the next network. In another network, call the "Measure program runtime" instruction a second time and assign the same memory to the in/out parameter as you did during the first call of the instruction. The "Measure program runtime" instruction in the third network reads an internal CPU counter and calculates the current runtime of the program block or the command sequence according to the internal counter frequency and writes it to the output RET_VAL.

The "Measure program runtime" instruction uses an internal high-frequency counter to calculate the time. If the counter overruns, the instruction returns values <= 0.0. This can occur up to once per minute for S7-1200 CPUs with firmware version <V4.2. Ignore these runtime values.

Note

The runtime of a command sequence cannot be determined exactly, because the sequence of instructions within a command sequence is changed during optimized compilation of the program.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	InOut	LREAL	I, Q, M, D, L	The content is for internal purposes only.
Function value		LREAL	I, Q, M, D, L	Returns the measured runtime in seconds

Example

The following example shows the how the instruction works based on the runtime calculation of a program block:

```
SCL
"Tag_Result" := RUNTIME("Tag_Memory");

"Best_before_date_DB" ();

"Tag_Result" := RUNTIME("Tag_Memory");
```

The starting point for the runtime measurement is set with the first call of the instruction and buffered as reference for the second call of the instruction in the "TagMemory" operand.

The "Best_before_date" program block FB1 is called.

When the program block FB1 has been processed, the instruction is executed a second time. The second call of the instruction calculates the runtime of the program block and writes the result to the output "Tag_Result".

You can find a more detailed example of how you can measure the total cycle time of a program in the Siemens Industry Online Support under the following entry ID: 87668055 (https://support.industry.siemens.com/cs/ww/en/view/87668055)

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

Word logic operations (S7-1200, S7-1500)

DECO: Decode (S7-1200, S7-1500)

Description

The instruction "Decode" sets a bit specified by the input value in the output value.

The instruction "Decode" reads the value of the parameter IN and sets the bit in the output value, whose bit position corresponds to the read value. The other bits in the output value are filled with zeroes. If the value of the IN parameter is greater than 31, a modulo 32 instruction is executed.

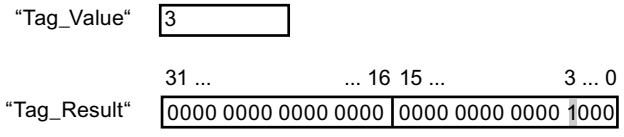
Use the following syntax to change the data type of the instruction:

DECO_<data type>();

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	UINT	I, Q, M, D, L, P	Position of the bit in the output value which is set.
_<Data type>		Bit strings default: DWORD	-	Data type of the function value: 1. You can specify the data type of the instruction explicitly using "_". 2. If you do not specify the data type explicitly, it will be determined by the utilized tags or type-coded constants. 3. If you neither specify the data type explicitly nor specify defined tags or type-coded constants, the default data type will be used.
Function value		Bit strings	I, Q, M, D, L, P	Current output value



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := DECO(IN := "Tag_Value");
"Tag_Result2" := DECO_BYTE(IN := "Tag_Value2");
```

The following figure shows how the instruction works using specific operand values:

The instruction reads the number "3" from the value of the operand "Tag_Value" and sets the third bit to the value of the operand "Tag_Result".

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

ENCO: Encode (S7-1200, S7-1500)

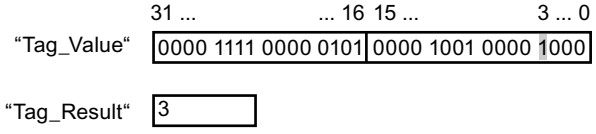
Description

The instruction "Encode" reads the bit number of the lowest-value bit set in the input value and issues this as a result.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	Bit strings	I, Q, M, D, L, P	Input value
Function value		INT	I, Q, M, D, L, P	Bit number of the bit in the input value that is read out.



For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := ENCO(IN := "Tag_Value");
```

The following figure shows how the instruction works using specific operand values:

The instruction reads the lowest-value set bit of the operand "Tag_Value" and writes the bit position "3" in the operand "Tag_Result".

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

SEL: Select (S7-1200, S7-1500)

Description

The instruction "Select" selects one of the parameters IN0 or IN1 depending on a switch (G parameter) and issues its content as a result. When the parameter G has the signal status "0", the value at parameter IN0 is moved. When the parameter G has the signal status "1", the value at parameter IN1 is moved and returned as a function value.

The instruction is only executed if the tags of all parameters have the same data type class.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
G	Input	BOOL	BOOL	I, Q, M, D, L	Switch
IN0	Input	Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	Second input value
Function value		Binary numbers, integers, floating-point numbers, timers, strings, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, timers, strings, DATE, TOD, LTOD, DT, LDT	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := SEL(G := "Tag_Value",
                    IN0 := "Tag_0",
                    IN1 := "Tag_1");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Value	0	1
Tag_0	W#16#0000	W#16#4C
Tag_1	W#16#FFFF	D#16#5E
Tag_Result	W#16#0000	D#16#5E

MUX: Multiplex (S7-1200, S7-1500)

Description

The "Multiplex" instruction copies the value of a selected input parameter and issues it. You can use the parameter K to determine the number of the input parameter whose value will be moved. Numbering starts at IN0 and is incremented continuously with each new input. You can declare a maximum of 32 inputs.

Numerical data types and time data types are permitted at the inputs. All tags with assigned parameters must be of the same data type.

The function value is invalid if any of the following requirements are met:

- Errors occurred during execution of the instruction.
- If the input at the K parameter is located outside the available inputs and the INELSE input is not used, the function value is invalid.

Note

K parameter has a negative integer

If a tag with a valid data type is specified at the input parameters and the K parameter has a negative integer, the value of the tag is changed.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
K	Input	Integers	Integers	I, Q, M, D, L, P	Specifies the parameter whose content is to be transferred. • If K = 0 => Parameter IN0 • If K = 1 => Parameter IN1, etc.
IN0	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	First input value
IN1	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Second input value
INn	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Optional input values

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
INELSE	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Specifies the value to be copied when K <> n.
Function value		Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, TOD, LTOD, DATE, timers, DT, LDT	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := MUX(K := "Tag_Number",
                    IN0 := "Tag_1",
                    IN1 := "Tag_2",
                    INELSE := "Tag_3");
```

The result of the instruction is returned in the operand "Tag_Result" as a function value.

The following table shows how the instruction works using specific operand values:

Operand	Value	
Tag_Number	1	4
Tag_1	DW#16#00000000	DW#16#00000000
Tag_2	DW#16#003E4A7D	DW#16#003E4A7D
Tag_3	DW#16#FFFF0000	DW#16#FFFF0000
Tag_Result	DW#16#003E4A7D	DW#16#FFFF0000

DEMUX: Demultiplex (S7-1200, S7-1500)

Description

The "Demultiplex" instruction transfers the value of the input parameter IN to a selected output parameter. The selection of the input parameter takes place independent of the parameter value K. The K parameter specifies the output parameter number to which the value of the input parameter IN is transferred. The other output parameters are not changed. Numbering starts at OUT0 and continues consecutively with each new output. You can declare a maximum of 32 output parameters.

If the value of the K parameter is greater than the number of output parameters, the content of the IN input parameter is copied to the OUTELSE output parameter and the signal state "0" is assigned to the enable output ENO.

The function value is invalid if any of the following requirements are met:

- The value of the K parameter is greater than the number of available outputs.
- Errors occurred during execution of the instruction.

Note

K parameter < 0 or K > available outputs

If you specify at the K parameter a value that is outside the available outputs (K < 0 or K > available outputs), the value of the IN input parameter is output at the OUTELSE output parameter.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
K	Input	Integers	Integers	I, Q, M, D, L, P	Specifies the output to which the input value (IN) will be copied. • If K = 0 => Parameter OUT0 • If K = 1 => Parameter OUT1, etc.
IN	Input	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Input value
OUT0	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	First output
OUT1	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Second output

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
OUTn	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Optional outputs
OUTELSE	Output	Binary numbers, integers, floating-point numbers, timers, STRING, CHAR, WCHAR, TOD, DATE, DT	Binary numbers, integers, floating-point numbers, strings, timers, TOD, LTOD, DATE, DT, LDT	I, Q, M, D, L, P	Output to which the value at input IN is copied if K > n.

For additional information on available data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
DEMUX(K := "Tag_Number",
      IN := "Tag_Value",
      OUT0 := "Tag_1",
      OUT1 := "Tag_2",
      OUTELSE := "Tag_3");
```

The following tables show how the instruction works using specific operand values:

Input values of the "Demultiplex" instruction before the network execution

Parameters	Operand	Values	
K	Tag_Number	2	4
IN	Tag_Value	DW#16#FFFFFFFF	DW#16#003E4A7D

Output values of the "Demultiplex" instruction after the network execution

Parameters	Operand	Values	
OUT0	Tag_1	Unchanged	Unchanged
OUT1	Tag_2	DW#16#FFFFFFFF	Unchanged
OUTELSE	Tag_3	Unchanged	DW#16#003E4A7D

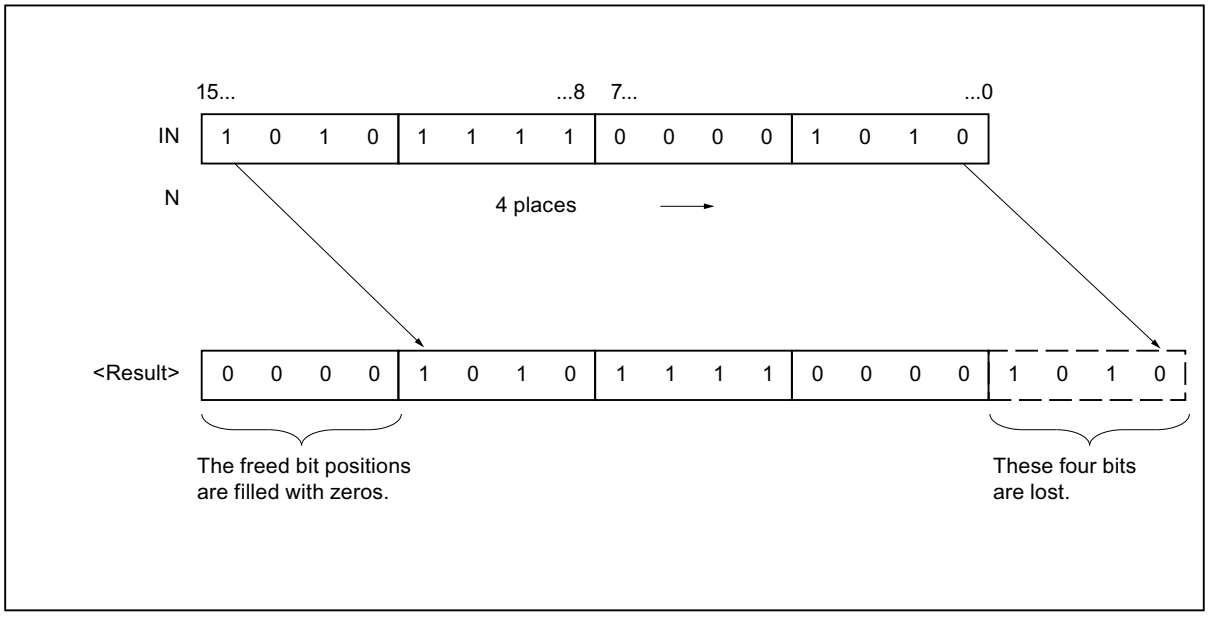
Basics of SCL (Page 4991)

Shift and Rotate (S7-1200, S7-1500)

SHR: Shift right (S7-1200, S7-1500)

Description



The "Shift right" instruction shifts the contents of the IN parameter bit-by-bit to the right and returns it as a function value. The parameter N is used to specify the number of bit positions by which the specified value should be shifted.

If the value of the N parameter is "0", the value of the IN parameter is given as a result.

If the value of the N parameter is greater than the number of available bit places, then the value of the IN parameter is shifted to the right by the available number of bit places.

The freed bit positions in the left area of the operand are filled by zeroes when values without signs are shifted. If the specified value has a sign, the free bit positions are filled with the signal state of the sign bit.

The following figure shows how the content of an integer data type operand is shifted by four bit positions to the right:

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bits by which the value (IN) is shifted
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := SHR(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	0011 1111 1010 1111
N	Tag_Number	3
Function value	Tag_Result	0000 0111 1111 0101

The content of the "Tag_Value" operand is shifted by three bit positions to the right. The result of the instruction is returned in the operand "Tag_Result" as a function value.

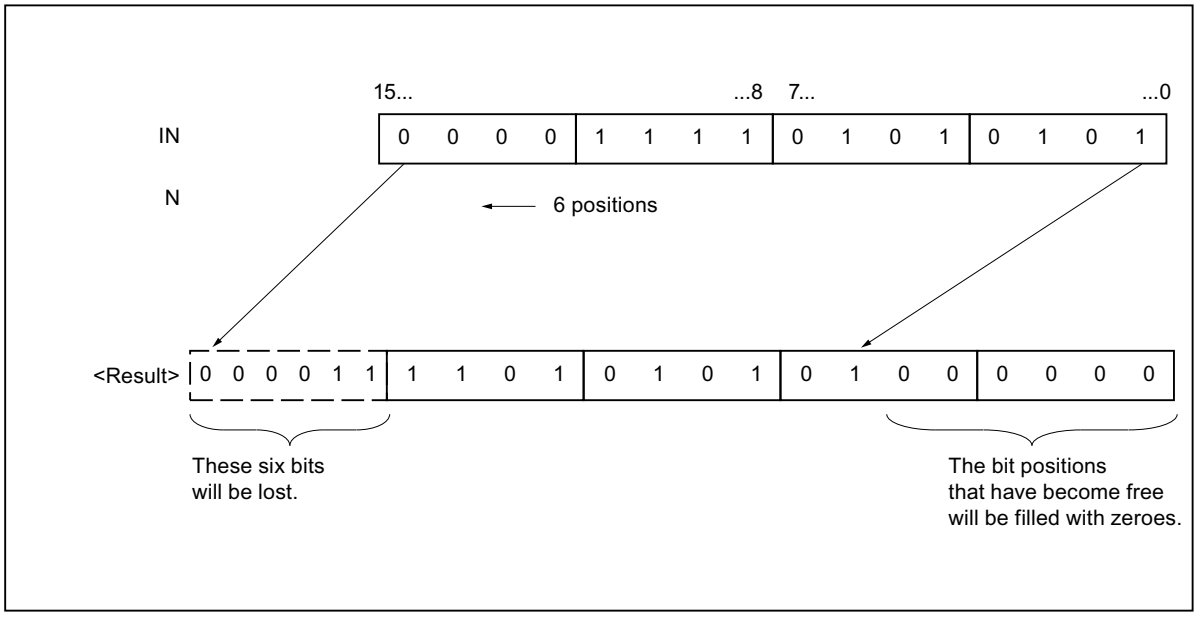
Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

SHL: Shift left (S7-1200, S7-1500)

Description



The "Shift left" instruction shifts the contents of the IN parameter bit-by-bit to the left and returns it as a function value. The parameter N is used to specify the number of bit positions by which the specified value should be shifted.

If the value of the N parameter is "0", the value of the IN parameter is given as a result.

If the value of the N parameter is greater than the number of bit places, the value of the IN parameter is shifted to the left by the available number of bit places.

The bit positions freed by the shift are filled with zeros in the result value.

The following figure shows how the content of an operand of the WORD data type is shifted six bit positions to the left:

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be shifted
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bits by which the value (IN) is shifted
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := SHL(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	0011 1111 1010 1111
N	Tag_Number	4
Function value	Tag_Result	1111 1010 1111 0000

The value of the "Tag_Value" operand is shifted by four bit places to the left. The result of the instruction is returned in the operand "Tag_Result" as a function value.

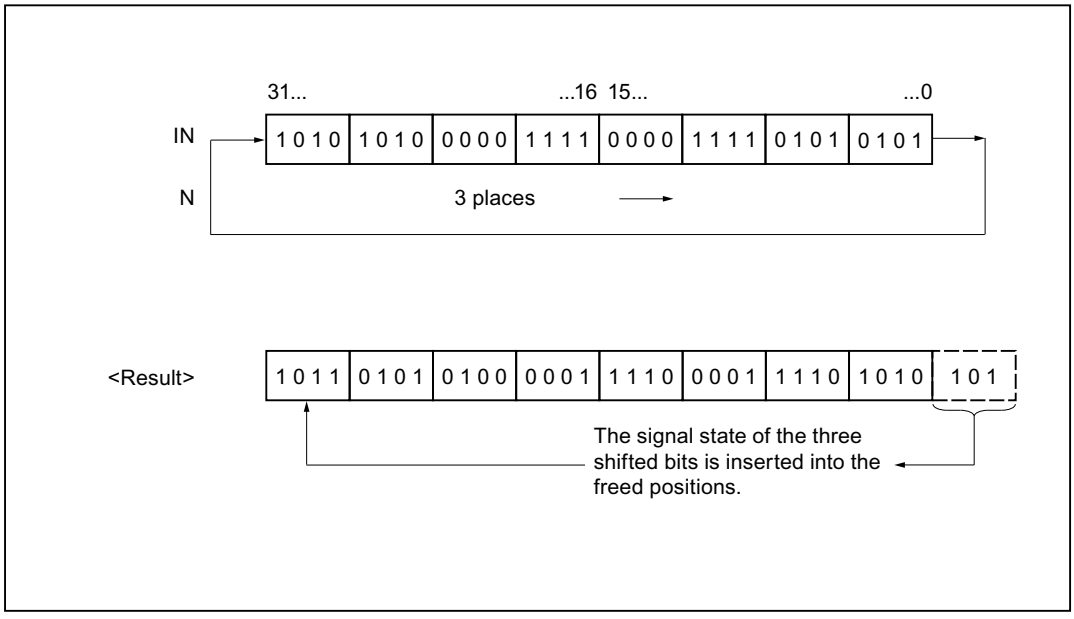
ROR: Rotate right (S7-1200, S7-1500)



Description

The "Rotate right" instruction rotates the content of the IN parameter bit-by-bit to the right and assigns the result to the specified operand. The parameter N is used to specify the number of bit places by which the specified value should be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

If the value of the N parameter is "0", the value at input IN is given as a result.

If the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is still rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the right:

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bit positions by which the value (IN) is rotated
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

SCL

```
"Tag_Result" := ROR(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	0000 1111 1001 0101
N	Tag_Number	5
Function value	Tag_Result	1010 1000 0111 1100

The content of the "Tag_Value" operand is rotated by five bit positions to the right. The result of the instruction is returned in the operand "Tag_Result" as a function value.

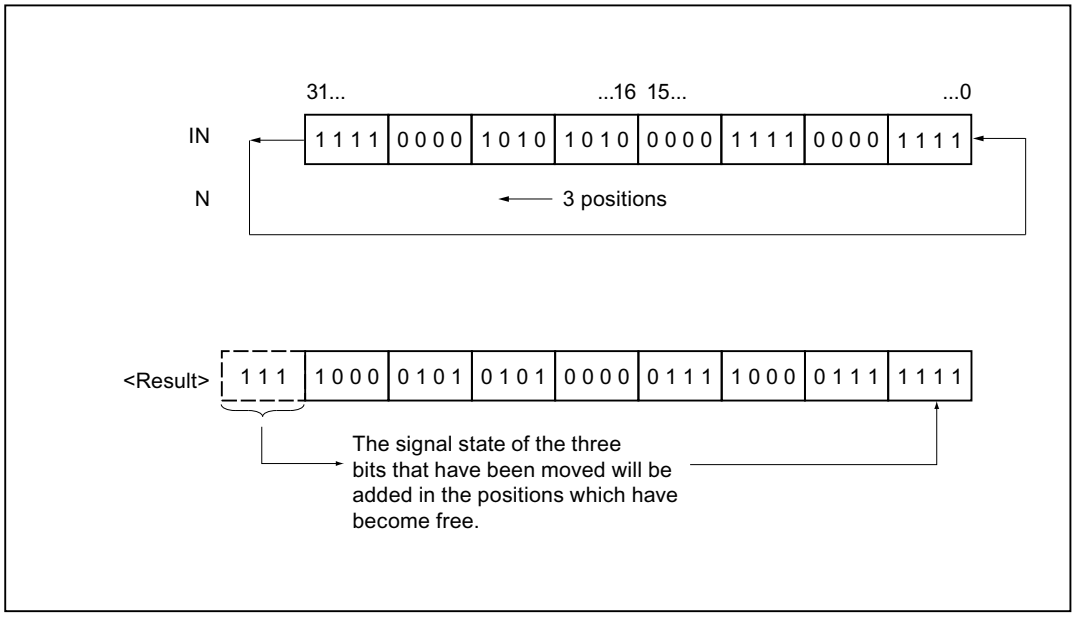
Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

ROL: Rotate left (S7-1200, S7-1500)



Description

The "Rotate left" instruction rotates the contents of the IN parameter bit-by-bit to the left and returns it as a function value. The parameter N is used to specify the number of bit places by which the specified value should be rotated. The bit positions freed by rotating are filled with the bit positions that are pushed out.

If the value of the N parameter is "0", the value at input IN is given as a result.

If the value at the N parameter is greater than the number of available bit positions, the operand value at the IN input is still rotated by the specified number of bit positions.

The following figure shows how the content of an operand of the DWORD data type is rotated three bit positions to the left:

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Value to be rotated
N	Input	USINT, UINT, UDINT	USINT, UINT, UDINT, ULINT	I, Q, M, D, L	Number of bit positions by which the value (IN) is rotated
Function value		Bit strings, integers	Bit strings, integers	I, Q, M, D, L	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := ROL(IN := "Tag_Value",
                    N := "Tag_Number");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value
IN	Tag_Value	1010 1000 1111 0110
N	Tag_Number	5
Function value	Tag_Result	0001 1110 1101 0101

The content of the operand "Tag_Value" is rotated five bit places to the left. The result of the instruction is returned in the operand "Tag_Result" as a function value.

Legacy (S7-1500)

DRUM: Implement sequencer (S7-1500)

Description

You can use the "Implement sequencer" instruction to assign the programmed values of the OUT_VAL parameter of the corresponding step to the programmed output bits (OUT1 to OUT16) and the output word (OUT_WORD). The specific step must thereby satisfy the conditions of the programmed enable mask on the S_MASK parameter while the instruction remains at this step. The instruction advances to the next step if the event for the step is true and the programmed time for the current step elapses, or if the value at the JOG parameter changes from "0" to "1". The instruction is reset when the signal state of the RESET parameter changes to "1". The current step is hereby equated to the preset step (DSP).

The amount of time spent on a step is determined by the product of the preset timebase (DTBP) and the preset counter value (S_PRESET) for each step. At the start of a new step, this calculated value is loaded into the DCC parameter, which contains the time remaining for the current step. If, for example the value at the DTBP parameter is "2" and the preset value for the first step is "100" (100 ms), the DCC parameter has the value "200" (200 ms).

A step can be programmed with a timer value, an event, or both. Steps that have an event bit and the timer value "0" advance to the next step as soon as the signal state of the event bit is "1". Steps that are programmed only with a timer value start the time immediately. Steps that are programmed with an event bit and a time value greater than "0" start the time when the signal state of the event bit is "1". The event bits are initialized with a signal state of "1".

When the sequencer is on the last programmed step (LST_STEP) and the time for this step has expired, the signal state on the Q parameter is set to "1"; otherwise it is set to "0". When the parameter Q is set, the instruction remains on the step until it is reset.

In the configurable mask (S_MASK) you can select the individual bits in the output word (OUT_WORD) and set or reset the output bits (OUT1 to OUT16) by means of the output values (OUT_VAL). When a bit of the configurable mask has a signal state of "1", the OUT_VAL value sets/resets the corresponding bit. If the signal state of a bit of the configurable mask is "0", the corresponding bit is left unchanged. All the bits of the configurable mask for all 16 steps are initialized with a signal state of "1".

The output bit on the OUT1 parameter corresponds to the least significant bit of the output word (OUT_WORD). The output bit on the OUT16 parameter corresponds to the most significant bit of the output word (OUT_WORD).

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
RESET	Input	BOOL	I, Q, M, D, L	The signal state "1" indicates a reset condition.
JOG	Input	BOOL	I, Q, M, D, L	When the signal state changes from "0" to "1", the instruction advances to the next step.
DRUM_EN	Input	BOOL	I, Q, M, D, L	The signal state "1" allows the sequencer to advance based on the event and time criteria.
LST_STEP	Input	BYTE	I, Q, M, D, L	Maximum step number (for example: LST_STEP = 16#08; a maximum of 8 steps is possible.)
EVENT(i), 1 ≤ i ≤ 16	Input	BOOL	I, Q, M, D, L	Event bit (i); Initial signal state is "1".
OUT(j), 1 ≤ j ≤ 16	Output	BOOL	I, Q, M, D, L	Output bit (j)
Q	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
OUT_WORD	Output	WORD	I, Q, M, D, L, P	Word address to which the sequencer writes the output values.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
JOG_HIS	Static	BOOL	I, Q, M, D, L	JOG parameter history bit
EOD	Static	BOOL	I, Q, M, D, L	The signal state "1" indicates that the time for the last step has elapsed.
DSP	Static	BYTE	I, Q, M, D, L, P	Preset step of the sequencer
DSC	Static	BYTE	I, Q, M, D, L, P	Current step of the sequencer
DCC	Static	DWORD	I, Q, M, D, L, P	Current counter value of the sequencer
DTBP	Static	WORD	I, Q, M, D, L, P	Preset timebase of the sequencer
PrevTime	Static	TIME	I, Q, M, D, L	Previous system time
S_PRESET	Static	ARRAY[1..16] of WORD	I, Q, M, D, L	Preset counter value for each step [1 to 16] where one clock pulse = 1 ms.
OUT_VAL	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L	Output values for each step [1 to 16, 0 to 15].
S_MASK	Static	ARRAY[1..16, 0..15] of BOOL	I, Q, M, D, L	Configurable mask for each step [1 to 16, 0 to 15]. Initial signal states are "1".

For additional information on valid data types, refer to "See also".

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

ERR_CODE*	Explanation
W#16#0000	No error
W#16#000B	The value at the LST_STEP parameter is less than 1 or greater than 16.
W#16#000C	The value at the DSC parameter is less than 1 or greater than the value of the LST_STEP parameter.
W#16#000D	The value at the DSP parameter is less than 1 or greater than the value of the LST_STEP parameter.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

In the following example the instruction advances from step 1 to step 2. The output bits (OUT1 to OUT16) and the output word (OUT_WORD) are set according to the mask configured for step 2 and the values of the OUT_VAL parameter.

Note

You can initialize static parameters in the data block.

SCL

```
"DRUM_DB"(RESET := "Tag_Reset"
          JOG := "Tag_Input_Jog"
          DRUM_EN := "Tag_Input_DrumEN"
          LST_STEP := "Tag_Number_LastStep"
          EVENT1 := "MyTag_Event_1"
          EVENT2 := "MyTag_Event_2"
          EVENT3 := "MyTag_Event_3"

OUT15 => "MyTag_Output_15"
OUT16 => "MyTag_Output_16"
Q => "Tag_Output_Q"
OUT_WORD => "Tag_OutputWord"
ERR_CODE => "Tag_ErrorCode");
```

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for initializing the input parameters:

Parameters	Operand	Address	Value
RESET	Tag_Reset	M0.0	FALSE
JOG	Tag_Input_JOG	M0.1	FALSE
DRUM_EN	Tag_Input_DrumEN	M0.2	TRUE
LST_STEP	Tag_Number_LastStep	MB1	B#16#08
EVENT2	MyTag_Event_2	M20.0	FALSE
EVENT4	MyTag_Event_4	M20.1	FALSE
EVENT6	MyTag_Event_6	M20.2	FALSE
EVENT8	MyTag_Event_8	M20.3	FALSE
EVENT10	MyTag_Event_10	M20.4	FALSE
EVENT12	MyTag_Event_12	M20.5	FALSE
EVENT14	MyTag_Event_14	M20.6	FALSE
EVENT16	MyTag_Event_16	M20.7	FALSE

The following values are saved in the "DRUM_DB" instance data block of the instruction:

Parameters	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSP	DBB13	W#16#0001
DSC	DBB14	W#16#0001
DCC	DBD16	DW#16#0000000A
DTBP	DBW20	W#16#0001
S_PRESET[1]	DBW26	W#16#0064
S_PRESET[2]	DBW28	W#16#00C8
OUT_VAL[1,0]	DBX58.0	TRUE
OUT_VAL[1,1]	DBX58.1	TRUE
OUT_VAL[1,2]	DBX58.2	TRUE
OUT_VAL[1,3]	DBX58.3	TRUE
OUT_VAL[1,4]	DBX58.4	TRUE
OUT_VAL[1,5]	DBX58.5	TRUE
OUT_VAL[1,6]	DBX58.6	TRUE

S_MASK[2,14]	DBX93.6	FALSE
S_MASK[2,15]	DBX93.7	TRUE

The output parameters are set to the following values before the execution of the instruction:

Parameters	Operand	Address	Value
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#FFFF
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	TRUE
OUT3	MyTag_Output_3	M4.2	TRUE
OUT4	MyTag_Output_4	M4.3	TRUE
OUT5	MyTag_Output_5	M4.4	TRUE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	TRUE
OUT8	MyTag_Output_8	M4.7	TRUE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	TRUE
OUT12	MyTag_Output_12	M5.3	TRUE
OUT13	MyTag_Output_13	M5.4	TRUE
OUT14	MyTag_Output_14	M5.5	TRUE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	TRUE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Address	Value
OUT1	MyTag_Output_1	M4.0	TRUE
OUT2	MyTag_Output_2	M4.1	FALSE
OUT3	MyTag_Output_3	M4.2	FALSE
OUT4	MyTag_Output_4	M4.3	FALSE
OUT5	MyTag_Output_5	M4.4	FALSE
OUT6	MyTag_Output_6	M4.5	TRUE
OUT7	MyTag_Output_7	M4.6	FALSE
OUT8	MyTag_Output_8	M4.7	FALSE
OUT9	MyTag_Output_9	M5.0	TRUE
OUT10	MyTag_Output_10	M5.1	TRUE
OUT11	MyTag_Output_11	M5.2	FALSE
OUT12	MyTag_Output_12	M5.3	FALSE
OUT13	MyTag_Output_13	M5.4	FALSE
OUT14	MyTag_Output_14	M5.5	FALSE
OUT15	MyTag_Output_15	M5.6	TRUE
OUT16	MyTag_Output_16	M5.7	FALSE
Q	Tag_Output_Q	M6.0	FALSE
OUTWORD	Tag_OutputWord	MW8	W#16#4321
ERR_CODE	Tag_ErrorCode	MW10	W#16#0000

The following values are changed in the instance data block "DRUM_DB" of the instruction after the execution of the instruction:

Parameters	Address	Value
JOG_HIS	DBX12.0	FALSE
EOD	DBX12.1	FALSE
DSC	DBB14	W#16#0002
DCC	DBD16	DW#16#000000C8

DCAT: Discrete control-timer alarm (S7-1500)

Description

You can use the "Discrete control-timer alarm" to count the time from the point at which the CMD parameter issues the command to open or close. The time is accumulated until the preset time (PT) is exceeded or the information is received that the device was opened or closed (O_FB or C_FB) within the specified time. If the preset time is exceeded before the information on the opening or closing of the device is received, the corresponding alarm is activated. If the signal state of the command input changes before the preset time, the time is restarted.

The "Discrete control-timer alarm" instruction has the following reactions to the input conditions:

- When the signal state of the CMD parameter changes from "0" to "1", the signal states of the parameters Q, CMD_HIS, ET (only if ET is < PT) OA and CA are influenced as follows:
  - The Q and CMD_HIS parameters are set to "1".
  - The ET, OA, and CA parameters are reset to "0".
- When the signal state on the parameter CMD changes from "1" to "0", the parameters Q, ET (only if ET < PT), OA, CA and CMD_HIS are reset to "0".
- When the signal state of the parameters CMD and CMD_HIS is "1" and the parameter O_FB is set to "0", the time difference (ms) since the last execution of the instruction is added to the value at the parameter ET. If the value of the ET parameter exceeds the value of the PT parameter, the signal state at the OA parameter is set to "1". If the value of the ET parameter does not exceed the value of the PT parameter, the signal state of the OA parameter is reset to "0". The value at the parameter CMD_HIS is reset to the value of the parameter CMD.
- When the signal state of the parameters CMD, CMD_HIS and O_FB are set to "1" and the parameter C_FB has the value "0", the signal state of the parameter OA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the parameter O_FB changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters CMD, CMD_HIS and C_FB have the value "0", the time difference (ms) since the last execution of the instruction is added to the value of the parameter ET. If the value of the ET parameter exceeds the value of the PT parameter, the signal state of the parameter CA is reset to "1". If the value at the parameter PT is not exceeded, the parameter CA has the signal state "0". The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters CMD, CMD_HIS and O_FB have the signal state "0" and the parameter C_FB is set to "1", the parameter CA is set to "0". The value of the ET parameter is set to the value of the PT parameter. If the signal state of the C_FB parameter changes to "0", the alarm is set the next time the instruction is executed. The value of the CMD_HIS parameter is set to the value of the CMD parameter.
- If the parameters O_FB and C_FB simultaneously have the signal state "1", the signal states of both alarm outputs are set to "1".

The "Discrete control-timer alarm" instruction has no error information.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
CMD	Input	BOOL	I, Q, M, D, L	A signal state of "0" indicates a "close" command. A signal state of "1" indicates an "open" command.
O_FB	Input	BOOL	I, Q, M, D, L	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L	Feedback input when closing
Q	Output	BOOL	I, Q, M, D, L	Shows the status of the parameter CMD
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
ET	Static	DINT	D, L	Currently elapsed time, where one count = 1 ms.
PT	Static	DINT	D, L	Preset timer value, where one clock pulse = 1 ms.
PREV_TIME	Static	DWORD	D, L	Previous system time
CMD_HIS	Static	BOOL	D, L	CMD history bit

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

Example

In the following example the parameter CMD changes from "0" to "1". After the execution of the instruction the parameter Q is set to "1" and the two alarm outputs OA and CA have the signal state "0". The CMD_HIS parameter of the instance data block is set to the signal state "1" and the ET parameter is reset to "0".

Note

You can initialize static parameters in the data block.

SCL

```
"DCAT_DB"(CMD := "Tag_Input_CMD",
          O_FB := "Tag_Input_O_FB",
          C_FB := "Tag_Input_C_FB",
          Q => "Tag_Output_Q",
          OA => "Tag_Output_OA",
          CA => "Tag_Output_CA");
```

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameters	Operand	Value
CMD	Tag_Input_CMD	TRUE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
Q	Tag_Output_Q	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#12
PT	DBD8	L#222
CMD_HIS	DBX16.0	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
Q	Tag_Output_Q	TRUE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE

The following values are saved in the instance data block "DCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#0
CMD_HIS	DBX16.0	TRUE

MCAT: Motor control-timer alarm (S7-1500)

Description

The "Motor control-timer alarm" instruction is used to accumulate the time from the point at which one of the command inputs (opening or closing) is switched on. The time is accumulated until the preset time is exceeded or the relevant feedback input indicates that the device has executed the requested operation within the specified time. If the preset time is exceeded before the feedback is received, the corresponding alarm is triggered.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory space	Description
O_CMD	Input	BOOL	I, Q, M, D, L	"Open" command input
C_CMD	Input	BOOL	I, Q, M, D, L	"Close" command input
S_CMD	Input	BOOL	I, Q, M, D, L	"Stop" command input
O_FB	Input	BOOL	I, Q, M, D, L	Feedback input when opening
C_FB	Input	BOOL	I, Q, M, D, L	Feedback input when closing
OO	Output	BOOL	I, Q, M, D, L	"Open" output
CO	Output	BOOL	I, Q, M, D, L	"Close" output
OA	Output	BOOL	I, Q, M, D, L	Alarm output when opening
CA	Output	BOOL	I, Q, M, D, L	Alarm output when closing
Q	Output	BOOL	I, Q, M, D, L	A signal state of "0" indicates an error condition.
ET	Static	DINT	D, L	Currently elapsed time, where one count = 1 ms
PT	Static	DINT	D, L	Preset timer value, where one clock pulse = 1 ms
PREV_TIME	Static	DWORD	D, L	Previous system time
O_HIS	Static	BOOL	D, L	"Open" history bit
C_HIS	Static	BOOL	D, L	"Close" history bit

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

Execution of the "Motor control-timer alarm" instruction

The following table shows the reactions of the "Motor control-timer alarm" instruction to the various input conditions:

Input parameters								Output parameters								
ET	O_HIS	C_HIS	O_CMD	C_CMD	S_CMD	O_FB	C_FB	OO	CO	OA	CA	ET	O_HIS	C_HIS	Q	Status
X	1	1	X	X	X	X	X	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	X	1	1	0	0	1	1	PT	0	0	0	Alarm
X	X	X	X	X	1	X	X	0	0	0	0	X	0	0	1	Stop
X	X	X	1	1	X	X	X	0	0	0	0	X	0	0	1	Stop
X	0	X	1	0	0	X	X	1	0	0	0	0	1	0	1	Start opening
<PT	1	0	X	0	0	0	X	1	0	0	0	INC	1	0	1	Open
X	1	0	X	0	0	1	0	0	0	0	0	PT	1	0	1	Opened
>=PT	1	0	X	0	0	0	X	0	0	1	0	PT	1	0	0	Opening alarm
X	X	0	0	1	0	X	X	0	1	0	0	0	0	1	1	Start closing
<PT	0	1	0	X	0	X	0	0	1	0	0	INC	0	1	1	Close

Input parameters								Output parameters								
X	0	1	0	X	0	0	1	0	0	0	0	PT	0	1	1	Closed
>=PT	0	1	0	X	0	X	0	0	0	0	1	PT	0	1	0	Closing alarm
X	0	0	0	0	0	X	X	0	0	0	0	X	0	0	1	Stopped

Legend:	
INC	Add the time difference (ms) since the last processing of the FB to ET
PT	PT is set to the same value as ET
X	Cannot be used
<PT	ET < PT
>=PT	ET >= PT

If the input parameters O_HIS and C_HIS both have the signal state "1", they are immediately set to signal state "0". In this case, the last row in the table (X) mentioned above is valid. Because it is therefore not possible to check whether the input parameters O_HIS and C_HIS have the signal state "1", the output parameters are set as follows in this case:

OO = FALSE

CO = FALSE

OA = FALSE

CA = FALSE

ET = PT

Q = TRUE

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

SCL

```
"MCAT_DB"(O_CMD := "Tag_Iput_O_CMD",
          C_CMD := "Tag_Input_C_CMD",
          S_CMD := "Tag_Input_S_CMD",
          O_FB := "Tag_Input_O_FB",
          C_FB := "Tag_Input_C_FB",
          OO => "Tag_OutputOpen",
          CO => "Tag_OutputClosed",
          OA => "Tag_Output_OA",
          CA => "Tag_Output_CA",
          Q => "Tag_Output_Q");
```

The following tables show how the instruction works using specific values.

Before processing

In this example, the following values are used for the input and output parameters:

Parameters	Operand	Value
O_CMD	Tag_Input_O_CMD	TRUE
C_CMD	Tag_Input_C_CMD	FALSE
S_CMD	Tag_Input_S_CMD	FALSE
O_FB	Tag_Input_O_FB	FALSE
C_FB	Tag_Input_C_FB	FALSE
OO	Tag_OutputOpen	FALSE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	FALSE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#2
PT	DBD8	L#22
O_HIS	DBX16.0	TRUE
C_HIS	DBX16.1	FALSE

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OO	Tag_OutputOpen	TRUE
CO	Tag_OutputClosed	FALSE
OA	Tag_Output_OA	FALSE
CA	Tag_Output_CA	FALSE
Q	Tag_Output_Q	TRUE

The following values are saved in the instance data block "MCAT_DB" of the instruction:

Parameters	Address	Value
ET	DBD4	L#0
O_HIS	DBX16.0	TRUE
CMD_HIS	DBX16.1	FALSE

IMC: Compare input bits with the bits of a mask (S7-1500)

Description

You can use the "Compare input bits with the bits of a mask" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bits of a mask. Up to 16 steps with masks can be programmed. The value of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. In the CMP_STEP parameter, you specify the step number of the mask that is used for the comparison. All programmed values are compared in the same manner. Unprogrammed input bits or unprogrammed bits of the mask have a default signal state FALSE.

If a match is found in the comparison, the signal state of the OUT parameter is set to "1". Otherwise the OUT parameter is set to "0".

If the value of the CMP_STEP parameter is greater than 15, the instruction is not executed. An error message is output at the ERR_CODE parameter.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN_BIT0	Input	BOOL	I, Q, M, D, L	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L	Input bit 12 is compared with bit 12 of the mask.

Parameters	Declaration	Data type	Memory area	Description
IN_BIT13	Input	BOOL	I, Q, M, D, L	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L	Input bit 15 is compared with bit 15 of the mask.
CMP_STEP	Input	BYTE	I, Q, M, D, L, P	The step number of the mask used for the comparison.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
ERR_COD E	Output	WORD	I, Q, M, D, L, P	Error information
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000A	The value at the CMP_STEP parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

SMC: Compare scan matrix (S7-1500)

Description

You can use the "Compare scan matrix" instruction to compare the signal state of up to 16 programmed input bits (IN_BIT0 to IN_BIT15) with the corresponding bit of the comparison masks for each step. Processing starts at step 1 and is continued until the last programmed step (LAST) or until a match is found. The input bit of the IN_BIT0 parameter is compared with the value of the mask CMP_VAL[x,0], with "x" indicating the step number. All programmed values are compared in the same manner. If a match is found the signal state of the OUT parameter is set to "1" and the step number with the matching mask is written in the OUT_STEP parameter. Unprogrammed input bits or unprogrammed bits of the mask have a default signal state FALSE. If more than one step has a matching mask, only the first one found is indicated in the OUT_STEP parameter. If no match is found, the signal state of the OUT parameter is set to "0". In this case the value at the OUT_STEP parameter is greater by "1" than the value at the LAST parameter.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN_BIT0	Input	BOOL	I, Q, M, D, L	Input bit 0 is compared with bit 0 of the mask.
IN_BIT1	Input	BOOL	I, Q, M, D, L	Input bit 1 is compared with bit 1 of the mask.
IN_BIT2	Input	BOOL	I, Q, M, D, L	Input bit 2 is compared with bit 2 of the mask.
IN_BIT3	Input	BOOL	I, Q, M, D, L	Input bit 3 is compared with bit 3 of the mask.
IN_BIT4	Input	BOOL	I, Q, M, D, L	Input bit 4 is compared with bit 4 of the mask.
IN_BIT5	Input	BOOL	I, Q, M, D, L	Input bit 5 is compared with bit 5 of the mask.
IN_BIT6	Input	BOOL	I, Q, M, D, L	Input bit 6 is compared with bit 6 of the mask.
IN_BIT7	Input	BOOL	I, Q, M, D, L	Input bit 7 is compared with bit 7 of the mask.
IN_BIT8	Input	BOOL	I, Q, M, D, L	Input bit 8 is compared with bit 8 of the mask.
IN_BIT9	Input	BOOL	I, Q, M, D, L	Input bit 9 is compared with bit 9 of the mask.
IN_BIT10	Input	BOOL	I, Q, M, D, L	Input bit 10 is compared with bit 10 of the mask.
IN_BIT11	Input	BOOL	I, Q, M, D, L	Input bit 11 is compared with bit 11 of the mask.
IN_BIT12	Input	BOOL	I, Q, M, D, L	Input bit 12 is compared with bit 12 of the mask.

Parameters	Declaration	Data type	Memory area	Description
IN_BIT13	Input	BOOL	I, Q, M, D, L	Input bit 13 is compared with bit 13 of the mask.
IN_BIT14	Input	BOOL	I, Q, M, D, L	Input bit 14 is compared with bit 14 of the mask.
IN_BIT15	Input	BOOL	I, Q, M, D, L	Input bit 15 is compared with bit 15 of the mask.
OUT	Output	BOOL	I, Q, M, D, L	The signal state "1" indicates that a match was found. A signal state of "0" indicates that no match was found.
OUT_STEP	Output	BYTE	I, Q, M, D, L, P	Contains the step number with the matching mask or the step number which is greater by "1" than the value of the LAST parameter, provided no match is found.
ERR_CODE	Output	WORD	I, Q, M, D, L, P	Error information
LAST	Static	BYTE	I, Q, M, D, L, P	Specifies the step number of the last step to be scanned for a matching mask.
CMP_VAL	Static	ARRAY OF WORD	I, Q, M, D, L	Comparison masks [0 to 15, 0 to 15]: The first number of the index is the step number and the second number is the bit number of the mask.

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
000E	The value at the LAST parameter is greater than 15.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

Overview of the valid data types (Page 2239)

Basics of SCL (Page 4991)

LEAD_LAG: Lead and lag algorithm (S7-1500)

Description

You can use the "Lead and lag algorithm" instruction to process signals with an analog tag. The gain value at the GAIN parameter must be greater than zero. The result of the "Lead and lag algorithm" instruction is calculated using the following equation:

$$OUT = \left[\frac{LG_TIME}{LG_TIME + SAMPLE_T}\right] PREV_OUT + GAIN \left[\frac{LD_TIME + SAMPLE_T}{LG_TIME + SAMPLE_T}\right] IN - GAIN \left[\frac{LD_TIME}{LG_TIME + SAMPLE_T}\right] * PREV_IN$$

The "Lead and lag algorithm" instruction supplies plausible results only when processing is in fixed program cycles. The same units must be specified at the parameters LD_TIME, LG_TIME and SAMPLE_T. At LG_TIME > 4 + SAMPLE_T, the instruction approaches the following function:

OUT = GAIN * ((1 + LD_TIME * s) / (1 + LG_TIME * s)) * IN

When the value of the GAIN parameter is less than or equal to zero, the calculation is not performed and an error information is output on the ERR_CODE parameter.

You can use the instruction "Lead and lag algorithm" in conjunction with loops as a compensator in dynamic feed-forward control. The instruction consists of two operations. The "Lead" operation shifts the phase of output OUT so that the output leads the input. The "Lag" operation, on the other hand, shifts the output so that the output lags behind the input. Because the "Lag" operation is equivalent to an integration, it can be used as a noise suppressor or as a low-pass filter. The "Lead" operation is equivalent to a differentiation and can therefore be used as a high-pass filter. The two instructions together (Lead and Lag) result in the output phase lagging behind the input at lower frequencies and leading it at higher frequencies. This means that the "Lead and lag algorithm" instruction can be used as a band pass filter.

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	REAL	I, Q, M, D, L, P	The input value of the current sample time (cycle time) to be processed. Constants can also be specified at the IN parameter.
SAMPLE_T	Input	INT	I, Q, M, D, L, P	Sample time Constants can also be specified at the SAMPLE_T parameter.
OUT	Output	REAL	I, Q, M, D, L	Result of the instruction
ERR_CODE	Output	WORD	I, Q, M, D, L	Error information

Parameters	Declaration	Data type	Memory area	Description
LD_TIME	Static	REAL	I, Q, M, D, L, P	Lead time in the same unit as sample time.
LG_TIME	Static	REAL	I, Q, M, D, L, P	Lag time in the same unit as sample time
GAIN	Static	REAL	I, Q, M, D, L, P	Gain as % / % (the ratio of the change in output to a change in input as a steady state).
PREV_IN	Static	REAL	I, Q, M, D, L, P	Previous input
PREV_OUT	Static	REAL	I, Q, M, D, L, P	Previous output

The static parameters are not visible when calling the instruction in the program. These are saved in the instance of the instruction.

ERR_CODE parameter

The following table shows the meaning of the values of the ERR_CODE parameter:

Error code* (W#16#...)	Explanation
0000	No error
0009	The value at the GAIN parameter is less than or equal to zero.
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".	

Example

The following example shows how the instruction works:

Note

You can initialize static parameters in the data block.

SCL

```
"LEAD_LAG_DB"(IN := "Tag_Input",
              SAMPLE_T := "Tag_Input_SAMPLE_T",
              OUT => "Tag_Output_Result",
              ERR_CODE => "Tag_ErrorCode");
```

The following tables show how the instruction works using specific values.

Before processing

In this example the following values are used for the input parameters:

Parameters	Operand	Value
IN	Tag_Input	2.0
SAMPLE_T	Tag_Input_SAMPLE_T	10

The following values are saved in the "LEAD_LAG_DB" instance data block of the instruction:

Parameters	Address	Value
LD_TIME	DBD12	2.0
LG_TIME	DBD16	2.0
GAIN	DBD20	1.0
PREV_IN	DBD24	6.0
PREV_OUT	DBD28	6.0

After processing

The following values are written to the output parameters after the instruction has been executed:

Parameters	Operand	Value
OUT	Tag_Output_Result	2.0

The following values are saved in the instance data block "LEAD_LAD_DB" of the instruction:

Parameters	Operand	Value
PREV_IN	DBD24	2.0
PREV_OUT	DBD28	2.0

Basics of SCL (Page 4991)

SEG: Create bit pattern for seven-segment display (S7-1500)

Description

The "Create bit pattern for seven-segment display" instruction is used to convert each of the four hexadecimal digits of the specified source word (IN) into an equivalent bit pattern for a 7-segment display. The result of the instruction is output in the double word on the OUT parameter.

The following relation exists between the hexadecimal digits and the assignment of the 7 segments (a, b, c, d, e, f, g):

Input digit (Binary)	**Assignment of the segments - g f e d c b a**	**Display** (Hexadecimal)	**Seven-segment display**
0000	00111111	0	
0001	00000110	1	
0010	01011011	2	
0011	01001111	3	
0100	01100110	4	
0101	01101101	5	
0110	01111101	6	
0111	00000111	7	
1000	01111111	8	
1001	01100111	9	
1010	01110111	A	
1011	01111100	B	
1100	00111001	C	
1101	01011110	D	
1110	01111001	E	
1111	01110001	F	

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
IN	Input	WORD	I, Q, M, D, L, P	Source word with four hexadecimal digits
OUT	Output	DWORD	I, Q, M, D, L, P	Bit pattern for the seven-segment display
Function value		VOID		Empty function value

Example

The following example shows how the instruction works:

SCL

```
SEG(IN := "Tag_Input",
    OUT => "Tag_Output");
```

The following table shows how the instruction works using specific operand values:

Parameters	Operand	Value	
		Hexadecimal	Binary
IN	Tag_Input	W#16#1234	0001 0010 0011 0100
OUT	Tag_Output	DW16#065B4F66	00000110 01011011 01001111 01100110 Display: 1234

BCDCPL: Create tens complement (S7-1500)

Description

The "Create tens complement" instruction is used to create the tens complement of a seven-digit BCD number specified by the operand. This instruction uses the following mathematical formula to calculate:

10000000 (as BCD)

– 7-digit BCD value

Tens complement (as BCD)

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	Bit strings	I, Q, M, D, L, P	7-digit BCD number
Function value		DWORD	I, Q, M, D, L, P	Result of the instruction

For additional information on valid data types, refer to "See also".

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := BCDCPL("Tag_Input");
```

The following table shows how the instruction functions using specific values:

Operand	Value*
Tag_Input	DW#16#01234567
Tag_Result	DW#16#08765433
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

BITSUM: Count number of set bits (S7-1500)

Description

The "Count number of set bits" instruction is used to count the number of bits of an operand that are set to the signal state "1".

Parameters

The following table shows the parameters of the instruction:

Parameters	Declaration	Data type	Memory area	Description
<Operand>	Input	DWORD	I, Q, M, D, L, P	Operand whose set bits are counted
Function value		INT	I, Q, M, D, L, P	Result of the instruction

Example

The following example shows how the instruction works:

```
SCL
"Tag_Result" := BITSUM("Tag_Input");
```

The following table shows how the instruction functions using specific values:

Operand	Value*
Tag_Input	DW#16#12345678
Tag_Result	W#16#000D (13 bits)
*The error codes can be displayed as integer or hexadecimal value in the program editor. For information on toggling display formats, refer to "See also".

11.4.4 Extended instructions (S7-1200, S7-1500)

11.4.4.1 Date and time-of-day (S7-1200, S7-1500)

T_COMP: Compare time tags (S7-1500)

Description

This instruction is used to compare the contents of two tags of the "Timers" or "Date and time" data type.

The instruction supports the comparison of the following data types: DATE, TIME, LTIME, TOD (TIME_OF_DAY), LTOD (LTIME_OF_DAY), DT (DATE_AND_TIME), LDT (DATE_AND_LTIME), DTL, S5Time.

The data types must be the same length and format to carry out the comparison.

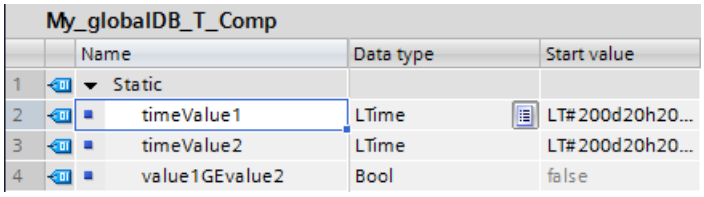
The comparison result is output at the OUT parameter as a return value. For this purpose, the parameter OUT is set to "1" if the condition used for the comparison is satisfied.

The following comparison options are available:

Symbol	Description
EQ	The return value has the signal state “1" if the time is the same at the parameters IN1 and IN2.
NE	The return value has the signal state “1" if the time at the parameter IN1 is not the same as that at the parameter IN2.
GE	The return value has the signal state "1" if the time at parameter IN1 is greater (more recent) than or equal to the time at parameter IN2 .
LE	The return value has the signal state "1" if the time at parameter IN1 is smaller (less recent) than or equal to the time at parameter IN2.
GT	The return value has the signal state "1" if the time at parameter IN1 is greater (more recent) than the time at parameter IN2.
LT	The return value has the signal state "1" if the time at parameter IN1 is smaller (older) than the time at parameter IN2 .

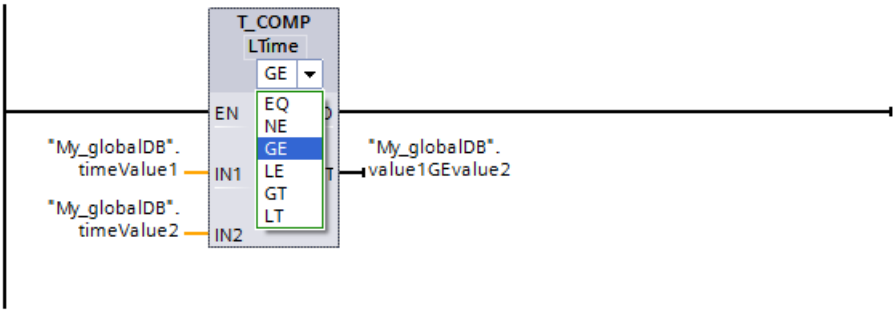
Parameters

The following table shows the parameters of the "T_COMP" instruction:



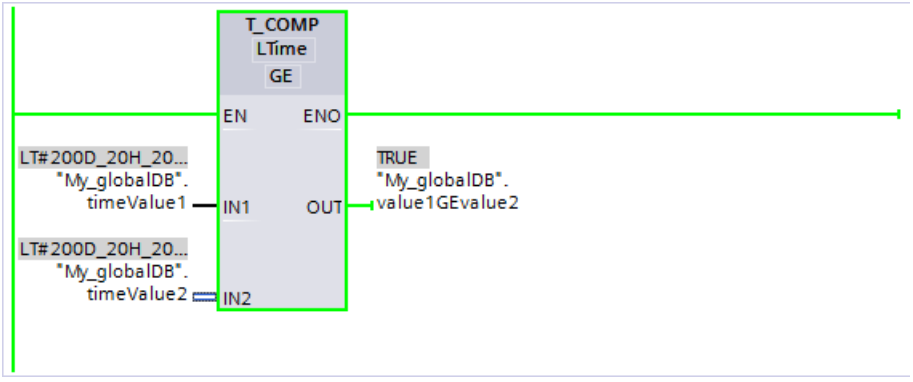
Parameter	Declaration	Data type	Memory area	Description
IN1	Input	DATE, TIME, LTIME, TOD, LTOD, DT, LDT, DTL, S5Time	I, Q, M, D, L, P or constant	First value to be compared.
IN2	Input	DATE, TIME, LTIME, TOD, LTOD, DT, LDT, DTL, S5Time	I, Q, M, D, L, P or constant	Second value to be compared.
OUT	Output	BOOL	I, Q, M, D, L, P	Return value

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you use the "Greater or equal" comparison option to compare two times with the LTIME data type.



Create three tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows. Select the "GE" comparison option.

Since the time of the first value to be compared ("timeValue1") is greater than or equal to the second value ("timeValue2"), the return value ("value1GEvalue2") shows the signal state "TRUE".

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

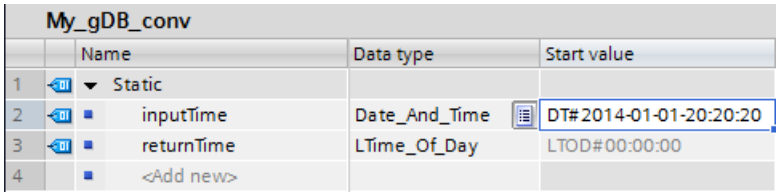
T_CONV: Convert times and extract (S7-1200, S7-1500)

Description

You use the instruction "T_CONV" to convert the data type of the IN input parameter to the data type that is output at the OUT output. You select the data formats for the conversion from the instruction boxes of the input and output.

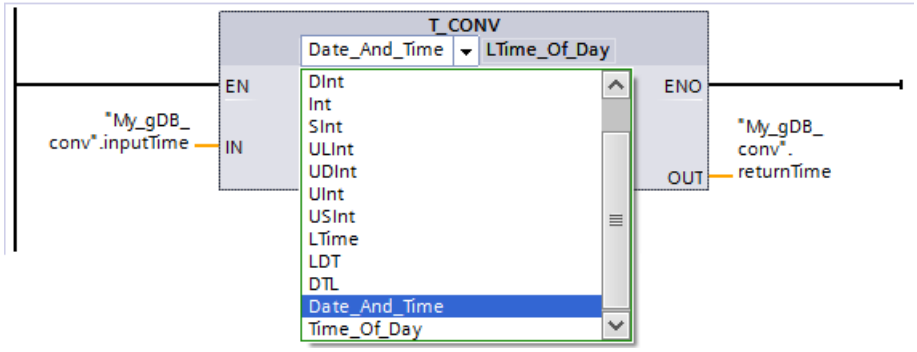
Parameters

The following table shows the parameters of the instruction "T_CONV". If an input and output parameter of the same data type is used, the instruction copies the corresponding value.



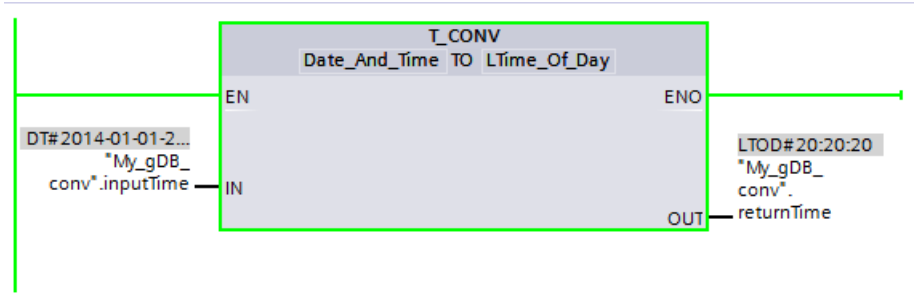
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	Integers, TIME, date and time*	WORD, integers, timers, date and time*	I, Q, M, D, L, P or constant	Value to be converted
OUT	Return	Integers, TIME, date and time*	WORD, integers, timers, date and time*	I, Q, M, D, L, P	Result of the conversion
* The range of supported data types depends on the CPU. Please refer to the overviews of valid data types for information on the data types supported by the S7-1200 and S7-1500 modules.					

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you convert a time with the DATE AND TIME data type to a time with the LTIME OF DAY data type.



Create two tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows and select the data types.

The value to be converted ("inputTime") is output at the output parameter as a new value ("returnTime"). The information for the date is lost.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

T_ADD: Add times (S7-1200, S7-1500)

Description

You use this instruction to add the time information in the IN1 input to the time information in the IN2 input. You can query the result in the OUToutput parameter. You can add the following formats:

- Addition of a time period to another time period.
  Example: Addition of a TIME data type to another TIME data type.
- Addition of a time period to a time.
  Example: Addition of a TIME data type to the DTL data type.

The data type for the value at input parameter IN1 and output parameter OUT is defined by the selection in the instruction boxes of the input and output. You can only specify time information in TIME format in the IN2 input parameter (for S7-1500 modules, also LTIME).

Note

Overflow/underflow

The largest possible value of the OUT output parameter may be exceeded or the smallest possible value undershot during the calculation. Evaluate the enable output ENO to detect this.

Parameters

The following tables show the parameters of the "T_ADD" instruction, according to the possible conversions:

Table 11-18 Addition of a time period to another time period

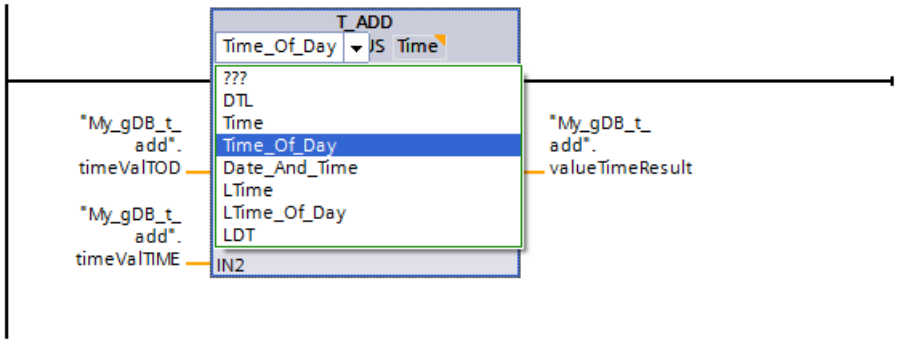
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	First number to be added
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Second number to be added
OUT	Return	DINT, DWORD, TIME, TOD	TIME, LTIME,	I, Q, M, D, L, P	Result of addition The data type selection depends on the data types selected for the IN1 and IN2 input parameters.

Table 11-19 Addition of a time period to a time

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, TOD	DT, TOD, LTOD, LDT, DTL	I, Q, M, D, L, P or constant	First number to be added For LTIME at parameter IN2, only LTOD, LDT or DTL can be used.
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Second number to be added
OUT	Return	DINT, DWORD, TIME, TOD, UDINT, DTL	DT, DTL, LDT, TOD, LTOD	I, Q, M, D, L, P	Result of addition The data type selection depends on the data types selected for the IN1 and IN2 input parameters.

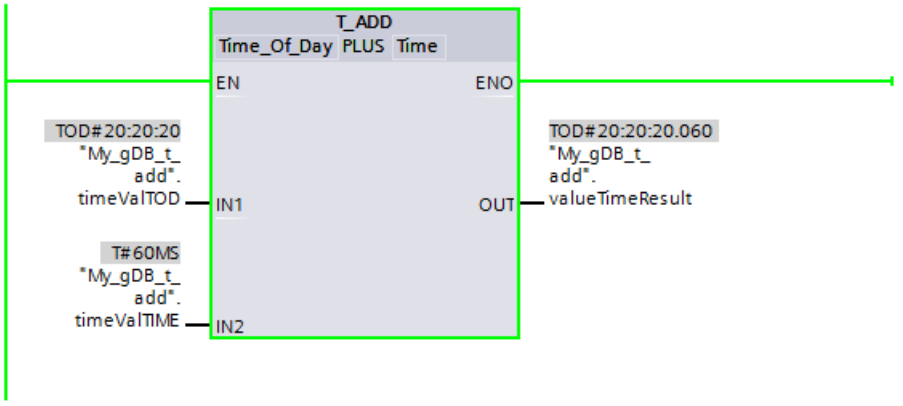
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you add a time duration with the TIME data type to a time of day with the TOD data type.

Create three tags in a global data block for storing the data.



My_gDB_t_add

		Name	Data type	Start value
1		Static		
2		timeValTOD	Time_Of_Day	TOD#20:20:20
3		timeValTIME	Time	T#60ms
4		valueTimeResult	Time_Of_Day	TOD#00:00:00

Interconnect the parameters of the instruction as follows. You select the data types for time of day ("timeValTOD") and time period ("timeValTIME").

The time of day ("timeValTOD") and the time period ("timeValTIME") are added and the result is displayed as a time of day at output parameter OUT ("valueTimeResult").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

T_SUB: Subtract times (S7-1200, S7-1500)

Description

You use this instruction to subtract the time information in the IN2 input parameter from the time information in the IN1 input parameter. You can query the difference at the OUT output parameter. You can subtract the following formats:

- Subtraction of a time period from another time period
  Example: Subtraction of a time period of the data type TIME from another time period of the data type TIME. The result can be output to a tag with the TIME format.
- Subtraction of a time period from a time
  Example: Subtraction of a time period of the data type TIME from a time of the data type DTL. The result can be output to a tag with the DTL format.

You decide the formats of the values in the IN1 input parameter and the OUT output parameter by selecting the data types for the input and output parameters of the instruction.

Note

Overflow/underflow

The largest possible value of the OUT output parameter may be exceeded or the smallest possible value undershot during the calculation. Evaluate the enable output ENO to detect this.

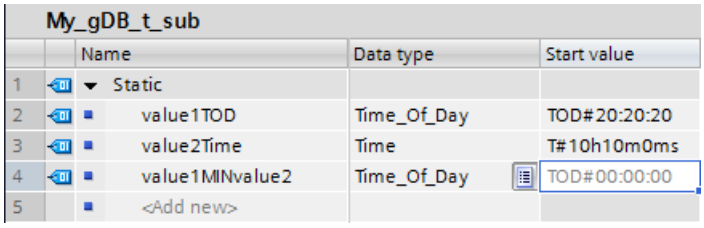
Parameters

The following tables show the parameters of the "T_SUB" instruction, according to the possible conversions:

Table 11-20 Subtraction of a time period from another time period

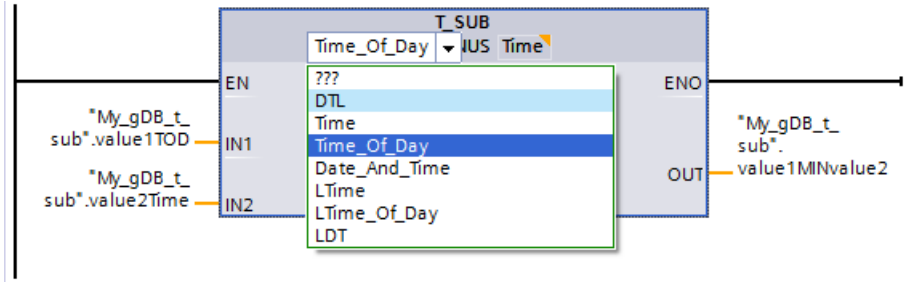
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Minuend
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	DINT, DWORD, TIME, TOD, UDINT	TIME, LTIME	I, Q, M, D, L, P	Result of subtraction

Table 11-21 Subtraction of a time period from a time



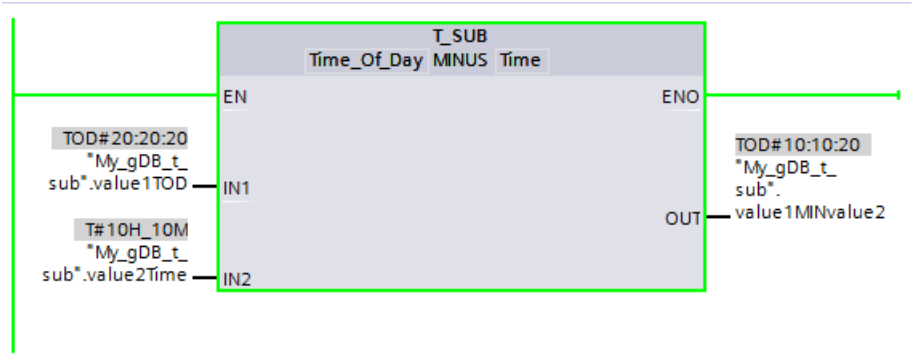
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, TOD	TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P or constant	Minuend For LTIME at parameter IN2, only LTOD, LDT or DTL are used.
IN2	Input	TIME	TIME, LTIME	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	DTL, DINT, DWORD, TIME, TOD, UDINT	TOD, LTOD, DTL, DT, LDT	I, Q, M, D, L, P	Result of subtraction

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you subtract a time period with the TIME data type from a time of day with the TOD data type.



Create three tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows. You select the data type for the time of day ("value1TOD") and the data type for the time period ("value2Time").

The time of day ("value1TOD") and the time period ("value2Time") are subtracted and the result is displayed as a time of day at output parameter OUT ("value1MINvalue2").

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

T_DIFF: Time difference (S7-1200, S7-1500)

Description

You use this instruction to subtract the time information in the IN2 input parameter from the time information in the IN1 input parameter. The result is sent at output parameter OUT.

- If the time information at the IN2 input parameter is greater than the time information at the IN1 input parameter, the result is output as a negative value at the OUT output parameter.
- If the result of the subtraction is outside the TIME number range, the enable output ENO is = "0". Depending on the data types used, you get either a truncated result or "0" (0:00).
  - If you select the minuend and subtrahend parameters of the DTL data type, the result has the TIME data type. It may not be greater than 24 days, otherwise the enable output ENO = "0" and the result is "0".
  - If you select the minuend and subtrahend parameters of the LDT data type, this restriction is avoided.

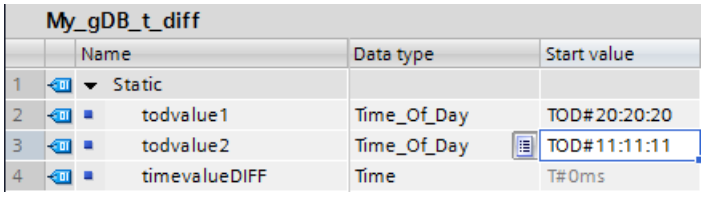
Parameters

The following table shows the parameters of the "T_DIFF" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DTL, DATE, TOD	DTL, DATE, DT, TOD, LTOD, LDT	I, Q, M, D, L, P or constant	Minuend
IN2	Input	DTL, DATE, TOD	DTL, DATE, DT, TOD, LTOD, LDT	I, Q, M, D, L, P or constant	Subtrahend
OUT	Return	TIME, INT	TIME, LTIME, INT	I, Q, M, D, L, P	Difference of input parameters

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

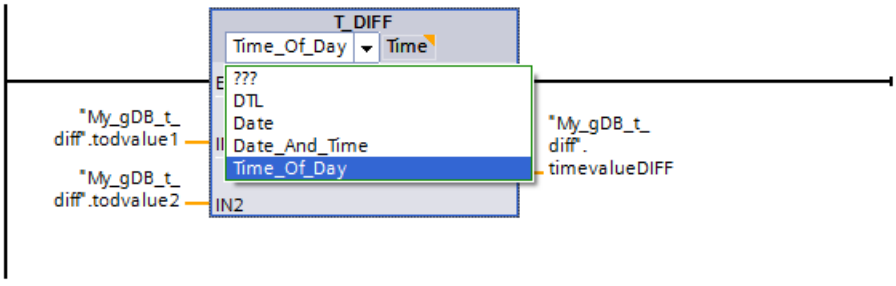


Use of the "T_DIFF instruction in SCL

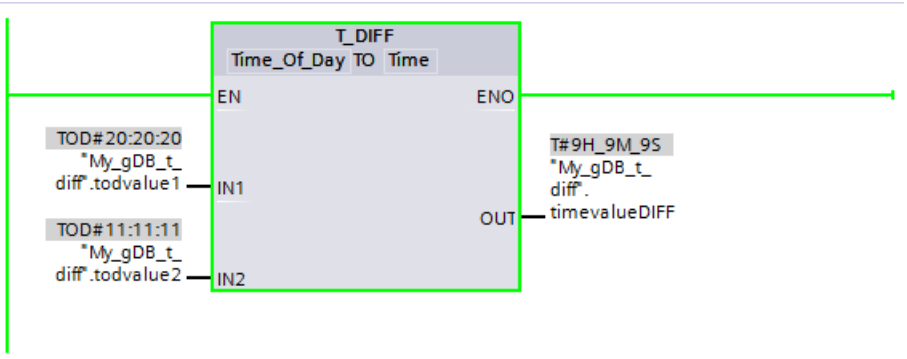
In SCL, the data type TIME is preset for the OUT parameter (see also: Basic information on the data types of SCL instructions (Page 5034) If you want to use the data type INT for OUT, you need to extend the instruction name T_DIFF by adding "_INT" (see also: Changing the data type of an SCL instruction (Page 5035)).

Example

In the following example, you calculate the difference between two times of day with the TOD data type. You specify the difference in the "TIME" data type.



Create three tags in a global data block for storing the data.



My_gDB_t_diff

	Name	Data type	Start value
1	Static		
2	todvalue1	Time_Of_Day	TOD#20:20:20
3	todvalue2	Time_Of_Day	TOD#11:11:11
4	timevalueDIFF	Time	T#0ms

Interconnect the parameters of the instruction as follows and select the data types. With the first selection option, you specify the data type of the points in time. With the second selection option, you specify the data type of the difference.

The first time of day ("todvalue1") and the second time of day ("todvalue2") are subtracted and the difference is displayed as a time period at output parameter OUT ("timevalueDIFF").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

T_COMBINE: Combine times (S7-1200, S7-1500)

Description

The instruction combines the value of a date with the value of a time, resulting in a combined date and time value.

- The date is output at the input parameter IN1. Use a value between DATE and 1990-01-01 for the data type 2089-12-31 (this is not checked).
- The time is input at the IN2 input value (TOD/LTOD data type).
- The combined data type for the date and time value is output at the OUT output value.

Parameters

The following table shows the parameters of the "T_COMBINE" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN1	Input	DATE	DATE	I, Q, M, D, L, P or constant	Input tag of the date
IN2	Input	TOD	TOD, LTOD	I, Q, M, D, L, P or constant	Input tag of the time
OUT	Return	DTL	DT, DTL, LDT	I, Q, M, D, L, P	Return value of the date and time

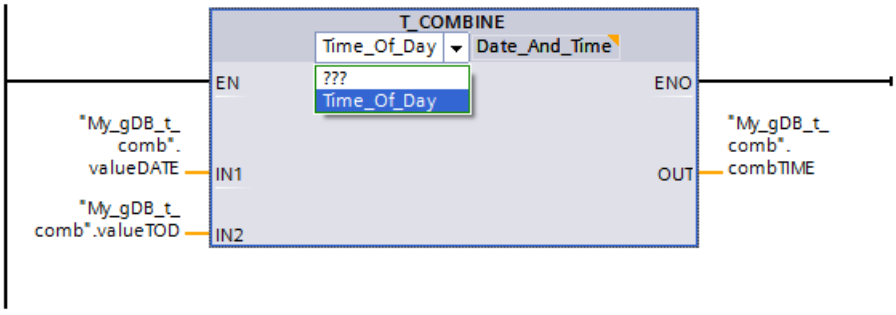
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

Use of T_COMBINE in SCL programs

When you drag the instruction "T_COMBINE" from the "Instructions" task card to the SCL programming window, the internal instruction CONCAT_DATE_TOD or CONCAT_DATE_LTOD is displayed there.

Example



In the following example, you combine a time of day with the TOD data type and a date with the DATE data type. You specify the return value in the DT data type.

Create three tags in a global data block for storing the data.

My_gDB_t_comb

	Name	Data type	Start value
1	Static		
2	valueDATE	Date	D#2014-01-01
3	valueTOD	Time_Of_Day	TOD#20:22:20
4	combTIME	Date_And_Time	DT#1990-01-01-00:00:00

Interconnect the parameters of the instruction as follows and select the data types. With the first selection option, you specify the data type of the time of day ("valueTOD"). With the second selection option, you specify the data type of the return value ("combTIME").

The date ("valueDATE") is expanded by the specification of the time of day ("valueTOD") and the return value is displayed at output parameter OUT ("combTIME").

My_gDB_t_comb

	Name	Data type	Start value	Monitor value
1	Static			
2	valueDATE	Date	D#2014-01-01	D#2014-1-1
3	valueTOD	Time_Of_Day	TOD#20:22:20	TOD#20:22:20
4	combTIME	Date_And_Time	DT#1990-01-01-0	DT#2014-01-01-20:22:20

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Time-of-day functions (S7-1200, S7-1500)

WR_SYS_T: Set time-of-day (S7-1200, S7-1500)

Description

You use this instruction to set the date and time-of-day (module time) of the CPU clock. Enter the date and time-of-day at the input parameter IN . The value must be in the following range:

- With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999
- With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2200-12-31-23:59:59.999999999
- With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31-23:59:59.999999999

You can query whether errors have occurred during execution of the instruction in the RET_VAL output parameter.

The "WR_SYS_T" instruction is not used to pass information about the local time zone or daylight saving time.

Note

Module time of CPU clock

The CPU clock interprets the module time as the coordinated universal time (UTC). Accordingly, the module time is always stored without the factors "local time zone" or "summer time" in the CPU clock. The CPU clock then calculates the local time of the CPU clock based on the module time.

The module time of the CPU clock is used as template for all time processes starting from the CPU. Examples of use:

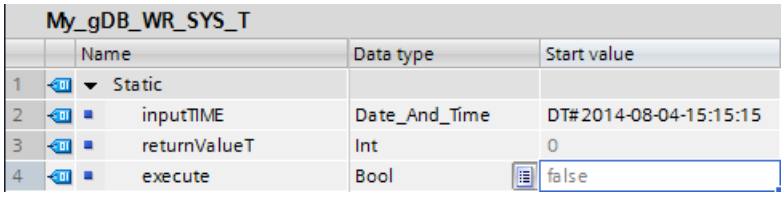
- Calculation of local time of CPU clock based on module time
- Representation of the module time in local time under "Online & Diagnostics"
- Block properties
- Entries in the diagnostics buffer of the CPU

Parameter

The following table shows the parameters of the "WR_SYS_T" instruction:

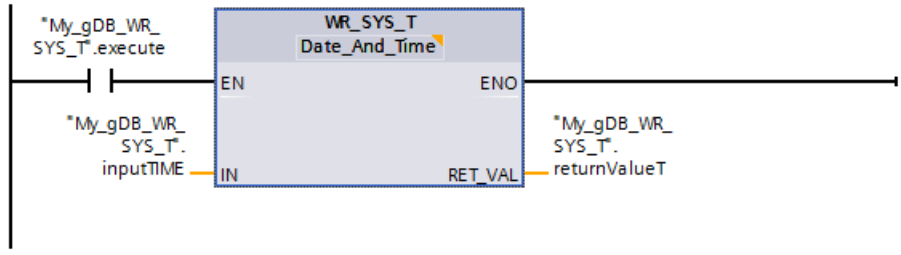
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	DTL	DT **, DTL, LDT	I, Q, M, D, L, P or constant *	Date and time
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
* The data types DT and DTL are not used for the following memory areas: input, output and bit memory.					
** When using the data type DT the milliseconds are not transferred to the CPU.					

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



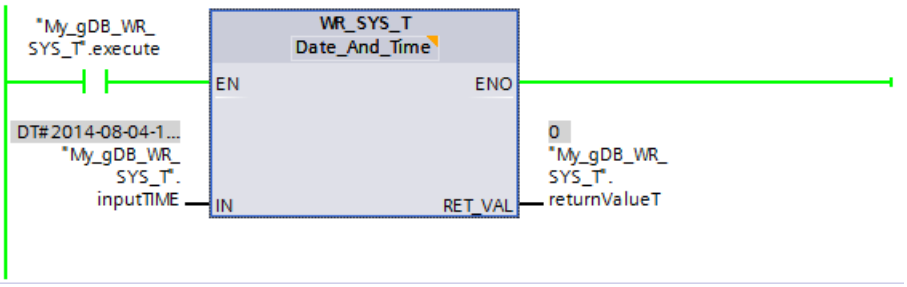
Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
8080	Error in date
8081	Error in time
8082**	Invalid value specified for the month (byte 2 in DTL format).
8083**	Invalid value specified for the day (byte 3 in DTL format).
8084**	Invalid value specified for the hour (byte 5 in DTL format).
8085**	Invalid value specified for the minute (byte 6 in DTL format).
8086**	Invalid value specified for the second (byte 7 in DTL format).
8087**	Invalid value specified for the nanosecond (bytes 8 to 11 in DTL format).
80B0	The real-time clock has failed
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	
** Only if the date and time are specified at the parameter IN in DTL format	



Example

In the following example, you set the date and time of the CPU clock. The data type used is DATE AND TIME.



Create three tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.

If the normally open contact ("execute") supplies the signal state "TRUE", the "WR_SYS_T" instruction is executed. The module time of the CPU clock is overwritten with the time to be set ("inputTIME"). The output parameter RET_VAL ("returnValueT") indicates that processing took place without errors.

You can establish whether the new module time ("inputTIME") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > General".
- Using TIA Portal: Read out the module time of the CPU clock using the "RD_SYS_T (Page 3469)" instruction.
- Using TIA Portal: Navigate to the "Online & Diagnostics" entry of the CPU, and open the "Functions > Set time of day" tab.
  The Coordinated Universal Time (UTC) is set for the module time of the CPU clock. Central European Time is set as local time in the TIA Portal in this example. Accordingly, an hour is added to the time to be set ("inputTIME") in the "Online & Diagnostics" entry in the TIA Portal. Another hour is added when daylight saving time is used. The calculated local time is output in 12-hour clock format.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

RD_SYS_T: Read time-of-day (S7-1200, S7-1500)

Description

You use this instruction to read the current date and current time-of-day (module time) of the CPU clock.

The read dates are output at the OUT output parameter of the instruction. The provided value does not include information about the local time zone or daylight saving time.

Note

Module time of CPU clock

The CPU clock interprets the module time as the coordinated universal time (UTC). Accordingly, the module time is always stored without the factors "local time zone" or "summer time" in the CPU clock. The CPU clock then calculates the local time of the CPU clock based on the module time.

The module time of the CPU clock is used as template for all time processes starting from the CPU. Examples of use:

- Calculation of local time of CPU clock based on module time
- Representation of the module time in local time under "Online & Diagnostics"
- Block properties
- Entries in the diagnostics buffer of the CPU

You can query whether errors have occurred during execution of the instruction in the RET_VALoutput.

Parameters

The following table shows the parameters of the "RD_SYS_T" instruction:

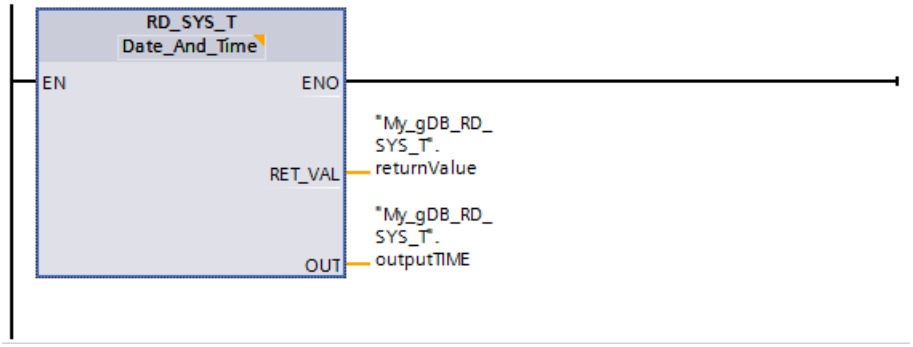
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
OUT	Output	DTL	DT, DTL, LDT	I, Q, M, D, L, P *	Date and time of CPU
* The data types DT and DTL cannot be used for the memory areas: input, output and bit memory.					

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
8081	Time value specified at the OUT parameter is outside the valid value range: • With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999 • With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2262-04-11-23:47:16.854775807 • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2262-04-11-23:47:16.854775807
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example



In the following example, you read out the module time of the CPU clock. The data type used is DATE AND TIME.

Create two tags in a global data block for storing the data.

My_gDB_RD_SYS_T

	Name	Data type	Start value
1	Static		
2	outputTIME	Date_And_Time	DT#1990-01-01-00:00:00
3	returnValue	Int	0

Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.

The module time of the CPU clock is read out and displayed at output parameter OUT ("outputTIME"). The output parameter RET_VAL ("returnValue") indicates that processing took place without errors.

My_gDB_RD_SYS_T

	Name	Data type	Start value	Monitor value
1	Static			
2	outputTIME	Date_And_Time	DT#1990-01-01-00:00:00	DT#2014-08-04-15:15:15
3	returnValue	Int	0	0

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

RD_LOC_T: Read local time (S7-1200, S7-1500)

Description

You use this instruction to read the current local time from the CPU clock and output this at the OUT output. Information on the time zone and the start of daylight saving time and standard time, which you have set in the configuration of the CPU clock, is used to output the local time.

Parameters

The following table shows the parameters of the "RD_LOC_T" instruction:

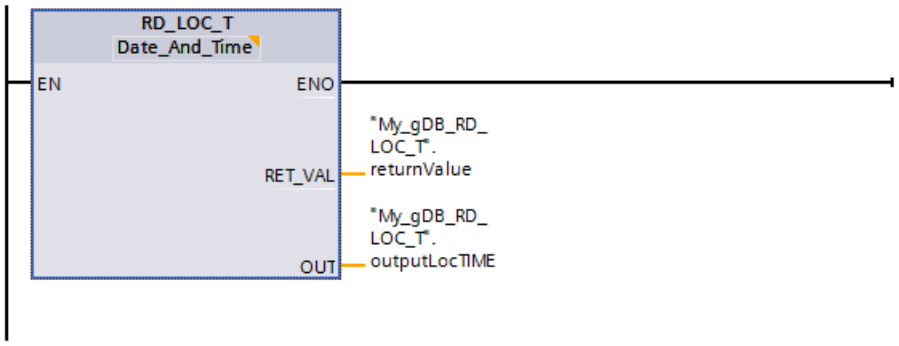
Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Status of the instruction
OUT	Output	DTL	DT, LDT, DTL	I, Q, M, D, L, P *	Local time
* The data types DT and DTL cannot be used for the memory areas: input, output and bit memory.					

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
0001	No error. Local time is output as daylight saving time.
8080	Local time cannot be read.
8081	Time value specified at the OUT parameter is outside the valid value range: • With DT: min. DT#1990-01-01-0:0:0, max. DT#2089-12-31-23:59:59.999 • With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2262-04-11-23:47:16.854775807 • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2262-04-11-23:47:16.854775807
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

Example



In the following example, you read out the local time of the CPU clock. The data type used is DATE AND TIME.

Create two tags in a global data block for storing the data.

My_gDB_RD_LOC_T

	Name	Data type	Start value
1	Static		
2	outputLocTIME	Date_And_Time	DT#1990-01-01-00:00:00
3	returnValue	Int	0

Interconnect the parameters of the instruction as follows. Select the DATE AND TIME data type.

The local time of the CPU clock is read out and displayed at output parameter OUT ("outputLocTIME"). Output parameter RET_VAL ("returnValue") indicates that processing took place without errors and the local time is output as daylight saving time with this call.

My_gDB_RD_LOC_T

		Name	Data type	Start value	Monitor value
1		Static			
2		outputLocTIME	Date_And_Time	DT#1990-01-01-00:00:00	DT#2014-08-04-16:15:15.001
3		returnValue	Int	0	1

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

WR_LOC_T: Write local time (S7-1200, S7-1500)

Description

The instruction "WR_LOC_T" is used to set the date and time of the CPU clock. Enter the date and time-of-day as local time at the input parameter LOCTIME.

The value must be in the following range:

- With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31 23:59:59.999999999
- With LDT: min. LDT#1970-01-01-0:0:0.000000000, max. LDT#2200-12-31 23:59:59.999999999

The granularity of the time information for local time and system time is product-specific and is at least one millisecond. Input values at the LOCTIME parameter which are less than those supported by the CPU are rounded up during system time calculation.

You can query whether errors have occurred during execution of the instruction in the RET_VAL output parameter.

Parameters

The following table shows the parameters of the "WR_LOC_T" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
LOCTIME	Input	DTL	DTL, LDT	I, Q, M, D, L, P or constant *	Local time
DST	Input	BOOL	BOOL	I, Q, M, D, L, P, T, C or constant	**D**aylight **S**aving **T**ime Is only evaluated during the "double hour" at changeover to standard time. • TRUE = daylight saving time (first hour) • FALSE = standard time (second hour)
RET_VAL	Return	INT	INT	I, Q, M, D, L, P	Error message (see "RET_VAL parameter")
* The data type DTL cannot be used for the memory areas: input, output and bit memory.					

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter DST (Daylight Saving Time)

The parameter DST is evaluated only during the changeover from daylight saving to standard time:

- Use of DST during changeover from daylight saving to standard time
  The clock is set back by (1) one hour at 3 a.m. This means there are two hours between 02:00:00:000000000 AM and 02:59:59:999999999 AM.
  For all times for LOCTIME that are between 02:00:00:000000000 AM and 02:59:59:999999999 AM, you therefore need to declare whether the time is before or after the time changeover. The DST parameter is used for this:
  – With DST=TRUE, the time is in the first of the two hours, i.e. still in daylight saving time.
  – With DST=FALSE, the time is in the second of the two hours, i.e. in standard time.

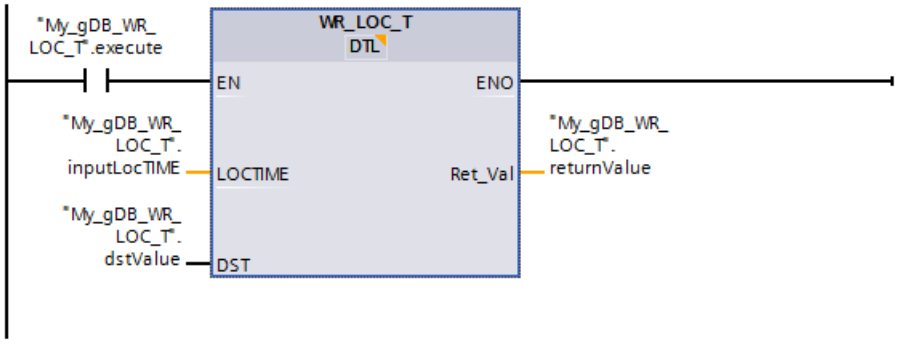
  For all times for LOCTIME that are outside the double hour, DST is irrelevant.
- Changeover from standard to daylight saving time
  The parameter DST is not relevant for the changeover from standard to daylight saving time.
  The clock is set forward by (1) one hour at 2 a.m. This means there is no hour between 02:00:00:000000000 AM and 02:59:59:999999999 AM.
  If you specify a time within this hour at LOCTIME, the error code W#16#8089 is output.

(1)The description here assumes Central European Time (CET). The changeover time for CET is 2:00 AM (start of daylight saving), or 3:00 AM (end of daylight saving). Different changeover times may apply correspondingly to other time zones.

Parameter RET_VAL

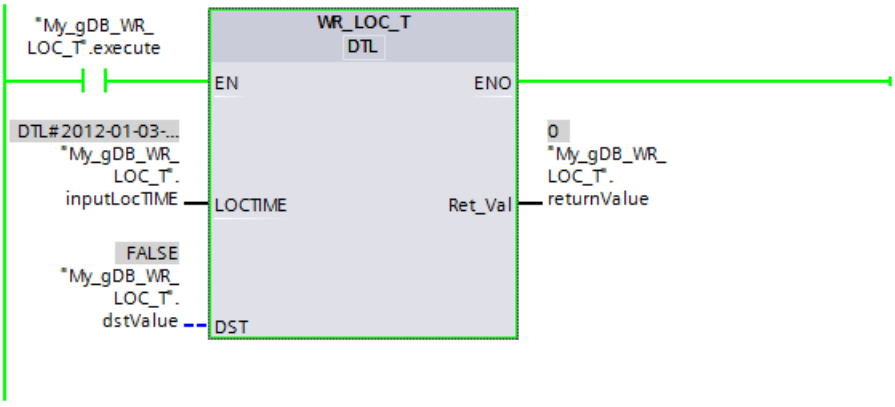
Error code* (W#16#....)	Description
0000	No error.
8080	The LOCTIME parameter has an invalid value.
8081	Time value specified at the LOCTIME parameter is outside the valid value range: • With DTL: min. DTL#1970-01-01-00:00:00.0, max. DTL#2200-12-31 23:59:59.999999999 • With LDT: min. LDT#1970-1-1-0:0:0.000000000, max. LDT#2200-12-31 23:59:59.999999999
8082**	Invalid value specified for the month (byte 2 in DTL format).
8083**	Invalid value specified for the day (byte 3 in DTL format).
8084**	Invalid value specified for the hour (byte 5 in DTL format).
8085**	Invalid value specified for the minute (byte 6 in format DTL).
8086**	Invalid value specified for the second (byte 7 in DTL format).
8087**	Invalid value specified for the nanosecond (byte 8 to 11 in DTL format).
8089	Time value does not exist (hour already passed upon changeover to daylight saving time).
80B0	The real-time clock has failed.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	
** Only for local time information at the LOCTIME parameter in DTL format.	

Example



In the following example, you set the local time of the CPU clock. The data type used is DTL.

Create four tags in a global data block for storing the data.



My_gDB_WR_LOC_T

	Name	Data type	Start value
1	Static		
2	inputLocTIME	DTL	DTL#2012-01-03-12:12:12
3	dstValue	Bool	false
4	returnValue	Int	0
5	execute	Bool	false

Interconnect the parameters of the instruction as follows. Select the DTL data type.

If the normally open contact ("execute") supplies the signal state "TRUE", the "WR_LOC_T" instruction is executed. The local time of the CPU clock is overwritten with the time to be set ("inputLocTIME"). The output parameter RET_VAL ("returnValue") indicates that the process took place without errors. Input parameter DST ("dstValue") specifies that the time information refers to standard time. This parameter is only relevant for the "double hour" (see description "Parameter DST").

You can establish whether the new local time ("inputLocTIME") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > General".
- Using TIA Portal: Read out the local time of the CPU clock using the "RD_LOC_T (Page 3471)" instruction.
- Using TIA Portal: Navigate to the "Online & Diagnostics" entry of the CPU, and open the "Functions > Set time of day" tab.
  The local time is output in a 12-hour clock format.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

SET_TIMEZONE: Set time zone (S7-1200, S7-1500)

Description

Use the instruction "SET_TIMEZONE" to set the parameter for the local time zone and the daylight saving / standard time changeover.

The settings which are carried out with the instruction "SET_TIMEZONE" correspond with the settings for the time-of-day in the properties of the CPU. Define the corresponding parameters in the system data type TimeTransformationRule for execution of the instruction "SET_TIMEZONE".

The local time is calculated based on the system time using the settings for the time zone and the daylight saving / standard time changeover. The system time of the CPU is the UTC time. The system time is used exclusively for communication within the system.

Note

Calling the "SET_TIMEZONE" instruction

The instruction "SET_TIMEZONE" writes data internally to the load memory of the CPU. Accordingly, the change in time zone also applies after a power failure. Calling the instruction again is unnecessary.

Call the instruction once every time the time zone has to be changed. For example, it is advisable to call "SET_TIMEZONE" in a startup OB.

Note

Use with CPUs of the S7-1500 series

The "SET_TIMEZONE" instruction can only be used with a CPU of the S7-1500 series starting from firmware version V1.7.

Parameters

The following table shows the parameters of the "SET_TIMEZONE" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, P or constant	Setting of parameters that are stored at parameter TimeZone.
TimeZone	Input	TimeTransformationRule	D, L	You interconnect the TimeTransformationRule system data type (see below) at parameter TimeZone.
DONE	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: Job not yet started or still in progress • 1: Job completed without error
BUSY	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: Job not yet started or already completed • 1: Job not yet completed. A new job cannot be started.
ERROR	Output	BOOL	I, Q, M, D, L, P	Status parameter: • 0: No error • 1: Error occurred
STATUS	Output	WORD	I, Q, M, D, L, P	Detailed error and status information is output at the parameter STATUS. The parameter is only set for the duration of one call. To display the status, you should therefore copy the STATUS parameter to a free data area.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter TimeZone

You store the parameters for the local time zone and the daylight saving/standard time changeover in the TimeTransformationRule system data type

You create the TimeTransformationRule by entering TimeTransformationRule as the data type in a data block or the local interface of a function block.

The structure of the TimeTransformationRule is as follows:

Name	Data type	Description
TimeTransformationRule	STRUCT	

Name	Data type	Description
Bias	INT	Time difference between the local time and the system time (UTC) in minutes. The value must be between -720 and +780 minutes (-12 to +13 hours). The value (UTC -12 to +13 hours) corresponds to the time zones that you specify in the properties of the CPU.
DaylightBias	INT	Time difference between standard and daylight saving time in minutes. The value must be between 0 and 120 minutes. • The value "0" deactivates the changeover between daylight saving time and standard time. The values for "DaylightStart..." and "StandardStart..." are set to "0". Only the value of Bias is evaluated (time difference local time/ system time). • If the value is not "0", all tags of the TimeTransformationRule structure are evaluated. If an entry is invalid, error code 808F is output at parameter STATUS.
Specification of the time of day for changeover to daylight saving time. The following times always refer to the local time.		
DaylightStartMonth	USINT	Month in which change is made to daylight saving time: 1 = January 2 = February 3 = March ... 12 = December
DaylightStartWeek	USINT	Week in which change is made to daylight saving time. 1 = First occurrence of the weekday in the month ... 5 = Last occurrence of the weekday in the month
DaylightStartWeek-day	USINT	Weekday on which change is made to daylight saving time: 1 = Sunday ... 7 = Saturday
DaylightStartHour	USINT	Hour in which change is made to daylight saving time
DaylightStartMinute	USINT	Minute in which change is made to daylight saving time
Specification of the time of day for changeover to standard time. The following times always refer to the local time.		
StandardStartMonth	USINT	Month in which change is made to standard time: 1 = January 2 = February 3 = March ... 12 = December
StandardStartWeek	USINT	Week in which change is made to standard time: 1 = First occurrence of the weekday in the month ...

Name		Data type	Description
			5 = Last occurrence of the weekday in the month
	StandardStartWeek-day	USINT	Weekday on which change is made to standard time: 1 = Sunday ... 7 = Saturday
	StandardStartHour	USINT	Hour in which change is made to standard time
	StandardStartMinute	USINT	Minute in which change is made to standard time
	TimeZoneName	STRING[80]	Not used: The configured character string is ignored and not written to the CPU-internal data.

Parameter STATUS

Error code* (W#16#....)	Description
7000	No job processing active.
7001	Start of job processing. Parameter BUSY = 1, DONE = 0
7002	Intermediate call (REQ irrelevant): Instruction already active; BUSY has the value "1".
808F	The structure, content or data types of the TimeTransformationRule at the TimeZone parameter are invalid or inconsistent.
80C3	Temporary resource error: The CPU is currently processing the maximum possible number of simultaneous block calls. "SET_TIMEZONE" cannot be executed until at least one of the block calls is finished.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

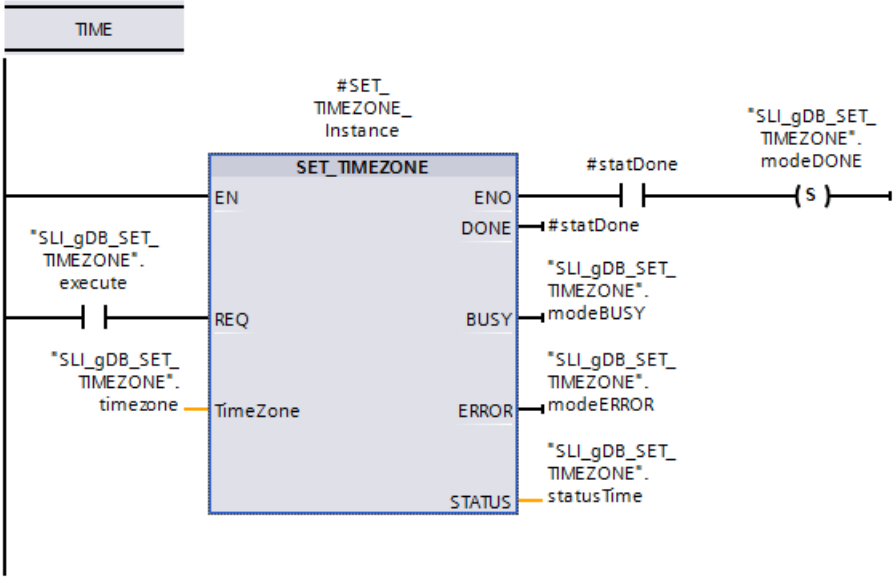
Example

In the following example, you set the parameters for the local time zone and the daylight saving/standard time changeover. You are advised to call the example in a startup OB.

Create the following for storing the data in a global data block: The "timezone" structure (with the TimeTransformationRule data type) and five additional tags.

Note

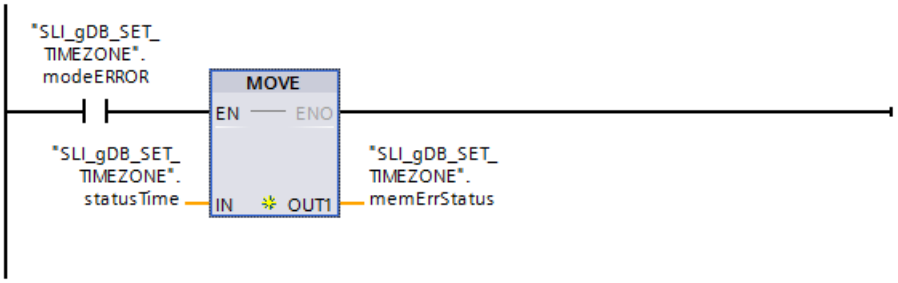
If you want to call the example in a startup OB: Set the start value of the tag "execute" to "TRUE".



SLI_gDB_SET_TIMEZONE

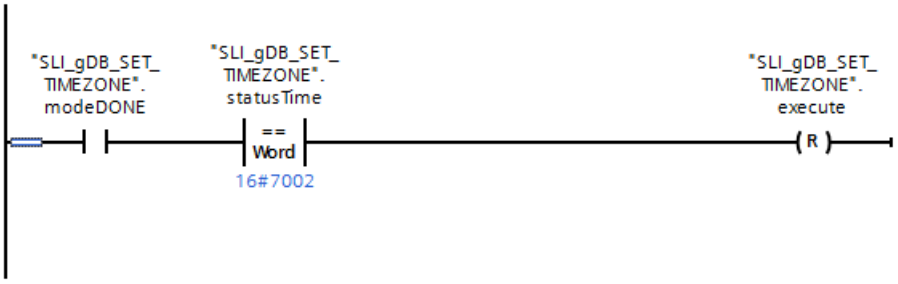
	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	timezone	TimeTransformatio...	
4	Bias	Int	120
5	DaylightBias	Int	60
6	DaylightStartMonth	USInt	3
7	DaylightStartWeek	USInt	5
8	DaylightStartWeekday	USInt	7
9	DaylightStartHour	USInt	2
10	DaylightStartMinute	USInt	0
11	StandardStartMonth	USInt	10
12	StandardStartWeek	USInt	5
13	StandardStartWeekday	USInt	1
14	StandardStartHour	USInt	3
15	StandardStartMinute	USInt	0
16	TimeZoneName	String[80]	'My_GMT+'
17	modeDONE	Bool	false
18	modeBUSY	Bool	false
19	modeERROR	Bool	false
20	statusTime	Word	16#0
21	memErrStatus	Word	16#0

Create a local tag for the interconnection of the output parameter DONE.

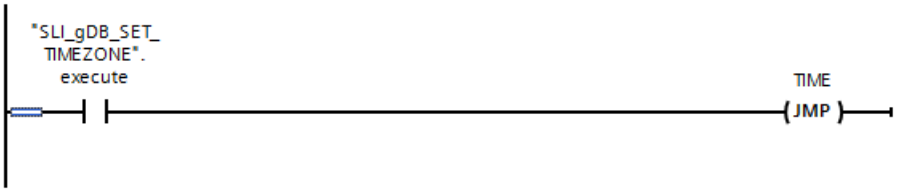


9	statDone	Bool	false	Non-retain

Network 1: Interconnect the parameters of the "SET_TIMEZONE" instruction as follows.



Also, create the following additional interconnections:



Network 2: In case of error, you save the status in the "memErrStatus" tag.

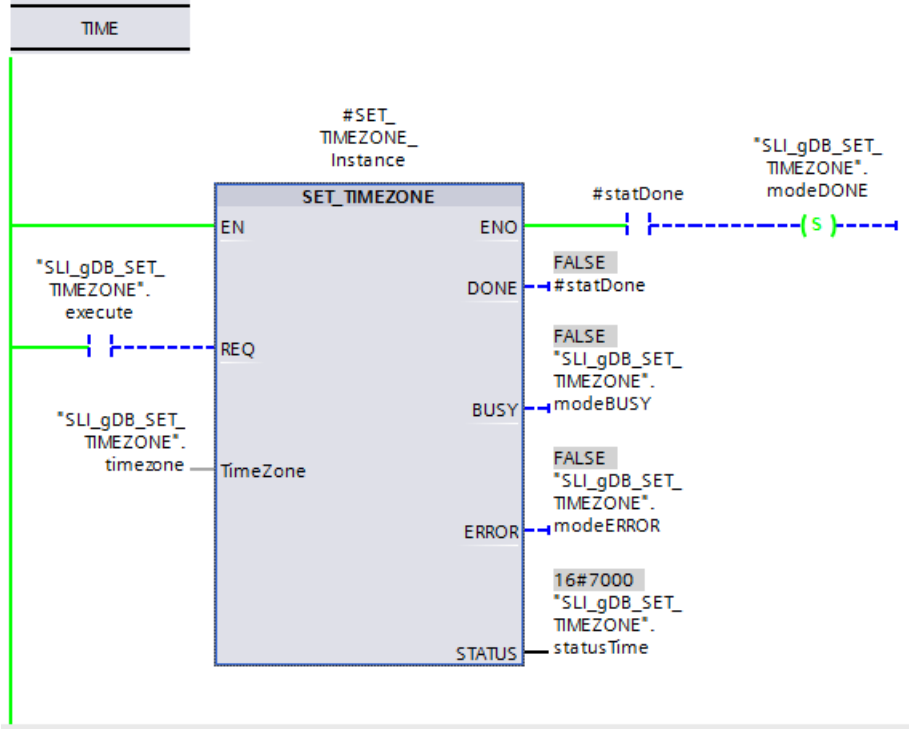
Network 3: After successful processing, have the input parameter REQ ("execute") automatically reset as follows.

Network 4: To ensure that the instruction "SET_TIMEZONE" is fully processed when called in a startup OB, use the instructions JMP (in network 4) and Label (see network 1).

Note

If you want to call the example in a startup OB, the CPU for processing the example must be in startup. Set the CPU to STOP mode before you load the example to the CPU. Then set the CPU to RUN mode.

If the input parameter REQ ("execute) returns the signal state "TRUE", the data for the time zone of the CPU clock is overwritten by the data to be set ("timezone"). That also means that:



- Output parameter BUSY ("modeBUSY") goes to signal state "TRUE". After processing, output parameter BUSY shows the value "FALSE" and output parameter DONE ("#statDone") shows the value "TRUE". The success status is saved to the "modeDONE" tag.
- The output parameter STATUS ("statusTime") indicates how processing is running*. (*The job processing begins (value "7001") and the instruction is then shown as already active (value "7002").)
- The output parameter ERROR ("modeERROR") indicates that processing is running without errors (signal state is "FALSE").

SLI_gDB_SET_TIMEZONE

	Name	Data type	Start value	Monitor value
1	Static			
2	execute	Bool	false	FALSE
3	timezone	TimeTransformatio...		
4	Bias	Int	120	120
5	DaylightBias	Int	60	60
6	DaylightStartMonth	USInt	3	3
7	DaylightStartWeek	USInt	5	5
8	DaylightStartWeekday	USInt	7	7
9	DaylightStartHour	USInt	2	2
10	DaylightStartMinute	USInt	0	0
11	StandardStartMonth	USInt	10	10
12	StandardStartWeek	USInt	5	5
13	StandardStartWeekday	USInt	1	1
14	StandardStartHour	USInt	3	3
15	StandardStartMinute	USInt	0	0
16	TimeZoneName	String[80]	'My_GMT+'	'My_GMT+'
17	modeDONE	Bool	false	TRUE
18	modeBUSY	Bool	false	FALSE
19	modeERROR	Bool	false	FALSE
20	statusTime	Word	16#0	16#7000
21	memErrStatus	Word	16#0	16#0000

Note: The "SET_TIMEZONE" instruction is level-triggered. The instruction is executed only when the input parameter REQ ("execute") returns the signal state "TRUE".

After successful processing of SET_TIMEZONE ("modeDONE" is "TRUE"), the input parameter REQ ("execute") is automatically reset to the value "FALSE". The value "16#7002" is queried for "statusTime" for this purpose. After the reset, the status value "16#7000" is output.

You can establish whether the data to be set ("timezone") has been correctly received by the CPU clock as follows:

- Using the display of an S7-1500 CPU: Navigate on the CPU display to "Settings > Date & Time > Daylight Saving Time".
- Using TIA Portal: Read out the local time of the CPU clock using the "RD_LOC_T (Page 3471)" instruction.
- Using TIA Portal: Read out the module time of the CPU clock using the "RD_SYS_T (Page 3469)" instruction.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

SNC_RTCB: Synchronize slave clocks (S7-1500)

Definition: Synchronization of slave clocks

The synchronization of clock slaves refers to the transfer of the date and time-of-day from the clock master of a bus segment to all clock slaves of this bus segment.

Description

You use this instruction to synchronize all slave clocks present locally on the CPU or locally on a bus segment independent of the set synchronization interval (the external interface of a CP or CM belongs to a different bus segment). Successful synchronization is only possible if "SNC_RTCB" is called on a CPU whose real-time clock was assigned as the master clock for at least one bus segment.

Parameters

The following table shows the parameters of the "SNC_RTCB" instruction:

Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Output	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred during synchronization.
0001	The existing clock was not assigned the master clock function for any of the bus segments.

Error code* (W#16#...)	Explanation
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

TIME_TCK: Read system time (S7-1500)

Description

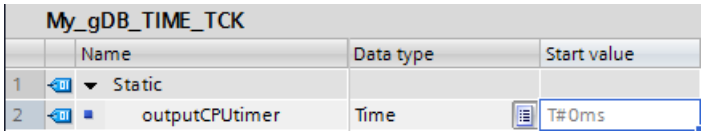
With the "TIME_TCK" instruction, you read the system time of the CPU. The system time is a time counter that counts from 0 to a maximum of 2147483647 ms. In case of an overflow, the system time is counted again starting with "0". The time scale and the accuracy of the system time is 1 ms. The system time is only influenced by the operating modes of the CPU. You can use the system time, for example, to measure the duration of processes by comparing the results of two "TIME_TCK" calls. The instruction does not provide any error information.

The following table provides an overview of how the system time changes depending on the operating modes of the CPU.

Operating mode	System time ...
Startup	... is constantly updated.
RUN	
STOP	... is stopped and retains the current value.
Warm restart	... is deleted and restarts with "0".

Parameters

The following table shows the parameters of the "TIME_TCK" instruction:

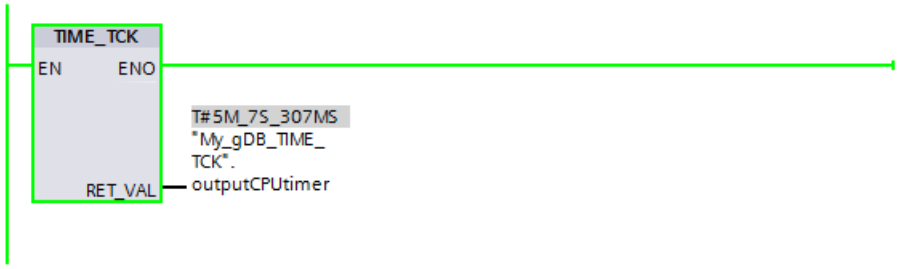


Parameter	Declaration	Data type	Memory area	Description
RET_VAL	Return	TIME	I, Q, M, D, L	The RET_VAL parameter contains the read system time in the range from 0 to 2^{31} -1 ms.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example

In the following example, you read out the system time of the CPU. You specify the return value in the TIME data type.



Create one tag for storing the data in a global data block.

Interconnect the parameters of the instruction as follows.

The system time of the CPU is read out and displayed at output parameter RET_VAL ("outputCPUtimer").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

RTM: Runtime meters (S7-1200, S7-1500)

Description

You can use this instruction to set, start, stop, and read out a 32-bit operating hours counter of your CPU.

Ensure that the operating hours counter can also be stopped or restarted during execution of the user program, which may render the saved values incorrect.

Parameters

The following table shows the parameters of the "RTM" instruction:

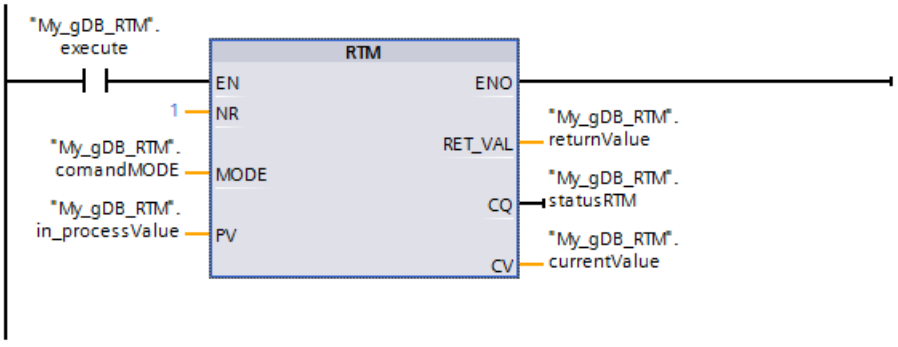
Parameter	Declaration	Data type	Memory area	Description
NR	Input	RTM	I, Q, M, D, L or constant	Number of the operating hours counter Numbering starts with 0. For information on the number of operating hours counters of your CPU, refer to the technical specifications.
MODE	Input	BYTE	I, Q, M, D, L or constant	Job ID: • 0: Read out (the status is then written to CQ and the current value to CV). After the operating hours counter has reached (2^31) - 1 hours, it stops at the highest value that can be displayed and outputs an "Overflow" error message. • 1: start (at the last counter value) • 2: stop • 4: set to the value specified in the parameter PV • 5: set to the value specified in the parameter PV and start • 6: set to the value specified in the parameter PV and stop
PV	Input	DINT	I, Q, M, D, L or constant	New value for the operating hours counter
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
CQ	Output	BOOL	I, Q, M, D, L	Status of the operating hours counter (1: running)
CV	Output	DINT	I, Q, M, D, L	Current value of the operating hours counter

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

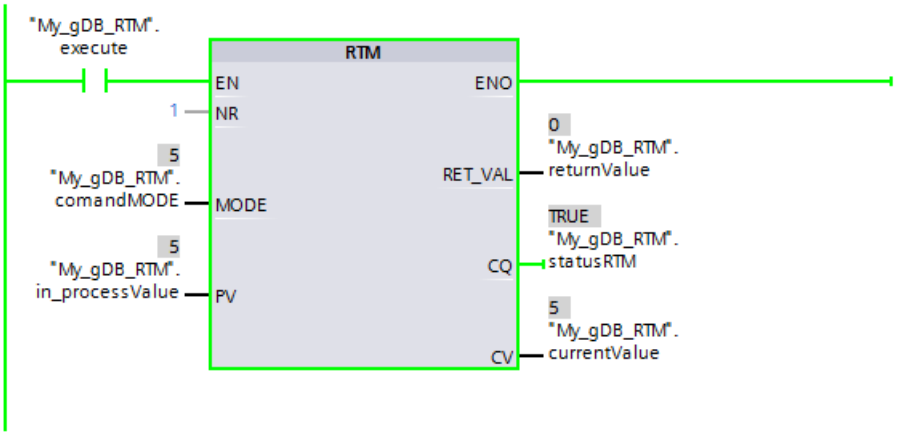
Error code (W#16#...)	Explanation
0000	No error
8080	Wrong number for the operating hours counter
8081	A negative value was passed to the PV parameter.
8082	Overflow of the operating hours counter
8091	The MODE input parameter contains an invalid value.
General error information	See also: Evaluating errors with GET_ERR_ID (Page 3409)

Example



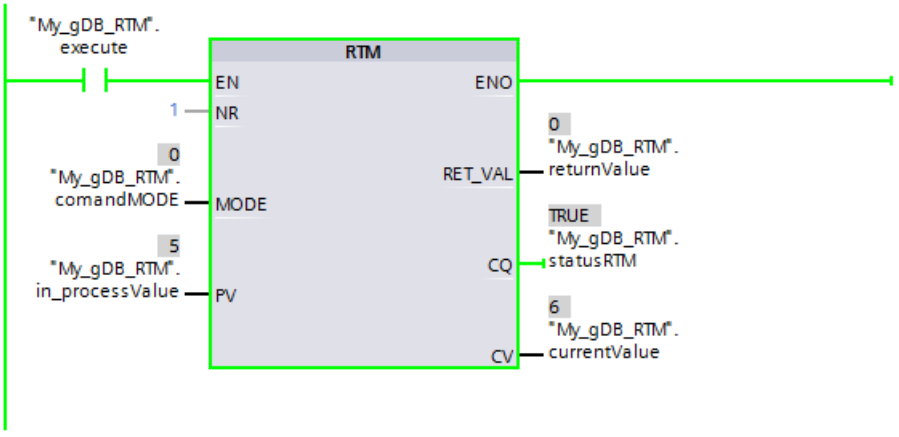
In the following example, you set the operating hours counter of the CPU and read out the value after an hour.

Create six tags in a global data block for storing the data.



My_gDB_RTM

	Name	Data type	Start value
1	Static		
2	execute	Bool	false
3	in_processValue	DInt	5
4	returnValue	Int	0
5	statusRTM	Bool	false
6	currentValue	DInt	0
7	comandMODE	Byte	5



Interconnect the parameters of the instruction as follows. At input parameter NR, specify the number of the operating hours counter of the CPU.

If the normally open contact ("execute") supplies the signal state "TRUE", the "RTM" instruction is executed. The operating hours counter of the CPU is set to the value to be set ("in_processValue") and started. After the start of the operating hours counter, set the value of input parameter MODE ("comandMODE") to "0". (To do so, click the parameter and select "Modify operand > Set to 0".) As a result, the "RTM" instruction only reads the current value ("currentValue") of the operating hours counter without changing it. Output parameter CQ ("statusRTM") indicates after the start of the operating hours counter that the operating hours counter is running (value is "TRUE"). The output parameter RET_VAL ("returnValue") indicates that processing is running without errors.

After an hour, output parameter CV ("currentValue") indicates the value "6".

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

11.4.4.2 String + Char (S7-1200, S7-1500)

S_MOVE: Move character string (S7-1200, S7-1500)

Description

You can use this instruction to write the content of a character string (W)STRING from parameter IN to the data area that you specify at parameter OUT.

To copy tags of data type ARRAY, use the "MOVE_BLK" and "UMOVE_BLK" instructions.

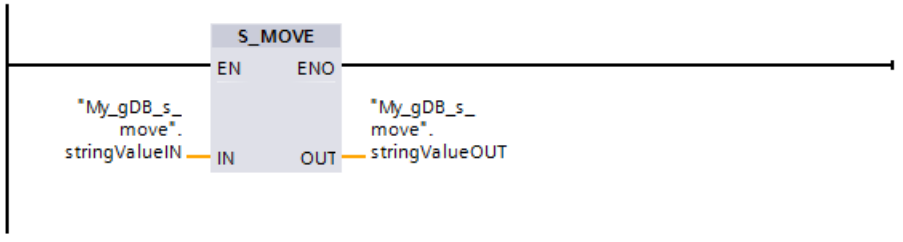
Parameters

The following table shows the parameters of the "S_MOVE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Source string
OUT	Output	STRING, WSTRING	D, L	Destination string

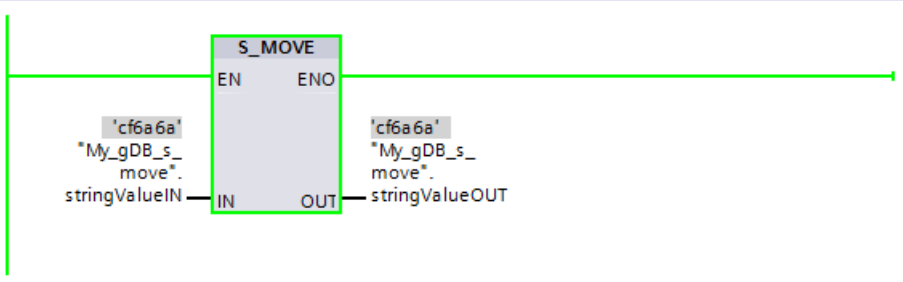
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you copy the content of a character string from input parameter IN to another character string at output parameter OUT. The data type used is STRING.

Create two tags in a global data block for storing the data.



My_gDB_s_move

	Name	Data type	Start value
1	Static		
2	stringValueIN	String	'cf6a6a'
3	stringValueOUT	String	''

Interconnect the parameters of the instruction as follows.

The result of the character string to be copied ("stringValueIN") is output at output parameter OUT ("stringValueOUT").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

S_COMP: Compare character strings (S7-1500)

Description

The instruction compares the contents of two tags in the (W)STRING format and outputs the result of the comparison as a return value. The tags that are to be compared will be interconnected at the IN1 and IN2 inputs. You can only assign a symbolically defined tag for the input parameters.

Use the instruction box to select the comparison condition. If the comparison condition (for example, greater than or equal to) is satisfied, the signal state is set to "1" at the output parameter OUT .

Select one of the following comparison conditions:

Symbol	Description
EQ	The return value has the signal state "1" if the string at the parameter IN1 is equal to the string at the parameter IN2 .
NE	The return value has the signal state "1" if the string at the parameter IN1 is not equal to the string at the parameter IN2 .
GT (1)	The return value has the signal state "1" if the string at the parameter IN1 is greater than the string at the parameter IN2 .
LT (1)	The return value has the signal state "1" if the string at the parameter IN1 is less than the string at the parameter IN2 .
GE (1)	The return value has the signal state "1" if the string at the parameter IN1 is greater than or equal to the string at the parameter IN2 .
LE (1)	The return value has the signal state "1" if the string at the parameter IN1 is less than or equal to the string at the parameter IN2 .
(1) The characters are compared by their ASCII code (for example, 'a' is greater than 'A'), starting from the left. The first character to be different decides the result of the comparison. If the left part of the longer string is identical to the shorter string, the longer string is considered greater.	

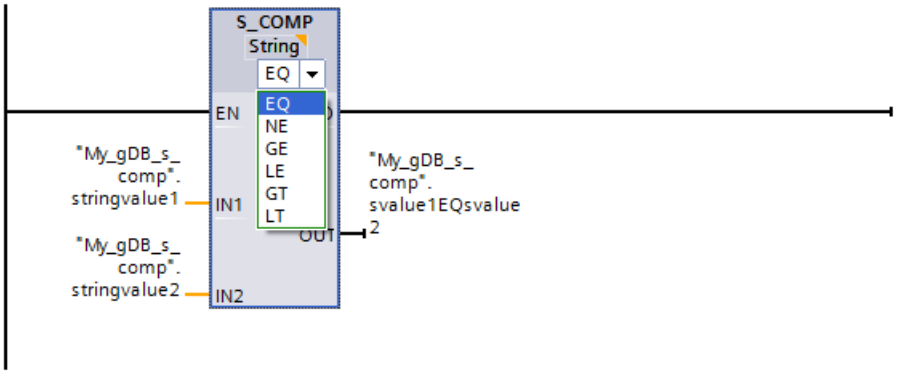
Parameters

The following table shows the parameters of the "S_COMP" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING*	D, L or constant	Input tag in the STRING / WSTRING format.
IN2	Input	STRING, WSTRING*	D, L or constant	Input tag in the STRING / WSTRING format.
OUT	Output	BOOL	I, Q, M, D, L	Result of comparison
* Define the maximum length of the character string if you use the data type STRING / WSTRING in the interface declaration for a temporary tag (you will find further information in the description of the data type).				

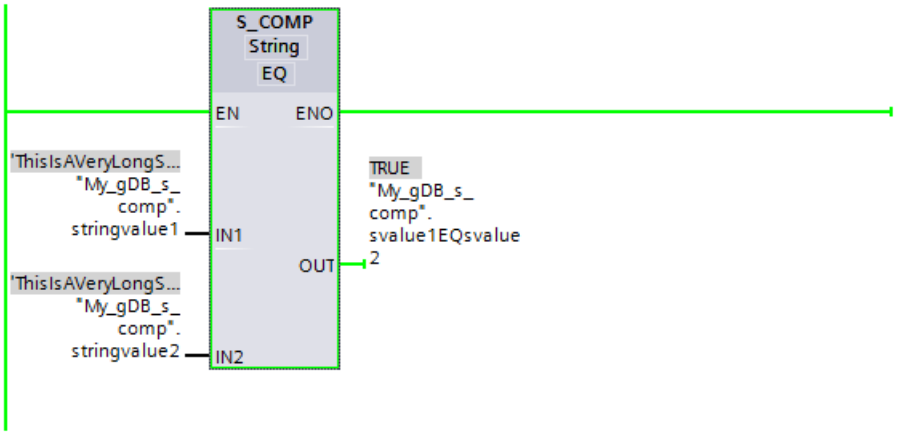
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you use the "Equal" comparison option to compare two character strings with the "STRING" data type.

Create three tags in a global data block for storing the data.



My_gDB_s_comp

	Name	Data type	Start value
1	Static		
2	stringvalue1	String	'ThisIsAVeryLongStringWithSomeNumbers646'
3	stringvalue2	String	'ThisIsAVeryLongStringWithSomeNumbers646'
4	svalue1EQsvalue2	Bool	false

Interconnect the parameters of the instruction as follows. Select the STRING data type and the EQ comparison option.

Since the value of the first character string to be compared ("stringvalue1") is equal to the second character string ("stringvalue2"), the comparison result ("svalue1EQsvalue2") shows the signal state "TRUE".

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

S_CONV: Convert character string (S7-1200, S7-1500)

Description

You use this instruction to convert the value at the IN input to the data format you have specified in the OUT output. You decide the output format of the conversion by selecting a data type for the OUT output parameter.

The following conversions are possible:

- Conversion of a string
- Conversion of a numerical value or character to a string
- Conversion of a character to a character

Note

Explicit conversions

You can find more information on explicit conversions here:

- For an S7-1200-CPU: Explicit conversions (Page 2487)
- For an S7-1500-CPU: Explicit conversions (Page 2382)

Conversion of a string

- To a numerical value (integer or floating point):
  The conversion is performed for all characters of the character string specified in the IN input parameter. Permitted characters are the digits "0" to "9", the decimal point, and the plus and minus signs. The first character of the string may be a valid number or a sign. Leading spaces and exponential notations are ignored.
- To a character:
  When a character string is converted to a character, the first character of the character string is transferred to parameter OUT.
- To a string

Conversion of a numerical value or character to a string

- You decide the format of the numeric value to be converted by selecting a data type for the IN input. Specify a valid tag of the OUT data type at the (W)STRING output. The length of the character string after conversion depends on the value at the IN input.
- The conversion result is saved as a string starting at the third byte. The first byte of the string records the maximum length and the second byte the actual length of the character string. Positive numeric value are output without a sign.
- If the numeric value 0, which exists as an INT or UINT data type, is converted to a string (e.g. INT_TO_STRING(0)), the string in the result has a length of 6 characters.

- When a numeric value is converted to a string, the first characters of the string are padded with spaces. The number of spaces depends on the length of the numerical value.

  Note

  STL/SCL-specific information

  When a numerical value is converted to a string, the first characters of the string are **not** padded with spaces.

  If you want the first character of the string to be padded with spaces, use the "VAL_STRG" instruction.

- When a (W)CHAR character is converted, the character is written at the first position of the character string.

Note

Exponential notation during conversion from floating-point numbers

Do not use exponential notation ("e" or "E") for the conversion from floating-point numbers with the instruction "S_CONV". Instead, use the "STRG_VAL" instruction for the conversion of floating-point numbers with exponential notation. Select the input format of the exponential notation via the FORMAT parameter of the instruction.

Parameters

The following tables show the parameters of the "S_CONV" instruction, according to the possible conversions:

Table 11-22 Parameters for converting a character string to a numeric value:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Value to be converted
OUT	Output	CHAR, WCHAR, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	I, Q, M, D, L	Result of the conversion

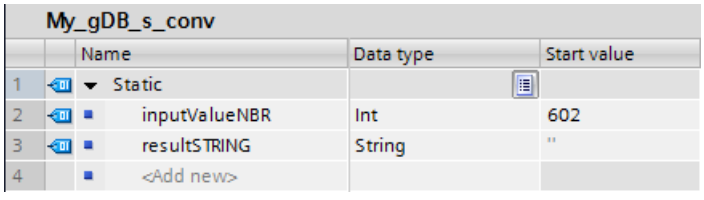
Table 11-23 Parameters for converting a character string to a character string:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Value to be converted
OUT	Output	STRING, WSTRING	D, L	Result of the conversion (possible conversions: STRING to WSTRING and vice-versa)

Table 11-24 Parameters for converting a numerical value or character to a character string:

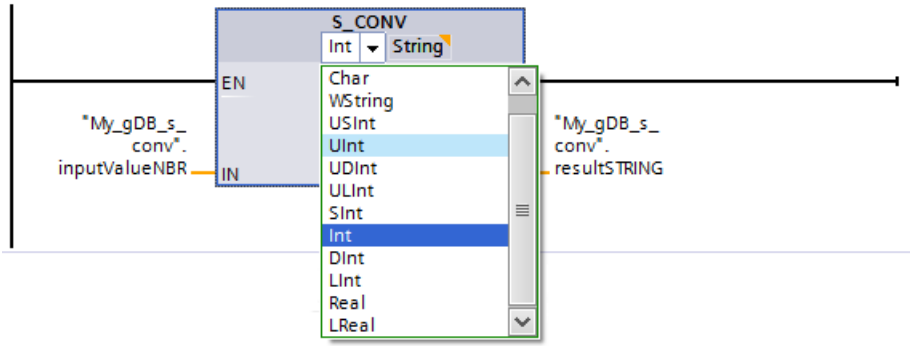
Parameter	Declaration	Data type	Memory area	Description
IN	Input	CHAR, WCHAR, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	I, Q, M, D, L or constant	Value to be converted
OUT	Output	STRING, WSTRING	D, L	Result of the conversion

Table 11-25 Parameters for converting a character to a character:



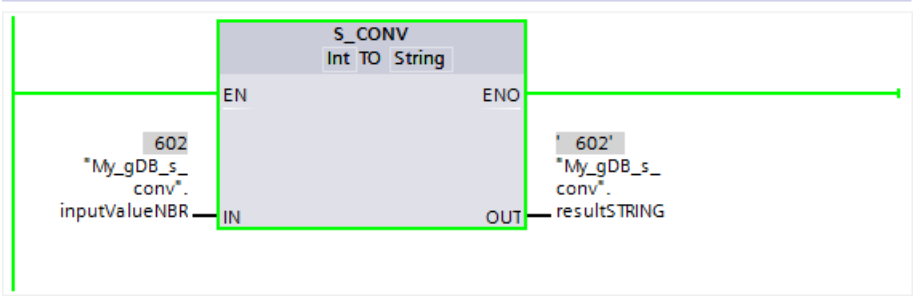
Parameter	Declaration	Data type	Memory area	Description
IN	Input	CHAR, WCHAR	I, Q, M, D, L or constant	Value to be converted
OUT	Output	CHAR, WCHAR	I, Q, M, D, L	Result of the conversion (possible conversions: CHAR to WCHAR and vice-versa)

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, convert a number with the INT data type to a character string with the STRING data type.



Create two tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows. In doing so, select the data types. With the first selection option, you specify the data type of the value to be converted ("inputValueNBR"). With the second selection option, you specify the data type of the character string to be generated ("resultSTRING").

The value to be converted ("inputValueNBR") is converted to the output format. Blank spaces are written to the empty places at the start of the character string. The result of the conversion is output at output parameter OUT ("resultSTRING") as a string.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

See also

STRG_VAL: Convert character string to numerical value (Page 3497)

STRG_VAL: Convert character string to numerical value (S7-1200, S7-1500)

Description

The "STRG_VAL" instruction converts a character string to an integer or a floating-point number:

- You specify the character string to be converted in the IN input parameter.
- You define the format of the output value by selecting a data type for the OUT output parameter.

Permitted characters for the conversion are the digits "0" to "9", the decimal point, the decimal comma, notations "E" and "e", and the plus and minus characters. The conversion is canceled if a invalid character is found.

Parameters

The following table shows the parameters of the "STRG_VAL" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	STRING, WSTRING	STRING, WSTRING	D, L or constant	Number string to be converted
FORMAT	Input	WORD	WORD	I, Q, M, D, L, P or constant	Input format of the characters
P	Input	UINT	UINT	I, Q, M, D, L, P or constant	Reference to the first character to be converted (first character = 1, the value "0" or a value > length of the string is invalid)
OUT	Output	USINT, SINT, UINT, INT, UDINT, DINT, REAL, LREAL	USINT, SINT, UINT, INT, UDINT, DINT, ULINT, LINT, REAL, LREAL	I, Q, M, D, L, P	Result of the conversion

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter FORMAT

You use the FORMAT parameter to specify how the characters of a character string are to be interpreted. Exponential values are also converted and represented with the "STRG_VAL" instruction.

The following table shows the possible values of the FORMAT parameter and their meaning:

Value (W#16#....)	Notation	Decimal representation
0000	Decimal fraction	"."
0001		","
0002	Exponential	"."
0003		","
0004 to FFFF	Invalid values	

Parameter P

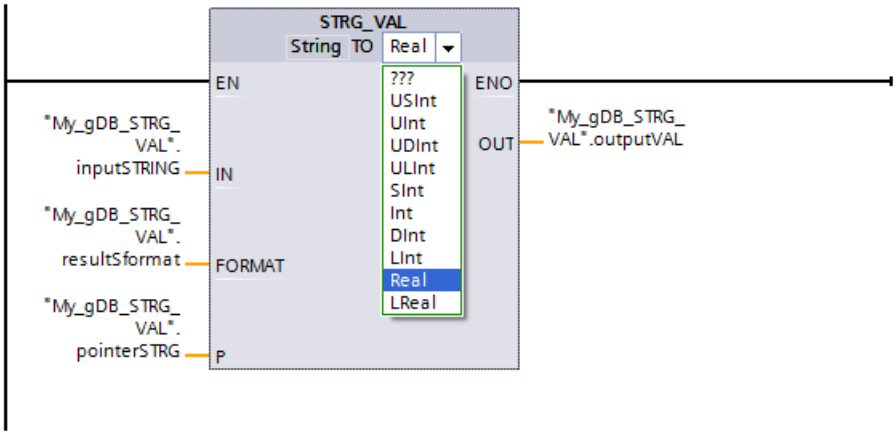
The conversion starts at the character whose position you specified in the P parameter. If, for example, the value "1" is specified in the P parameter, the conversion starts at the first character of the specified character string.

Example

The following table shows examples of the conversion of a character string to a numeric value:

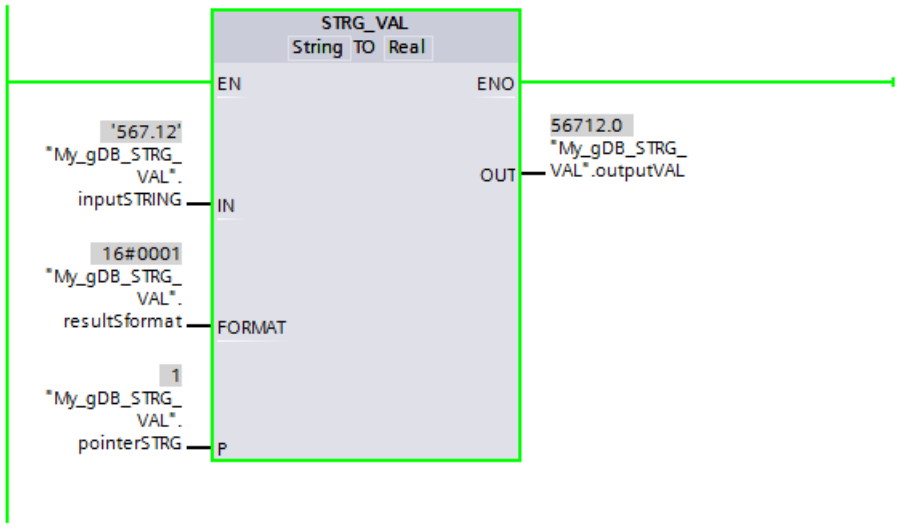
IN (STRING)	FORMAT (W#16#....)	OUT (data type)	OUT (value)	ENO status
'123'	0000	INT/DINT	123	1
'-00456'	0000	INT/DINT	-456	1
'123.45'	0000	INT/DINT	123	1
'+2345'	0000	INT/DINT	2345	1
'00123AB'	0000	INT/DINT	123	1
'123'	0000	REAL	123.0	1
'-00456'	0001	REAL	-456.0	1
'+00456'	0001	REAL	456.0	1
'123.45'	0000	REAL	123.45	1
'123.45'	0001	REAL	12345.0	1
'123,45'	0000	REAL	12345.0	1
'123,45'	0001	REAL	123.45	1
'.00123AB'	0001	REAL	123.0	1
'1.23e-4'	0000	REAL	1.23	1
'1.23E-4'	0000	REAL	1.23	1
'1.23E-4'	0002	REAL	1.23E-4	1
'12,345.67'	0000	REAL	12345.67	1
'12,345.67'	0001	REAL	12.345	1
'3.4e39'	0002	REAL	W#16#7F800000	0
'-3.4e39'	0002	REAL	W#16#FF800000	0
'1.1754943e-38'	0002	REAL	0.0	1
'12345'	-/-	SINT	0	0
'A123'	-/-	-/-	0	0
''	-/-	-/-	0	0
'++123'	-/-	-/-	0	0
'+-123'	-/-	-/-	0	0

Example



In the following example, you convert a number string with the STRING data type to a floating-point number with the REAL data type. The result will have a length of 32 bits and may have a sign due to the REAL data type.

Create four tags in a global data block for storing the data.



My_gDB_STRG_VAL

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'567.12'
3	resultSformat	Word	16#0001
4	pointerSTRG	UInt	1
5	outputVAL	Real	0.0

Interconnect the parameters of the instruction as follows. Using the left selection option, select the data type for the character string. Using the right selection option, select the data type for the floating-point number.

The number string is converted starting from the first character according to the value "1" of parameter P ("pointerSTRG"). The period in the number string is interpreted as a thousands delimiter due to the value "0001" of parameter FORMAT ("resultSformat"). (The comma is the decimal separator for the value "0001".) The value to be converted ("inputSTRING") is output at output parameter OUT ("outputVAL") as a floating point number.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

VAL_STRG: Convert numerical value to character string (S7-1200, S7-1500)

Description

The "VAL_STRG" instruction is used to convert a numerical value into a character string.

- You specify the value to be converted in the IN input parameter. You decide the format of the numeric value by selecting a data type.
- You query the result of the conversion in the OUT output parameter.

Permitted characters for the conversion are the digits "0" to "9", the decimal point, the decimal comma, notations "E" and "e", and the plus and minus characters. The conversion is interrupted by invalid characters.

Parameter

The following table shows the parameters of the "VAL_STRG" instruction:

Parameter	Declaration	Data type		Memory area	Description
		S7-1200	S7-1500		
IN	Input	USINT, SINT, UINT, INT, UDINT, DINT, REAL, LREAL	USINT, SINT, UINT, INT, UDINT, DINT, ULINT, LINT, REAL, LREAL	I, Q, M, D, L, P or constant	Value to be converted
SIZE	Input	USINT	USINT	I, Q, M, D, L, P or constant	Number of character positions
PREC	Input	USINT	USINT	I, Q, M, D, L, P or constant	Number of decimal places
FORMAT	Input	WORD	WORD	I, Q, M, D, L, P or constant	Output format of the characters
P	InOut	UINT	UINT	I, Q, M, D, L, P or constant	Character starting at which the result is written.
OUT	Output	STRING, WSTRING	STRING, WSTRING	D, L	Result of the conversion

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter P

With the P parameter, you specify the character in the string starting at which the result is written. If, for example, the value "2" is specified in the P parameter, the converted value is saved starting at the second character of the string.

SIZE and P parameters

Use the SIZE parameter to specify how many characters of the character string will be written. This is counted starting from the character specified in the P parameter. If the output value is shorter than the specified length, the result is written to the character string right-justified. The empty character positions are filled with blanks.

Parameter FORMAT

Use the FORMAT parameter to specify how the numerical value is interpreted during conversion and written to the character string. You can specify only tags of the FORMAT data type in the USINT parameter.

The following table shows the possible values of the FORMAT parameter and their meaning:

Value (W#16#....)	Notation	Sign	Decimal representation
0000	Decimal fraction	"-"	"."
0001			","
0002	Exponential		"."
0003			","
0004	Decimal fraction	"+" and "-"	"."
0005			","
0006	Exponential		"."
0007			","
0008 to FFFF	Invalid values		

Note

Relevance of values 2, 3, 6 and 7 of the FORMAT parameter

The values 2, 3, 6 and 7 of the FORMAT parameter are only relevant if the parameter IN has data type REAL or LREAL.

Parameter PREC

Use the PREC parameter to define the number of decimal places when converting floating-point numbers. A maximum precision of seven numbers is supported for numerical values of the REAL data type. If the value to be converted is an integer, you use the PREC parameter to specify the position where the decimal point will be placed.

Example

The following table shows examples of the conversion of numeric values to a character string if the parameters OUT contains an empty string before the call of VAL_STRG.

IN (value)	IN (data type)	P	SIZE	FORMAT (W#16#....)	PREC	OUT (STRING)	ENO status
123	UINT	16	10	0000	0	`xxxxxxx123 C`	1
0	UINT	16	10	0000	2	`xxxxxx0.00 C`	1

IN (value)	IN (data type)	P	SIZE	FORMAT (W#16#....)	PREC	OUT (STRING)	ENO status
12345678	UDINT	16	10	0000	3	x12345.678 C	1
12345678	UDINT	16	10	0001	3	x12345.678 C	1
123	INT	16	10	0004	0	xxxxxx+123 C	1
-123	INT	16	10	0004	0	xxxxxx-123 C	1
-0.00123	REAL	16	10	0004	4	xxx-0.0012 C	1
-0.00123	REAL	16	10	0006	4	-1.2300E-3 C	1
-Inf [1]	REAL	16	10	-/-	4	xxxxxx-INF C	0
+Inf [2]	REAL	16	10	-/-	4	xxxxxx+INF C	0
NaN [3]	REAL	16	10	-/-	4	xxxxxxxNaN C	0
12345678	UDINT	16	6	-/-	3	xxxxxxxxxx C	0
"x" represents blanks [1]-Inf: Floating-point number representing a negative infinite value. [2]+Inf: Floating-point number representing a positive infinite value. [3]NaN: Value returned as the result of invalid math operations.							

Example

The following table shows examples of the conversion of numeric values to a character string when the parameter OUT contains an empty string prior to calling VAL_STRG.

In all cases, the parameters IN, SIZE, PREC, FORMAT and P have the same values: IN=123, SIZE=16, PREC=0, FORMAT=4, P=10. Only the default of OUT is different.

- OUT contains a string that is shorter than P.
  The CPU fills OUT after the existing string with spaces up to the (P-1)th position. As of position P OUT It is written taking into account leading spaces.

OUT before the call of VAL_STRG:	ABCDEFxxxxxxxxxx xxxxxxxxxxxxxxx
OUT after the call of VAL_STRG:	ABCDEFxxxxxxxxxx xxxxxx123xxxxxxx
"x" represents a space	

- OUT contains a string that is longer than P+SIZE
  As of position P the CPU fills OUT with SIZE characters taking into account the leading spaces.

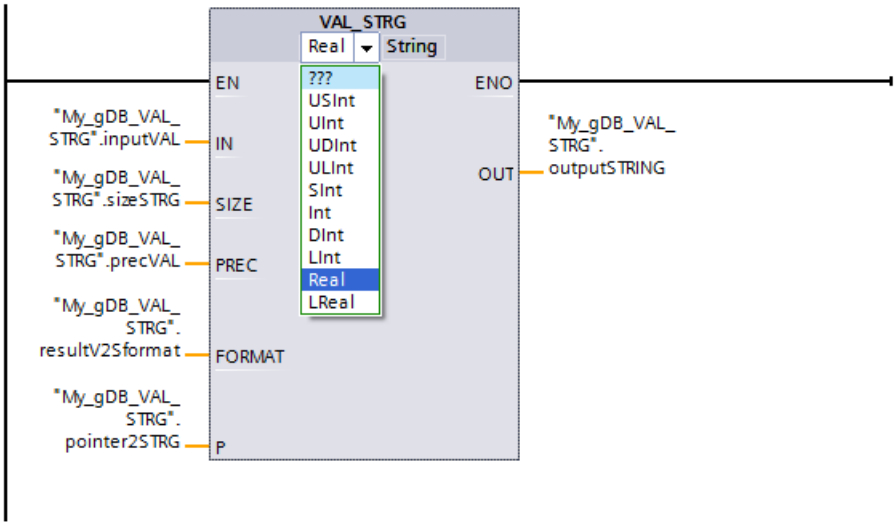
OUT before the call of VAL_STRG:	ABCDEFGHIJKLMNOP QRSTUVWXYZABCDEF
OUT after the call of VAL_STRG:	ABCDEFGHIxxxxxxx xxxxxx123ZABCDEF
"x" represents a space	

- OUT contains a string that is longer than P but shorter than P+SIZE
  As of position P the CPU fills OUT with SIZE characters taking into account the leading spaces.

OUT before the call of VAL_STRG:	ABCDEFGHIJKLMNOP xxxxxxxxxxxxxxx
OUT after the call of VAL_STRG:	ABCDEFGHIxxxxxxx xxxxxx123xxxxxxx
"x" represents a space	

Example

In the following example, you convert a floating-point number with the REAL data type to a character string with the STRING data type.



Create six tags in a global data block for storing the data.

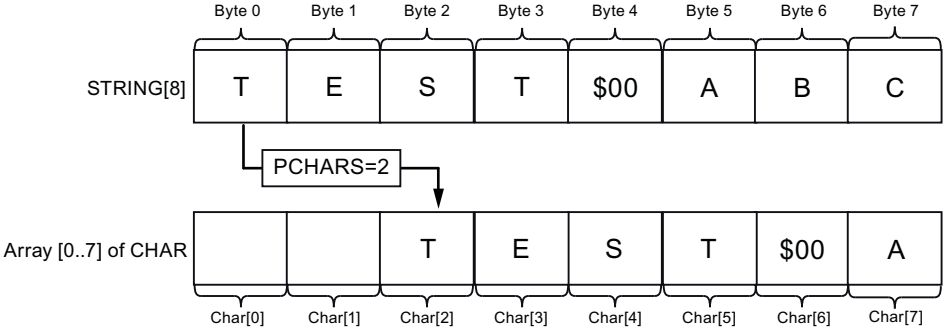
My_gDB_VAL_STRG

	Name	Data type	Start value
1	Static		
2	inputVAL	Real	-567.12
3	pointer2STRG	UInt	16
4	sizeSTRG	USInt	10
5	precVAL	USInt	3
6	outputSTRING	String	''
7	resultV2Sformat	Word	16#0004

Interconnect the parameters of the instruction as follows. Select the data types:

- The left selection option is for the value to be converted.
- The right selection option is for the character string to be generated.

The character string is written starting from the 16th character according to the value "16" of parameter P" ("pointer2STRG") . Starting from this point, the character string is 10 characters long, according to the "10" value of the SIZE parameter ("sizeSTRG"). The point of the value to be converted ("inputVAL") is interpreted as a decimal separator due to the value "0004" of parameter FORMAT ("resultV2Sformat"). Three decimal places are written to the string according to the value "3" of parameter PREC ("precVAL"). The sign of the value to be converted is stored as a character in the string and prefixes the numbers. The remaining 10 characters of the string are written as spaces in front of the sign. The character string is output at output parameter OUT ("outputSTRING").



You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Strg_TO_Chars: Convert character string to Array of CHAR (S7-1200, S7-1500)

Description

With the "Strg_TO_Chars" instruction, you copy a character string of the data type STRING to an Array of CHAR or Array of BYTE or a character string of the data type WSTRING to an Array of WCHAR or Array of WORD. Only ASCII characters are valid for the copy process.

- Specify the character string at the input parameter STRG.
- The characters are written at the parameter CHARS to a Array of CHAR / BYTE / WCHAR / WORD data type.
  - The number of characters in the destination field must be at least the same as the number copied from the source string.
  - If the destination field contains fewer characters than the source string, the characters are written up to the maximum length of the destination field.
  - If the character string contains a "$00" or W#16#0000 character, this has no effect on the copy operation (see graphic).
  - The number of copied characters is output at parameter CNT.
- Use the parameter PCHARS to indicate from which position writing will begin in the destination field.
  - Example: If writing should take place starting from the third position, use the value "2" at parameter PCHARS:

  - The default for PCHARS is "0". When PCHARS = 0, the low index limit of the array is used (e.g. CHAR[0] for an Array [0..5] of CHAR). This also applies if the low limit of the array is negative (e.g. CHAR[-5] for an Array [-5..5] of CHAR).

Note

Use of the instruction with S7-1200 V2.0

S7-1200 up to Version 2.0 only supports Array [0 .. n] of CHAR / BYTE. Negative index limits (e.g. Array [-3..2] of CHAR) are not permissible. This restriction is not checked by the software.

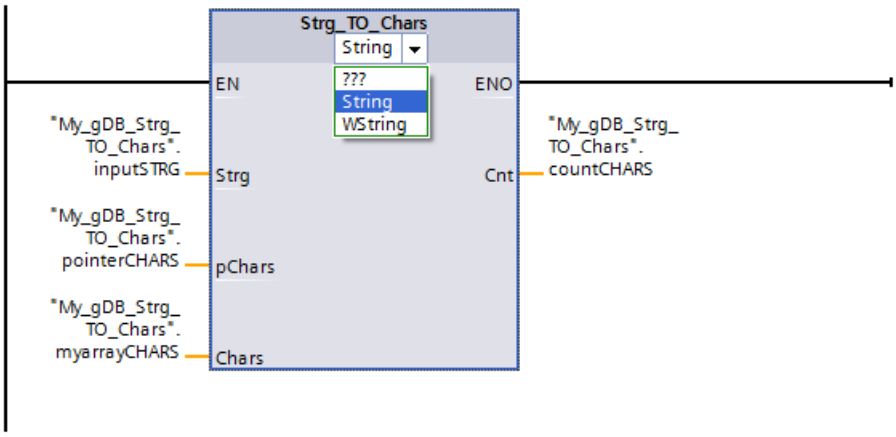
Parameters

The following table shows the parameters of the "Strg_TO_Chars" instruction:

Parameter	Declaration	Data type	Memory area	Description
STRG	Input	STRING, WSTRING	D, L or constant	Source of the copy operation
PCHARS	Input	DINT	I, Q, M, D, L, P or constant	Position in the structure Array of (W)CHAR / BYTE / WORD starting from which the characters of the character string are written.
CHARS	InOut	VARIANT	D, L	Destination of the copy operation Copy the characters to a structure of the Array of (W)CHAR/ BYTE/ WORD data type.
CNT	Output	UINT	I, Q, M, D, L, P	Number of moved characters

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you copy characters of a character string with the STRING data type to a structure of the Array of CHAR data type.

Create four tags in a global data block for storing the data.

My_gDB_Strg_TO_Chars

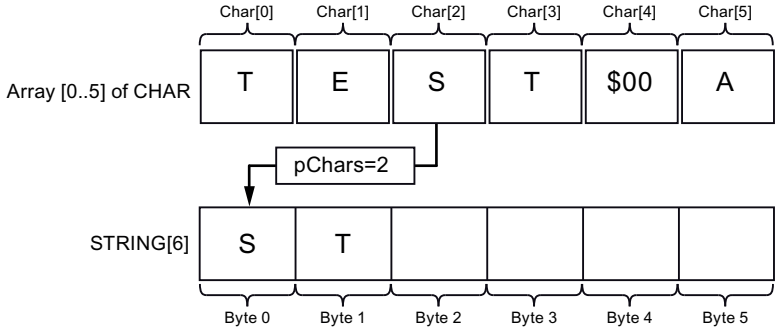
	Name	Data type	Start value
1	Static		
2	inputSTRG	String[10]	'cf7a7a#'
3	pointerCHARS	DInt	2
4	myarrayCHARS	Array[0..9] of Char	
5	myarrayCHARS[0]	Char	' '
6	myarrayCHARS[1]	Char	' '
7	myarrayCHARS[2]	Char	' '
8	myarrayCHARS[3]	Char	' '
9	myarrayCHARS[4]	Char	' '
10	myarrayCHARS[5]	Char	' '
11	myarrayCHARS[6]	Char	' '
12	myarrayCHARS[7]	Char	' '
13	myarrayCHARS[8]	Char	' '
14	myarrayCHARS[9]	Char	' '
15	countCHARS	UInt	0

Interconnect the parameters of the instruction as follows and select the data type of the character string.

A structure made up of individual characters is created due to the Array of CHAR data type. The CHARS structure ("myarrayCHARS") is ten characters long (Array ... [0..9]). According to the value "2" of parameter PCHARS ("pointerCHARS"), writing begins starting from the third character in the structure ("0" and "1" are empty, "2" contains the first character of the character string ("inputSTRG")). Once the characters of the string ("inputSTRG") are written to the structure ("myarrayCHARS"), the last character of the structure to be created is written empty. The number of characters of the character string that are moved is output at output parameter CNT ("countCHARS").

My_gDB_Strg_TO_Chars

	Name	Data type	Start value	Monitor value
1	Static			
2	inputSTRG	String[10]	'cf7a7a#'	'cf7a7a#'
3	pointerCHARS	DInt	2	2
4	myarrayCHARS	Array[0..9] of Char		
5	myarrayCHARS[0]	Char	' '	' '
6	myarrayCHARS[1]	Char	' '	' '
7	myarrayCHARS[2]	Char	' '	'c'
8	myarrayCHARS[3]	Char	' '	'f'
9	myarrayCHARS[4]	Char	' '	'7'
10	myarrayCHARS[5]	Char	' '	'a'
11	myarrayCHARS[6]	Char	' '	'7'
12	myarrayCHARS[7]	Char	' '	'a'
13	myarrayCHARS[8]	Char	' '	'#'
14	myarrayCHARS[9]	Char	' '	' '
15	countCHARS	UInt	0	7



You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Chars_TO_Strg: Convert Array of CHAR to character string (S7-1200, S7-1500)

Description

With the "Chars_TO_Strg" instruction you copy characters from an Array of CHAR or Array of BYTE to a character string of the data type STRING or from an ARRAY of WCHAR or Array of WORD to a character string of the data type WSTRING. For the copy operation only ASCII characters are valid.

- Specify the characters of the Array of (W)CHAR / BYTE / WORD that will be copied to a character string at the input parameter CHARS.
- The characters are written at the parameter STRG to a (W)STRING data type.
  - The number of characters in the string is at least the same number as were copied from the source field.
  - If the character string is shorter than the number of characters in the source field, the characters are written up to the maximum length of the string.
  - If the Array of CHAR / BYTE contains a "$00" character or if the Array of WCHAR / WORD contains a W#16#0000 character, the copy operation is only carried out up to the corresponding position (see graphic).
- Using the PCHARS parameter, specify the position of the source field as of which the characters will be copied. PCHARS = 0 is the default value and always specifies the lower index limit of the array even if this is negative.
  - Example: if copying is to start with the third character of the source field, use the value "2" at parameter PCHARS:

  - If an index is specified at parameter PCHARS and the index is not contained in the copy source (e.g. "7" at Array [0..5] of CHAR) then the instruction is not executed.

Note

Use of the instruction with S7-1200 V2.0

S7-1200 up to Version 2.0 only supports Array [0 .. n] of CHAR / BYTE. Negative index limits (e.g. Array [-3..2] of CHAR) are not permissible. This restriction is not checked by the software.

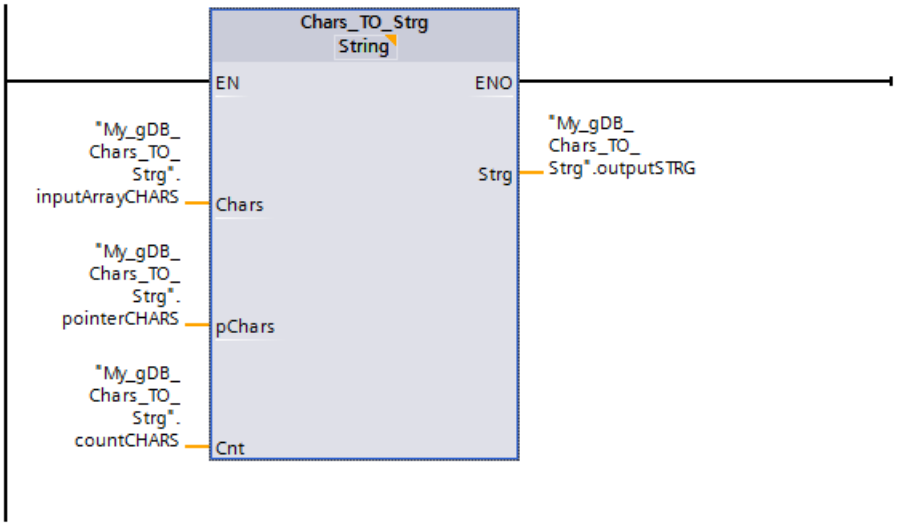
Parameters

The following table shows the parameters of the "Chars_TO_Strg" instruction:

Parameter	Declaration	Data type	Memory area	Description
CHARS	Input	VARIANT	D, L	Source of the copy operation Array of (W)CHAR / BYTE / WORD from which the characters are copied.
PCHARS	Input	DINT	I, Q, M, D, L, P or constant	Position in the Array of (W)CHAR / BYTE / WORD starting at which the characters are copied.
CNT	Input	UINT	I, Q, M, D, L, P or constant	Number of characters to be copied. Use "0" to copy all characters.
STRG	Output	STRING, WSTRING	D, L	Destination of the copy operation Character string with the (W)STRING data type. Observe the maximum length of the data types: • STRING: 254 characters • WSTRING: 254 characters (default) / 16382 characters (maximum) When using WSTRING, note that you must define a length > 254 characters explicitly with square brackets (e.g., WSTRING[16382]).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you copy characters of a structure of the Array of CHAR data type to a character string with the STRING data type.

Create four tags in a global data block for storing the data.

My_gDB_Chars_TO_Strg

	Name	Data type	Start value
1	Static		
2	inputArrayCHARS	Array[0..9] of Char	
3	inputArrayCHARS[0]	Char	'M'
4	inputArrayCHARS[1]	Char	'y'
5	inputArrayCHARS[2]	Char	'S'
6	inputArrayCHARS[3]	Char	'7'
7	inputArrayCHARS[4]	Char	'P'
8	inputArrayCHARS[5]	Char	'L'
9	inputArrayCHARS[6]	Char	'C'
10	inputArrayCHARS[7]	Char	' '
11	inputArrayCHARS[8]	Char	' '
12	inputArrayCHARS[9]	Char	' '
13	pointerCHARS	DInt	2
14	outputSTRG	String	''
15	countCHARS	UInt	0

Interconnect the parameters of the instruction as follows and select the data type of the character string.

The CHARS structure ("inputArrayCHARS") is ten characters long (Array ... [0..9]). According to the value "2" of parameter PCHARS ("pointerCHARS"), characters are copied starting from the third position of the structure to the character string ("outputSTRG"). Starting from position "2", all characters of the structure ("inputArrayCHARS") are copied to the character string ("outputSTRG"), since parameter CNT ("countCHARS") has the value "0".

My_gDB_Chars_TO_Strg

	Name	Data type	Start value	Monitor value
1	Static			
2	inputArrayCHARS	Array[0..9] of Char		
3	inputArrayCHARS[0]	Char	'M'	'M'
4	inputArrayCHARS[1]	Char	'y'	'y'
5	inputArrayCHARS[2]	Char	'S'	'S'
6	inputArrayCHARS[3]	Char	'7'	'7'
7	inputArrayCHARS[4]	Char	'P'	'P'
8	inputArrayCHARS[5]	Char	'L'	'L'
9	inputArrayCHARS[6]	Char	'C'	'C'
10	inputArrayCHARS[7]	Char	' '	' '
11	inputArrayCHARS[8]	Char	' '	' '
12	inputArrayCHARS[9]	Char	' '	' '
13	pointerCHARS	DInt	2	2
14	outputSTRG	String	''	'S7PLC '
15	countCHARS	UInt	0	0

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

MAX_LEN: Determine the length of a character string (S7-1200, S7-1500)

Description

A tag of the (W)STRING data type contains two lengths: the maximum length and the current length (this is the number of currently valid characters).

- The maximum length of the character string is specified for each tag in the STRING keyword in square brackets. The number of bytes occupied by a string is 2 greater than the maximum length.
- The maximum length of the character string is specified for each tag in the WSTRING keyword in square brackets. The number of words occupied by a character string is 2 greater than the maximum length.
- The current length represents the number of the character places actually used. The current length must be less than or equal to the maximum length.

You use the "MAX_LEN" instruction to determine the maximum length of the character string specified at the IN input parameter This is output as numerical value at the output par OUT.

Note

Checking the character string

The "MAX_LEN" instruction does not check the character string at the parameter "IN".

If errors occur during processing of the instruction, the value "0" is output at the OUT parameter.

Note

Reading out the current length

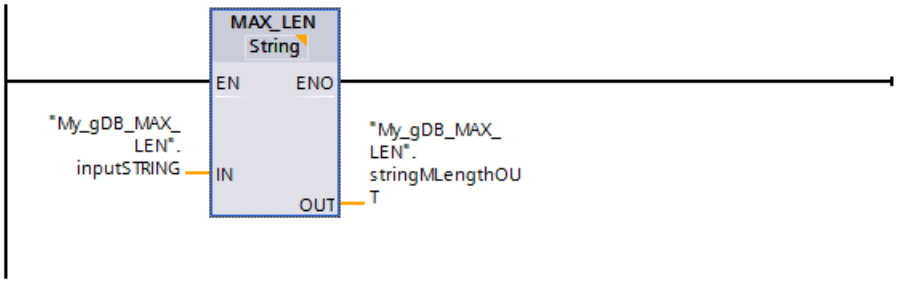
You use the "LEN (Page 3531)" instruction to read out the current length of a string.

Parameter

The following table shows the parameters of the "MAX_LEN" instruction:

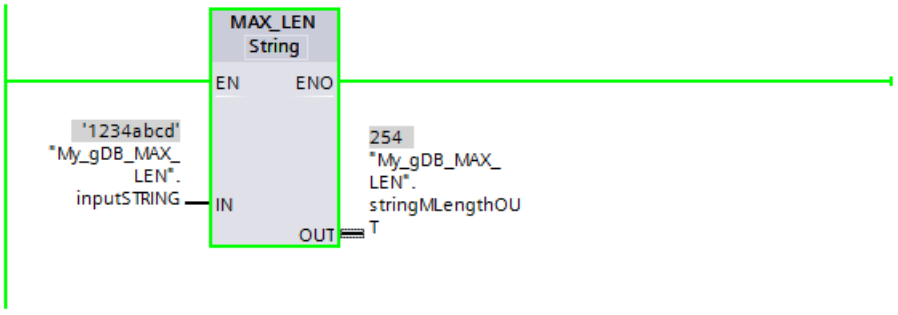
Parameter	Declaration	Data type	Memory area	Description
IN	Input	• STRING • WSTRING	D, L or constant	Character string
OUT	Return	• INT • DINT	I, Q, M, D, L, P	Maximum number of characters

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you determine the maximum length of a character string with the STRING data type.



Create two tags in a global data block for storing the data.

My_gDB_MAX_LEN			
	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	stringMLengthOUT	Int	0

Interconnect the parameters of the instruction as follows.

The maximum length of the specified character string ("inputSTRING") is determined and returned at output parameter OUT ("stringMLengthOUT") as a numerical value.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

JOIN: Join multiple strings (S7-1500)

Description

The "JOIN" instruction connects multiple strings into an array.

To convert multiple strings into a single one, the instruction provides the following functions:

- **Format selection**
  You can use the first bit at the Mode parameter to specify whether the sequence of the source strings for an array should be in the format CSV or FSR.
  In the following example, two source strings are specified by the two columns of the table. The maximum number of characters amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.

1963	1974
Miller	Jackson
John	Peter
Roadname	VeryLongRoadna

  – With CSV (Comma Separated Values), the contents of the source strings are written consecutively into the destination array and separated with a delimiter. (See examples below.)
  – With FSR (Fixed Size Records), a certain number of characters is defined in the destination array for each source string. If the characters of a source string do not need the space reserved for them in the destination array, the corresponding array elements are filled with delimiters. However, if the number of characters in a source string is greater than the space reserved for them, the corresponding array elements are filled from the front, and the excess characters of the source string are truncated (see example below).

- **Selection of the delimiter for the source strings**
  The RecSeparator parameter is used to select the delimiter that will be used for each string. Select a character based on the content of the input strings at the SrcStruct parameter. If the input strings contain a comma within a string, for example, do not use the comma as a delimiter. The data type that you use for the delimiter must correspond to the destination array at the DstArray parameter As a result, the delimiters can also be written to the array.

- **Selection of the delimiter for the end of all source strings**
  You can use the third bit of the Mode parameter to specify whether an additional character will be written as a delimiter at the end of the copied characters in the destination array (DstArray parameter). At the EndSeparator parameter, specify the character that will be used as a delimiter. Make sure to use a character other than the one set for the RecSeparator parameter (delimiter for individual strings). If the two delimiters are indistinguishable, you will obtain unexpected results if you reverse the conversion using the "SPLIT" instruction.

- **Selection of the source strings**
  You specify the source strings at the SrcStruct parameter. For the data type, you can use Array of STRING or Array of WSTRING or structures which only contain the STRING or WSTRING data type. This also applies to user data types or nested structures. You can use these as long as they exclusively contain the data type STRING or WSTRING respectively.

- **Specification of the number of joined strings**
  If you use an Array of STRING or Array of WSTRING at the SrcStruct parameter (source string) (no nested structures), you can use the Count parameter to specify the number of source strings that are joined to form a single string. If you use a data type other than Array of (W)STRING at the SrcStruct parameter, the Count parameter is ignored. It is only possible to connect a larger part of an array in this way.

- **Selection of a destination area for writing the array**
  You use the Array of (W)CHAR data type at the DstArray parameter. In this case, it is not possible to use the STRING or WSTRING data types, because the length is limited to 254 characters or 256 bytes for STRING.
- **Index of the position in the array (DestArray target parameter)**
  The conversion starts at this position. The instruction reads the Position parameter to determine the position at which the conversion is completed. This enables follow-up calls of the instruction for filling the array.

Parameter

The following table shows the parameters of the "JOIN" instruction:

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	DWORD	I, Q, M, D, L or constant	Specifies how the merger to string is performed (see Mode" parameter).
RecSeparator	Input	VARIANT	I, Q, M, D, L	Delimiter for the source strings • With CSV: Character that is used as a delimiter for the individual strings. • With FSR: Character that is used as a fill character for the individual strings.
EndSeparator	Input	VARIANT	I, Q, M, D, L	Delimiter for the end of the conversion Delimiter that is written at the end of the characters if bit 3 = 1 has been set for the Mode parameter.
SrcStruct	Input	VARIANT	I, Q, M, D, L	Pointer to the source strings.
Count	Input	UDINT	I, Q, M, D, L or constant	Number of strings that were joined. The Count parameter can only be used when an Array of (W)STRING has been used at the SrcStruct parameter.
DestArray	InOut	VARIANT	I, Q, M, D, L	Area in which the characters are written after the conversion. Use the Array [0 .. x] of CHAR/WCHAR data type at the DestArray parameter. You can set the length (x) of the array based on the length of the source strings at the SrcStruct parameter.
Position	InOut	UDINT	I, Q, M, D, L	Index the position in the total string
Ret_Val	Return	INT	I, Q, M, D, L	Status of instruction (see table "RET_VAL parameter").

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter Mode

Bit	Bit value "0"	Bit value "1"	Description
0	CSV format (Comma Separated Values)	FSR format (Fixed Size Record)	Selection of the format: • With CSV, the source strings are separated by a delimiter in the destination array. • With FSR, the source strings are written into the destination array with the fill characters defined at the RecSeparator parameter.
1	-	-	Irrelevant for the "JOIN" instruction.
2	-	-	Reserved (irrelevant for bit value)
3	Write no additional delimiters.	Write character defined by the EndSeparator parameter at the end of the read characters.	Select whether an additional character will be written as a delimiter at the end of the characters in the array (DestArray parameter).
4	-	-	Irrelevant for the "JOIN" instruction.

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error.
8190	Selection at the Mode parameter is not supported.
8x20	Source strings invalid.
8x53	VARIANT points to data structure that is too short.
8x54	Invalid data type
8082	The value at parameter Count is greater than the number of source character strings in SrcStruct.
8xB4	Different data types at parameters SrcStruct (source) and DestArray (destination) or at separators (parameters RecSeparator and EndSeparator).
80B5	Buffer overflow with the instruction. The characters are not completely output at parameter DestArray, or the value at parameter Position is outside of DestArray.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)

* Note the following for the error codes:

- The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".
- The "x" in the second position of the listed error codes stands for the parameter that caused the error.
  Example: Error code 8352 hex = error occurred at 3rd Parameter (EndSeparator), see Parameter table.
- If the error cannot be clearly assigned to a specific parameter, "0" is output.
  Example: The CHAR data type is used for the delimiter (RecSeparator parameter). WCHAR is used as data type for the array at the DestArray parameter. Error code 80B4 is output in this case.

Two examples for the JOIN instruction when the destination ARRAY should have the format CSV

- First example:
  The following source strings are available:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  If you select "," as the delimiter, calling JOIN provides the following destination array:
  `1963,Miller,John,Roadname`
- Second example:
  The following source strings are available:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadname`

  If you select "," as the delimiter, calling JOIN provides the following destination array:
  `1974,Jackson,Peter,VeryLongRoadname`

Two examples for the JOIN instruction when the destination ARRAY should have the format FSR

- First example:
  The following source strings are available:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  The number of reserved characters in the destination array amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  If you select "," as the fill characters, calling JOIN provides the following destination array:
  `1963Miller,,,,,,,John,,,,,,Roadname,,,,,,`
- Second example:
  The following source strings are available:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadname`

  The number of reserved characters in the destination array amounts to 4 characters for the first source string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  If you select "," as the fill characters, calling JOIN provides the following destination array:
  `1974Jackson,,,,,,Peter,,,,,VeryLongRoadna`

SPLIT: Splitting an array of characters into multiple strings (S7-1500)

Description

The "SPLIT" instruction converts an array (Array of CHAR / WCHAR) into several separate strings (Array of STRING / WSTRING or structure).

To convert the array into several strings, specify the following information:

- **Selection of array to be read**
  You specify the array to be read at the SrcArray parameter. Make sure that the data types used for the input and output parameters match any other parameters used. If you use an array with the CHAR data type at the SrcArray parameter, for example, you must use the CHAR data type for the delimiter (Rec/EndSeparator) and the structure must only contain strings with the STRING data type at the DestStruct parameter.
- **Format selection for the source array**
  You use the first bit of the Mode parameter to specify whether the array to be read has the CSV or FSR format.
  - With CSV (Comma Separated Values), characters in the source array that belong together are separated by a delimiter from the next characters that belong together. Two examples of a source array:
    `1963,Miller,John,CitynameA,Roadname`
    `1974,Jackson,Peter,CitynameB,VeryLongRoadname`
  - With FSR (Fixed Size Records), a certain number of characters is defined for each item of logical information of the source array. Each item of information should fit into the space defined for it. When information does not need the space defined for it, it is filled with delimiters.
    Two examples of source arrays, whereby the length of the information is 4 characters for the first information item (year of birth), 13 characters for the second (last name), 10 characters for the third (first name), 9 characters for the fourth (city) and 16 characters for the fifth (street):
    `1963Miller,,,,,,,John,,,,,,CitynameARoadname,,,,,,,,`
    `1974Jackson,,,,,,Peter,,,,,CitynameBVeryLongRoadname`
- **Delimiter used for the array to be read**
  - If the array to be read has CSV format, use the RecSeparator parameter to specify which delimiter was used.
  - If the array to be read has FSR format, use the RecSeparator parameter to specify which fill character was used.
- **Selection of the delimiter for the end of the total string**
  Specify the delimiter after which the reading of the array should stop at the EndSeparator parameter. The "SPLIT" instruction stops at this position and outputs the string that has been found. Note that the EndSeparator delimiter is evaluated with higher priority than the RecSeparator delimiter. If the delimiter at the EndSeparator parameter was used in a string to be read (between two RecSeparator delimiters), all content after the EndSeparator delimiter is ignored.
- **Specification of the position starting at which the array is read**
  The conversion starts at this position in the array and the instruction reads the Position parameter to determine the position at which the conversion is completed. This enables follow-up calls of the instruction for filling the various strings at the DestStruct parameter.
- **Outputting the number of read strings**
  If you use an Array of STRING at the DestStruct parameter, you can use the Count parameter to output the number of read strings. Only strings with content are counted. If you use a data type other than Array of STRING at the DestStruct parameter, "0" is output at the Count parameter.

Parameters

The following table shows the parameters of the "SPLIT" instruction:

Parameter	Declaration	Data type	Memory area	Description
Mode	Input	DWord	I, Q, M, D, L or constant	Specifies how the split into multiple strings is performed (see "Mode" parameter).
RecSeparator	Input	Variant	I, Q, M, D, L	Delimiter or fill character • With CSV: Character that was used in the array to be read to identify the individual strings. • With FSR: Character that has been used as a fill character in the array to be read.
EndSeparator	Input	Variant	I, Q, M, D, L	Delimiter used to define the end of the total string in the array to be read.
SrcArray	Input	Variant	I, Q, M, D, L	Pointer to the array to be read (Array of CHAR/WCHAR)
DestStruct	InOut	Variant	I, Q, M, D, L	Structure which includes the converted strings (Array of STRING / WSTRING).
Position	InOut	UDInt	I, Q, M, D, L	Position from which the array is to be read at the SrcArray parameter.
Ret_Val	Return	Int	I, Q, M, D, L	Result of instruction execution / error code (see table "Ret_Val parameter")
Count	Output	UDInt	I, Q, M, D, L	Number of strings that were found.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter "Mode"

Bit	Bit value "0"	Bit value "1"	Description
0	CSV format (Comma Separated Values)	FSR format (Fixed Size Record)	Basic mode: Selection of CSV or FSR
1	• With CSV: Additional characters cause an error. • With FSR: Additional fill characters remain in string.	• With CSV: Additional characters are ignored. • With FSR: Additional fill characters are removed.	Use bit 1 to specify how you want to deal with additional characters: • With CSV: – If the bit is set, additional characters that do not fit in the destination string are ignored. Example: The instruction writes to a string with a length of 16 characters (STRING[16] data type). No delimiter is contained in the source after the first 16 characters. If bit 1 is set, the extra characters are ignored and the instruction continues to read the array. – If the bit is not set, the instruction stops in such a case and generates an error message at the Ret_Val parameter. • With FSR: – If the bit is set, the fill characters located to the right of characters containing information are not written to the destination character string when the source array is transferred to the destination character strings (see example). – If the bit is not set, the fill characters located to the right of characters containing information are written to the destination character string when the source array is transferred to the destination character strings (see example).
2	-	-	Reserved for use in future versions.
3	Separator is retained.	Separator is removed.	Specification of whether the delimiter is removed at the end of the total string.
4	Leave unwritten strings (STRING) at length.	Set unwritten strings (STRING) to length "0".	Specification of whether unused strings (STRING) at the DestStruct parameter are set to the length "0".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error.
0001	Additional characters are ignored.
8190	Selection at the Mode parameter is not supported.
8x20	Source strings invalid.
8x53	VARIANT points to data structure that is too short.
8x54	Invalid data type
8x84	Additional characters found.
8xB4	Different data types at parameters SrcArray (source) and DestStruct (destination) or at separators (parameters RecSeparator and EndSeparator).
80B5	Buffer overflow with the instruction. The character strings are not completely output at parameter DestStruct.

Error code* (W#16#...)	Explanation
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)

* Note the following for the error codes:

- The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".
- The "x" in the second position of the listed error codes stands for the parameter that caused the error.
  Example: Error code 8352 hex = error occurred at 3rd parameter (EndSeparator), see Parameter table.
- If the error cannot be clearly assigned to a specific parameter, "0" is output.
  Example: The CHAR data type is used for the delimiter (RecSeparator parameter). WCHAR is used as data type for the array at the DestArray parameter. Error code 80B4 is output in this case.

Two examples for the SPLIT instruction when the ARRAY to be read has the CSV format

In the first step, the source array is split into strings as specified by the delimiter (RecSeparator parameter, e.g. ",").

In the second step, the resulting strings after the split are stored in destination strings. You can use the DestStruct parameter to specify their length.

If the strings produced by the split have more characters than can fit in the destination string, the behavior of SPLIT after this point depends on the Mode parameter. With Mode=2#00, this results in an error: The associated error code is returned and no other destination strings are

filled. With Mode=2#10, the surplus characters are ignored and the next destination string is filled with the characters after the next delimiter.

- First example:
  In this example, there are these two source arrays:
  - `1963,Miller,John,Roadname`
  - `1974,Jackson,Peter,VeryLongRoadname`

  The length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  The first call for SPLIT produces the following destination strings with Mode=2#10:
  - `1963`
  - `Miller`
  - `John`
  - `Roadname`

  The second call for SPLIT produces the following destination strings with Mode=2#10:
  - `1974`
  - `Jackson`
  - `Peter`
  - `VeryLongRoadna`
- Second example:
  In this example, the logical information in the source array is not in the order expected. There are these two source arrays:
  - `1963,Miller,Roadname,John`
  - `1974,Jackson,VeryLongRoadname,Peter`

  As in the first example, the length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  The first call for SPLIT produces the following destination strings with Mode=2#10:
  - `1963`
  - `Miller`
  - `Roadname`
  - `John`

  The second call for SPLIT produces the following destination strings with Mode=2#10:
  - `1974`
  - `Jackson`
  - `VeryLongRo`
  - `Peter`

Two examples for the SPLIT instruction when the ARRAY to be read has format FSR

The source array is split into strings as you specified in the DestStruct parameter for the length of the destination string.

With regard to the fill characters (RecSeparator parameter e.g. ","), the behavior of SPLIT depends on the Mode parameter: With Mode=2#01, the fill characters are entered in the destination strings; with Mode=2#11, they are not entered.

- First example:
  In this example, there are these two source arrays:
  - `1963Miller,,,,,,,John,,,,,,Roadname,,,,,,`
  - `1974Jackson,,,,,,Peter,,,,,VeryLongRoadname`

  The length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth. The first call for SPLIT produces the following destination strings with Mode=2#01:
  - `1963`
  - `Miller,,,,,,,`
  - `John,,,,,,`
  - `Roadname,,,,,,`

  The second call for SPLIT produces the following destination strings with Mode=2#01:
  - `1974`
  - `Jackson,,,,,,`
  - `Peter,,,,,`
  - `VeryLongRoadna`
- Second example:
  In this example, the logical information in the source array is not in the order expected. There are these two source arrays:
  - `1963Miller,,,,,,,Roadname,,,,,,John,,,,,,`
  - `1974Jackson,,,,,,VeryLongRoadnamePeter,,,,,`

  As in the first example, the length of the destination string amounts to 4 characters for the first destination string, 13 characters for the second, 10 characters for the third and 14 characters for the fourth.
  The first call for SPLIT produces the following destination strings with Mode=2#11:
  - `1963`
  - `Miller`
  - `Roadname`
  - `,,,,John`

  Explanation: The SPLIT instruction lays templates over the source array, so to speak. The length of these templates is determined by the length of the destination strings. During transfer to the destination strings, only those commas to the right of characters with information content are interpreted as fill characters. The fill characters are not entered with Mode=2#11. In the first call, the commas are to the right of the "John" fill characters. The commas to the left of "John", however, are not fill characters, because the relevant "John" characters follow before the end of the corresponding destination string is reached. Therefore, the commas to the left of "John" appear in the destination string.
  The second call for SPLIT produces the following destination strings with Mode=2#11:

- 1974
- Jackson
- VeryLongRo
- adnamePeter

ATH: Convert ASCII string to hexadecimal number (S7-1200, S7-1500)

Description

You use the instruction "ATH" to convert the ASCII character string specified at the IN input parameter into a hexadecimal number. The result of the conversion is output to the OUT output parameter.

- You can reference the following data types using the pointer at the IN parameter (ASCII): STRING, WSTRING, CHAR, BYTE, Array of CHAR, Array of BYTE, WCHAR, Array of WCHAR, Array of WORD.
- You can reference the following data types using the pointer at the OUT parameter (hexadecimal): Array of CHAR, Array of BYTE, Array of WORD, STRING, BYTE, CHAR, WORD, INT, DWORD, DINT, SINT, USINT, UINT, UDINT. Only with S7-1500: Array of WCHAR, WSTRING, WCHAR, ULINT, LINT, LWORD

You specify the number of ASCII characters to be converted with the N parameter. A maximum of 32767 valid ASCII characters can be converted. Only digits "0" to "9", upper case letters "A" to "F", and lower case letters "a" to "f" can be interpreted. All other characters are converted to zeros.

Since 8 bits are required for the ASCII character and only 4 bits for the hexadecimal digit, the output word length is only half of the input word length. The ASCII characters are converted and positioned in the output in the same order as they are read in. If there is an odd number of ASCII characters, the hexadecimal number is padded with zeros in the nibble to the right of the last converted hexadecimal number.

Parameter

The following table shows the parameters of the "ATH" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	D, L	Pointer to ASCII character string
N	Input	INT	I, Q, M, D, L or constant	Number of ASCII characters to be converted
RET_VAL	Return	WORD	I, Q, M, D, L	Status of the instruction
OUT	Output	VARIANT	I, Q, M, D, L	Hexadecimal number

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code (W#16#....)*	Description
0000	No error
0007	Invalid character. Only the following ASCII characters may be used: Digits "0" to "9", upper case letters "A" to "F", lower case letters "a" to "f".
8101	Invalid pointer at the IN parameter, e.g., because a non-existing data block is referenced.
8182	Input buffer is too small for data in the N parameter.
8120	Invalid format in the IN parameter.
8151	Non-supported data type in the IN parameter.
8401	Invalid pointer at the OUT parameter, e.g., because a non-existing data block is referenced.
8482	Output buffer is too small for data in the N parameter.
8420	Invalid format in the OUT parameter.
8451	Non-supported data type in the OUT parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ASCII characters and hexadecimal values

The following table shows the ASCII characters and the corresponding hexadecimal values:

ASCII character	ASCII-coded hexadecimal value	Hexadecimal digit
"0"	30	0
"1"	31	1
"2"	32	2
"3"	33	3
"4"	34	4
"5"	35	5
"6"	36	6
"7"	37	7
"8"	38	8
"9"	39	9
"A"	41	A
"B"	42	B
"C"	43	C
"D"	44	D
"E"	45	E
"F"	46	F

Example

The following table shows examples of the conversion of ASCII character strings to hexadecimal numbers:

Data type of IN	IN	N	OUT	ENO status
STRING, WSTRING	'0a23'	4	• WORD#16#0A23 • UINT#10#2595	1
STRING, WSTRING	‘123aFx1a23’	10	• LWORD#16#123AF01A_23000000 • ULINT#10#1 313 626 236 378 939 392	0
STRING, WSTRING	‘a23’	3	WORD#16#A230	1
STRING, WSTRING	‘0a23’	4	• WORD#[16#0A23, 16#0000] • BYTE#[16#0A, 16#23]	1
STRING, WSTRING	‘aFbE’	1	• CHAR#‘A’ • WCHAR#‘A’	1
STRING, WSTRING	‘0a23’	4	• CHAR#[‘0’, ‘A’, ‘2’, ‘3’] • WCHAR#[‘0’, ‘A’, ‘2’, ‘3’]	1
STRING, WSTRING	‘123aFC1a23’	10	• STRING#‘123AFC1A23’ • WSTRING#‘123AFC1A23’	1
ArrayOfCHAR, ArrayOfWCHAR	[‘a’, ‘B’, ‘E’, ‘3’]	4	WORD#16#ABE3	1
ArrayOfBYTE	[16#39, 16#32, 16#35]	3	WORD#16#9250	1
ArrayOfWORD	[16#1234, 16#0032, 16#0031, 16#0000]	3	WORD#16#0210	0
ArrayOfWORD	[16#0031, 16#0032, 16#0033, 16#0034]	4	WORD#16#1234	1
ArrayOfWORD	[16#AB31, 16#32AF, 16#4333, 16#0034]	4	WORD#16#0004	0
ArrayOfWORD	[16#0031, 16#0032, 16#0033, 16#0034]	4	[16#1234, 16#0000, 16#0000, 16#0000]	1
ArrayOfWORD	[16#0034, 16#0035, 16#0036, 16#0037, 16#0041, 16#0042, 16#0043, 16#0044]	8	DWORD#16#4567_ABCD	1

HTA: Convert hexadecimal number to ASCII string (S7-1200, S7-1500)

Description

You use the instruction "HTA" to convert the hexadecimal number specified at the IN input into an ASCII character string. The result of the conversion is stored at the address specified in the OUT parameter.

- You can reference the following data types using the pointer in the IN parameter (hexadecimal): Array of CHAR, Array of BYTE, STRING, BYTE, CHAR, WORD, Array of WORD, INT, DWORD, Array of DWORD, DINT, SINT, USINT, UINT, UDINT. Only with S7-1500: Array of WCHAR, WSTRING, WCHAR, ULINT, LINT, LWORD, Array of LWORD
- You can reference the following data types using the pointer in the OUT parameter (ASCII): STRING, WSTRING, Array of CHAR, Array of WCHAR, Array of BYTE, Array of WORD

You specify the number of hexadecimal bytes to be converted with the N parameter. Since 8 bits are required for the ASCII character and only 4 bits for the hexadecimal digit, the output value is twice as long as the input value. Each nibble of the hexadecimal number is converted to a character while maintaining the original order.

A maximum of 32767 characters are written to the ASCII character string. The result of the conversion is represented by the digits "0" to "9" and upper-case letters "A" to "F".

If the complete result of the conversion cannot be displayed in the OUT parameter, the result is will only be partially written to the parameter.

Parameter

The following table shows the parameters of the "HTA" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	VARIANT	I, Q, M, D, L	Start address of the hexadecimal digits
N	Input	UINT	I, Q, M, D, L or constant	Number of hexadecimal bytes to be converted
RET_VAL	Return	WORD	I, Q, M, D, L	Error message
OUT	Output	VARIANT	D, L	Address at which the result is stored.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#....)	Description
0000	No error
8101	Invalid pointer at the IN parameter, e.g., because a non-existing data block is referenced.
8182	Input buffer is too small for data in the N parameter.
8120	Invalid format in the IN parameter.

Error code* (W#16#....)	Description
8151	Non-supported data type in the IN parameter.
8401	Invalid pointer at the OUT parameter, e.g., because a non-existing data block is referenced.
8482	Output buffer is too small for data in the N parameter.
8420	Invalid format in the OUT parameter.
8451	Non-supported data type in the OUT parameter.
* The error codes can be displayed as integer or hexadecimal values in the program editor. For information on switching the display formats, refer to "See also".	

ASCII characters and hexadecimal values

The following table shows the ASCII characters and the corresponding hexadecimal values:

Hexadecimal digit	ASCII-coded hexadecimal value	ASCII character
0	30	"0"
1	31	"1"
2	32	"2"
3	33	"3"
4	34	"4"
5	35	"5"
6	36	"6"
7	37	"7"
8	38	"8"
9	39	"9"
A	41	"A"
B	42	"B"
C	43	"C"
D	44	"D"
E	45	"E"
F	46	"F"

Example

The following table shows examples of the conversion of hexadecimal numbers to ASCII character strings:

IN	N	OUT	Data type of OUT	ENO status
• WORD#16#0123 • UINT#10#291	2	'0123'	STRING, WSTRING	1
• DWORD#16#123AF012 • INT#10#305852434	4	'123AF012'	STRING, WSTRING	1
WORD#16#ABE3	2	CHAR#['A', 'B', 'E', '3']	ArrayOfCHAR, ArrayOfW-CHAR	1
WORD#16#9250	2	[16#39, 16#32, 16#35, 16#30]	ArrayOfBYTE	1

IN	N	OUT	Data type of OUT	ENO status
ArrayOfWORD#[16#123A, 16#0000, 16#ABCD, 16#0000]	2	[16#0031, 16#0032, 16#0033, 16#0041]	ArrayOfWORD	1
WORD#16#1234	2	[16#0031, 16#0032, 16#0033, 16#0034]	ArrayOfWORD	1
DWORD#16#4567ABCD	4	[16#0034, 16#0035, 16#0036, 16#0037, 16#0041, 16#0042, 16#0043, 16#0044]	ArrayOfWORD	1
ArrayOfD-WORD#[16#A800_0037, 16#0000_0041]	1	'A8'	STRING, WSTRING	1
• CHAR#['0', 'A', '2', '3'] • WCHAR#['0', 'A', '2', '3']	2	'3041'	STRING, WSTRING	1
• STRING#'123AFC1A23' • WSTRING#'123AFC1A23'	5	'3132334146'	STRING, WSTRING	1
• Char#'A' • Byte#16#41	1	'41'	STRING, WSTRING	1

LEN: Determine the length of a character string (S7-1200, S7-1500)

Description

A tag of the (W)STRING data type contains two lengths: the maximum length and the current length (this is the number of currently valid characters).

- The maximum length of the character string is specified for each tag in the STRING keyword in square brackets. The number of bytes occupied by a string is 2 greater than the maximum length.
- The maximum length of the character string is specified for each tag in the WSTRING keyword in square brackets. The number of words occupied by a character string is 2 greater than the maximum length.
- The current length represents the number of the character places actually used. The current length must be less than or equal to the maximum length.

You use the instruction "LEN" to query the current length of the character string specified at the IN input parameter. This is output as numerical value at the output par OUT. An empty string ('') has the length zero.

If errors occur during processing of the instruction, the value "0" is output at the OUT parameter.

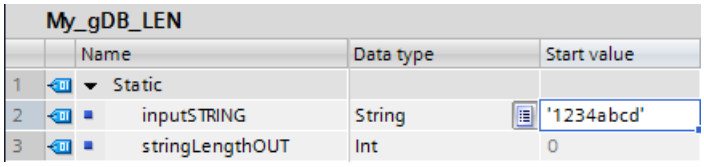
Note

Reading out the maximum length

You use the "MAX_LEN (Page 3512)" instruction to read out the maximum length of a string.

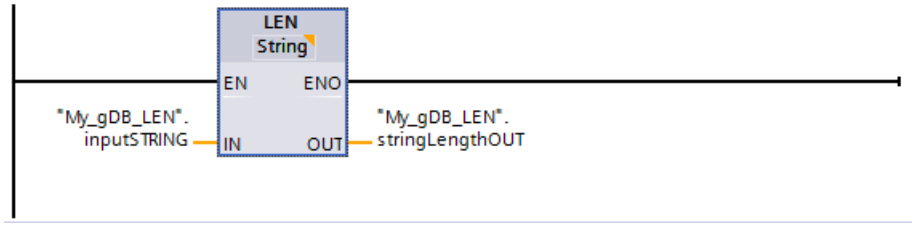
Parameter

The following table shows the parameters of the "LEN" instruction:



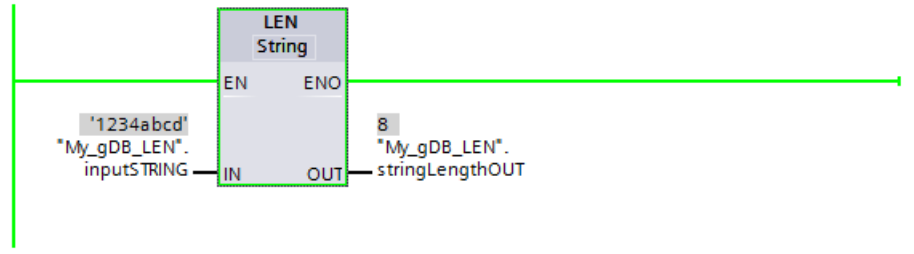
Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
OUT	Return	INT	I, Q, M, D, L	Number of valid characters

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you determine the length of a character string with the STRING data type.



Create two tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows.

The number of actually occupied characters of the character string ("inputSTRING") is determined and returned as a numerical value at output parameter "OUT" ("stringLengthOUT").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

CONCAT: Combine character strings (S7-1200, S7-1500)

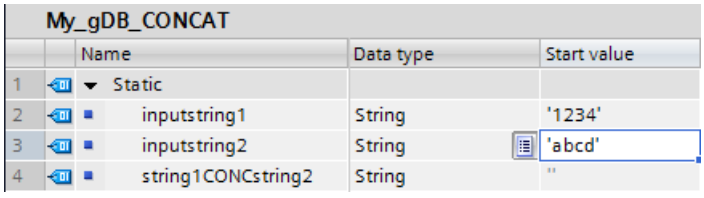
Description

You use the instruction "CONCAT" to combine the character string at the IN1 input parameter with the character string at the IN2 input parameter. The result is output at the OUT output parameter in (W)STRING format. If the resulting character string is longer than the tag specified in the OUT output parameter, then the resulting character string will be limited to the available length.

If errors occur during processing of the instruction and it is possible to write the OUT output parameter, an empty string will be output.

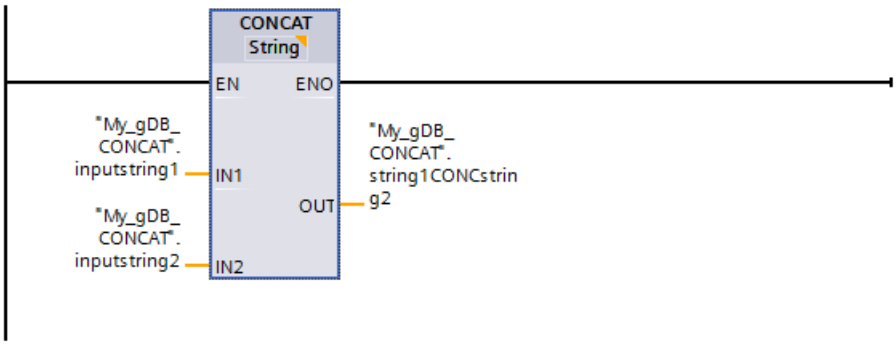
Parameters

The following table shows the parameters of the "CONCAT" instruction:



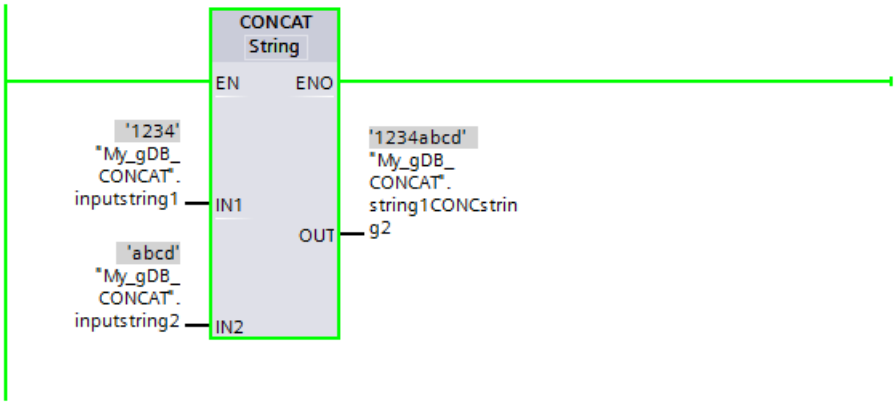
Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	Character string
IN2	Input	STRING, WSTRING	D, L or constant	Character string
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you connect two character strings with the STRING data type.



Create three tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows.

The characters of the second character string ("inputstring2") are appended to the first character string ("inputstring1") and the result is output at output parameter OUT ("string1CONCstring2").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

LEFT: Read the left character of a character string (S7-1200, S7-1500)

Description

You use the instruction "LEFT" to extract a partial string beginning with the first character of the string at the IN input parameter. You specify the number of characters to be extracted in the L parameter. The extracted characters are output at the OUT output parameter in (W)STRING format.

If the number of characters to be extracted is greater than the current length of the character string, the OUT output parameter returns the input character string as a result. If the L parameter contains the value "0" or the input value is an empty string, an empty string will be returned. If the value in the L parameter is negative, an empty string will be output.

If errors occur during processing of the instruction and it is possible to write the OUT output parameter, an empty string will be output.

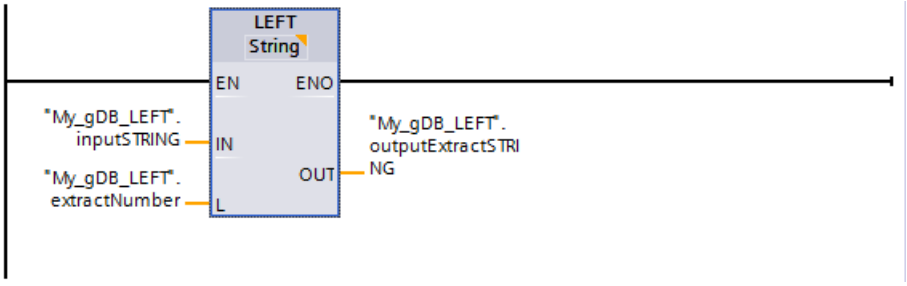
Parameters

The following table shows the parameters of the "LEFT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be extracted
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

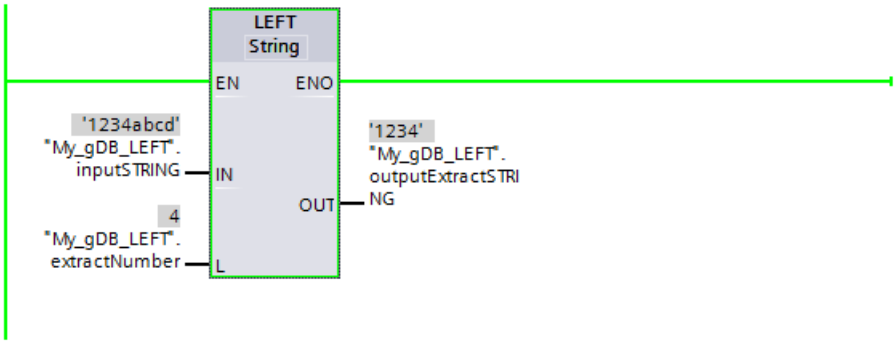
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you extract a partial character string with the STRING data type from a character string starting from the first character.

Create three tags in a global data block for storing the data.



My_gDB_LEFT

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	extractNumber	Int	4
4	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.

According to the value "4" of parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING") starting from the first character from the left. The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

RIGHT: Read the right characters of a character string (S7-1200, S7-1500)

Description

You use this instruction to extract the last L character in a character string in the input parameter IN. You specify the number of characters to be extracted in the L parameter. The extracted characters are output at the OUT output parameter in (W)STRING format.

If the number of characters to be extracted is greater than the current length of the character string, the OUT output parameter returns the input character string as a result. If the L parameter contains the value "0" or the input value is an empty string, an empty string will be returned. If the value in the L parameter is negative, an empty string will be output.

If errors occur during processing of the instruction and it is possible to write the OUT output parameter, an empty string is output.

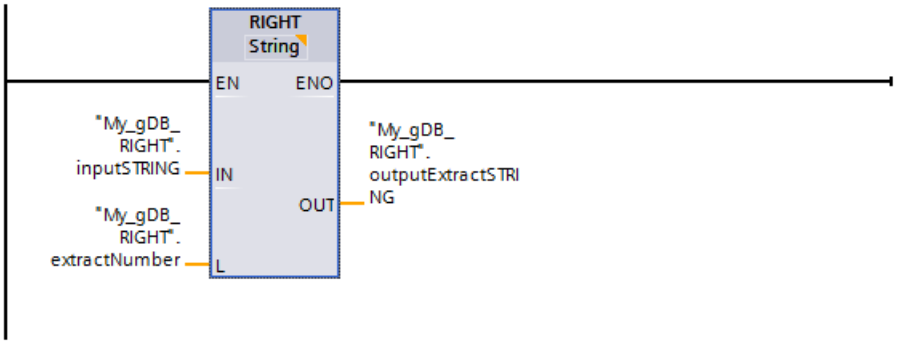
Parameters

The following table shows the parameters of the "RIGHT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be extracted
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

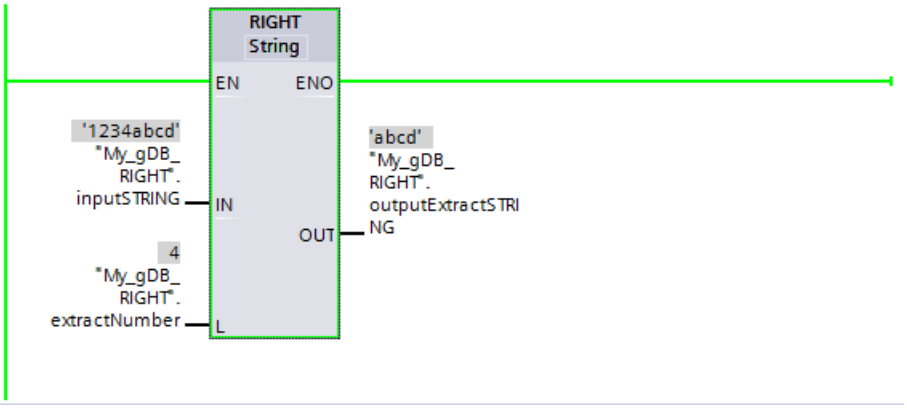
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you extract a partial character string with the STRING data type from a character string starting from the last character.

Create three tags in a global data block for storing the data.



My_gDB_RIGHT

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	extractNumber	Int	4
4	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.

According to the value "4" of input parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING") starting from the first character from the right. The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

MID: Read middle characters of a character string (S7-1200, S7-1500)

Description

You use this instruction to extract a portion of the character string in the IN input parameter. With the P parameter, you specify the position of the first character to be extracted. With the L parameter, you define the length of the character string to be extracted. The extracted partial character string is output to the OUT output parameter.

Note the following rules when executing the instruction:

- If the number of characters to be extracted exceeds the current length of the character string in the IN input parameter, a partial character string will be output. The partial character string starts at the P character string and is continued until the end of the character string.
- If the character position specified in the P parameter falls outside the current character string length in the IN input parameter, an empty character string will be output in the OUT output parameter.
- If the value of the P or L parameter equals zero or is negative, an empty character string will be output in the OUT output parameter.

If errors occur during processing of the instruction and it is possible to write the OUT output parameter, an empty string will be output.

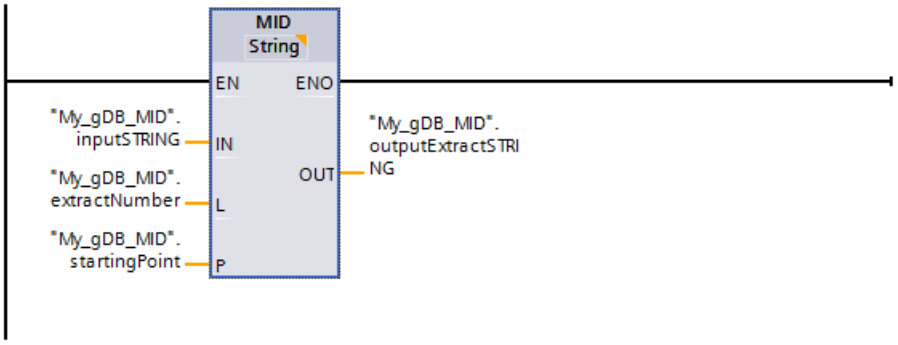
Parameters

The following table shows the parameters of the "MID" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Length of the string to be extracted
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of the first character to be extracted (first character = 1)
OUT	Return	STRING, WSTRING	D, L	Extracted partial string

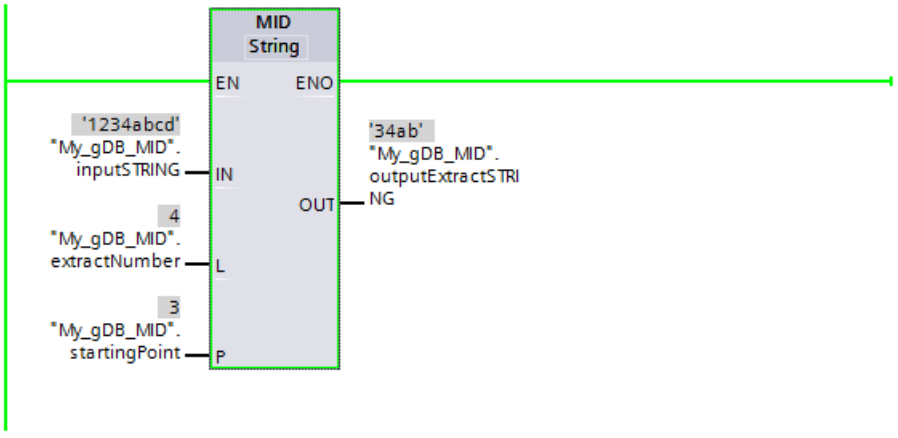
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you extract a partial character string with the STRING data type from the middle of a character string.

Create four tags in a global data block for storing the data.



My_gDB_MID

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	startingPoint	Int	3
4	extractNumber	Int	4
5	outputExtractSTRING	String	''

Interconnect the parameters of the instruction as follows.

According to the value "4" of input parameter L ("extractNumber"), you extract a four-character partial character string from the character string ("inputSTRING"). The extraction starts from the third character ("startingPoint" has the value "3") of the character string ("inputSTRING"). The extracted partial character string is output at output parameter OUT ("outputExtractSTRING").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

DELETE: Delete characters in a character string (S7-1200, S7-1500)

Description

You use this instruction to delete a portion of the character string in the IN input parameter. With the P parameter, you specify the position of the first character to be deleted. You specify the number of characters to be deleted in the L parameter. The remaining partial character string is output at the OUT output parameter in (W)STRING format.

Note the following rules when executing the instruction:

- If the value in the P parameter is less than or equals zero, an empty character string will be output in the OUT output parameter.
- If the value in the P parameter is greater than the current length of the character string in the IN input, the input character string will be returned in the OUT output parameter.

- If the value in the L parameter equals zero, the input character string will be returned in the OUT output parameter.
- If the number of characters to be deleted at the L parameter is greater than the length of the character string at the IN input parameter, the characters starting at the position specified by the P parameter are deleted. The string resulting from this is output.
- If the value in the L parameter is negative, an empty character string will be output.

If errors occur during processing of the instruction and it is possible to write the OUT output parameter, an empty string will be output.

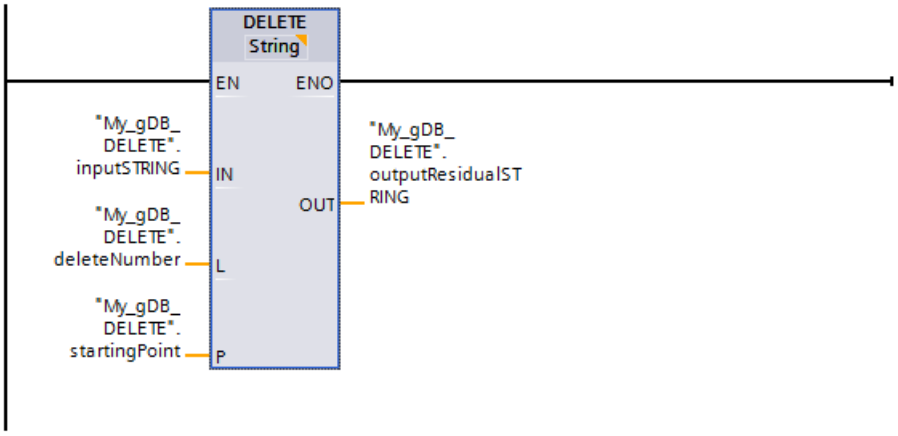
Parameters

The following table shows the parameters of the "DELETE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN	Input	STRING, WSTRING	D, L or constant	Character string
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be deleted
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of first character to be deleted
OUT	Return	STRING, WSTRING	D, L	Resulting character string

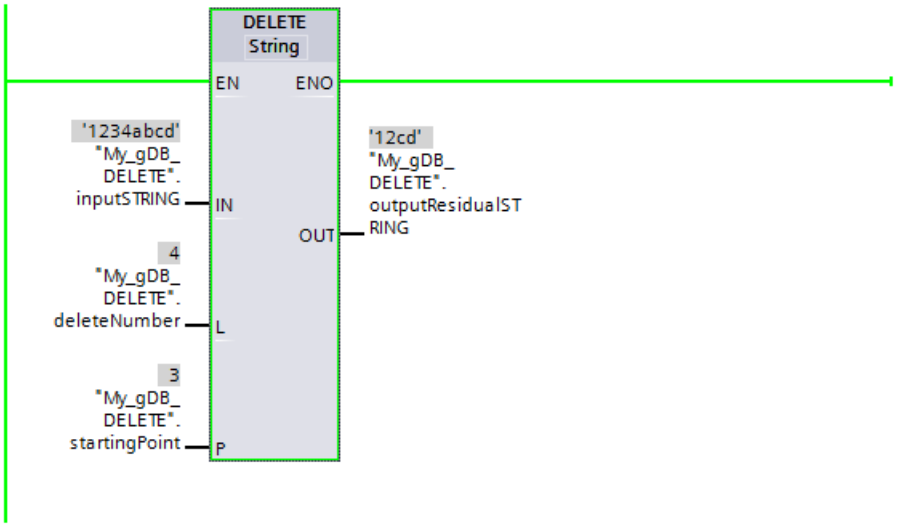
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you delete characters from a character string with the STRING data type.

Create four tags in a global data block for storing the data.



My_gDB_DELETE

	Name	Data type	Start value
1	Static		
2	inputSTRING	String	'1234abcd'
3	startingPoint	Int	3
4	deleteNumber	Int	4
5	outputResidualSTRING	String	''

Interconnect the parameters of the instruction as follows.

According to the value "4" of input parameter L ("deleteNumber"), you delete four characters from the character string ("inputSTRING") starting from the third character ("startingPoint" has the value "3"). The remaining character string is output at output parameter OUT ("outputResidualSTRING").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

INSERT: Insert characters in a character string (S7-1200, S7-1500)

Description

You use this instruction to insert the character string in the IN2 input parameter to the character string in the IN1 input parameter. With the P parameter, you specify the position of the character starting at which the characters are inserted. The result is output at the OUT output parameter in (W)STRING format.

Note the following rules when executing the instruction:

- If the value in the P parameter exceeds the current length of the character string in the IN1 input parameter, the character string of the IN2 input parameter will be appended to the character string of the IN1 input parameter.
- If the value at the P parameter is zero, the character string at the OUT parameter followed by the character string at the IN2 parameter will be output in the IN1 parameter.
- If the value in the P parameter is negative, an empty character string will be output in the OUT output parameter.
- If the resulting character string is longer than the tag specified in the OUT output parameter, the resulting character string will be limited to the available length.

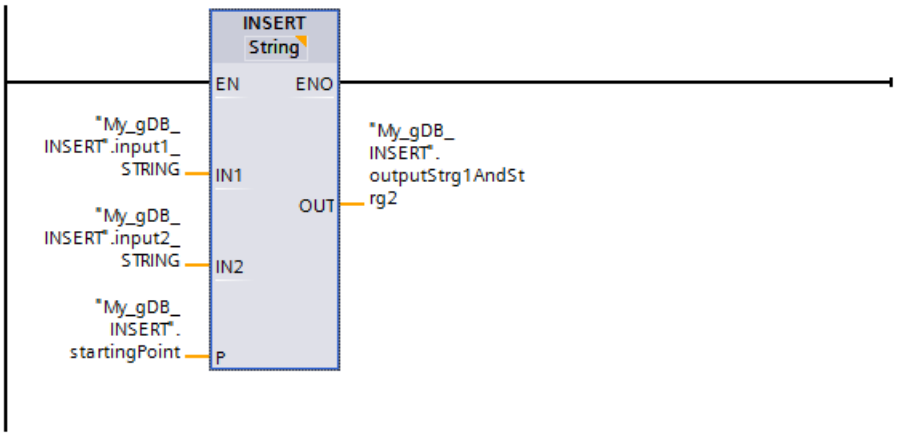
Parameters

The following table shows the parameters of the "INSERT" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	Character string
IN2	Input	STRING, WSTRING	D, L or constant	String to insert
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Insert position
OUT	Return	STRING, WSTRING	D, L	Resulting character string

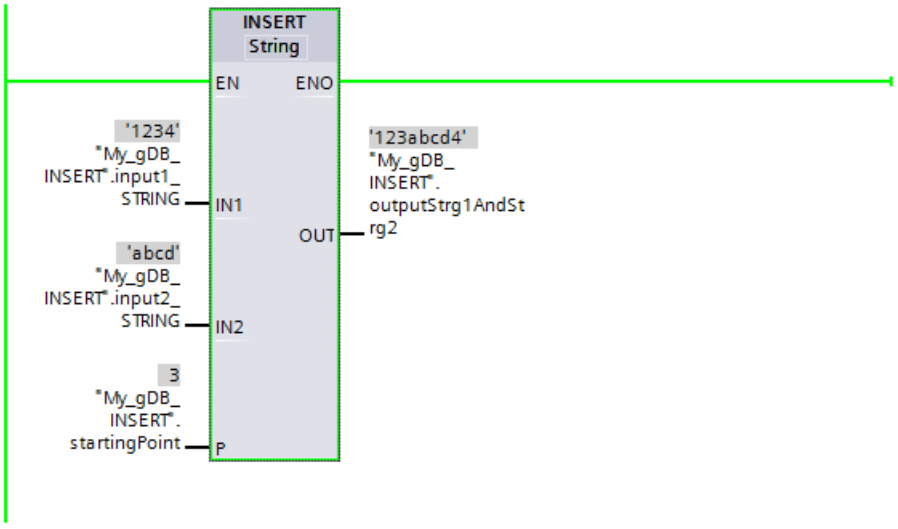
You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you insert a character string in another character string. The data type used is STRING.

Create four tags in a global data block for storing the data.



My_gDB_INSERT

	Name	Data type	Start value
1	Static		
2	input1_STRING	String	'1234'
3	input2_STRING	String	'abcd'
4	startingPoint	Int	3
5	outputStrg1AndStrg2	String	''

Interconnect the parameters of the instruction as follows.

The characters of the second character string ("input2_STRING") are inserted in the first character string ("input1_STRING"). According to the value "3" of parameter P ("startingPoint"), characters are inserted after the third character of the first character string ("input1_STRING"). The result is output at output parameter OUT ("outputStrg1AndStrg2").

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

REPLACE: Replace characters in a character string (S7-1200, S7-1500)

Description

You use this instruction to replace a portion of the character string in the IN1 input with the character string in the IN2 input parameter. You specify the position of the first character to be replaced in the P parameter. You specify the number of characters to be replaced in the L parameter. The result is output at the OUT output parameter in (W)STRING format.

Note the following rules when executing the instruction:

- If the value in the P parameter is less than or equals zero, an empty character string will be output in the OUT output parameter.
- If the value in the L parameter is less than zero, an empty character string will be output in the OUT output parameter.
- If P equals one, the character string in the IN1 input will be replaced beginning with (and including) the first character.
- If the value in the P parameter exceeds the current length of the character string in the IN1 input parameter, the character string of the IN2 input parameter will be appended to the character string of the IN1 input parameter.
- If the resulting character string is longer than the tag specified in the OUT output parameter, the resulting character string will be limited to the available length.
- If the value at parameter L is zero, characters are not replaced but inserted. Similar conditions apply as with the instruction INSERT. See also: INSERT: Insert characters in a character string (Page 3541)

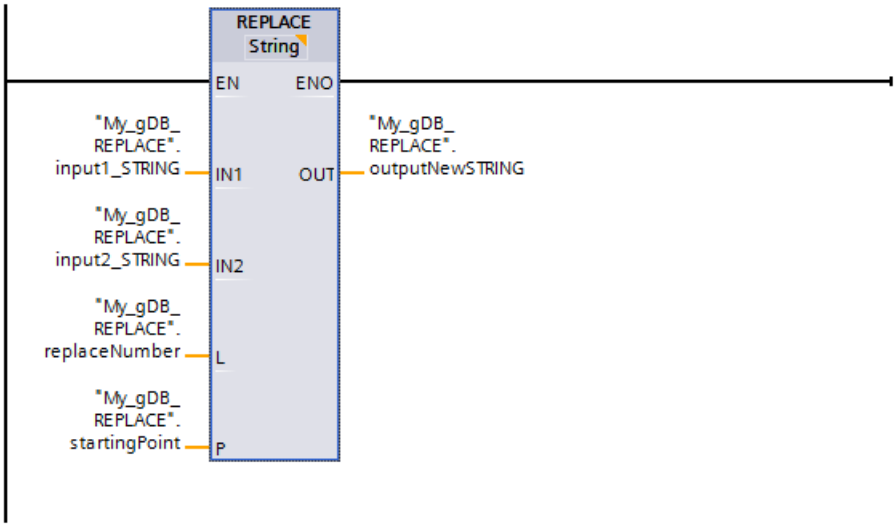
Parameters

The following table shows the parameters of the "REPLACE" instruction:

Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	String with characters to be replaced.
IN2	Input	STRING, WSTRING	D, L or constant	String with characters to be inserted.
L	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Number of characters to be replaced
P	Input	BYTE, INT, SINT, USINT	I, Q, M, D, L or constant	Position of first character to be replaced
OUT	Return	STRING, WSTRING	D, L	Resulting character string

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you replace part of a character string with another character string. The data type used is STRING.

Create five tags in a global data block for storing the data.

My_gDB_REPLACE

	Name	Data type	Start value
1	Static		
2	input1_STRING	String	'1234'
3	input2_STRING	String	'abcd'
4	replaceNumber	Int	2
5	startingPoint	Int	3
6	outputNewSTRING	String	''

Interconnect the parameters of the instruction as follows.

The second character string ("input2_STRING") is added to the first character string ("input1_STRING") starting from the third character ("startingPoint" has the value "3"). According to the value "2" of parameter L ("replaceNumber"), the third and fourth characters of the first character string ("input1_STRING") are replaced in the process. The result is output at output parameter OUT ("outputNewSTRING").

My_gDB_REPLACE

	Name	Data type	Start value	Monitor value
1	Static			
2	input1_STRING	String	'1234'	'1234'
3	input2_STRING	String	'abcd'	'abcd'
4	replaceNumber	Int	2	2
5	startingPoint	Int	3	3
6	outputNewSTRING	String	''	'12abcd'

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

FIND: Find characters in a character string (S7-1200, S7-1500)

Description

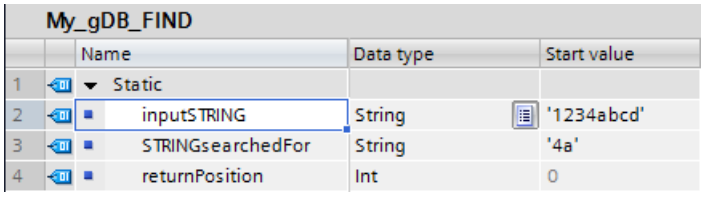
You use this instruction to search through the character string at the IN1 input parameter for a specific character string.

- You specify the value to be searched for in the IN2 input parameter. The search is made from left to right.
- The position of the first occurrence is output in the OUT output parameter. If the search returns no match, the value "0" will be output in the OUT output parameter.

If an invalid character is specified at the IN2 parameter or if an error occurs during processing, the value "0" is output at the OUT parameter.

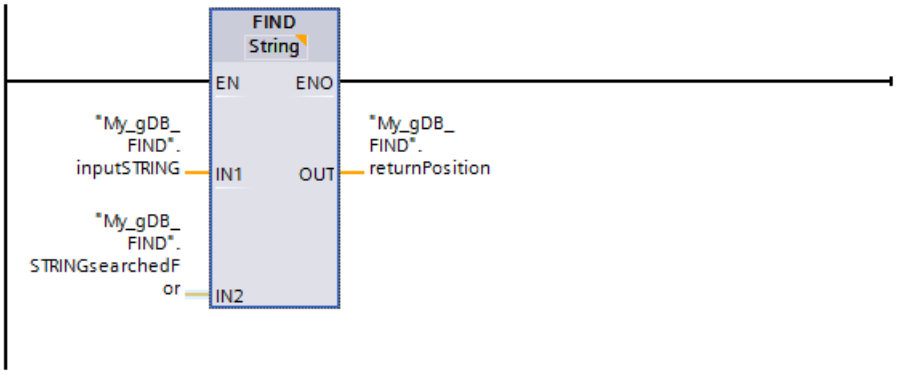
Parameters

The following table shows the parameters of the "FIND" instruction:



Parameter	Declaration	Data type	Memory area	Description
IN1	Input	STRING, WSTRING	D, L or constant	String searched through
IN2	Input	STRING, WSTRING	D, L or constant	Character string that is searched for
OUT	Return	INT	I, Q, M, D, L	Character position

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you search for a character string in another character string. The data type used is STRING.

Create three tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows.

The first character string ("inputSTRING") searches for the value "4a" of the second character string ("STRINGsearchedFor"). The character position ("4") at which the searched character string begins is output at output parameter OUT ("returnPosition").

My_gDB_FIND

	Name	Data type	Start value	Monitor value
1	Static			
2	inputSTRING	String	'1234abcd'	'1234abcd'
3	STRINGsearchedFor	String	'4a'	'4a'
4	returnPosition	Int	0	4

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Runtime information (S7-1200, S7-1500)

GetSymbolName: Read out a tag on the input parameter (S7-1200, S7-1500)

Description

With the "GetSymbolName" instruction, you use the input parameter of a block to read out the name of a tag interconnected at the parameter.

Note

Increased code memory requirement

The use of GetSymbolName leads to an increased code memory requirement. The more frequently the instruction is called and the longer the actual symbols are, the greater the memory requirement.

If a block is used multiple times in the project and called each time by a different tag, you can use the "GetSymbolName" instruction to evaluate the name of the calling tag. The process value of the tag is irrelevant in this case.

- You specify the input parameters of the block interface at the VARIABLE parameter. Use only an interface parameter for this parameter and no PLC or data block tags.
- To limit the length of the read tag name, use the SIZE parameter. If the name has been truncated, this is indicated by the characters "..." (Unicode character 16#2026) appears at the end of the name. Note that this character has the length 1.
  An example to illustrate the meaning of the SIZE parameter. The following tag name is read out via the block interface: "MyPLCTag" (The double quotes at the start and end belong to the name.)

SIZE	GetSymbolName returns	Explanation
1	'...'	• First character of WSTRING:' • Identifier that the name was truncated: ... • Last character of WSTRING:'
2	'"...'	• First character of WSTRING:' • The first character of the name and identifier that the name was truncated:"... • Last character of WSTRING:'
3	'"M...'	• First character of WSTRING:' • The first two characters of the name and identifier that the name was truncated:"... "M... • Last character of WSTRING:'
6	'"MyPL...'	• First character of WSTRING:' • The first five characters of the name and identifier that the name was truncated: "MyPL... • Last character of WSTRING:'
0	'"MyPLCTag"'	• First character of WSTRING:' • All characters of the name: "MyPLCTag" • Last character of WSTRING:'

- The name read is output at the OUT parameter.

Note

Truncating the tag name in SCL

If SIZE = 0 or SIZE is greater than the maximum length of WSTRING, the name is then truncated, without the character "..." at the end of the string, in SCL in cases where the tag name does not fit in OUT.

Parameter

The following table shows the parameters of the "GetSymbolName" instruction:

Parameter	Declaration	Data type	Memory area	Description
VARIABLE	Input	PARAMETER	Parameter sections Input, Output, InOut	Selection of the local interface to which you want to read out the name of the input parameter supply.
SIZE	Input	DINT	I, Q, M, D, L	Limits the number of characters output at the OUT parameter. • SIZE > 0: GetSymbolName returns the first SIZE characters of the name. • SIZE = 0: GetSymbolName returns the entire name. • SIZE < 0: GetSymbolName returns the last SIZE characters of the name.
OUT	Return	WSTRING	D, L	Output of the tag name of the input parameters supply

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example

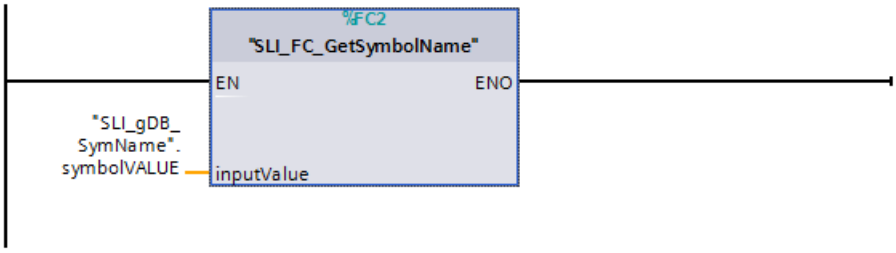
In the following example, you read out the name of a tag that is interconnected via the input parameter of a block.

Create two tags in a global data block for storing the data.

SLI_gDB_SymName

	Name	Data type	Start value
1	Static		
2	MySymNAME	WString	WSTRING#''
3	symbolVALUE	Byte	16#42

Create an FC "SLI_FC_GetSymbolName". Create the following local tag in the block.



SLI_FC_GetSymbolName

	Name	Data type
1	Input	
2	inputValue	Byte

Call the instruction "GetSymbolName" in the FC and interconnect "GetSymbolName" as follows.

Create an FC "SLI_FC_FCCall_GetSymbolName". In the FC, call the FC "SLI_FC_GetSymbolName" and interconnect this as follows:

The "GetSymbolName" instruction is executed in the "SLI_FC_GetSymbolName" block. Input parameter inputValue of the "SLI_FB_GetSymbolName" block is examined for its interconnection using input parameter VARIABLE of the instruction. In doing so, the "symbolVALUE" tag is read out and output as a character string at output parameter OUT ("MySymNAME"). According to the value of input parameter SIZE, the length of the character string is limited to 60 characters.

SLI_gDB_SymName

		Name	Data type	Start value	Monitor value
1		Static			
2		MySymNAME	WString	WSTRING#''	WSTRING#'"SLI_gDB_SymName".symbolVALUE'
3		symbolVALUE	Byte	16#42	16#42

Program code

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

Querying GetSymbolPath: actual parameter at beginning of a call path (S7-1200, S7-1500)

Description

Use the instruction "GetSymbolPath" to read the names of the parameters transferred at the beginning of a call path and passed via multiple block calls.

Note

Increased code memory requirement

The use of GetSymbolPath leads to an increased code memory requirement. The more frequently the instruction is called and the longer the actual symbols are, the greater the memory requirement.

- At the parameter VARIABLE of the instruction, you specify the formal parameter names from which the name is to be read when the interconnected actual parameter is called during runtime.
  - If the tag of a data block is used to supply the input parameters, this tag - consisting of the name of the DB and access path to the structured tag, is output.
  - If a PLC tag is used to supply the input parameters, the name of the PLC tag is output.
  - If a constant is used to supply the input parameters, this constant is output.
- To limit the length of the read tag name, use the SIZE parameter. If the name has been truncated, this is indicated by the character "..." (Unicode character 16#2026) at the end of the name. Note that this character has the length 1.
  An example to illustrate the meaning of the SIZE parameter. The following tag name is read out by the block interface: "MyPLCTag" (The double quotes at the start and end belong to the name.)

SIZE	GetSymbolPath returns	Explanation
1	'...'	• First character of WSTRING:' • Identifier that the name was truncated: ... • Last character of WSTRING:'
2	'"...'	• First character of WSTRING:' • The first character of the name and identifier that the name was truncated:"... • Last character of WSTRING:'
3	'"M...'	• First character of WSTRING:' • The first two characters of the name and identifier that the name was truncated:"... "M... • Last character of WSTRING:'
6	'"MyPL...'	• First character of WSTRING:' • The first five characters of the name and identifier that the name was truncated: "MyPL... • Last character of WSTRING:'
0	'"MyPLCTag"'	• First character of WSTRING:' • All characters of the name: "MyPLCTag" • Last character of WSTRING:'

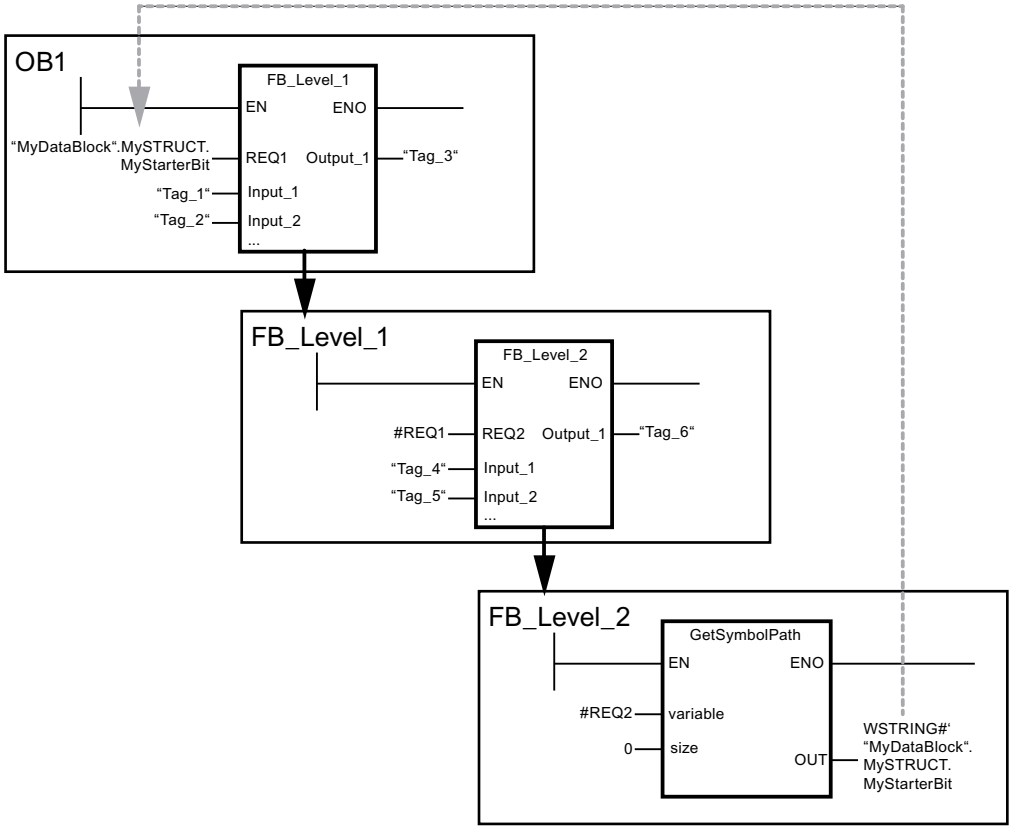
Note

Truncating the tag name in SCL

If SIZE = 0 or SIZE is greater than the maximum length of WSTRING, the name is then truncated, without the character "..." at the end of the string, in SCL in cases where the tag name does not fit in OUT.

Parameter

The following table shows the parameters of the "GetSymbolPath" instruction:



Parameter	Declaration	Data type	Memory area	Description
VARIABLE	Input	PARAMETER	Parameter sections Input, Output, InOut	Selection of the formal parameter for which you want to read out the name of the corresponding actual parameter at the beginning of the call path.
SIZE	Input	DINT	I, Q, M, D, L or constant	Limits the number of characters output at the OUT parameter. • SIZE > 0: GetSymbolPath returns the first SIZE characters of the name. • SIZE = 0: GetSymbolPath returns the entire name. • SIZE < 0: GetSymbolPath returns the last SIZE characters of the name.
OUT	Output	WSTRING	D, L	Output of the tag name of the input parameters supply.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example

The following example shows the use of GetSymbolPath over several call levels:

- The FB_Level_1 block is called from the organization block OB1. In turn, the FB_Level_2 block is called from this.
- GetSymbolPath is executed in the FB_Level_2 block to read the name of the parameter whose value is passed at the beginning of the call path to REQ2.
- At the REQ1 parameter, the MyStarterBit tag is interconnected as actual parameter. The bit is located in the MySTRUCT structure in the MyDatablock data block.
  This information is read by GetSymbolPath and output at the OUT parameter.

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

GetInstanceName: Read out name of the read instance (S7-1200, S7-1500)

Description

You can use the "GetInstanceName" instruction to read the name of the instance data block within a function block.

- To limit the length of the read instance name, use the SIZE parameter. If the name has been truncated, this is indicated by the character "..." (Unicode character 16#2026) at the end of the name. Note that this character has the length 1.
  An example to illustrate the meaning of the SIZE parameter. The following instance name is read out via the block interface: "Level1_DB" (The double quotes at the start and end belong to the name.)

SIZE	GetSymbolPath returns	Explanation
1	'...'	• First character of WSTRING:' • Identifier that the name was truncated: ... • Last character of WSTRING:'
2	'"...'	• First character of WSTRING:' • The first character of the name and identifier that the name was truncated:"... • Last character of WSTRING:'
3	'"L...'	• First character of WSTRING:' • The first two characters of the name and identifier that the name was truncated:"... "L... • Last character of WSTRING:'
6	'"Leve...'	• First character of WSTRING:' • The first five characters of the name and identifier that the name was truncated: "Leve... • Last character of WSTRING:'
0	'"Level1_DB"'	• First character of WSTRING:' • All characters of the name: "Level1_DB" • Last character of WSTRING:'

- The name of the instance data block is written to the OUT parameter. If the name of the instance data block is longer than the maximum length of WSTRING, the name is truncated.

Note

Truncating the instance DB name in SCL

If SIZE = 0 or SIZE is greater than the maximum length of WSTRING, the name is then truncated, without the character "..." at the end of the string, in SCL in cases where the instance DB name does not fit in OUT.

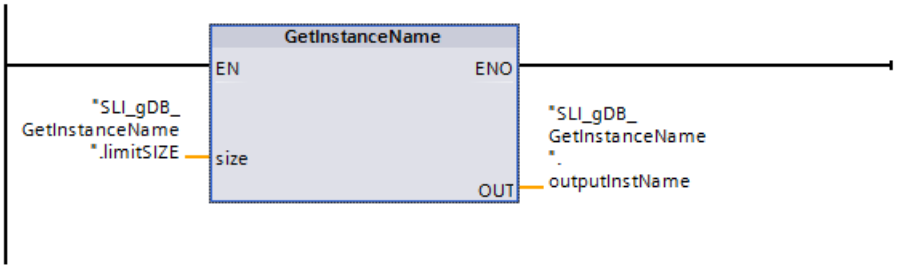
Parameter

The following table shows the parameters of the "GetInstanceName" instruction:

Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	DINT	I, Q, M, D, L or constant	Limits the number of characters output at the OUT parameter. • SIZE > 0: GetInstanceName returns the first SIZE characters of the name. • SIZE = 0: GetInstanceName returns the entire name. • SIZE < 0: GetInstanceName returns the last SIZE characters of the name.
OUT	Output	WSTRING	D, L	Read name of the instance data block

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Example



In the following example, you read out the name of an instance data block.

Create two tags in a global data block for storing the data.

SLI_gDB_GetInstanceName

	Name	Data type	Start value
1	Static		
2	limitSIZE	DInt	0
3	outputInstName	WString	WSTRING#''

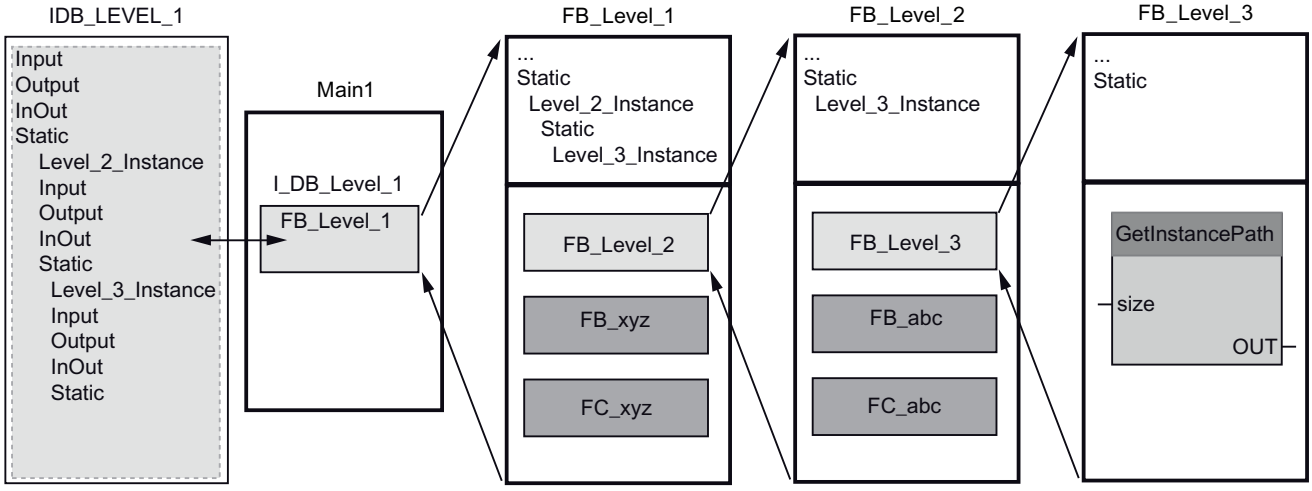
Create an FB "SLI_FB_GetInstanceName". Interconnect the parameters of the "GetInstanceName" instruction as follows.

The "GetInstanceName" instruction is executed in the "SLI_FB_GetInstanceName" block. By means of the "GetInstanceName" instruction, the associated instance data block of the "SLI_FB_GetInstanceName" block is determined and output as a character string at output parameter OUT ("outputInstName"). According to the value "0" of parameter SIZE ("limitSIZE"), the length of the character string is unlimited.

SLI_gDB_GetInstanceName

	Name	Data type	Start value	Monitor value
1	Static			
2	limitSIZE	DInt	0	0
3	outputInstName	WString	WSTRING#''	WSTRING#'"SLI_FB_GetInstanceName_DB"'

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)



GetInstancePath: Query composite global name of the block instance (S7-1200, S7-1500)

Description

You use the "GetInstancePath" instruction to read the composed global name of the block instance within a function block. The composed global name of the block instance is the path of the complete call hierarchy when multi-instances are used.

In the following example, the "GetInstancePath" instruction is called in the FB_Level_3 function block.

- The FB_Level_3 function block stores its data in the calling FB_Level_2 function block.
- The FB_Level_2 function block in turn stores its data in the calling FB_Level_1 function block.
- The FB_Level_1 function block in turn stores its data in its instance data block IDB_LEVEL_1. Through the use of multi-instances, the instance data block of FB_Level_1 contains all data of the three function blocks.

The "GetInstancePath" instruction returns the following values for this example:

SIZE	GetInstancePath returns	Explanation
1	'...'	• First character of WSTRING:' • Identifier that the name was truncated: ... • Last character of WSTRING:'
2	'"...'	• First character of WSTRING:' • The first character of the name and identifier that the name was truncated:"... • Last character of WSTRING:'

SIZE	GetInstancePath returns	Explanation
3	'"I...'	• First character of WSTRING:' • The first two characters of the name and identifier that the name was truncated:"... "I... • Last character of WSTRING:'
6	'"IDB_...'	• First character of WSTRING:' • The first five characters of the name and identifier that the name was truncated: "IDB_... • Last character of WSTRING:'
0	'"IDB_LEVEL_1".Level_2_Instance.Level_3_Instance'	• First character of WSTRING:' • All characters of the name: "IDB_LEVEL_1".Level_2_Instance.Level_3_Instance • Last character of WSTRING:'

Note

Use of "GetInstancePath" in function blocks with single instance

If the function block in which you call "GetInstancePath" saves data in its own instance data block, the name of the single instance is output as the global name. The result at parameter OUT corresponds in this case to the ""GetInstanceName (Page 3554)" instruction.

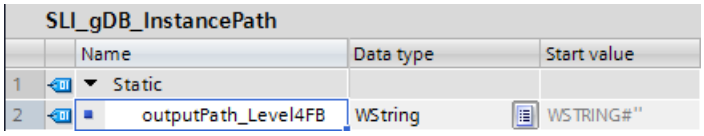
Note

Truncating the global name of the block instance in SCL

If SIZE = 0 or SIZE is greater than the maximum length of WSTRING, the name is then truncated, without showing the character "..." at the end of the string, in SCL in cases where the block instance name does not fit in OUT.

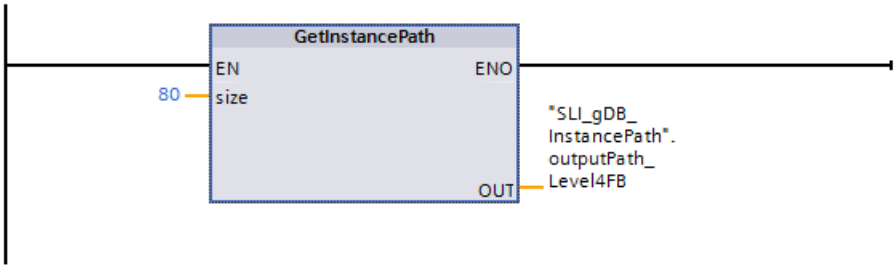
Parameter

The following table shows the parameters of the "GetInstancePath" instruction:



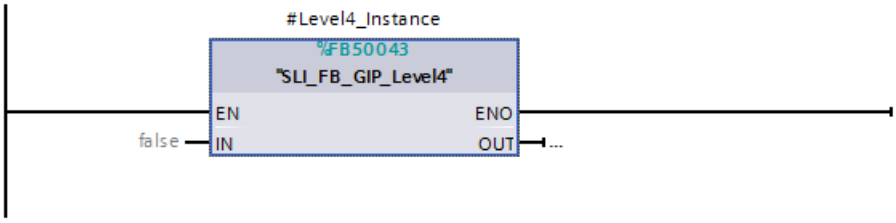
Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	DINT	I, Q, M, D, L or constant	Limits the number of characters output at the OUT parameter. • SIZE > 0: GetInstancePath returns the first SIZE characters of the name. • SIZE = 0: GetInstancePath returns the entire name. • SIZE < 0: GetInstancePath returns the last SIZE characters of the name.
OUT	Output	WSTRING	D, L	Read global name of the block instance. If the global name of the block instance is longer than the maximum length of WSTRING (254 characters), the name is truncated.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

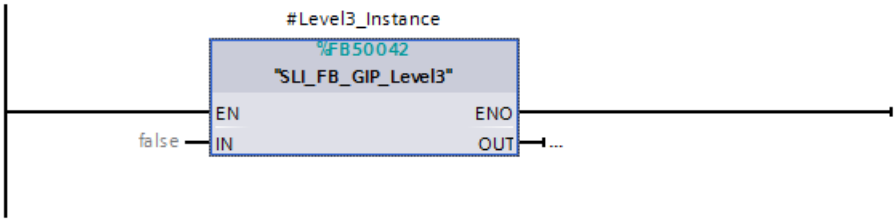


Example

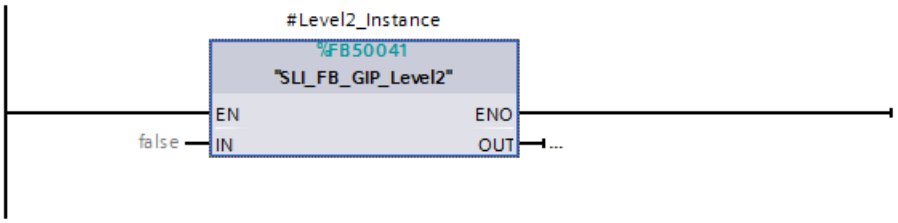
In the following you read out the assembled global names of the block instance.



Create one tag for storing the data in a global data block.



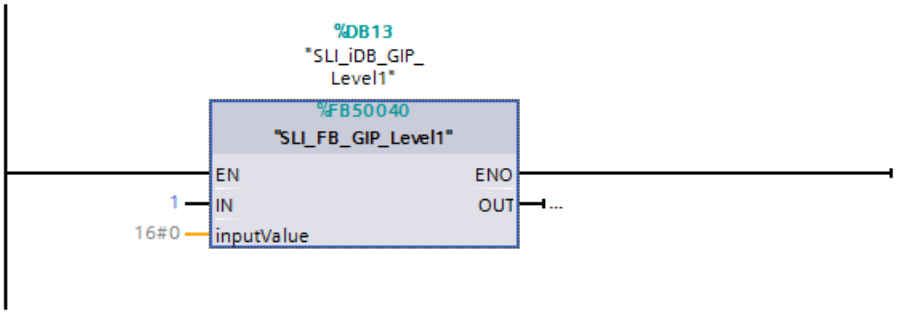
Create an FB "SLI_FB_GIP_Level4" and call the instruction "GetInstancePath" in it.



Create an FB "SLI_FB_GIP_Level3" and call the instruction "SLI_FB_GIP_Level4" in it.

Create an FB "SLI_FB_GIP_Level2" and call the instruction "SLI_FB_GIP_Level3" in it.

Create an FB "SLI_FB_GIP_Level1" and call the instruction "SLI_FB_GIP_Level2" in it.



Create the following local tags in the function block "SLI_FB_GIP_Level1".

SLI_FB_GIP_Level1

		Name	Data type	Default value
1		Input		
2		IN	Bool	false
3		inputValue	Byte	16#0
4		Output		
5		OUT	Bool	false
6		InOut		
7		<Add new>		
8		Static		
9		Level2_Instance	"SLI_FB_GIP_Level2"	

Create a cycle OB (OB123" and call the instruction "SLI_FB_GIP_Level1" in it. Interconnect the function block as follows.

The instruction "GetInstancePath" is executed in the OB123. The instruction "GetInstancePath" reads out the instances of all function blocks, from call of instruction in the FB "SLI_FB_GIP_Level4" to the call in the OB123. The names of the instances are output as strings at the output parameter OUT ("outputPath_Level4FB") of the instruction "GetInstancePath". The length of the character string is limited to 80 characters, according to the value of input parameter SIZE of the operation "GetInstancePath".

SLI_gDB_InstancePath

		Name	Data t..	St...	Monitor value
1		Static			
2		outputPath_Level4FB	W...	WSTR	WSTRING#'"SLI_iDB_GIP_Level1".Level2_Instance.Level3_Instance.Level4_Instance'

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

GetBlockName: Read out name of the block (S7-1200, S7-1500)

Description

You can use the "GetBlockName" instruction to read the name of the block in which the instruction is called.

- If the length of the block name is to be limited to a certain number of characters, specify the max. length at the SIZE parameter. If the name has been truncated, this is indicated by the character "..." (Unicode character 16#2026) at the end of the name. Note that this character has the length 1.
  An example to illustrate the meaning of the SIZE parameter. The following block name is read out: "Level1_gbn" (The double quotes at the start and end belong to the name.)

SIZE	GetBlockName returns	Explanation
1	'...'	• First character of WSTRING:' • Identifier that the name was truncated: ... • Last character of WSTRING:'
2	'"...'	• First character of WSTRING:' • The first character of the name and identifier that the name was truncated:"... • Last character of WSTRING:'
3	'"L...'	• First character of WSTRING:' • The first two characters of the name and identifier that the name was truncated:"... "L... • Last character of WSTRING:'
6	'"Leve...'	• First character of WSTRING:' • The first five characters of the name and identifier that the name was truncated: "Leve... • Last character of WSTRING:'
0	'"Level1_gbn"'	• First character of WSTRING:' • All characters of the name: "Level1_gbn" • Last character of WSTRING:'

- The name of the block is written at the RET_VAL parameter. If the name of the block is longer than the maximum length of WSTRING, the name is truncated.

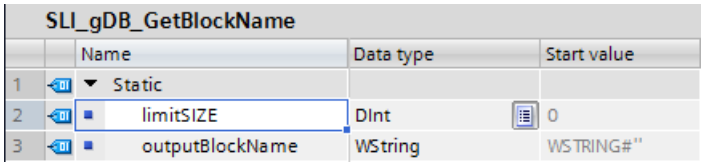
Note

Truncating the block name in SCL

If SIZE = 0 or SIZE is greater than the maximum length of WSTRING, the name is then truncated, without the character "..." at the end of the string, in SCL in cases where the block name does not fit in RET_VAL.

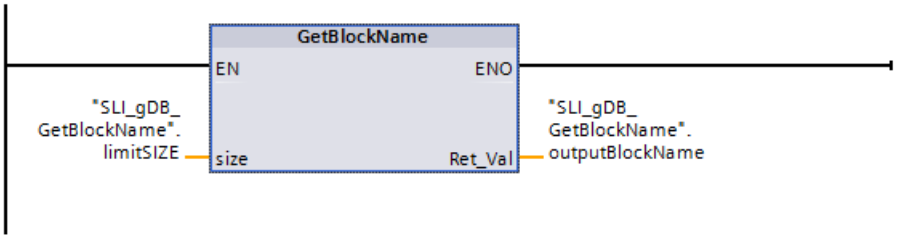
Parameter

The following table shows the parameters of the "GetBlockName" instruction:



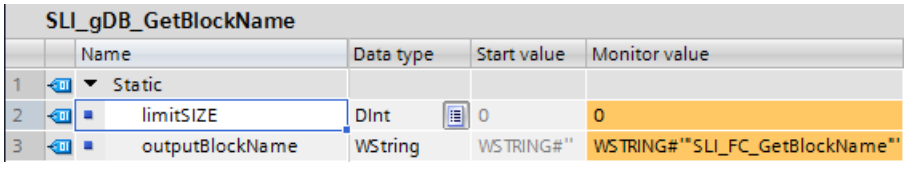
Parameter	Declaration	Data type	Memory area	Description
SIZE	Input	UINT	I, Q, M, D, L or constant	Limits the number of characters output at the RET_VAL parameter. • SIZE > 0: GetBlockName returns the first SIZE characters of the name. • SIZE = 0: GetBlockName returns the entire name. • SIZE < 0: GetBlockName returns the last SIZE characters of the name.
RET_VAL	Output	WSTRING	D, L	Read name of the instance data block

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".



Example

In the following example, you read out the block name.



Create two tags in a global data block for storing the data.

Interconnect the parameters of the instruction as follows.

The "GetBlockName" instruction is executed in the "SLI_FC_GetBlockName" block. By means of the "GetBlockName" instruction, the name of the "SLI_FC_GetBlockName" block is read out and output as a character string at output parameter RET_VAL ("outputBlockName"). According to the value "0" of parameter SIZE ("limitSIZE"), the length of the character string is unlimited.

Program code

You can find additional information and the program code for the above named example here: Sample Library for Instructions (Page 2568)

11.4.4.3 Process image (S7-1500)

UPDAT_PI: Update the process image inputs (S7-1500)

Description

With the instruction, you update a partial image partition of the inputs defined in the configuration.

If you have configured repeated signaling of I/O access errors for the system-side process image update, then the selected process image will be updated constantly.

Otherwise, the update can only be performed when the selected process image partition is not updated by the system; in other words if you have not assigned this process image partition to an interrupt OB.

Note

Each logical address that you have assigned to a process image partition of the inputs per configuration no longer belongs to the OB 1 process image of the inputs.

When you update a process image partition with "UPDAT_PI", you must not perform a simultaneous update with the "SYNC_PI (Page 3568)" instruction.

System-side updating of the OB 1 process image of the inputs and the process image partitions of inputs that you have assigned to an interrupt OB takes place independently of "UPDAT_PI" calls.

Parameter

The following table shows the parameters of the "UPDAT_PI" instruction:

Parameter	Declaration	Data type	Memory area	Description
PART	Input	PIP	I, Q, M, D, L or constant	Number of the process image partition of the inputs to be updated. Maximum value range (depending on the CPU): 1 <= n <= 31 (means process image partition n).
RET_VAL	Return	INT	I, Q, M, D, L, P	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P	Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

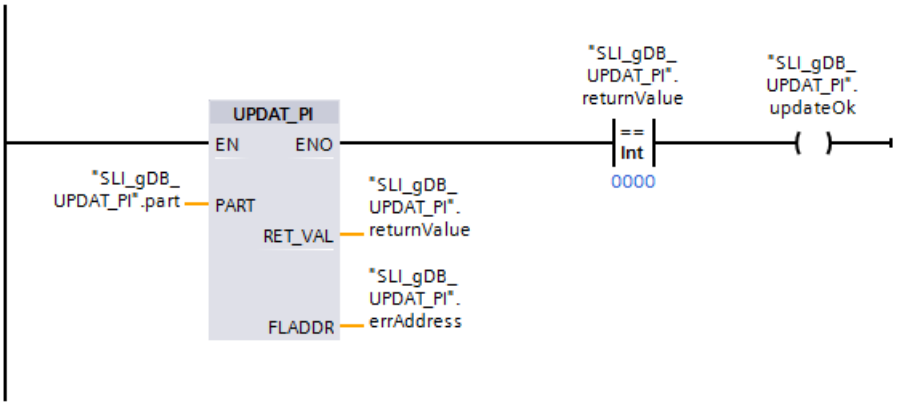
Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Illegal value for PART parameter
8091	The specified process image partition was not yet defined.
8092	The process image partition is being updated by the system and must not be used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	An access error was detected when accessing the I/O.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Note

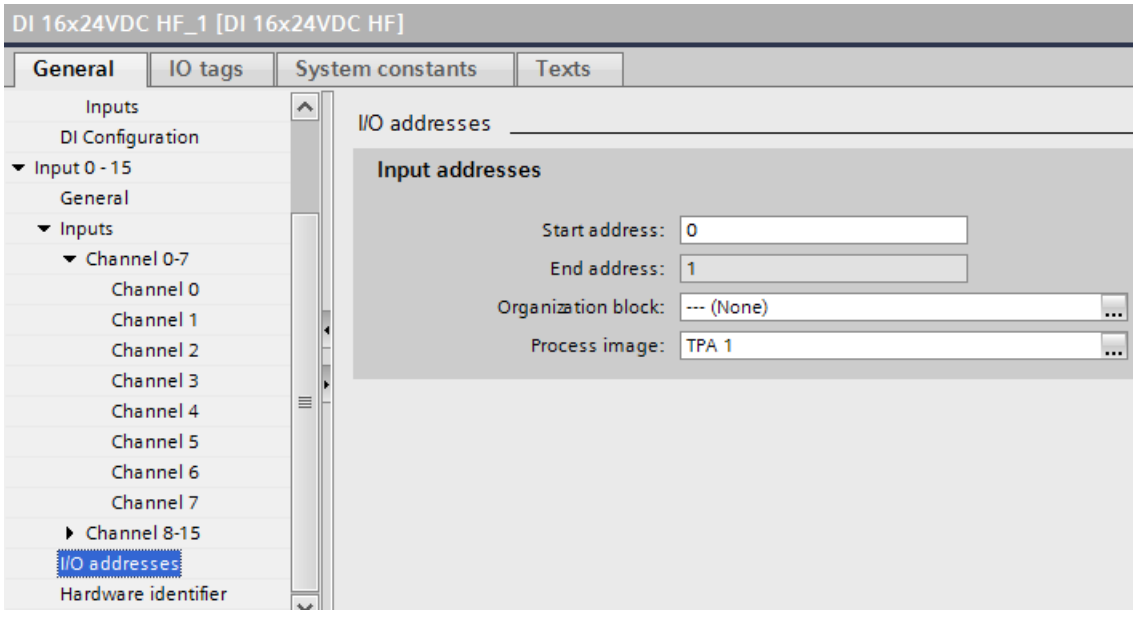
If you use the instruction for process image partitions of DP standard slaves, the error codes of the "DPRD_DAT (Page 3700)" instruction are also possible. This is the case if you have defined consistency areas greater than 32 bytes.

Example



In the following example, you update the process image partition "1" of the inputs defined in the configuration.

Create four tags in a global data block for storing the data.



SLI_gDB_UPDAT_PI

	Name	Data type	Start value
1	Static		
2	part	PIP	1
3	returnValue	Int	0
4	errAddress	Word	16#0
5	updateOk	Bool	false

Interconnect the parameters of the instruction as follows.

You create an input module (DI) for your CPU, and configure the process image partition "1" under "Properties > Input 0 - 15 > I/O addresses". You also do not assign the process image partition to any OB.

The number of the process image partition that is to be updated is stored in the input parameter PART ("part") of the instruction "UPDAT_PI". The specified process image partition is updated when the instruction "UPDAT_PI" is called.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors. Processing without errors sets the coil ("updateOk") to "TRUE". Because no access error occurs, the error address ("errAddress") of the instruction "UPDAT_PI" shows the value "16#0000".

SLI_gDB_UPDAT_PI

	Name	Data type	Start value	Monitor value
1	Static			
2	part	PIP	1	1
3	returnValue	Int	0	0
4	errAddress	Word	16#0	16#0000
5	updateOk	Bool	false	TRUE

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

UPDAT_PO: Update the process image outputs (S7-1500)

Description

You use the instruction to transfer the signal states of a process image partition of the outputs defined by configuration to the output modules.

If you have specified a consistency range for the selected process image partition, corresponding data is transferred as consistent data to the respective I/O module.

Note

Each logical address you have assigned to a process image partition of the outputs during configuration no longer belongs to the OB 1 process image of the outputs.

Outputs that you update with "UPDAT_PO" must not be updated simultaneously with the "SYNC_PO (Page 3569)" instruction.

The OB 1 process image of the outputs and the process image partitions of the outputs that you have assigned to an interrupt OB are transferred by the system to the output modules independently of "UPDAT_PO" calls.

Parameter

The following table shows the parameters of the "UPDAT_PO" instruction:

Parameter	Declaration	Data type	Memory area	Description
PART	Input	PIP	I, Q, M, D, L or constant	Number of the process image partition of the outputs to be transferred. Maximum value range (depending on the CPU): 1 <= n <= 31 (means process image partition n)
RET_VAL	Return	INT	I, Q, M, D, L, P	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P	Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

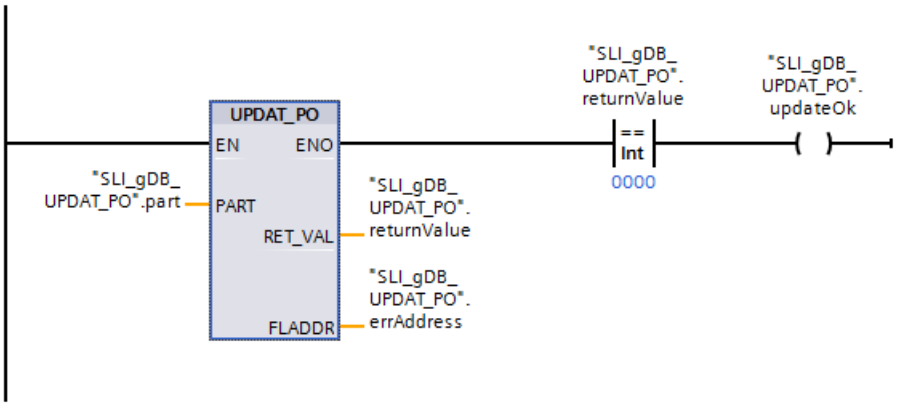
Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	Illegal value for PART parameter
8091	The specified process image partition was not yet defined.
8092	The process image partition is being updated by the system and must not be used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	An access error was detected when accessing the I/O.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Note

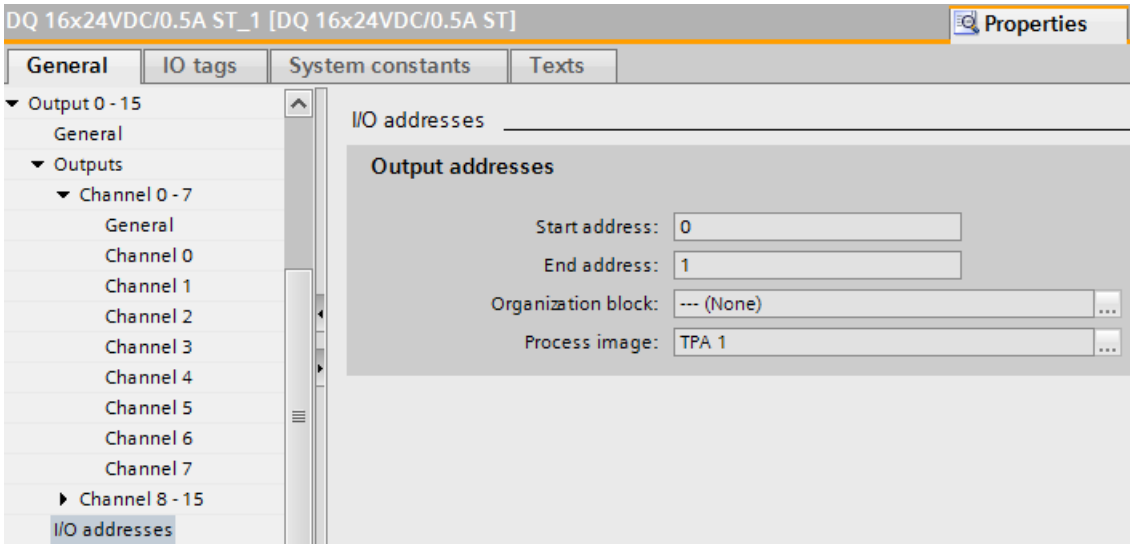
If you use the instruction for process image partitions of DP standard slaves, the error codes of the "DPWR_DAT (Page 3702)" instruction are also possible. This is the case if you have defined consistency areas greater than 32 bytes.

Example



In the following example, you update the process image partition "1" of the outputs defined in the configuration.

Create four tags in a global data block for storing the data.



SLI_gDB_UPDAT_PO

	Name	Data type	Start value
1	Static		
2	part	PIP	1
3	returnValue	Int	0
4	errAddress	Word	16#0
5	updateOk	Bool	false

Interconnect the parameters of the instruction as follows.

You create an output module (DQ) for your CPU, and configure the process image partition "1" under "Properties > Output 0 - 15 > I/O addresses". You also do not assign the process image partition to any OB.

The number of the process image partition that is to be updated is stored in the input parameter PART ("part") of the instruction "UPDAT_PO". The specified process image partition is updated when the instruction "UPDAT_PO" is called.

The output parameter RET_VAL ("returnValue") indicates that processing took place without errors. Processing without errors sets the coil ("updateOk") to "TRUE". Because no access error occurs, the error address ("errAddress") of the instruction "UPDAT_PO" shows the value "16#0000".

SLI_gDB_UPDAT_PO

	Name	Data type	Start value	Monitor value
1	Static			
2	part	PIP	1	1
3	returnValue	Int	0	0
4	errAddress	Word	16#0	16#0000
5	updateOk	Bool	false	TRUE

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

SYNC_PI: Synchronize the process image inputs (S7-1500)

Description

The "SYNC_PI" is used to update the process image partition of inputs in isochronous mode. A user program linked to a DP cycle or PN send cycle uses this instruction to update input data acquired in a process image partition of the inputs isochronously and consistently.

Call

"SYNC_PI" is interruptible and is only be called in OBs 61, 62, 63 and 64.

Note

The call of the "SYNC_PI" instruction is only permitted in OBs 61 to 64 if you have assigned the affected process image partition to the associated OB in the HW configuration. A process image partition that you update with "SYNC_PI" must not be updated simultaneously with the "UPDAT_PI (Page 3562)" instruction.

Parameter

The following table shows the parameters of the "SYNC_PI" instruction:

Parameter	Declaration	Data type	Memory area	Value range	Description
PART	Input	PIP	I, Q, M, D, L or constant	1 to 31	Number of the process image partition of the inputs to be updated isochronously.
RET_VAL	Return	INT	I, Q, M, D, L, P	-	Error information
FLADDR	Output	WORD	I, Q, M, D, L, P		Address of the first byte to cause an error if an access error has occurred.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code (W#16#...)*	Explanation
0000	No error occurred.
0001	Consistency warning. The update of the process image partition was distributed over two DP or PN cycles. However, the data in one submodule were consistently transferred.
8090	Illegal value at PART parameter or updating the specified process image partition of the inputs is not permitted in this OB. The specified process image partition was possibly not yet defined. The process image partition of the inputs was not updated.
8092	The process image partition is being updated by the system and must not be used for the PART parameter.

Error code (W#16#...)*	Explanation
8093	The process image partition update is being processed in another OB.
80A0	During updating an access error was detected. The affected inputs were set to "0".
80A1	The update time is after the permitted access window. The process image partition of the inputs was not updated. The DP or PN cycle is too short to ensure enough time for processing the instruction. You must therefore increase the TDP (also known as T_DC), Ti and To timers.
80A2	Access error with consistency warning In the case of update of the specified process image partition an access error with simultaneous consistency warning was detected. • The data of the incorrect inputs was not read by the I/O. In the process image partition of the inputs, the affected inputs are set to "0". • The update of the process image partition of the not involved by an access error input data was distributed over two DP and PN cycles.
80C1	The update time is before the permitted access window. The process image partition of the inputs was not updated.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Note

If you use the "SYNC_PI" instruction for process image partitions of DP standard slaves, error codes of the "DPRD_DAT" instruction are also possible. This is the case if you have defined consistency areas greater than 32 bytes.

See also

DPRD_DAT: Read consistent data of a DP standard slave (Page 3700)

SYNC_PO: Synchronize the process image outputs (S7-1500)

Description

The instruction "SYNC_PO" is used to update a process image partition of outputs in isochronous mode. An application program linked to a DP cycle or a PN send cycle can use this instruction for the consistent isochronous transfer of the computed output data of a process image partition from outputs to the I/O devices.

Call

"SYNC_PO" is interruptible and should only be called in OBs 61, 62, 63 and 64.

Note

The call of the "SYNC_PO" instruction in OBs 61 to 64 is only permitted if you have assigned the affected process image partition to the associated OB in the HW configuration. A process image partition that you update with "SYNC_PO" must not be updated simultaneously with the "UPDAT_PO (Page 3565)" instruction.

Parameter

The following table shows the parameters of the "SYNC_PO" instruction:

Parameter	Declaration	Data type	Memory area	Value range	Description
PART	Input	PIP	I, Q, M, D, L or constant	1 to 31	Number of the process image partition of the outputs to be updated isochronously.
RET_VAL	Return	INT	I, Q, M, D, P	-	If an error occurs while the instruction is being executed, the return value contains an error code.
FLADDR	Output	WORD	I, Q, M, D, L, P	-	Address of the first byte that has caused the error.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code (W#16#...)*	Explanation
0000	No error occurred.
0001	Consistency warning. The update of the process image partition was distributed over two DP or PN cycles. However, the data in one submodule were consistently transferred.
8090	Illegal value at PART parameter or updating of the specified process image partition of the outputs is not permitted in this OB. The specified process image partition was possibly not yet defined. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
8092	The process image partition is being updated by the system and is not used for the PART parameter.
8093	The process image partition update is being processed in another OB.
80A0	In the case of update of the specified process image partition of the outputs an access error was detected. Incorrect outputs were not transferred to the I/O. During process image partition of the outputs, these outputs remain unchanged.
80A1	Access error with consistency warning In the case of update of the specified process image partition of the outputs an access error with simultaneous consistency warning was detected. • The data of the incorrect outputs were not transferred to the I/O. During process image partition of the outputs, the involved outputs remain unchanged. • The update of the process image partition of the not involved by an access error input data was distributed over two DP and PN cycles.

Error code (W#16#...)*	Explanation
80A2	The update time is after the permitted access window. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
80C1	The update time is before the permitted access window. Outputs were not transferred to the I/O. The process image partition of the outputs remains unchanged.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

Note

If you use the "SYNC_PO" instruction for process image partitions of DP standard slaves, error codes of the "DPWR_DAT" instruction are also possible. This is the case if you have defined consistency areas greater than 32 bytes.

11.4.4.4 Distributed I/O (S7-1200, S7-1500)

Overview of the types of data records (S7-1200, S7-1500)

Introduction

The data record as property of the hardware corresponds to the summary of data that reflects certain properties of the hardware. Each hardware can have numerous data records as properties. The data records can hereby be distinguished based on their use and their scope of information.

Below you can familiarize yourself with the types of data records and you will be guided through working with data records by assigning modules, systems and instructions.

The following information applies to the S7-1200 and S7-1500 automation systems as well as the ET 200MP and ET 200SP distributed I/O systems.

Types of data records

The following types of data records exist:

Types		Uses
Parameter data records	a) for input modules	Parameter data records contain the properties of the input/output function of the relevant I/O module. With the data record, you, for example, read out a wire break or change the input delay. Parameter data records can be read and written.
	b) for technology modules or modules with the use of the technology function	
	a) for output modules	
Control data records	a) to configure a central or distributed setup	The control data record contains the hardware configuration of the system or setup and allows reconfiguration of a module or an IO system via the user program. The control data record can be read and written.
	b) to reconfigure an IO system	
I&M data records	a) for central setup or distributed setup via PROFINET IO	The I&M data records contain the identification and maintenance data of a module (I&M = Identification & Maintenance). The data differs as follows: • Identification data: – depends on vendor data – read-only – You can, for example, read out the serial number. • Maintenance data – depends on the system and the use of the device – can be read and written. – can be used to change the installation location of the module, for example.
	b) for central setup or distributed setup via PROFIBUS DP	
Diagnostics data records and configuration data records	a) for distributed setup via PROFINET IO	Diagnostics data records and configuration data records each have the same structure and vary only in content and size. The data records can be distinguished as follows: • Diagnostics data records: – The diagnostics data records contain the diagnostics and monitoring data of a module. – Channel diagnostics data records are generated if a channel is in an error state and / or has triggered an interrupt. A diagnostics data record of length 0 is returned if there is no fault/error. – The structure and size of vendor-specific diagnostics data records depend on the vendor. – Diagnostics data records are read-only. • Configuration data records: – The configuration data records contain the data of the actual configuration or preset configuration of a module. – Configuration data records are readable (actual configuration, preset configuration) and writable (preset configuration).
	b) for distributed setup via PROFIBUS DP	

Note

The recipe data records used in WinCC are not properties of the module and have nothing to do with the data records being discussed here.

Use of a data record in the proect

Before you use a data record in you project, please read the relevant manual for the data record structure and any requirements. The "Additional information" section references the respective manual.

Parameter data records

Note

Reading out channels

The data records 0..X and 64..64+X contain channel-specific parameters. Accordingly for example the data record 0 contains the information of channel 0.

The data record 128 contains the information of all channels of the relevant module from the hardware configuration.

The RD_DPAR instruction can only be executed on an S7-1500 CPU or an ET 200 distributed I/O.

Type:	**Parameter data records (a)**				
Relates to the module:	Input module				
Location:	Central setup (S7-1500) or ET 200MP		S7-1200 or ET 200SP (*)		
Instructions:	RDREC, WRREC	RD_DPAR	RDREC, WRREC		RD_DPAR (not for S7-1200)
Data record (DR):	DR 0.X (DR = channel; X = the last channel of the input module)	DR 128	DR 128	*For ET 200SP Namur: DR 0.X (DR = channel; X = the last channel of the input module) or DR 128	DR 128
HW ID:	Use HW ID of the input module				
Example:	For example, S7-1500 DI16x24VDC HF --> channels 0..15; (e.g., use DR 13). See also "Use the program example of the parameter data record with WRREC & RDREC (Page 3598)".	For example, S7-1500 DI16x24VDC HF --> DR 128. See also "Program example of RD_DPAR (Page 3783)".	1st example: Use input module of an S7-1212C CPU --> HW ID of CPU, DR 128 and RDREC / WRREC. 2nd example: Use ET 200SP DI8x24VDC HF --> HW ID of DI module, DR 128 and RDREC / WRREC or RD_DPAR. See also "Program example of RD_DPAR (Page 3783)".		

Type:	**Parameter data records (b)**	
Relates to the module:	Technology modules or module with the use of the technology function	
Location:	Central setup (S7-1500 or S7-1200) or distributed setup (ET 200MP or ET 200SP)	
Instructions:	RDREC, WRREC	RD_DPAR (not for S7-1200)

Type:	**Parameter data records (b)**		
Data record (DR):	DR 128	Alternatively, for DI modules of S7-1500: DR 0.X (DR = channel; X = the last channel of the input module)	DR 128
HW ID:	Use HW ID of the affected module / I/O module.		
Example:	1) Example: CPU S7-1511 PN; high speed counter of the S7-1500 DI16x24VDC HF --> for example, DR 1; use HW ID of the DI module (HSC). Use WRREC/RDREC. 2) Example: TM Count 2x24V --> DR 128; use HW ID of the TM. Use WRREC / RDREC or RD_DPAR. 3) Example: High speed counter of an S7-1200 CPU --> DR 128; use HW ID of CPU and WRREC / RDREC.		

Type:	**Parameter data records (c)**				
Relates to the module:	Output module				
Location:	Central setup (S7-1500) or ET 200MP		S7-1200 or ET 200SP (*)		
Instructions:	RDREC, WRREC	RD_DPAR	RDREC, WRREC		RD_DPAR (not for S7-1200)
Data record (DR):	DR 64.64 + X (DR 64 = channel 0; X = the last channel of the output module)	DR 128	DR 128	*For ET 200SP Namur: DS 64..64 + X (DR 64 = channel 0; X = the last channel of the output module) or DR 128	DR 128
HW ID:	Use HW ID of the output module.				
Example:	For example, DQ16x24VDC/0.5A ST --> channels 0..15; (e.g. for channel 13 use the DR 77).	For example, DQ16x24VDC/0.5A ST --> DR 128.	For example, ET 200SP DQ8x24VDC/0.5A ST --> DR 128.		

Note

Further data records

There may be more data records. E.g. for the input modules:

- With the ET 200SP AI RTD there is the DR 237 for deactivating the wire break check.
- With the ET 200SP AI Energy Meter ST there is the DR 142 for reading the measured data.

Note

Interface module with PROFIBUS DP

If you use an interface module with PROFIBUS DP, you cannot read out parameter data records "0" and "1" from the downstream input/output module. Instead read out the content of the diagnostics data records "0" and "1".

For example with output modules the "parameter data record 0" is the "DR 64" and the "parameter data record 1"is the "DR 65".

Additional information

You can find additional information on the parameter data record in the manual for the relevant I/O module (e.g. S7-1500 DI16x24VDC HF (https://support.industry.siemens.com/cs/ww/en/view/59193001)).

Control data records

Type:	Control data records			
Relates to the module:	All modules of the setup that are to be used			IO system and required IO devices
Location:	Central setup (S7-1200, S7-1500)	Distributed setup (e.g. ET 200MP, ET 200SP)		PROFINET IO
Instructions:	WRREC, RDREC	WRREC, RDREC	RDREC	ReconfigIOSystem
Data record (DR):	DR 196	DR 196	DR 197 (feedback data record)	DR "CTRLREC" (parameter of ReconfigIOSystem)
HW ID:	Use HW ID 33.	Use HW ID of the head [Head] of the IM of the distributed I/O.		Use HW ID of the PROFINET interface (IO controller). Specify the corresponding HW IDs via CTRLREC according to the connections and IO devices that are to be set up.
Example:	For example, for CPU S7-1511-1 PN with DI16x24VDC HF. See also "Use the program example of the control data record with WRREC & RDREC (Page 3607)".	For example, DI16x24VDC HF, ET 200MP IM 155-5 PN ST --> use the ID of "<IO-device_V2.0[Head]>". The real setup contains an additional DI16x24VDC HF, which is not to be considered during the configuration.		For example, connect and activate an S7-1500 CPU (IO controller) with an ET 200MP (IO device) and an ET 200SP (as optional IO device). See also "Program example for ReconfigIOSystem (Page 3683)".

Additional information

For more information on the control data record 196, refer to the system manual of the relevant automation system (e.g. "S7-1500 automation system (https://support.industry.siemens.com/cs/ww/en/view/59191792)").

For more information on the control data record 197, refer to the system manual of the relevant interface module (e.g. "ET 200MP IM 155-5 PN ST (https://support.industry.siemens.com/cs/ww/en/view/59193106)").

You can find more information on the control data record "CTRLREC" with the instruction "ReconfigIOSystem: Reconfigure IO system (Page 3677)".

I&M data records

Note the following use of the I&M data records:

- The data record "I&M0" ("16#AFF0") is used to transfer general information about the module or device.
- The data record "I&M1" ("16#AFF1") is used to transfer the function and installation location of the module or device.
- The data record "I&M2" ("16#AFF2") is used to transfer the installation date of the module or device.
- The data record "I&M3" ("16#AFF3") is used to transfer individual additional information about the module or device.

Note

The data record "I&M0" ("16#AFF0") is supported by every module. All other I&M data records are optional.

Type:	**I&M data records**				
Relates to the module:	Device / module				
Location:	Central setup or distributed setup via PROFINET IO or PROFIBUS DP				
Instructions:	RDREC, WRREC				
Data record (DR):	DR 16#AFF0	DR 16#AFF1	DR 16#AFF2	DR 16#AFF3	Alternatively, for distributed setup via PROFIBUS DP: DR 255
HW ID:	Use HW ID of the module.				
Example:	1) Example: For CPU S7-1511-1 PN --> DR 16#AFF0; use the HW ID of the CPU. See also "Program example of I&M data record with read RDREC (Page 3580)".				2) Example: For ET 200SP with IM 155-6 DP ST --> DR 255; use the HW ID of the IM.

Additional information

You can find additional information on the relevant I&M data record:

- in the system manual of the relevant automation system (e.g. "S7-1500 automation system (https://support.industry.siemens.com/cs/ww/en/view/59191792)").
- In the programming manual "SIMATIC NET PROFINET IO-Base user programming interface (https://support.industry.siemens.com/cs/ww/en/view/26435491)".

Diagnostics data records and configuration data records

Type:	**Diagnostics data records and configuration data records**
Relates to the module:	Device/module or submodule in the IO system
Location:	Distributed setup (PROFINET IO, PROFIBUS DP)

Type:	**Diagnostics data records and configuration data records**			
Instructions:	RDREC, WRREC	RDREC		
Data record (DR):	Configuration (actual/preset):	Channel diagnostics:	Manufacturer-specific diagnostics via interface module:	
	Use DR for the relevant module. See also the addressing level and DR for "PROFINET IO (https://support.industry.siemens.com/cs/ww/en/view/19289930)".		For PROFINET IO: See Interface module	For PROFIBUS DP: DR 0, 1
HW ID:	Use hardware ID of the relevant module (HW ID with "Hw_SubModule" data type).		Use hardware ID of the relevant module (HW ID with "Hw_SubModule" data type).	
Example:	For example, IO controller S7-1513-1 PN; use HW ID of the module on the slot level for the IO device (ET 200MP IM 155-5 PN HF). Read out the preset configuration with DR 16#C001.	For example, IO device (ET 200MP IM 155-5 PN HF) with DQ module causes a wire break. Use the hardware ID of the header module of the IO device. IO controller is S7-1513-1 PN. Use DR 16#E00A for channel diagnostics. See also "Read program example for diagnostic data record with RDREC (Page 3584)".	For example, PROFIBUS DP: ET 200MP with IM 155-5 DP ST; Read DI module --> HW ID ("Hw_SubModule" data type) of the DI module and use DR 1 for diagnostics.	

Additional information

The addressing level, the setup and the important data records for diagnostics and configuration of PROFINET IO are available at:

- in the programming manual "From PROFIBUS DP to PROFINET IO (https://support.industry.siemens.com/cs/ww/en/view/19289930)".

You can find additional and general information on channel diagnostics data records:

- in the online help of STEP 7 in "Diagnostics of PROFINET devices".
- in the system manual for PROFINET (e.g. "PROFINET with STEP 7 as of V13 (https://support.industry.siemens.com/cs/ww/en/view/49948856)").

You can find more information on manufacturer-specific diagnostics data records:

- in the manual for the relevant interface module (for example, ET 200MP IM 155-5 DP ST (https://support.industry.siemens.com/cs/ww/en/view/78324181)).

See also

Sample Library for Instructions (Page 2568)

RDREC: Read data record (Page 3578)

WRREC: Write data record (Page 3596)

RDREC: Read data record (S7-1200, S7-1500)

RDREC: Read data record (S7-1200, S7-1500)

Description

You use the instruction "RDREC" to read the data record with the number INDEX from the module addressed using the ID. This may be a module in a central rack or a distributed module (PROFIBUS DP or PROFINET IO).

- Use the parameter ID to select from which module (DP/PROFINET IO) a data record is to be read. Use only the hardware identifier (HW ID) of the module for the ID parameter. You can find the hardware identifier of the module in "PLC tags > System constants". For example, for an S7-1500 DI module: This is shown as <Name of DI module> with the data type "Hw_SubModule".
- Use the INDEX parameter to select which data record is read from the module. Which data records can be read with which data record number depends on the module. You can find additional information on this in the manual for the relevant module.
- The data records readable via "RDREC" have a different length. Use MLEN to specify the maximum number of data record bytes you want to read. If length "0" is selected at the parameter MLEN, the complete data record is written at the parameter RECORD.
- Select the target range RECORD at least MLEN bytes long. If you read out the full data record with MLEN=0, use the maximum length of the data record for RECORD. The structure (configuration, data types and length) that you use at the parameter RECORD, also depends on which data record is read out by which module.
- The value TRUE for the output parameter VALID indicates that the data record was successfully transferred to the target range RECORD. In this case, the LEN output parameter contains the length of the read data in bytes.
- If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR. In this case, the output parameter STATUS contains the error information.

Note

The interface of the "RDREC" instruction is identical to that in the "RDREC" FB defined in the standard "PROFIBUS and PROFINET Guideline Communication Function Blocks on PROFIBUS DP and PROFINET IO".

Functional description

"RDREC" is an instruction that works asynchronously, which means its execution extends over multiple calls. You start the data record transfer by calling "RDREC" with REQ= 1.

The job status is displayed via the output parameter BUSY and the two central bytes of output parameter STATUS. The two central bytes of STATUS correspond to the RET_VAL output parameter of the instructions that operate asynchronously.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

The transfer of the data record is complete when the output parameter BUSY has the value FALSE .

Parameter

The following table shows the parameters of the "RDREC" instruction:

Parameter	Declaration	Data type*	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T**, C** or constant	REQ = 1: Transfer data record
ID	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the hardware module (DP/PROFINET IO) The number is assigned automatically and is stored in the properties of the module or of the interface in the hardware configuration.
INDEX	Input	DINT	I, Q, M, D, L or constant	Data record number
MLEN	Input	UINT	I, Q, M, D, L or constant	Maximum length in bytes of the data record information to be read
VALID	Output	BOOL	I, Q, M, D, L	New data record was received and is valid.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the reading process.
STATUS	Output	DWORD	I, Q, M, D, L	Block status or error information
LEN	Output	UINT	I, Q, M, D, L	Length of the read data record information
RECORD	InOut	VARIANT	I, Q, M, D, L	Target range for the data record read.
* There is no implicit conversion in STL, which is why the range of valid data types may be limited. During programming in STL, note the permissible data types in each case in the tooltip of the parameter ** For S7-1500 only.				

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

If you use "RDREC" to read a data record for PROFINET IO, then negative values in the INDEX, MLEN, and LEN parameters will be interpreted as an unsigned 16-bit integer.

Parameter STATUS

For interpretation of the STATUS parameter, see Parameter STATUS (Page 3638).

Diagnostics for Windows applications

It may be possible that Windows can no longer send a signal to the CPU in case of a bluescreen. The OB82 is not called in this case and no diagnostic entry is created.

For additional information, call the instruction "RDREC" (SFB52) with a cyclical OB (e.g. OB1).

To determine the Windows status with the "RDREC" instruction, a new data record index (0x7FFE) is defined for all input/output interfaces.

The "RDREC" instruction is called with the following input parameters:

Input	Type	Value
(HIC) ID	HW_IO	59 (Host Interface RID)
INDEX	DINT	0x7FFE
MLEN	UINT	9
RECORD	VARIANT	Address for each area of 9 bytes

The data record for the Windows status is output by the eighth byte and can have the following content:

- 0x01: Windows running
- 0x02: Windows not running
- 0x03: Bluescreen

Examples

You can find an example here: Program example of I&M data record with read RDREC (Page 3580).

You can find another example here: Read program example for diagnostic data record with RDREC (Page 3584).

You can find additional information and the program code for the examples here: Sample Library for Instructions (Page 2568).

See also

Overview of the types of data records (Page 3571)

Program example of I&M data record with read RDREC (S7-1200, S7-1500)

Introduction

In the following example, you read out the I&M0 data record of a CPU S7-1500.

For more information on data records, refer to the Overview of the types of data records (Page 3571).

Requirement

Create nine tags and a structure in a global data block for storing the data.

You read the hardware identifier of the CPU in “PLC tags > System constants. The CPU should be displayed there as <Local> with the data type “Hw_SubModule“. You store the hardware identifier via the input parameter ID ("id").

SLI_gDB_RDREC_I-M

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	id	HW_IO	49
4	dataRecNbr	DInt	16#AFF0
5	maxLen	UInt	0
6	checkedValid	Bool	false
7	busy	Bool	false
8	error	Bool	false
9	status	DWord	16#0

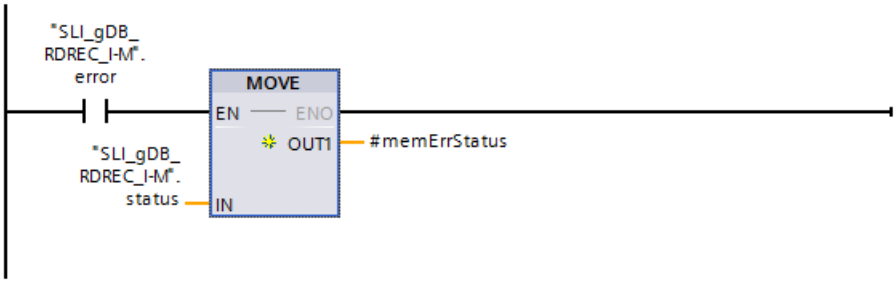
12	BlockType	Word	16#0
13	BlockLength	UInt	0
14	BlockVersion_HL	Word	16#0
15	VendorID_HL	Word	16#0
16	OrderID	Array[0..19] of Byte	
17	IM_SerialNbr	Array[0..15] of Byte	
18	IM_HWrev	UInt	0
19	IM_SWrev	Struct	
20	IM_RevCounter	UInt	0
21	IM_ProfileID	UInt	0
22	IM_ProfileSpecType	Word	16#0
23	IM_Version	Word	16#0
24	IM_Supported	Word	16#0

Create the following local tags in an FB.



memErrStatus	DWord	16#0	Set in IDB

Interconnect parameters

Network 1: Interconnect the parameters of the "RDREC" instruction as follows.

Network 2: To save the status if an error occurs, interconnect the “status“ variable as follows

Result

When the input parameter REQ ("start") returns the signal state "TRUE", the "RDREC" instruction is started. Via the input parameter ID ("id") the instruction "RDREC" calls the module. With the input parameter INDEX ("dataRecNbr") the I&M0 data record of the CPU is called.

Over several calls the "RDREC" instruction reads out the I&M0 data record and saves the data record using the parameter RECORD ("recordIM0").

Among other things the I&M0 data record contains the following information.

- The vendor name ("VendorID_HL")
- The article (“OrderID“) & device number (“IM_SerialNbr“)

- Hardware ("IM_HWrev") & software information ("IMSWrev")
- IM version ("IM_Version") and the bandwidth supported I&Mdata records ("IM_Supported")

recordIM0	Struct		
BlockType	Word	16#0	16#0020
BlockLength	UInt	0	56
BlockVersion_HL	Word	16#0	16#0100
VendorID_HL	Word	16#0	16#002A
OrderID	Array[0..19] of Byte		
IM_SerialNbr	Array[0..15] of Byte		
IM_HWrev	UInt	0	3
IM_SWrev	Struct		
Refix	Byte	16#0	16#56
FunctEnh	Byte	16#0	16#01
BugFix	Byte	16#0	16#05
InternalChange	Byte	16#0	16#00
IM_RevCounter	UInt	0	0
IM_ProfileID	UInt	0	0
IM_ProfileSpecType	Word	16#0	16#0000
IM_Version	Word	16#0	16#0101
IM_Supported	Word	16#0	16#001E

The length of the read data record is stored using the output parameter LEN ("len"). According to the value of the input parameter MLEN ("maxLen"), has the value “0“ the data record information that is to be read is unlimited.

During processing the output parameter BUSY ("busy") is set to "TRUE" and VALID ("checkedValid") to "FALSE". A successful reading result ("checkedValid" to "TRUE") is not output until processing is complete. The block status is displayed at the output parameter STATUS ("status"). Processing takes place without errors.

SLI_gDB_RDREC_I-M

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	TRUE
3	id	HW_IO	49	16#0031
4	dataRecNbr	DInt	16#AFF0	45040
5	maxLen	UInt	0	0
6	checkedValid	Bool	false	TRUE
7	busy	Bool	false	FALSE
8	error	Bool	false	FALSE
9	status	DWord	16#0	16#0000_0000
10	len	UInt	0	60
11	recordIM0	Struct		

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

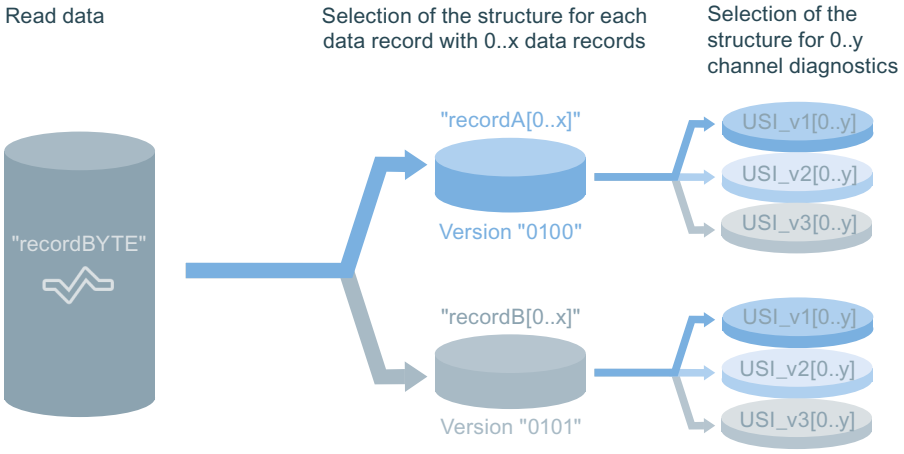
See also

RDREC: Read data record (Page 3578)

Read program example for diagnostic data record with RDREC (S7-1200, S7-1500)

Introduction

In the following example, you use RDREC to read the diagnostic data record "16#E00A" of an IO device. When a wire break is triggered, the error information is output as a diagnostic data record.



For more information on data records, refer to the Overview of the types of data records (Page 3571).

Note

Number of diagnostic data records

Each slot of a module triggering an error generates its own data record for the IO device. Diagnostics can thus contain multiple records.

The example is intended to read multiple hardware errors (channel errors) of multiple modules and copy them to the appropriate structure of a memory array. The memory arrays ("recordA", "recordB") can hold a maximum of six data records with a maximum of 16 channels each based on a specified setting.

Requirements

Hardware installed

The following hardware is required:

- An IO controller (e.g. S7-1513-1 PN)
- An IO device (e.g. ET 200MP IM 155-5 PN HF)
- One or more digital output modules of the HF type (for example, DQ 4x24VDC HF)

Note

Trigger wire break

Make sure that the channels of the DQ module that are to trigger the wire break are not wired.

Note

Procedure for configuration of the hardware

Configure the hardware as follows:

1. Connect the CPU and IO device over PROFINET and assign the CPU to the IO device as an IO controller.
2. Open the path "Properties > Output 0-x > Outputs > Channel 0-y" for the respective DQ module.
3. Select each channel to be configured and select the "Wire break" option in the ""Diagnostics" area.

PLC data types created

You need the following PLC data types for the transfer and storage of data records:

- For the body content of the "A"/"0100" structure:

Rd_0100body

	Name	Data type	Default value
1	BlockType	Word	16#0
2	BlockLength	UInt	0
3	BlockVersion_HL	Word	16#0
4	SlotNumber	UInt	0
5	SubSlotNumber	UInt	0
6	ChannelLocation	Word	16#0
7	ChannelProperties	Array[0..15] of Bool	
8	UserStructureIdentifier	Word	16#0

- For the body content of the "B"/"0101" structure:

Rd_0101body

	Name	Data type	Default value
1	BlockType	Word	16#0
2	BlockLength	UInt	0
3	BlockVersion_HL	Word	16#0
4	API	DWord	16#0
5	SlotNumber	UInt	0
6	SubSlotNumber	UInt	0
7	ChannelLocation	Word	16#0
8	ChannelProperties	Array[0..15] of Bool	
9	UserStructureIdentifier	Word	16#0

- For the structure of type 1 in accordance with the value from "UserStructureIdentifier": Type 1 of the structure is used for basic channel diagnostics.

USI_v1

	Name	Data type	Default value
1	ChannelNumber	UInt	0
2	ChannelProperties	Array[0..15] of Bool	
3	ChannelErrorType	Word	16#0

- For the structure of type 2 in accordance with the value from "UserStructureIdentifier": Type 2 of the structure is used for extended channel diagnostics.

USI_v2

	Name	Data type	Default value
1	ChannelNumber	UInt	0
2	ChannelProperties	Array[0..15] of Bool	
3	ChannelErrorType	Word	16#0
4	ExtChErrorType	Word	16#0
5	ExtChAddValue	DWord	16#0

- For the structure of type 3 in accordance with the value from "UserStructureIdentifier": Type 3 of the structure is used for manufacturer-specific channel diagnostics. The configuration of the structure is not defined in this example. For this example, a length of 28 bytes is assumed for type 3.

USI_v3

	Name	Data type	Default value
1	ChannelDiagData3	Array[0..27] of Byte	

- For the summary of the "A"/"0100" structure:

RECdiag_0100

	Name	Data type
1	Body0100	"Rd_0100body"
2	USI_DetailsType1	Array[0..15] of "USI_v1"
3	USI_DetailsType2	Array[0..15] of "USI_v2"
4	USI_DetailsType3	Array[0..15] of "USI_v3"

- For the summary of the "B"/"0101" structure:

RECdiag_0101

	Name	Data type
1	Body0101	"Rd_0101body"
2	USI_DetailsType1	Array[0..15] of "USI_v1"
3	USI_DetailsType2	Array[0..15] of "USI_v2"
4	USI_DetailsType3	Array[0..15] of "USI_v3"

Note

Size of the arrays

If you want to change the array sizes (for read memory, data record or channels), you need to do the following:

- For channels: Adapt the size of the arrays ("Array[0..y] of USI_v..") in the PLC data types ("RECdiag_0100", "RECdiag_0101"). Adapt the "maxChannelPos" value in the gDB.
- For data records: Adapt the size of the arrays ("recordA", "recordB") in the gDB. Adapt the "maxRecordPos" value in the gDB.
- For the read memory ("recordBYTE"): Adapt the size of the array ("recordBYTE") and the value of "maxPosition" in the gDB. Note that the diagnostics data record "16#E00A" can have a maximum total of 4176 bytes.

Watch table created

To trigger a wire break, use the "Force" function of a watch table.

If you force the value "16#FFFF" for the "%QW0" output, for example, all channels with configured wire break using the output trigger a hardware error.

Storage of data

Create the following tags and structures for storing data in a global data block (gDB):

SLI_gDB_RDREC_Diag

	Name	Data type	Start value
1	Static		
2	id	HW_IO	262
3	dataRecNbr	DInt	16#E00A
4	startRead	Bool	false
5	maxLength	UInt	0
6	maxPosition	UInt	4175
7	recordBYTE	Array[0..4175] of Byte	
8	readLength	UInt	0
9	checkedValid	Bool	false
10	busy	Bool	false
11	error	Bool	false
12	memErrStatus	DWord	16#0
13	countCalls	UInt	0
14	maxChannelPos	UInt	15
15	maxRecordPos	UInt	5
16	recordA	Array[0..5] of "RECdiag_0100"	
17	recordB	Array[0..5] of "RECdiag_0101"	
18	data_sorting_done	Bool	false
19	outputOverflow	Struct	
20	Too_many_bytes	Bool	false
21	Too_many_records	Bool	false
22	Too_many_channels	Bool	false
23	different_structs_used	Bool	false
24	countRecs	UInt	0
25	chosenStruct	UInt	0
26	posForRec	UInt	0
27	posForChannel	UInt	0
28	resetOps	Struct	
29	reset	Bool	false

You read the hardware identifier of the head of the IO device and store the hardware identifier using the "id" tag. You can find the hardware identifier for the header module with "PLC tags > System constants" and with an entry such as <Head~IO_Device>. The data type used is "HW_SubModule".

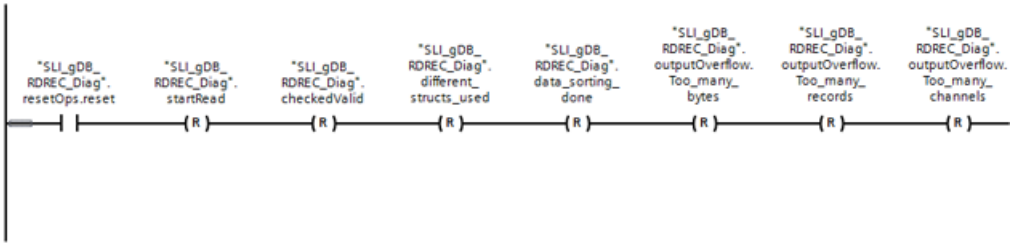
FC "SLI_FC_start_RDiag": Interconnect parameters

To start the "RDREC" instruction, based on a hardware fault, create the FC "SLI_FC_start_RDiag".

Create the following interconnection in the FC.

You call the FC "SLI_FC_start_RDiag" in a diagnostic interrupt OB (OB82).

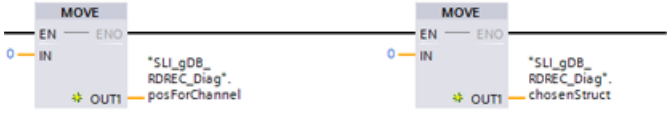
FC "SLI_FC_reset_RDiag": Interconnect parameters



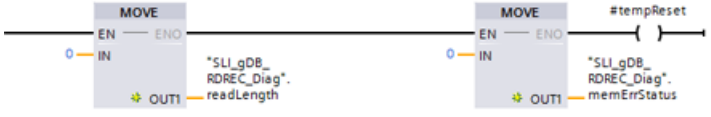
To reset process values after an error, create the FC "SLI_FC_reset_RDiag".

Create the following local tag in the FC.

Create the following interconnections in the FC.



Network 1: To reset the process values, create the following interconnections. Part 1:



Part 2:

Part 3:

Part 4:

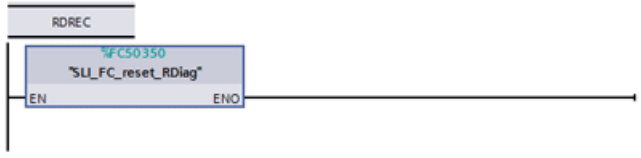
Network 2: To reset the "reset" tag, create the following interconnections.

FB "SLI_FB_chooseStruct_RDiag": Interconnect parameters

You create the FB "SLI_FB_chooseStruct_RDiag" to select the appropriate structure for the data record and to copy the data to the appropriate location in the array.

You can find additional information in the "Result" section ("Network 6") or in the comment field of the networks (see "Program code").

FB "SLI_FB_RDREC_Diag": Interconnect parameters

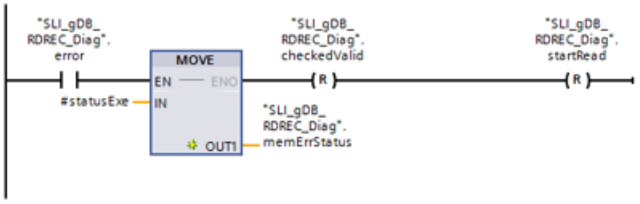


You create the FB "SLI_FC_start_RDiag" to call and process the "RDREC" instruction and all other subsequent processes.

Create the following local tags in the FB.

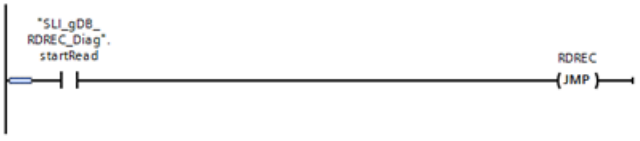
	Static			
	statusExe	DWord	16#0	Nicht re...
	checkExe	Bool	false	Nicht rema...
	lengthOut	UInt	0	Nicht rema...
	RDREC_Instance00	RDREC		

Create the following interconnections in the FB:

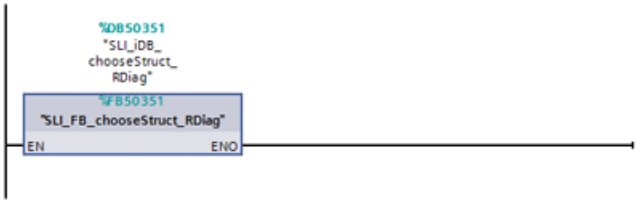


Network 1: Call the FC "SLI_FC_reset_RDiag" and create the "Label" instruction with the name "RDREC".

Network 2: Interconnect the parameters of the "RDREC" instruction as follows.



Network 3: To save the status if a RDREC error occurs, interconnect the parameter as follows



Network 4: To end the processing of RDREC, create the following interconnections.

Network 5: To jump back to network 1, create the following interconnections.

Network 6: Call the FB "SLI_FB_chooseStruct_RDiag" as follows.

You call the FB "SLI_FB_RDREC_Diag" in a cyclic OB (OB1).

Event FB "SLI_FB_RDREC_Diag"

Network 1:

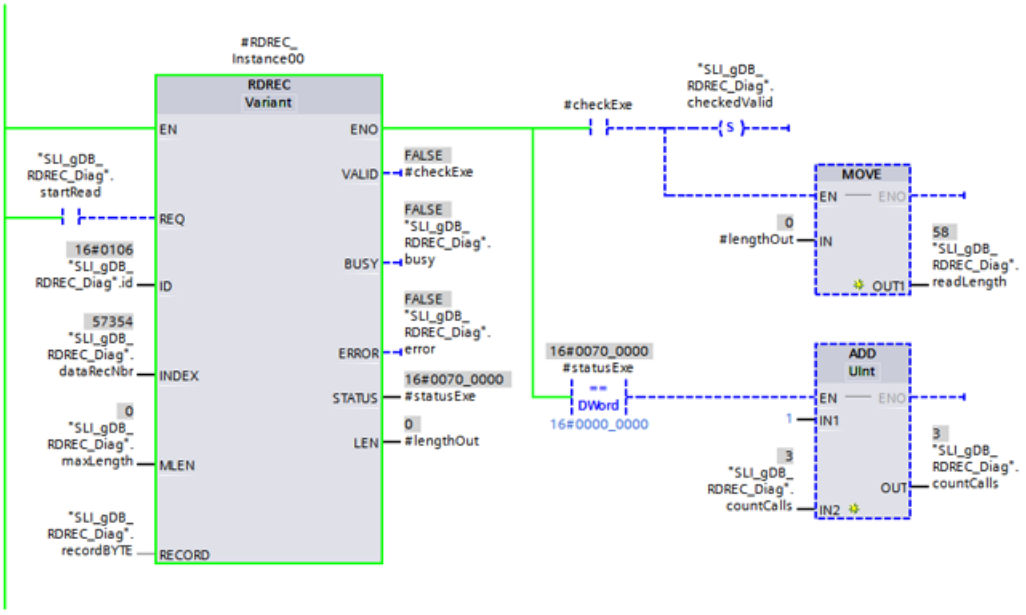
If the NO contact ("reset") has the "TRUE" signal state, the process values of the FB "SLI_FB_chooseStruct_RDiag" and the process values of the global data block are reset.

Network 2:

When the input parameter REQ ("startRead") returns the signal state "TRUE", the "RDREC" instruction is started.

Note

Calling "startRead"



In accordance with the call by OB82, "startRead" is set to "TRUE" every time a hardware error is detected. The successful calls of RDREC can be counted using the "countCalls" tag. After three triggered channel errors, the "countCalls" value is "3".

The "RDREC" instruction calls the header module of the IO device using the input parameter ID ("id"). The input parameter INDEX ("dataRecNbr") is used to call the "16#E00A" diagnostics data record of the IO device.

The "RDREC" instruction reads the diagnostic data over several calls and saves the data read (x data records) with the RECORD parameter ("recordBYTE"). The length of the read data is recorded in the LEN output parameter ("#lengthOut") and saved for further use with the "readLength" tag. In accordance with the value of the input parameter MLEN ("maxLength" has the value "0"), the length of the data to be read is not restricted.

During processing the output parameter BUSY ("busy") is set to "TRUE" and VALID ("checkedValid") to "FALSE". A successful reading result ("checkedValid" set to "TRUE") is not output until processing is complete; it is used by the FB "SLI_FB_chooseStruct_RDiag" as a start condition. To end processing of the FB "SLI_FB_chooseStruct_RDiag", the "checkedValid" tag is set to "FALSE".

The block status is displayed at the output parameter STATUS ("#statusExe"). In the example, processing takes place without errors.

Network 3:

When the NO contact ("error") supplies the signal state "TRUE", the status ("#statusExe") is saved if an error occurs ("memErrStatus"). The "checkedValid" and "startRead" tags are also reset. The processing of RDREC stops. The processing of the FB "SLI_FB_chooseStruct_RDiag" cannot be started.

Network 4:

When RDREC has been fully processed ("#statusExe" has the value "16#0070_0200"), "startRead" is set to "FALSE". The processing of RDREC stops.

Network 5:

If the NO contact ("startRead") has the signal state "TRUE", processing jumps to network 1 (with the "JMP" instruction) in accordance with the "RDREC" label.

Network 6:

If the "checkedValid" tag has the signal state "TRUE" and the "reset" tag has the signal state "FALSE", the sorting process is started in the FB "SLI_FB_chooseStruct_RDiag".

In the FB "SLI_FB_chooseStruct_RDiag", the structure type of the respective data record and the structure type corresponding to the UserStructureIdentifier are selected. The data of the data record is copied to the correct location in the appropriate array. In addition, processing may be repeated several times according to the size of the respective data record. The information of one or more channels is read in this case.

If the "length of the data record + preceding lengths " ("#allRecLEN") is less than the length of all read data ("readLength") at the end of processing the data record content, processing of the FB starts again from the top. Another data record is read, its contents compared and its data is copied to the correct location of the appropriate array.

The sorting process is completed by setting the local tags ("#readComplete", "#dbComplete", "#limitReach") and the global tag "checkedValid" to "FALSE".

The sorting process is documented based in the following tags:

- "data_sorting_done": This tag indicates that processing of the FB "SLI_FB_chooseStruct_RDiag" is complete and has ended. The "checkedValid" tag is reset, which means processing of the FB cannot be started again.
- "outputOverflow": This structure contains three tags, each of which records a different violation of array limits. For example, more data records might have been read than the corresponding array ("recordA" or "recordB") is capable of storing.
- "different_structs_used": If both "recordA" and "recordB" are used to store the diagnostic data records, the "different_structs_used" tag returns the value "TRUE".
- "countRecs": This tag counts the copied data records.
- "chooseStruct": This tag indicates the structure used last. The value "4" indicates that a data record was last stored in the "recordB" structure with the "USI Type 1" form.
- "posForRec": This tag stores the most recently used location in the array of the data records ("recordA" or "recordB"). The value "1" indicates that a data record was last stored in "recordB[1]" (see "chooseStruct").
- "posForChannel": This tag stores the most recently used location in the array of the channels ("USI_DetailsType[x]"). The value "0" indicates that a channel was stored in "recordB[1]/USI_DetailsType[0]" (see "chooseStruct" and "posForRec").

SLI_gDB_RDREC_Diag

	Name	Data type	Start value	Monitor value
1	Static			
2	id	HW_IO	262	16#0106
3	dataRecNbr	DInt	16#E00A	57354
4	startRead	Bool	false	FALSE
5	maxLength	UInt	0	0
6	maxPosition	UInt	4175	4175
7	recordBYTE	Array[0..4175] of B...		
8	readLength	UInt	0	58

RDREC: Read data record (Page 3578)

WRREC: Write data record (S7-1200, S7-1500)

WRREC: Write data record (S7-1200, S7-1500)

Description

The instruction "WRREC" is used to transfer the RECORD data record to the component addressed using ID. This may be a module in a central rack or a distributed component (PROFIBUS DP or PROFINET IO).

- Use the ID parameter to select the module for which a data record is to be written. Use only the hardware identifier (HW ID) of the module for the ID parameter. You can find the hardware identifier of the module in "PLC tags > System constants". For example, for an S7-1500 DI module: This is shown as <Name of DI module> with the data type "Hw_SubModule".
- Use the INDEX parameter to select which data record is written. The module determines which data records can be written with which data record number. You can find additional information on this in the manual for the relevant module.
- Use LEN to specify the length of the data record to be transmitted in bytes. Select the source area RECORD at least LEN bytes long.
- The value TRUE at output parameter DONE indicates that the data record has been successfully transferred.
- If an error has occurred during transfer of the data record, this is indicated by the output parameter ERROR. In this case, the output parameter STATUS contains the error information.

Note

The interface of the "WRREC" instruction is identical to that in the "WRREC" FB defined in the standard "PROFIBUS and PROFINET Guideline Communication Function Blocks on PROFIBUS DP and PROFINET IO".

Functional description

"WRREC" is an asynchronous instruction. Processing takes place across several calls. You start the data record transfer by calling "WRREC" with REQ = 1.

The job status is displayed via the output parameter BUSY and the two central bytes of output parameter STATUS. The two central bytes of STATUS correspond to the RET_VAL output parameter of the instructions that operate asynchronously.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Note that you must assign the same value to the actual parameter of RECORD for all "WRREC" calls that belong to one and the same job. The same applies to the actual parameters of LEN.

The transfer of the data record is complete when the output parameter BUSY has the value FALSE.

Parameter

The following table shows the parameters of the "WRREC" instruction:

Parameter	Declaration	Data type**	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T*, C* or constant	REQ = 1: Transfer data record
ID	Input	HW_IO	I, Q, M, D, L or constant	ID number of the hardware component (DP/PROFINET IO) The number is assigned automatically and is stored in the properties of the component or of the interface in the hardware configuration.
INDEX	Input	DINT	I, Q, M, D, L or constant	Data record number
LEN	Input	UINT	I, Q, M, D, L or constant	(hidden) Maximum length of the data record to be transferred in bytes
DONE	Output	BOOL	I, Q, M, D, L	Data record was transferred
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = 1: An error occurred during the writing process.
STATUS	Output	DWORD	I, Q, M, D, L	Block status or error information For interpretation of the STATUS parameter, see Parameter STATUS (Page 3638).
RECORD	InOut	VARIANT	I, Q, M, D, L	Data record

* For S7-1500 only.

** There is no implicit conversion in STL, which is why the range of valid data types may be limited. During programming in STL, please note the valid data types. These are displayed in the parameter tooltip.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

If you use "WRREC" to write a data record for PROFINET IO, negative values in the INDEX and LEN parameters will be interpreted as an unsigned 16-bit integer.

Parameter STATUS

For interpretation of the STATUS parameter, see Parameter STATUS (Page 3638).

Examples

You can find an example here: Use the program example of the parameter data record with WRREC & RDREC (Page 3598).

You can find another example here: Use the program example of the control data record with WRREC & RDREC (Page 3607).

You can find additional information and the program code for the examples here: Sample Library for Instructions (Page 2568).

See also

Overview of the types of data records (Page 3571)

Use the program example of the parameter data record with WRREC & RDREC (S7-1200, S7-1500)

Introduction

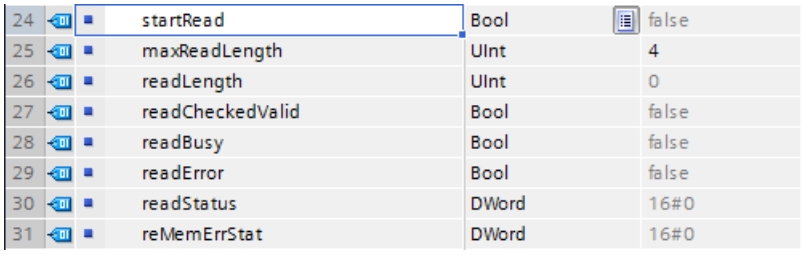
In the following example you read the parameter data record of a digital input module via RDREC and rewrite the data record via WRREC. When doing this you change the input delay.

You can find additional information on the data records in the Overview of the types of data records (Page 3571).

Requirement

Create the following tags for storing the data in a global data block:

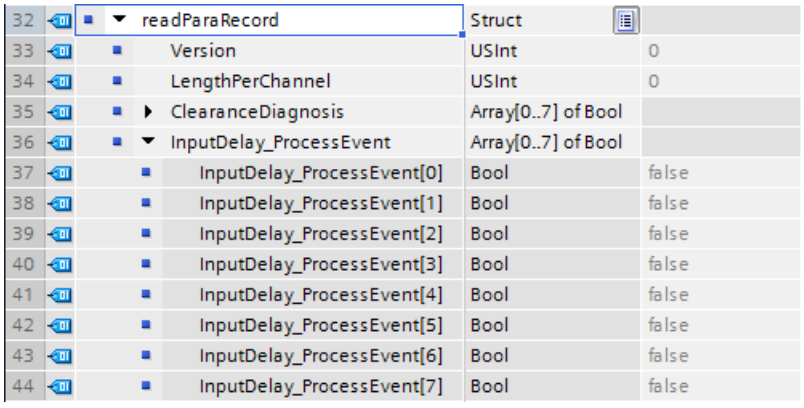
- two tags for general use and seven tags for WRREC:



SLI_gDB_WRREC_Para

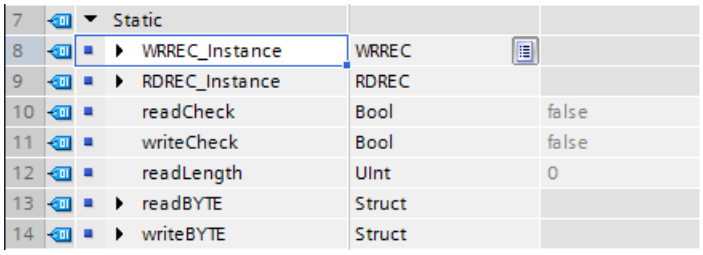
	Name	Data type	Start value
1	Static		
2	id	HW_IO	257
3	dataRecNbr	DInt	3
4	startWrite	Bool	false
5	maxWriteLength	UInt	4
6	writeCheckedValid	Bool	false
7	writeBusy	Bool	false
8	writeError	Bool	false
9	writeStatus	DWord	16#0
10	wrMemErrStat	DWord	16#0

- a structure for the data record at WRREC:



11	writeParaRecord	Struct	
12	Version	USInt	16
13	LengthPerChannel	USInt	2
14	ClearanceDiagnosis	Array[0..7] of Bool	
15	InputDelay_ProcessEvent	Array[0..7] of Bool	
16	InputDelay_ProcessEvent[0]	Bool	1
17	InputDelay_ProcessEvent[1]	Bool	false
18	InputDelay_ProcessEvent[2]	Bool	false
19	InputDelay_ProcessEvent[3]	Bool	false
20	InputDelay_ProcessEvent[4]	Bool	false
21	InputDelay_ProcessEvent[5]	Bool	false
22	InputDelay_ProcessEvent[6]	Bool	false
23	InputDelay_ProcessEvent[7]	Bool	false

- eight tags for RDREC:



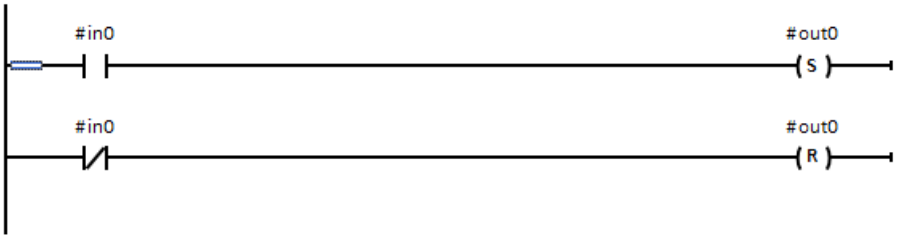
24	startRead	Bool	false
25	maxReadLength	UInt	4
26	readLength	UInt	0
27	readCheckedValid	Bool	false
28	readBusy	Bool	false
29	readError	Bool	false
30	readStatus	DWord	16#0
31	reMemErrStat	DWord	16#0

- a structure for the data record at RDREC:

32	readParaRecord	Struct	
33	Version	USInt	0
34	LengthPerChannel	USInt	0
35	ClearanceDiagnosis	Array[0..7] of Bool	
36	InputDelay_ProcessEvent	Array[0..7] of Bool	
37	InputDelay_ProcessEvent[0]	Bool	false
38	InputDelay_ProcessEvent[1]	Bool	false
39	InputDelay_ProcessEvent[2]	Bool	false
40	InputDelay_ProcessEvent[3]	Bool	false
41	InputDelay_ProcessEvent[4]	Bool	false
42	InputDelay_ProcessEvent[5]	Bool	false
43	InputDelay_ProcessEvent[6]	Bool	false
44	InputDelay_ProcessEvent[7]	Bool	false

Create the following local tags in an "SLI_FB_WRREC_Para" FB.

7	Static		
8	WRREC_Instance	WRREC	
9	RDREC_Instance	RDREC	
10	readCheck	Bool	false
11	writeCheck	Bool	false
12	readLength	UInt	0
13	readBYTE	Struct	
14	writeBYTE	Struct	

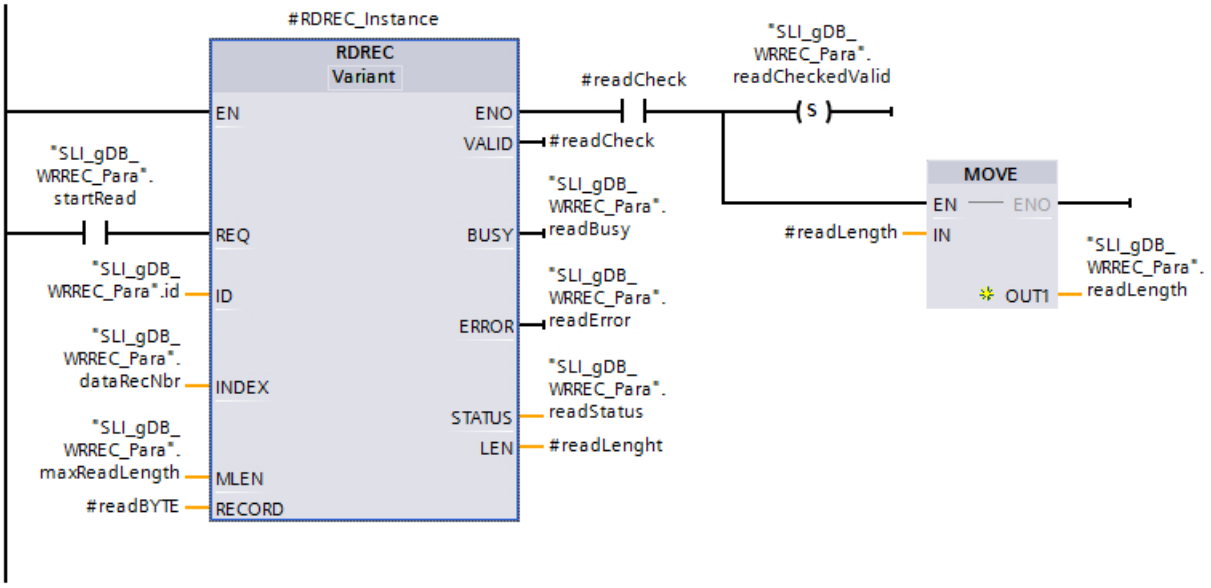


Interconnect parameters: "SLI_itemisePara_WRREC_Para" FC

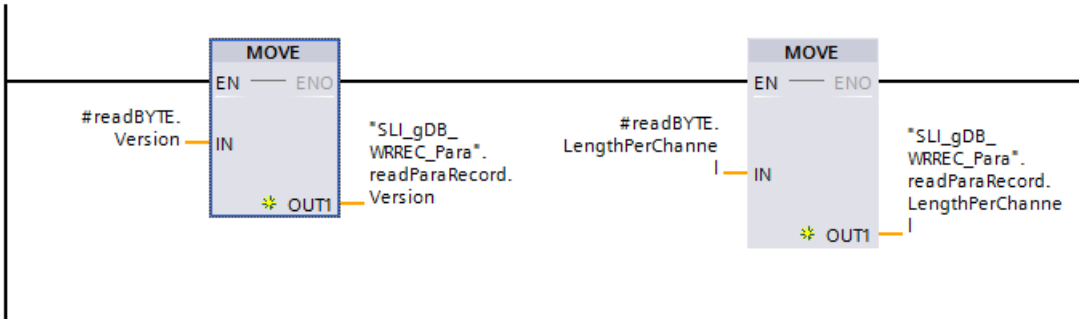
To transfer the values of a bit sequence (0..7) create the FC "SLI_itemisePara_WRREC_Para".

Create the following local tags in it.

SLI_itemisePara_WRREC_Para		
	Name	Data type
1	Input	
2	in0	Bool
3	in1	Bool
4	in2	Bool
5	in3	Bool
6	in4	Bool
7	in5	Bool
8	in6	Bool
9	in7	Bool
10	Output	
11	out0	Bool
12	out1	Bool
13	out2	Bool
14	out3	Bool
15	out4	Bool
16	out5	Bool
17	out6	Bool
18	out7	Bool

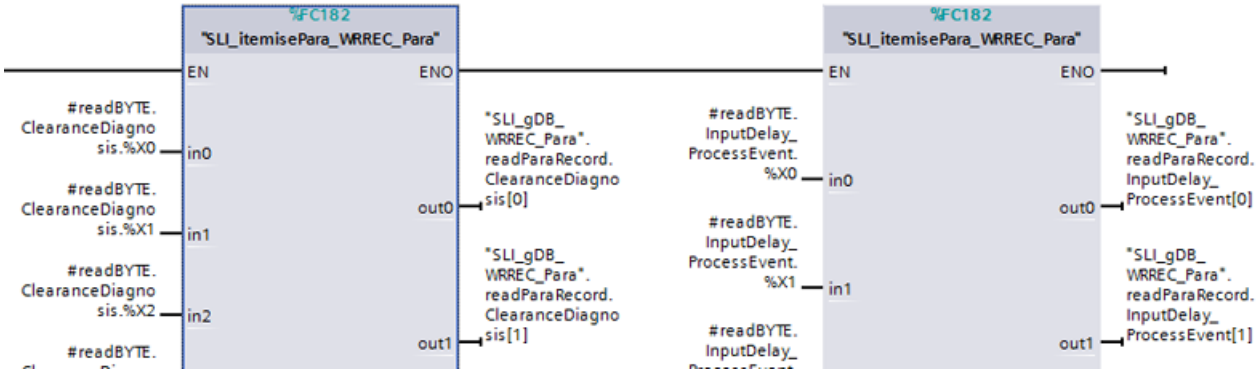


Network 1: According to the example of network 1, create interconnections for all bits (0..7).

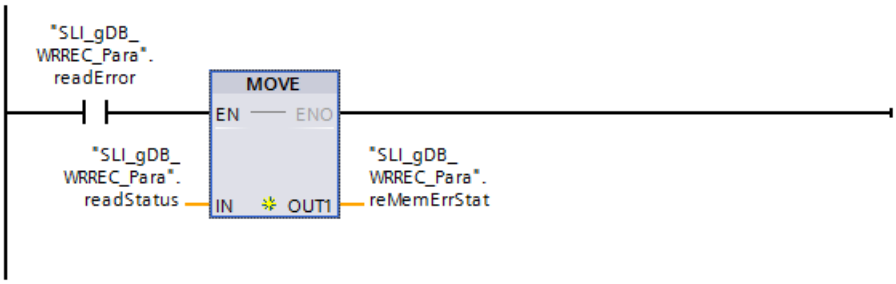


Interconnect parameters: "SLI_FB_WRREC_Para" FB

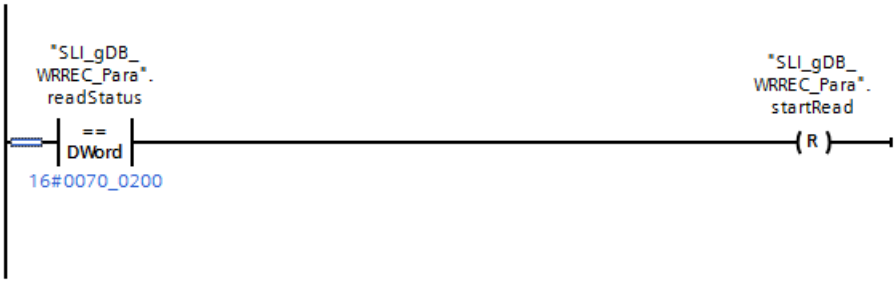
Create the following interconnections in the "SLI_FB_WRREC_Para" FB.



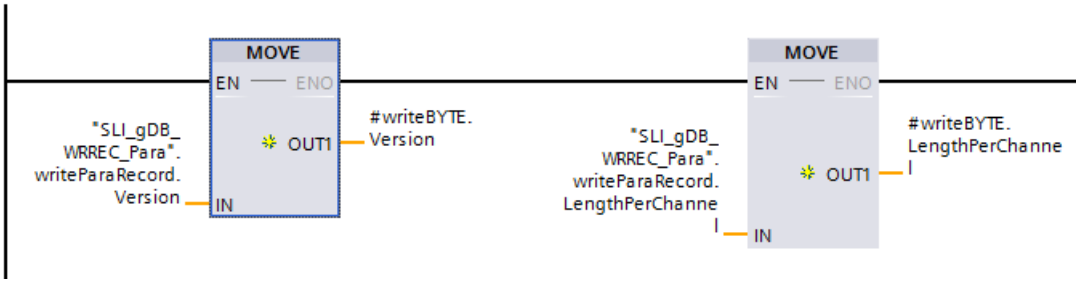
Network 1: Interconnect the parameters of the "RDREC" instruction as follows.



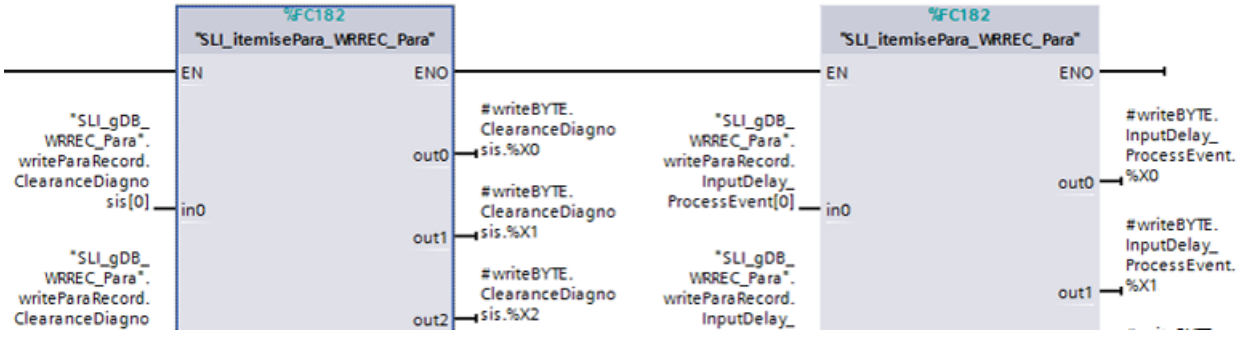
Network 2: Below interconnect all tags of the structure “#readBYTE“ with the structure “readParaRecord“. Part 1 of the network:



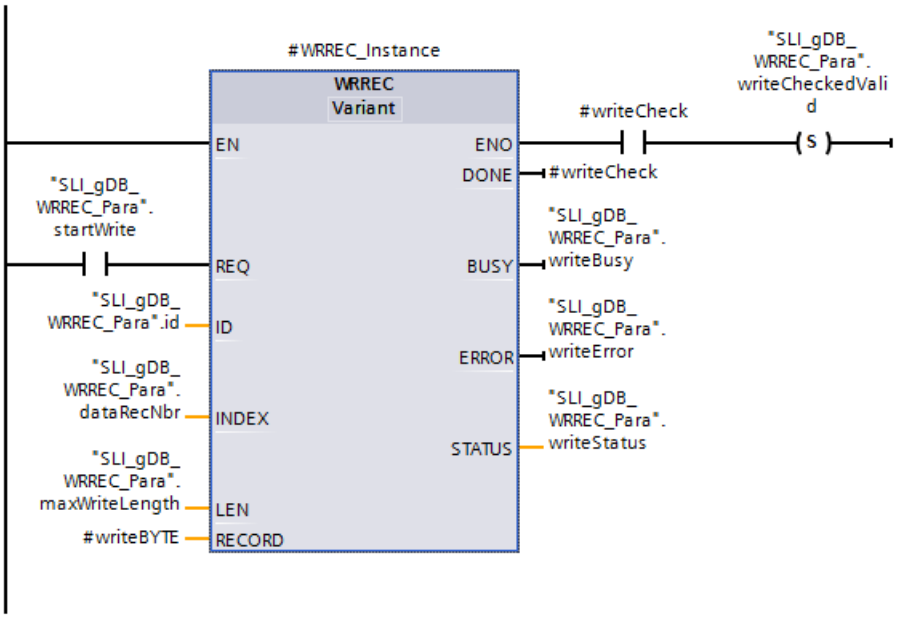
Part 2 of the network: Interconnect the tags "ClearanceDiagnosis" and "InputDelay_ProcessEvent" according to the example below.



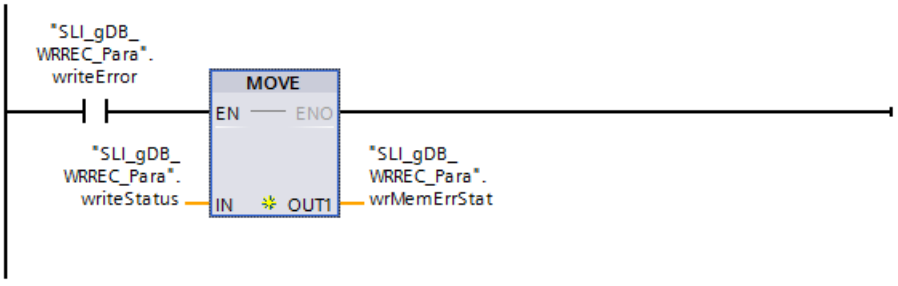
Network 3: Then interconnect the tags for the error situation of RDREC.



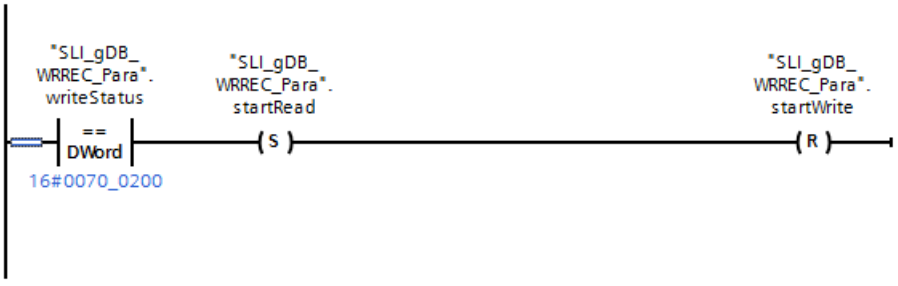
Network 4: Then interconnect the tags for ending RDREC.



Network 5: Below interconnect all tags of the structure “writeParaRecord“ with the structure “#writeBYTE“. Part 1 of the network:



Part 2 of the network:



Network 6: Interconnect the parameters of the "WRREC" instruction as follows.

Network 7: Then interconnect the tags for the error situation of WRREC.

Network 8: Then interconnect the tags for ending WRREC and calling RDREC again.

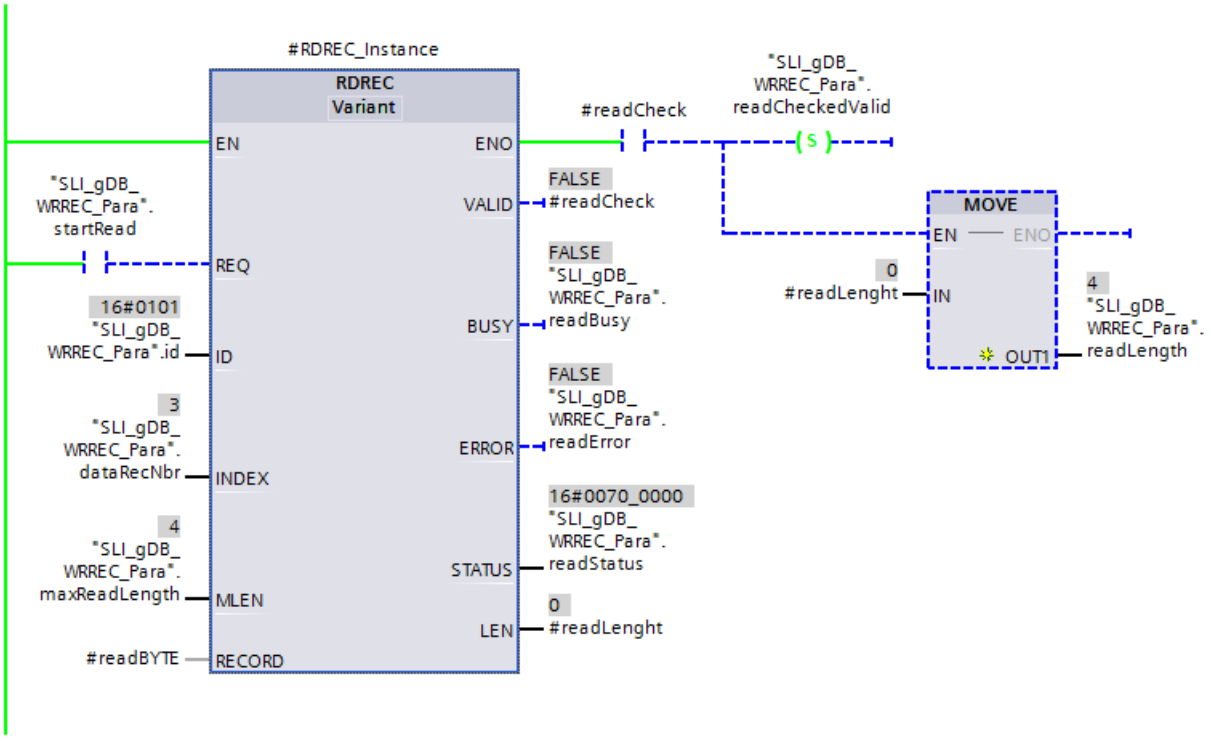
Result of network 1:

You create an input module and read the hardware ID in the properties of the input module. You store the hardware identifier via the input parameter ID ("id"). Using the input parameter INDEX ("dataRecNbr") the data record with the number "3" of the module is called. The data record corresponds to the channel with the same name.

SLI_gDB_WRREC_Para

	Name	Data type	Start value	Monitor value
1	Static			
2	id	HW_IO	257	16#0101
3	dataRecNbr	DInt	3	3

When the input parameter REQ ("startRead") returns the signal state "TRUE", the "RDREC" instruction is started. Via the input parameter ID ("id") the instruction "RDREC" calls the input module.



Over several calls the "RDREC" instruction reads out the data record and saves the data record using the parameter RECORD ("#readBYTE"). The length of the read data record is stored using the output parameter LEN ("#readLength"). According to the value of the input parameter MLEN ("maxReadLength"), the data record information that is to be read is limited to 4 bytes.

During processing the output parameter BUSY ("readBusy") is set to "TRUE" and VALID ("#readCheck") to "FALSE".

A successful reading result is output as follows when processing is complete.

- The output parameter VALID ("#readCheck") is set to "TRUE" and sets the tag "readCheckedValid" permanently to "TRUE".
- In addition to this the value of the local tag "#readLength" is stored permanently in the tag "readLength".

The block status is displayed at the output parameter STATUS ("readStatus"). Processing takes place without errors.

Result of network 2:

Using MOVE instructions and the FC SLI_itemisePara_WRREC_Para, the structure "#readBYTE" transfers the values of the tags to the tags of the structure "readParaRecord" with the same names. To improve understanding, the tags of the “readParaRecord“ structure are represented by descriptive names. The structure is described in the device manual of the module. For example "InputDelay_ProcessEvent" indicates an input delay of 3.2 ms. For the status of the channel (“ClearanceDiagnosis“) no disruption is output (bits 0 to 8 are “FALSE“.

32		readParaRecord	Struct		
33		Version	USInt	0	16
34		LengthPerChannel	USInt	0	2
35		ClearanceDiagnosis	Array[0..7] of Bool		
36		InputDelay_ProcessEvent	Array[0..7] of Bool		
37		InputDelay_ProcessEvent[0]	Bool	false	FALSE
38		InputDelay_ProcessEvent[1]	Bool	false	TRUE
39		InputDelay_ProcessEvent[2]	Bool	false	TRUE
40		InputDelay_ProcessEvent[3]	Bool	false	FALSE
41		InputDelay_ProcessEvent[4]	Bool	false	FALSE
42		InputDelay_ProcessEvent[5]	Bool	false	FALSE
43		InputDelay_ProcessEvent[6]	Bool	false	FALSE
44		InputDelay_ProcessEvent[7]	Bool	false	FALSE

Result of network 3:

When “readError“ supplies the signal status “TRUE“, the value of the tag “readStatus“ is stored in the tag “reMemErrStat“.

Result of network 4:

When the instruction “RDREC“ has been executed, “readStatus“ supplies the value “16#0070_0200“. After this a resetter sets the tag “startRead“ to “FALSE“

Result of network 5:

Using MOVE instructions and the FC SLI_itemisePara_WRREC_Para, the structure "writeParaRecord" transfers the values of the tags to the tags of the structure "#writeBYTE" with the same names. To improve understanding, the tags of the “writeParaRecord“ structure are represented by descriptive names.

Result of network 6:

When the input parameter REQ ("startWrite") returns the signal state "TRUE", the "WRREC" instruction is started.

The new data for the data record is stored at the RECORD (“#writeBYTE“) parameter. Over several calls, the instruction “WRREC“ writes the new data to the data record "3". According to the value of the input parameter LEN ("maxWriteLength"), the data record information that is to be written is limited to 4 bytes.

During processing the output parameter BUSY ("writeBusy") is set to "TRUE" and DONE ("#writeCheck") to "FALSE".

A successful writing result is output as follows when processing is complete.

- The output parameter DONE ("#writeCheck") is set to "TRUE".
- When "#writeCheck" supplies the signal state "TRUE" the tag "writeCheckedValid" is set permanently to "TRUE".

The block status is displayed at the output parameter STATUS ("writeStatus"). Processing takes place without errors.

4		startWrite	Bool	false	FALSE
5		maxWriteLength	UInt	4	4
6		writeCheckedValid	Bool	false	TRUE
7		writeBusy	Bool	false	FALSE
8		writeError	Bool	false	FALSE
9		writeStatus	DWord	16#0	16#0070_0000
10		wrMemErrStat	DWord	16#0	16#0000_0000

Result of network 7:

When “writeError“ supplies the signal status “TRUE“, the value of the tag “writeStatus“ is stored in the tag “wrMemErrStat“.

Result of network 8:

When the instruction “WRREC“ has been executed, “writeStatus“ supplies the value “16#0070_0200“. After this the resetter sets the tag “startWrite“ to “FALSE“ The tag “startRead“ is set to “TRUE“ after which the instruction “RDREC“ is executed again. The structure “readParaRecord“ shows the newly written values of the data record. Since in “InputDelay_ProcessEvent“ the bit 0 supplies the signal state “TRUE“, the channel 3 now has an input delay off 0.1 ms.

32	readParaRecord	Struct		
33	Version	USInt	0	16
34	LengthPerChannel	USInt	0	2
35	ClearanceDiagnosis	Array[0..7] of Bool		
36	InputDelay_ProcessEvent	Array[0..7] of Bool		
37	InputDelay_ProcessEvent[0]	Bool	false	TRUE
38	InputDelay_ProcessEvent[1]	Bool	false	FALSE
39	InputDelay_ProcessEvent[2]	Bool	false	FALSE
40	InputDelay_ProcessEvent[3]	Bool	false	FALSE
41	InputDelay_ProcessEvent[4]	Bool	false	FALSE
42	InputDelay_ProcessEvent[5]	Bool	false	FALSE
43	InputDelay_ProcessEvent[6]	Bool	false	FALSE
44	InputDelay_ProcessEvent[7]	Bool	false	FALSE

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

WRREC: Write data record (Page 3596)

RDREC: Read data record (Page 3578)

Use the program example of the control data record with WRREC & RDREC (S7-1200, S7-1500)

Introduction

In the following example, you write the control data record 196 using WRREC and check this by reading the data record out with RDREC. For the configuration select the central setup of an S7-1500

You can find additional information on the data records in Overview of the types of data records (Page 3571).

Requirement

Note

Enabling configuration control

To be able to write the control data record, the configuration control (option handling) of the CPU must be enabled. You will find these in “CPU properties > Configuration control”.

Create the following tags for storing the data in a global data block:

- three tags for general use and six for WRREC:

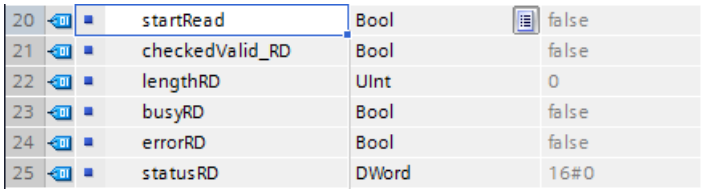
SLI_gDB_WRREC_Control

	Name	Data type	Start value
1	Static		
2	id	HW_IO	33
3	dataRecNbr	DInt	196
4	maxLength	UInt	0
5	configDone	Bool	false
6	checkedValid_WR	Bool	false
7	busyWR	Bool	false
8	errorWR	Bool	false
9	statusWR	DWord	16#0
10	memErrStatusWR	DWord	16#0

- a structure for the data at WRREC (data record 196):

11	recConfigCtrl_WR	Struct	
12	BlockLength	USInt	8
13	BlockID	USInt	196
14	Version	USInt	4
15	Subversion	USInt	0
16	Slot_0	USInt	0
17	Slot_1	USInt	1
18	Slot_2	USInt	2
19	Slot_3	USInt	3

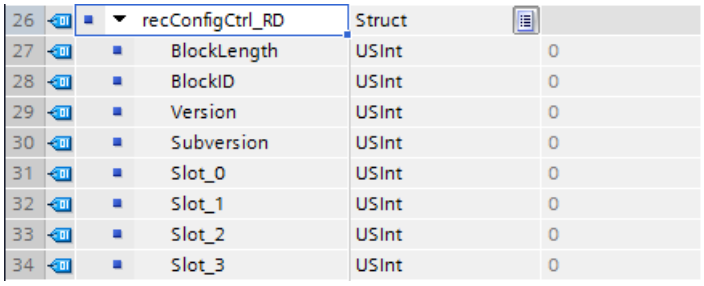
The data record is structured as follows:



– "BlockLength" indicates the length of the data record in Byte.

– "BlockID" indicates the data record number.

– "Version" indicates the type of structure. A central structure is used for the example. In a central structure "Subversion" has the value "0".

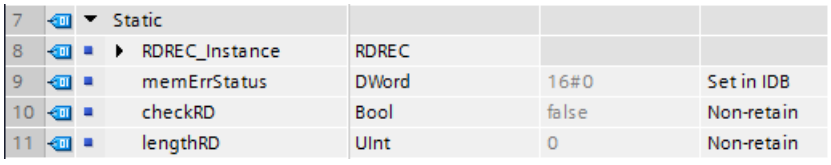


– "Slot_0" to "Slot_.." correspond to the slots used. The values of the slots indicate the numbering to be used.

- six tags for RDREC:

20		startRead	Bool	false
21		checkedValid_RD	Bool	false
22		lengthRD	UInt	0
23		busyRD	Bool	false
24		errorRD	Bool	false
25		statusRD	DWord	16#0

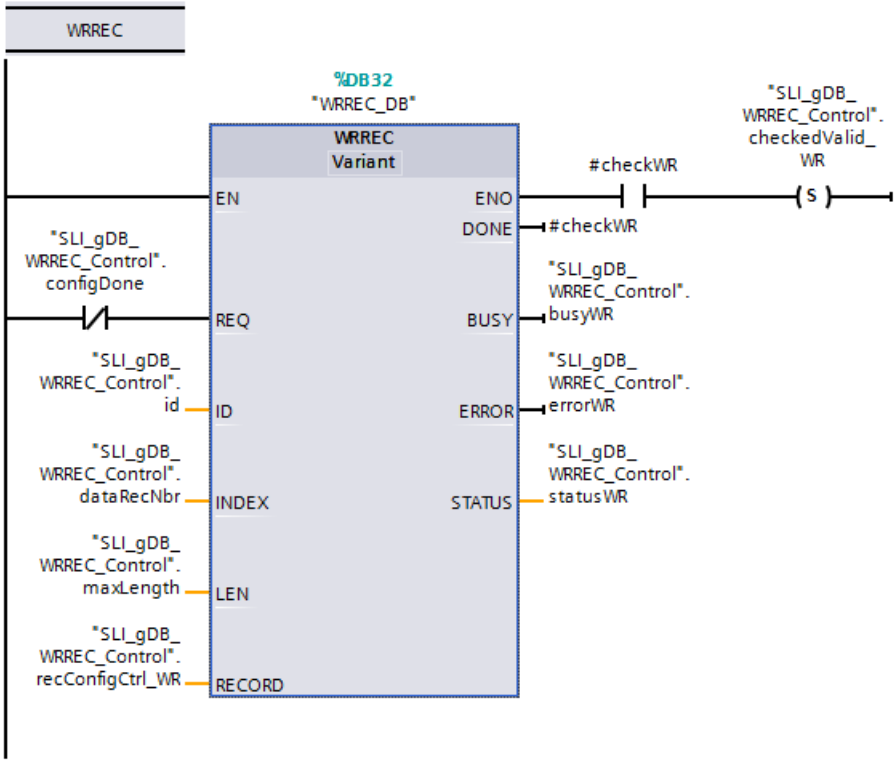
- a structure for the data at RDREC:



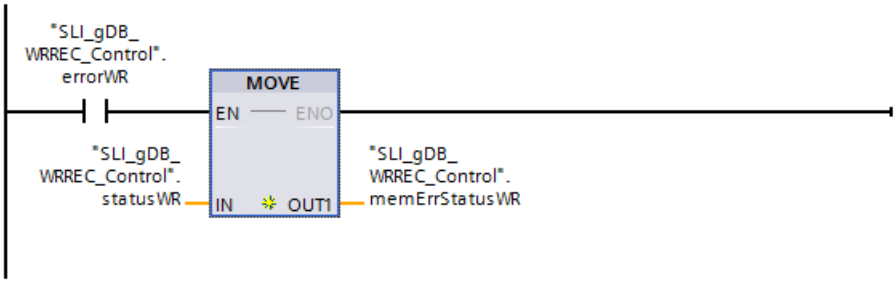
26		recConfigCtrl_RD	Struct	
27		BlockLength	USInt	0
28		BlockID	USInt	0
29		Version	USInt	0
30		Subversion	USInt	0
31		Slot_0	USInt	0
32		Slot_1	USInt	0
33		Slot_2	USInt	0
34		Slot_3	USInt	0

The instruction “WRREC“ for writing the control data recording must be called in a startup OB. In the startup OB create the following local tags for passing on the data.

4		Temp	
5		checkWR	Bool
6		statusWR	DWord

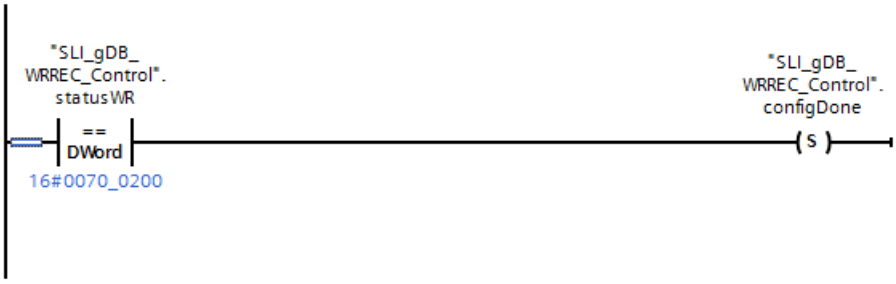


Create the following local tags in an FB. Call the FB in a program cycle OB (OB1).



7		Static			
8		RDREC_Instance	RDREC		
9		memErrStatus	DWord	16#0	Set in IDB
10		checkRD	Bool	false	Non-retain
11		lengthRD	UInt	0	Non-retain

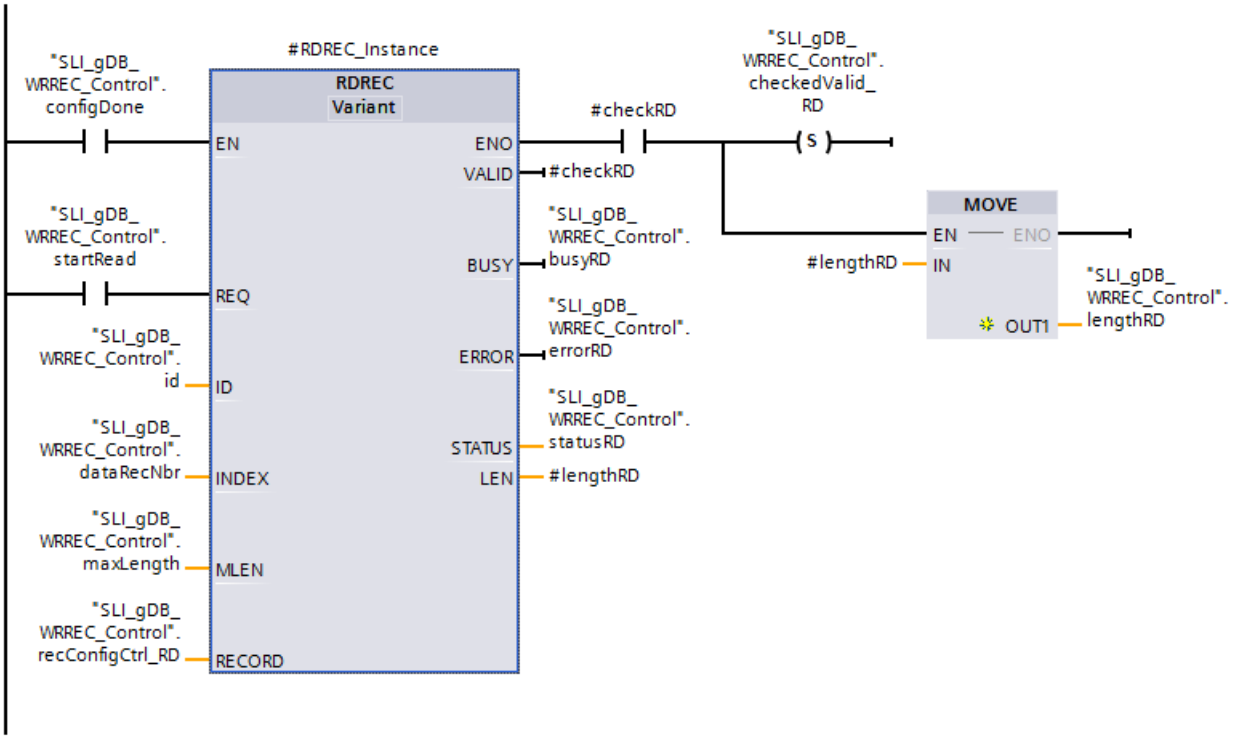
Interconnecting parameters in the startup OB



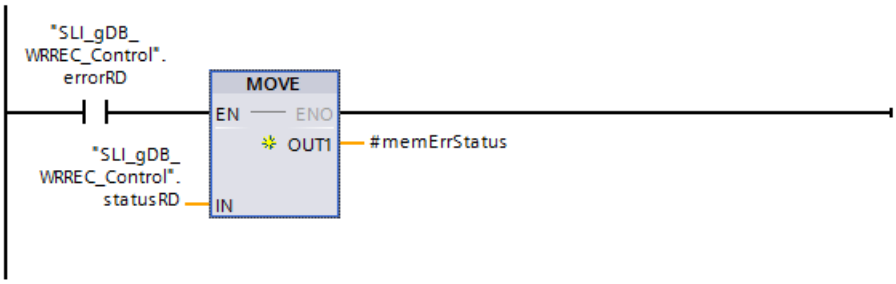
Network 1: Interconnect the parameters of the "WRREC" instruction as follows.

Network 2: Then interconnect the parameters for the error situation of WRREC.

Network 3: Then interconnect the parameters for ending WRREC.



Network 4: This is followed by interconnecting the parameters for requesting the repeated call of WRREC.



Interconnect parameters in the FB

Network 1: Interconnect the parameters of the "RDREC" instruction as follows.

Network 2: Then interconnect the parameters for the error situation of RDREC.

Network 3: Then interconnect the parameters for ending RDREC.

General parameters

You store the hardware identifier of the configuration of the CPU (“33“) via the input parameter ID (“id“). You store the control data record ("196") using the input parameter INDEX ("dataRecNbr"). According to the value of the tag maxLength" (with the value "0") the amount of data record information to be taken into account is unlimited.

Note

Loading in the CPU and processing of the program in startup.

1. To load the program, set the CPU to "STOP" mode.
2. Set the project to "Online" mode.
3. Set the CPU to "RUN" mode. The "Startup" mode is worked through.

In "Startup” mode the CPU works through the program sections located in the startup OB.

Startup OB: Result of network 1

Since the input parameter REQ supplies the signal state "TRUE", the "WRREC" instruction is started. The normally closed contact (“configDone“) has the signal state "FALSE".

The data for the control data record is stored at the RECORD (“recConfigCtrl_WR“) parameter. To improve understanding, the tags of the “recConfigCtrl_WR“ structure are represented by clear names and have the same structure as described in the system manual..

11	recConfigCtrl_WR	Struct		
12	BlockLength	USInt	8	8
13	BlockID	USInt	196	196
14	Version	USInt	4	4
15	Subversion	USInt	0	0
16	Slot_0	USInt	0	0
17	Slot_1	USInt	1	1
18	Slot_2	USInt	2	2
19	Slot_3	USInt	3	3

Over several calls, the instruction “WRREC“ writes the new data to the control data record. During processing of WRREC the output parameter BUSY ("busyWR") is set to "TRUE" and DONE ("#checkWR") to "FALSE".

A successful writing result is output as follows when processing is complete.

- The output parameter DONE ("#checkWR") is set to "TRUE" and sets the tag "checkedValid_WR" permanently to "TRUE".

The block status is displayed at the output parameter STATUS ("statusWR"). Processing takes place without errors.

SLI_gDB_WRREC_Control

	Name	Data type	Start value	Monitor value
1	Static			
2	id	HW_IO	33	16#0021
3	dataRecNbr	DInt	196	196
4	maxLength	UInt	0	0
5	configDone	Bool	false	TRUE
6	checkedValid_WR	Bool	false	TRUE
7	busyWR	Bool	false	FALSE
8	errorWR	Bool	false	FALSE
9	statusWR	DWord	16#0	16#0000_0000
10	memErrStatusWR	DWord	16#0	16#0000_0000

Startup OB: Result of network 2

If an error occurs when processing WRREC:

When “errorWR“ supplies the signal status “TRUE“, the value of the tag “statusWR“ is stored in the tag “memErrStatusWR“.

Startup OB: Result of network 3

When the instruction “WRREC“ has been executed, “statusWR“ supplies the value “16#0070_0200“. The tag "configDone" is then set to "TRUE". This ends the processing of WRREC.

Startup OB: Result of network 4

As long as the processing of the "WRREC" instruction has not yet ended ("configDone" has the value"FALSE" and "busyWR" has the value "TRUE") processing returns to network 1.

FB: Result of network 1

After processing the program sections located in the startup OB the CPU is in the “RUN“ mode.

When the input parameter EN ("configDone") supplies the signal state "TRUE", the "RDREC" instruction is released for processing. When the input parameter REQ ("startRead") returns the signal state "TRUE", the "RDREC" instruction is started.

Over several calls the "RDREC" instruction reads out the control data record and saves the data record using the parameter RECORD ("recConfigCtrl_RD").

26		recConfigCtrl_RD	Struct		
27		BlockLength	USInt	0	8
28		BlockID	USInt	0	196
29		Version	USInt	0	4
30		Subversion	USInt	0	0
31		Slot_0	USInt	0	0
32		Slot_1	USInt	0	1
33		Slot_2	USInt	0	2
34		Slot_3	USInt	0	3

The length of the read data record is stored using the output parameter LEN ("#readLength"). During processing of RDREC the output parameter BUSY ("busyRD") is set to "TRUE" and VALID ("#checkRD") to "FALSE".

A successful reading result is output as follows when processing is complete.

- The output parameter VALID ("#checkRD") is set to "TRUE". #checkRD then sets the tag "checkedValid_RD" permanently to "TRUE".
- In addition to this the value of the local tag "#lengthRD" is stored permanently in the tag "lengthRD".

The block status is displayed at the output parameter STATUS ("statusRD"). Processing takes place without errors.

20		startRead	Bool	false	FALSE
21		checkedValid_RD	Bool	false	TRUE
22		lengthRD	UInt	0	8
23		busyRD	Bool	false	FALSE
24		errorRD	Bool	false	FALSE
25		statusRD	DWord	16#0	16#0070_0000

FB: Result of network 2

If an error occurs when processing RDREC:

When “errorRD“ supplies the signal status “TRUE“, the value of the tag “statusRD“ is stored in the local tag “#memErrStatus“.

FB: Result of network 3

When the instruction “RDREC“ has been executed and has checked the data, “#checkRD“ supplies the value “TRUE“. The tag "startRead" is then set to "FALSE". Execution of the “RDREC“ instruction is then ended.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

WRREC: Write data record (Page 3596)

RDREC: Read data record (Page 3578)

GETIO: Read process image (S7-1200, S7-1500)

Description

You use the instruction "GETIO" to consistently read out all inputs of a DP standard slave/ PROFINET IO device. The instruction "GETIO" calls the instruction "DPRD_DAT (Page 3700)". If there was no error during the data transmission, the data that has been read is entered in the destination area indicated by INPUTS .

The destination area must have the same length that you configured for the selected component.

If you read from a DP standard slave with a modular configuration or with several DP identifiers, you only access the data of one component/DP identifier at the configured start address with a "GETIO" call.

Parameter

The following table shows the parameters of the "GETIO" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUB-MODULE	I, Q, M, D, L or constant	Hardware ID of the DP standard slave / PROFINET IO device.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPRD_DAT (Page 3700)" in the form DW#16#40xxxx00.
LEN	Output	INT	I, Q, M, D, L	Amount of data read in bytes
INPUTS	InOut	VARIANT	I, Q, M, D, L	Destination area for the read data. It must have the same length as the range that you configured for the selected DP standard slave / PROFINET IO device. Only the data type BYTE is valid.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

See also: DPRD_DAT: Read consistent data of a DP standard slave (Page 3700)

Example

You will find the example here: Program example for GETIO & SETIO (Page 3617).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

SETIO: Transfer process image (S7-1200, S7-1500)

Description

Transfer the data using the SETIO instruction. The source area of the transfer is defined using the OUTPUTS parameter. The data is transferred in a consistent state to the addressed DP standard slave
/ PROFINET IO device. If you have configured the relevant address area of the DP standard slave / PROFINET IO device as a consistent range in a process image, the data is transferred to the process image. "SETIO" calls the "DPWR_DAT (Page 3702)" instruction during this transfer.

The source range must have the same length that you configured for the selected component.

In the case of a DP standard slave / PROFINET IO device with modular configuration or with several DP identifiers, you can only access one DP identifier / component per "SETIO" call.

Parameter

The following table shows the parameters of the "SETIO" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUBMOD-ULE	I, Q, M, D, L or con-stant	Hardware ID of the DP standard slave / PROFINET IO device.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPWR_DAT (Page 3702)" in the form DW#16#40xxxx00.
OUTPUTS	InOut	VARIANT	I, Q, M, D, L	Source range for the data to be written. It must have the same length as the range that you configured for the selected DP standard slave / PROFINET IO device. Only the data type BYTE is valid.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

See also: DPWR_DAT: Write consistent data of a DP standard slave (Page 3702)

Example

You will find the example here: Program example for GETIO & SETIO (Page 3617).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Program example for GETIO & SETIO (S7-1200, S7-1500)

Introduction

In the following example, you read out the channels of a digital input module via GETIO and write new values to the channels of a digital output module via SETIO. You then read out the changes via GETIO and via the digital input module.

Requirements

- An IO device/DP slave is created with a digital input module and a digital output module.

  Note
  Change with SETIO, read out changes with GETIO

  The digital input module must be connected to the digital output module in order that the written value can be read via SETIO using GETIO

- To store the data, create nine tags and the two structures "readinputs" and "writeOutputs" in a global data block.
  Use the tag "id_Read" to store the hardware identifier of the digital input module. Use the tag "id_Write" to store the hardware identifier of the digital output module.

  Note
  Find hardware identifier

  Use "PLC tags > System constants" to find the hardware identifier. For example, for the digital input module, search for "Local~<Name of the DI module>", with the data type "HW_Submodule". The associated cell "value" contains the hardware identifier.

SLI_gDB_GETIO

	Name	Data type	Start value
1	Static		
2	id_Read	HW_SUBMODULE	257
3	executeRead	Bool	false
4	readInputs	Struct	
5	Channel_0-7	Array[0..7] of Bool	
6	Channel_8-15	Array[0..7] of Bool	
7	Channel_16-23	Array[0..7] of Bool	
8	Channel_24-31	Array[0..7] of Bool	
9	statusRead	DWord	16#0
10	lengthRead	Int	0
11	doneRead	Bool	false
12	id_Write	HW_SUBMODULE	258
13	executeWrite	Bool	false
14	writeOutputs	Struct	
15	Channel_0-7	Array[0..7] of Bool	
16	Channel_8-15	Array[0..7] of Bool	
17	Channel_16-23	Array[0..7] of Bool	
18	Channel_24-31	Array[0..7] of Bool	
19	statusWrite	DWord	16#0
20	doneWrite	Bool	false

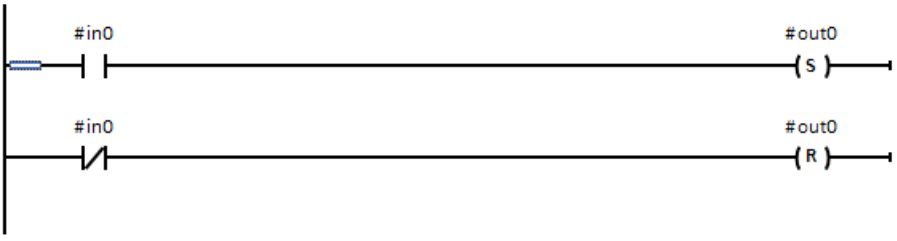
- To forward the data, create the following local tags in an "SLI_FB_GETIO_SETIO" FB.

7	Static			
8	GETIO_Instance	GETIO		
9	SETIO_Instance	SETIO		
10	readBYTE	Struct		Non-retain
11	Channel_0-7	Byte	16#0	Non-retain
12	Channel_8-15	Byte	16#0	Non-retain
13	Channel_16-23	Byte	16#0	Non-retain
14	Channel_24-31	Byte	16#0	Non-retain
15	writeBYTE	Struct		Non-retain
16	Channel_0-7	Byte	16#0	Non-retain
17	Channel_8-15	Byte	16#0	Non-retain
18	Channel_16-23	Byte	16#0	Non-retain
19	Channel_24-31	Byte	16#0	Non-retain

- To change the channel states, set the following bits (channel 1 and 2) in the global data block to "TRUE":

14	writeOutputs	Struct	
15	Channel_0-7	Array[0..7] of Bool	
16	Channel_0-7[0]	Bool	false
17	Channel_0-7[1]	Bool	1
18	Channel_0-7[2]	Bool	1
19	Channel_0-7[3]	Bool	false
20	Channel_0-7[4]	Bool	false
21	Channel_0-7[5]	Bool	false
22	Channel_0-7[6]	Bool	false
23	Channel_0-7[7]	Bool	false

Interconnect parameters: "SLI_itemiseByte_gsIO" FC

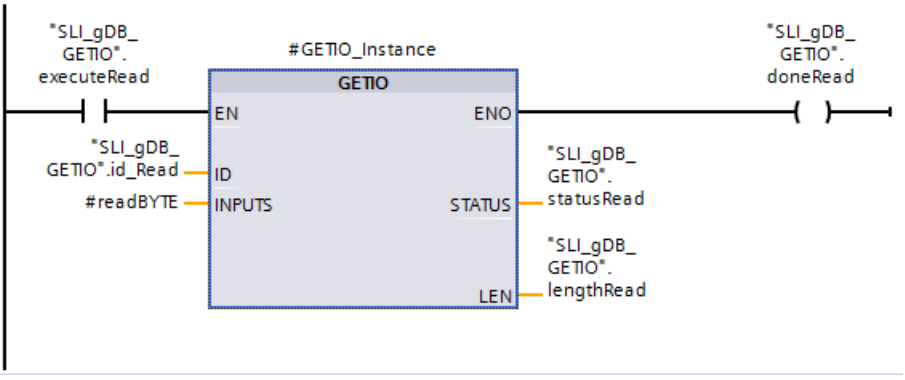


To transfer the values of a bit sequence (0..7) create the FC "SLI_itemiseByte_gsIO".

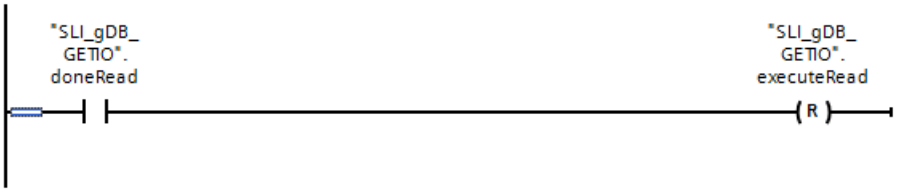
Create the following local tags in it.

SLI_itemiseByte_gsIO

		Name	Data type
1		Input	
2		in0	Bool
3		in1	Bool
4		in2	Bool
5		in3	Bool
6		in4	Bool
7		in5	Bool
8		in6	Bool
9		in7	Bool
10		Output	
11		out0	Bool
12		out1	Bool
13		out2	Bool
14		out3	Bool
15		out4	Bool
16		out5	Bool
17		out6	Bool
18		out7	Bool

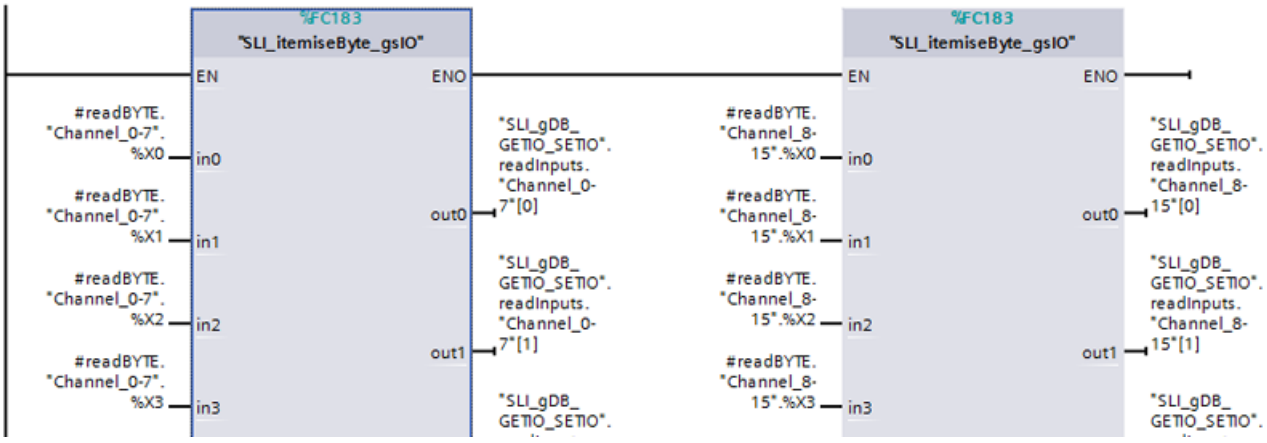


Network 1: According to the example of network 1, create interconnections for all bits (0..7).

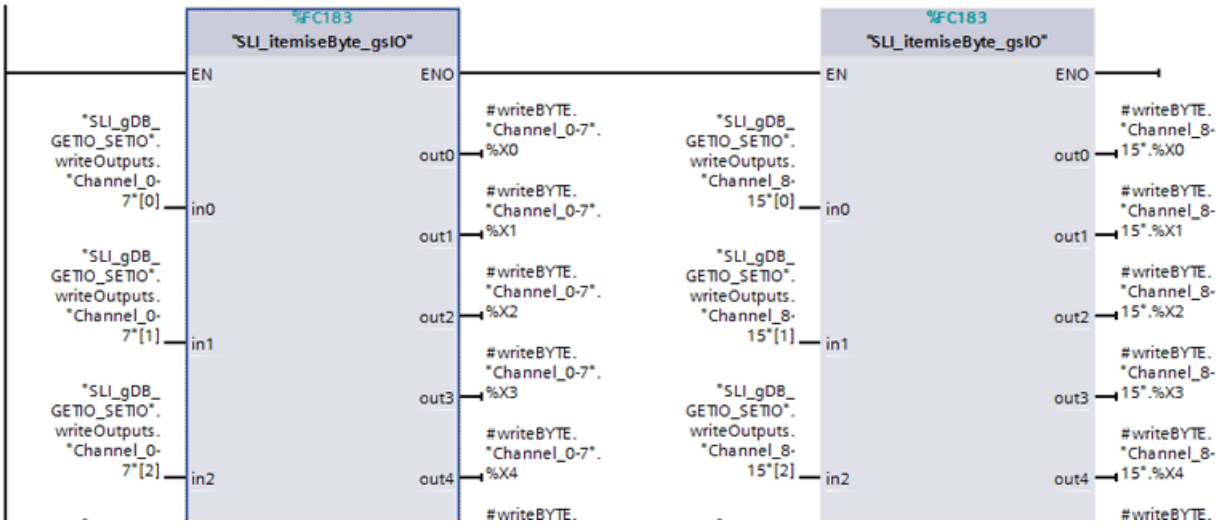


Interconnect parameters: "SLI_FB_GETIO_SETIO" FB

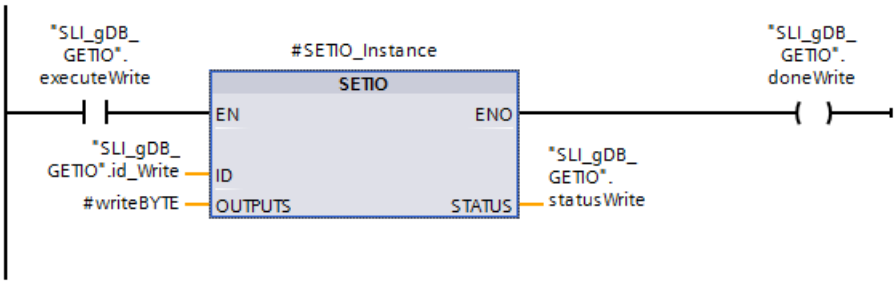
Create the following interconnections in the "SLI_FB_GETIO_SETIO" FB. On the IO device/ DP slave, then call the FB "SLI_FB_GETIO_SETIO" in a program cycle OB (OB1).



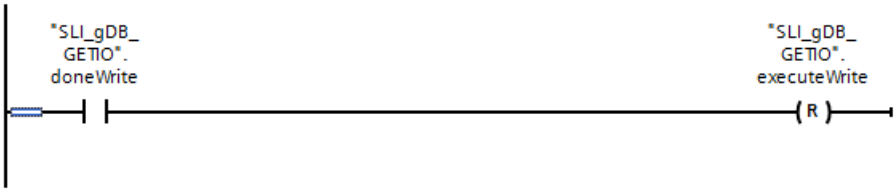
Network 1: Interconnect the parameters of the "GETIO" instruction as follows.



Network 2: Close the instruction "GETIO" as follows.

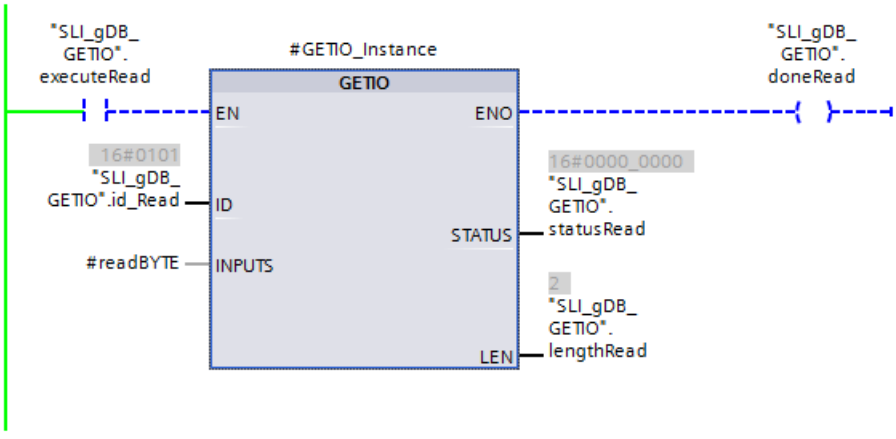


Network 3: Create the interconnections according to the following example to convert the channel values of GETIO. All inputs and outputs (0..7) of the "SLI_itemiseByte_gsIO" FC are interconnected in this case.



Network 4: Create the interconnections according to the following example to convert the channel values of SETIO. All inputs and outputs (0..7) of the "SLI_itemiseByte_gsIO" FC are interconnected in this case.

Network 5: Interconnect the parameters of the "SETIO" instruction as follows.



Network 6: Close the instruction "SETIO" as follows.

Result of network 1 (GETIO)

When the input parameter EN ("executeRead") returns the signal state "TRUE", the "GETIO" instruction is started. The instruction "GETIO" calls the input module via the input parameter ID ("id_Read"). The channels of the input module are read out via the input parameter INPUTS ("#readBYTE"). The length of the read channels in BYTE is recorded at the output parameter LEN ("lengthRead"). The value "2" references 16 input channels.

The block status is displayed at the output parameter STATUS ("statusRead"). Processing takes place without errors.

Result of network 2 (GETIO)

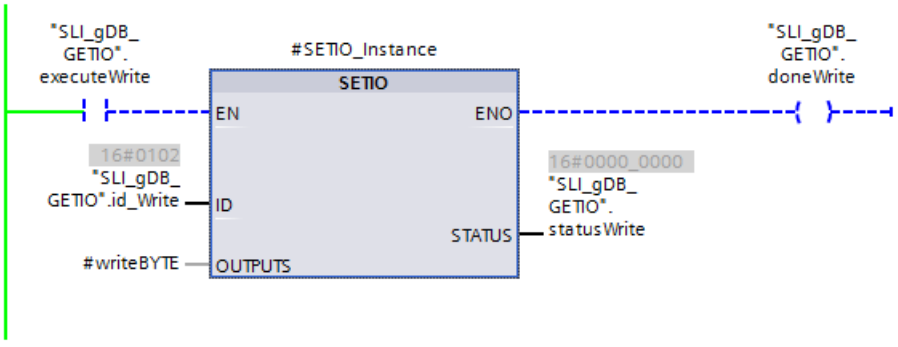
When the instruction "GETIO" has been executed, the output parameter ENO ("doneRead") returns the signal state "TRUE". After this, the resetter sets the tag "executeRead" to "FALSE" and ends the processing of "GETIO".

Result of network 3 (GETIO)

Using MOVE instructions and the FC SLI_itemiseByte_gsIO, the structure "#readBYTE" transfers the values of the tags to the tags of the structure "readInputs". The values of the channels 0 to 7 and 8 to 15 are hereby converted from BYTE to array of BOOL.

To improve understanding, the tags of the "readInputs" structure are represented by descriptive names.

Result of network 4 (SETIO)



Using MOVE instructions and the FC SLI_itemiseByte_gsIO, the structure "writeOutputs" transfers the values of the tags to the tags of the structure "#writeBYTE". The values of the channels 0 to 7 and 8 to 15 are converted from array of BOOL to BYTE.

To improve understanding, the tags of the "writeOutputs" structure are represented by descriptive names.

Result of network 5 (SETIO)

When the input parameter EN ("executeWrite") returns the signal state "TRUE", the "SETIO" instruction is started. The instruction "SETIO" calls the output module via the input parameter ID ("id_Write"). New values are written to the channels of the output module via the input parameter OUTPUTS ("#writeBYTE").

The block status is displayed at the output parameter STATUS ("statusWrite"). Processing takes place without errors.

Result of network 6 (SETIO)

When the instruction "SETIO" has been executed, the output parameter ENO ("doneWrite") returns the signal state "TRUE". After this, the resetter sets the tag "executeWrite" to "FALSE" and ends the processing of "SETIO".

Result of reprocessing of GETIO

If the tag "executeRead" is reset to "TRUE", the structure "readInputs" shows the new values on the channels of the input module after the execution of GETIO. The channels 1 and 2 ("Channel_0-7[1]..[2]") now return the signal state "TRUE".

4	readInputs	Struct		
5	Channel_0-7	Array[0..7] of Bool		
6	Channel_0-7[0]	Bool	false	FALSE
7	Channel_0-7[1]	Bool	false	TRUE
8	Channel_0-7[2]	Bool	false	TRUE
9	Channel_0-7[3]	Bool	false	FALSE
10	Channel_0-7[4]	Bool	false	FALSE
11	Channel_0-7[5]	Bool	false	FALSE
12	Channel_0-7[6]	Bool	false	FALSE
13	Channel_0-7[7]	Bool	false	FALSE
14	Channel_8-15	Array[0..7] of Bool		
15	Channel_16-23	Array[0..7] of Bool		
16	Channel_24-31	Array[0..7] of Bool		

Note

Changing the signal state of a channel

If a value is already assigned to a channel on which a signal state is to be changed (for example by a PLC tag), this pre-assignment can make a change by SETIO invalid. Make sure that the signal state of a channel to be changed is not already determined by other factors.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

See also

GETIO: Read process image (Page 3615)

SETIO: Transfer process image (Page 3616)

GETIO_PART: Read process image area (S7-1200, S7-1500)

Description

You use the instruction "GETIO_PART" to consistently read out a related part of the inputs of an IO module. "GETIO_PART" calls the instruction "DPRD_DAT (Page 3700)".

Use the ID input parameter to select the IO module by means of the hardware ID.

You use the OFFSET and LEN parameters to specify the portion of the process image area to be read. If the input area spanned by OFFSET and LEN is not completely covered by the module, the block returns the error code DW#16#40**80B7**00.

The length of the destination area must be larger than or equal to the amount of bytes to be read:

- If there was no error during the data transmission, ERROR receives the value FALSE. The data that is read is written to the destination area defined at the INPUTS parameter.
- If there was an error during the data transmission, ERROR receives the value TRUE. The STATUS parameter receives the error information from "DPRD_DAT".
- If the destination area is greater than LEN, then the first LEN bytes of the destination area will be written. ERROR receives the value FALSE.

Parameter

The following table shows the parameters of the "GETIO_PART" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUBMOD-ULE	I, Q, M, D, L or constant	Hardware identifier of the module
OFFSET	Input	INT	I, Q, M, D, L or constant	Number of the first byte to be read in the process image for the component (smallest possible value: 0).
LEN	Input	INT	I, Q, M, D, L or constant	Number of bytes to be read.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPRD_DAT" in the form DW#16#40xxxx00, if ERROR = TRUE.
ERROR	Output	BOOL	I, Q, M, D, L	Error display: ERROR = TRUE if an error occurs when "DPRD_DAT" is called.
INPUTS	InOut	VARIANT	I, Q, M, D, L	Destination area for read data: If the destination area is greater than LEN, the first LEN bytes of the destination area are written.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

See "RET_VAL" parameter of the "DPRD_DAT (Page 3700)" instruction.

Example

You will find the example here: Program example for GETIO_PART & SETIO_PART (Page 3627).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

SETIO_PART: Transfer process image area (S7-1200, S7-1500)

Description

You can use the "SETIO_PART" instruction to consistently write data from the source area spanned by OUTPUTS to the outputs of an IO module. "SETIO_PART" calls the instruction "DPWR_DAT (Page 3702)".

With the input parameter ID you select the I/O module based on the hardware identified. With the parameters OFFSET and LEN you specify the portion of the process image area to be written for the component addressed by ID. If the output area spanned by OFFSET and LEN is not completely covered by the module, the block returns the error code DW#16#40**80B7**00.

The length of the destination area must be larger than or equal to the amount of bytes to be read:

- If there was no error during the data transmission, ERROR receives the value FALSE.
- If there was an error during the data transmission, ERROR receives the value TRUE, and STATUS receives the error information of "DPWR_DAT".
- If the source area is greater than LEN, the first LEN bytes from OUTPUTS are transferred. ERROR receives the value FALSE.

Parameters

The following table shows the parameters of the "SETIO_PART" instruction:

Parameter	Declaration	Data type	Memory area	Description
ID	Input	HW_SUB-MODULE	I, Q, M, D, L or constant	Hardware identifier of the IO module.
OFFSET	Input	INT	I, Q, M, D, L or constant	Number of the first byte to be written in the process image for the component (smallest possible value: 0).
LEN	Input	INT	I, Q, M, D, L or constant	Number of bytes to be written.
STATUS	Output	DWORD	I, Q, M, D, L	Contains the error information of "DPWR_DAT" in the form DW#16#40xxxx00, if ERROR = TRUE.
ERROR	Output	BOOL	I, Q, M, D, L	Error display: ERROR = TRUE if an error occurs when "DPWR_DAT" is called.
OUTPUTS	InOut	VARIANT	I, Q, M, D, L	Source range for the data to be written: If the source area is greater than LEN, the first LEN bytes are transferred from OUT-PUTS.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

ERROR and STATUS parameters

See instruction "DPWR_DAT (Page 3702)".

Example

You will find the example here: Program example for GETIO_PART & SETIO_PART (Page 3627).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Program example for GETIO_PART & SETIO_PART (S7-1200, S7-1500)

Introduction

In the following example, you read out the channels of a digital input module via GETIO_PART and write new values to some of the channels of a digital output module via SETIO_PART. You then read out the changes via GETIO_PART and via the digital input module.

Requirements

- An IO device/DP slave is created with a digital input module and a digital output module.

  Note
  Change with SETIO_PART, read out changes with GETIO_PART

  The digital input module must be connected to the digital output module in order that the written value can be read via SETIO_PART using GETIO_PART

- To store the data, create 14 tags and the two structures "readinputs" and "writeOutputs" in a global data block.
  Use the tag "id_Read" to store the hardware identifier of the digital input module. Use the tag "id_Write" to store the hardware identifier of the digital output module.

  Note
  Find hardware identifier

  Use "PLC tags > System constants" to find the hardware identifier. For example, for the digital input module, search for "Local~<Name of the DI module>", with the data type "HW_Submodule". The associated cell "value" contains the hardware identifier.

SLI_gDB_GETIO_SETIO_PART

	Name	Data type	Start value
1	Static		
2	id_Read	HW_SUBMODULE	257
3	executeRead	Bool	false
4	firstByteRead	Int	0
5	maxLengthRead	Int	2
6	readInputs	Struct	
7	Channel_0-7	Array[0..7] of Bool	
8	Channel_8-15	Array[0..7] of Bool	
9	Channel_16-23	Array[0..7] of Bool	
10	Channel_24-31	Array[0..7] of Bool	
11	errorRead	Bool	false
12	statusRead	DWord	16#0
13	doneRead	Bool	false
14	id_Write	HW_SUBMODULE	258
15	executeWrite	Bool	false
16	firstByteWrite	Int	0
17	maxLengthWrite	Int	1
18	writeOutputs	Struct	
19	Channel_0-7	Array[0..7] of Bool	
20	Channel_8-15	Array[0..7] of Bool	
21	Channel_16-23	Array[0..7] of Bool	
22	Channel_24-31	Array[0..7] of Bool	
23	errorWrite	Bool	false
24	statusWrite	DWord	16#0
25	doneWrite	Bool	false

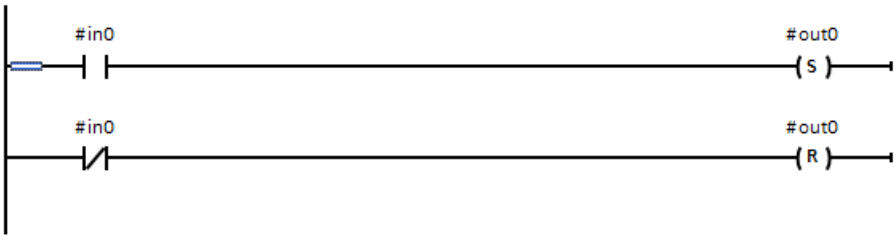
- To change the channel states, set the following bits (for BYTE 0 and BYTE 1) to "TRUE" in the global data block:

14	writeOutputs	Struct	
15	Channel_0-7	Array[0..7] of Bool	
16	Channel_0-7[0]	Bool	false
17	Channel_0-7[1]	Bool	1
18	Channel_0-7[2]	Bool	1
19	Channel_0-7[3]	Bool	false
20	Channel_0-7[4]	Bool	false
21	Channel_0-7[5]	Bool	false
22	Channel_0-7[6]	Bool	false
23	Channel_0-7[7]	Bool	false
24	Channel_8-15	Array[0..7] of Bool	
25	Channel_8-15[0]	Bool	false
26	Channel_8-15[1]	Bool	1

- To forward the data, create the following local tags in an "SLI_FB_GETIO_SETIO_PART" FB.

7	Static			
8	GETIO_PART_Instance	GETIO_PART		
9	SETIO_PART_Instance	SETIO_PART		
10	readBYTE	Struct		Non-retain
11	writeBYTE	Struct		Non-retain

Interconnect parameters: "SLI_itemiseByte_gpspIO" FC

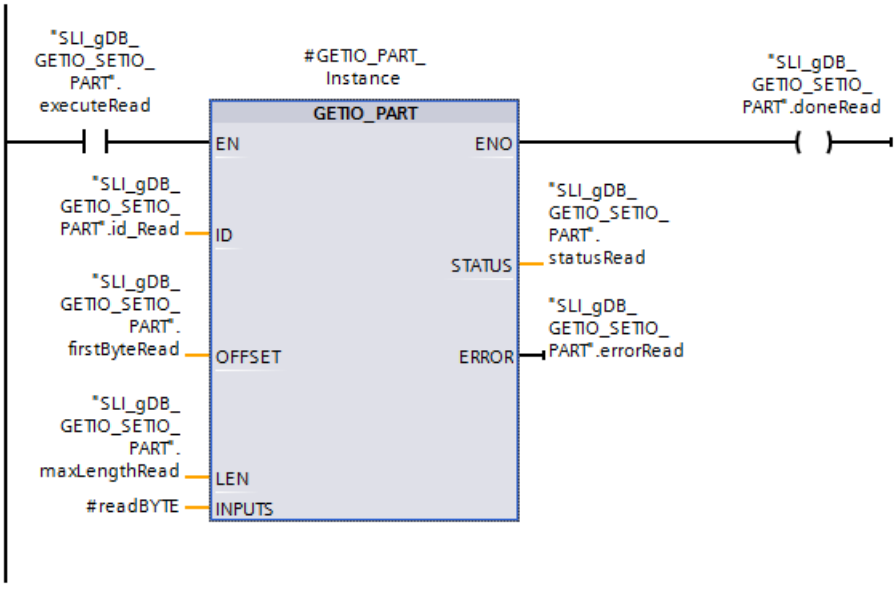


To transfer the values of a bit sequence (0..7) create the FC "SLI_itemiseByte_gpspIO".

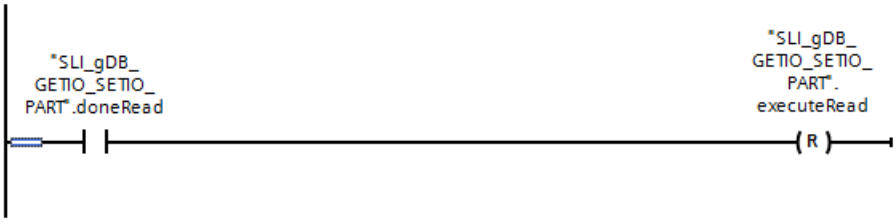
Create the following local tags in it.

SLI_itemiseByte_gpspIO

	Name	Data type
1	Input	
2	in0	Bool
3	in1	Bool
4	in2	Bool
5	in3	Bool
6	in4	Bool
7	in5	Bool
8	in6	Bool
9	in7	Bool
10	Output	
11	out0	Bool
12	out1	Bool
13	out2	Bool
14	out3	Bool
15	out4	Bool
16	out5	Bool
17	out6	Bool
18	out7	Bool

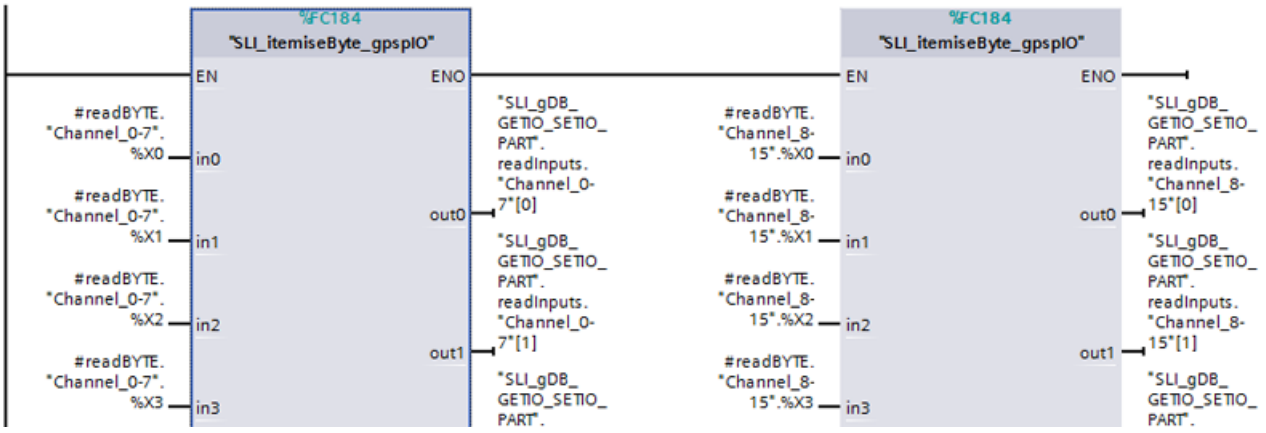


Network 1: According to the example of network 1, create interconnections for all bits (0..7).

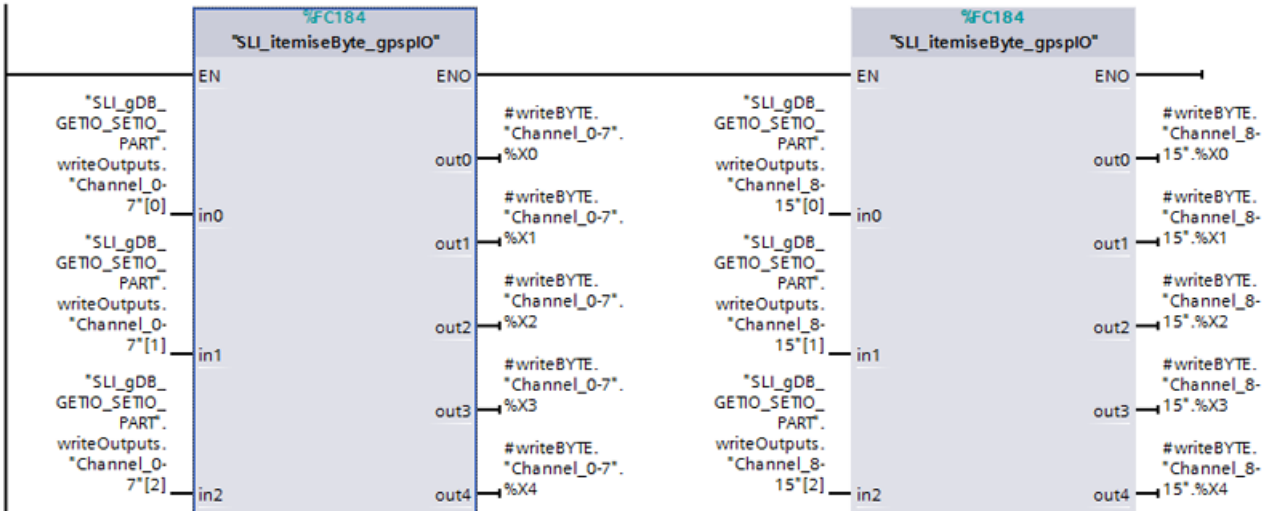


Interconnect parameters: "SLI_FB_GETIO_SETIO_PART" FB

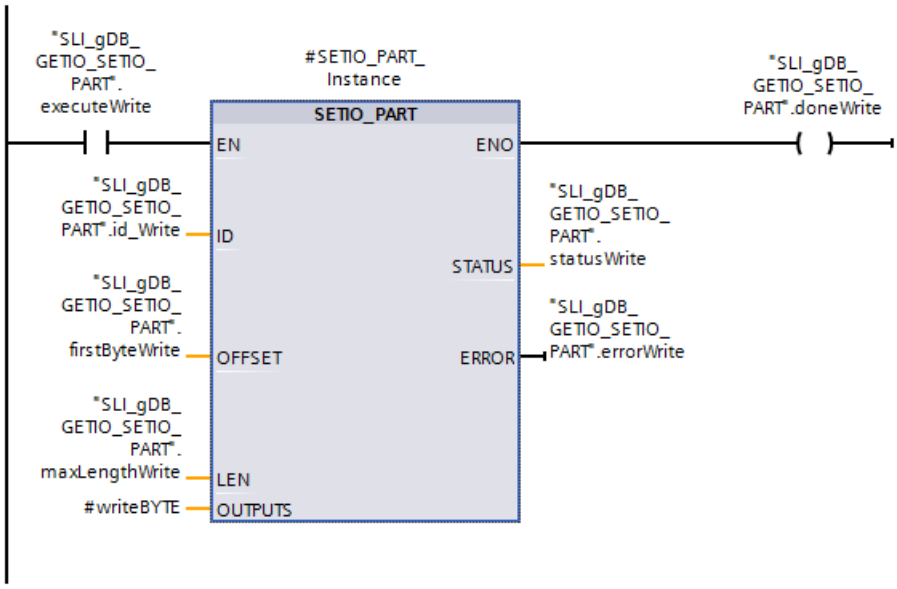
Create the following interconnections in the "SLI_FB_GETIO_SETIO_PART" FB. On the IO device/DP slave, then call the FB "SLI_FB_GETIO_SETIO_PART" in a program cycle OB (OB1).



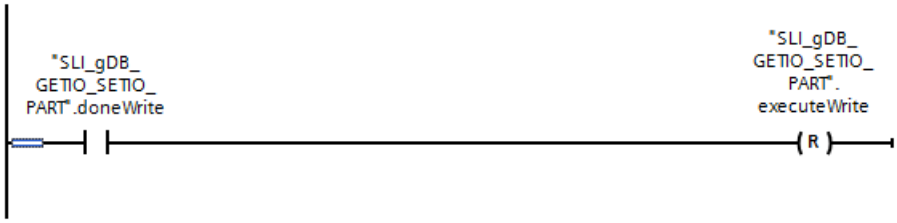
Network 1: Interconnect the parameters of the "GETIO_PART" instruction as follows.



Network 2: Close the instruction "GETIO_PART" as follows.



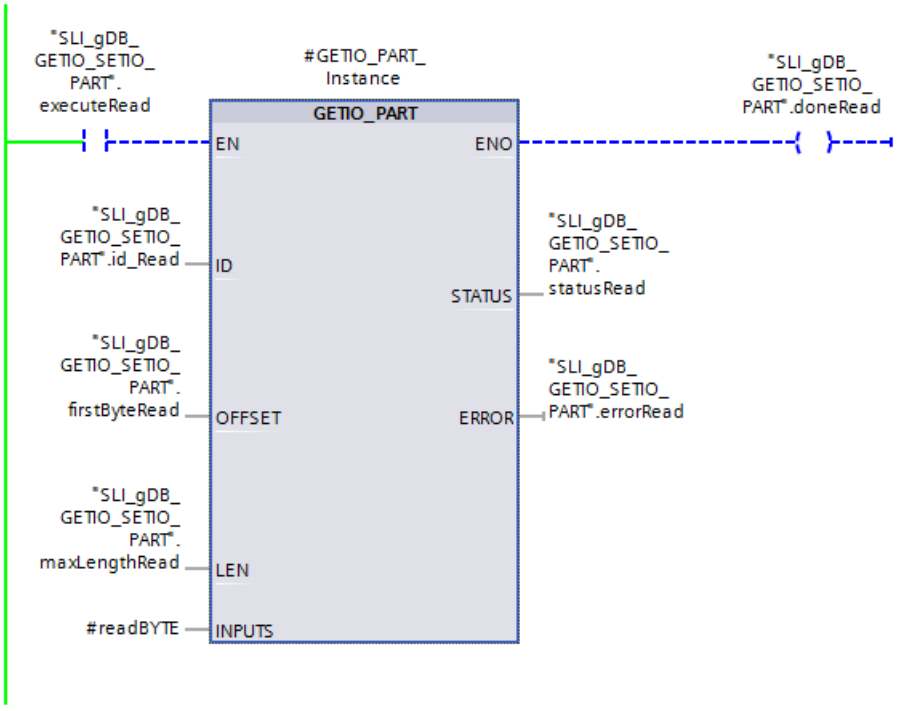
Network 3: Create the interconnections according to the following example to convert the channel values of GETIO_PART. All inputs and outputs (0..7) of the "SLI_itemiseByte_gpspIO" FC are interconnected in this case.



Network 4: Create the interconnections according to the following example to convert the channel values of SETIO_PART. All inputs and outputs (0..7) of the "SLI_itemiseByte_gpspIO" FC are interconnected in this case.

Network 5: Interconnect the parameters of the "SETIO_PART" instruction as follows.

Network 6: Close the instruction "SETIO_PART" as follows.



Result of network 1 (GETIO_PART)

When the input parameter EN ("executeRead") returns the signal state "TRUE", the "GETIO_PART" instruction is started. The instruction "GETIO_PART" calls the input module via the input parameter ID ("id_Read"). The channels of the input module are read out via the input parameter INPUTS ("#readBYTE").

Through the input parameter OFFSET ("firstByteRead") with the value "0", the instruction "GETIO_PART" starts to read channels of the input module starting from the "BYTE 0". Two BYTE (16 channels) are read out according to the value "2" of the input parameter LEN ("maxLengthRead"). In this example, this value corresponds to the channels 0 to 15.

The block status is displayed at the output parameter STATUS ("statusRead") and ERROR ("errorRead"). Processing takes place without errors.

Result of network 2 (GETIO_PART)

When the instruction "GETIO_PART" has been executed, the output parameter ENO ("doneRead") returns the signal state "TRUE". After this, the resetter sets the tag "executeRead" to "FALSE" and ends the processing of "GETIO_PART".

SLI_gDB_GETIO_SETIO_PART

	Name	Data type	Start value	Monitor value
1	Static			
2	id_Read	HW_SUBMODULE	257	16#0101
3	executeRead	Bool	false	FALSE
4	firstByteRead	Int	0	0
5	maxLengthRead	Int	2	2
6	readInputs	Struct		
7	errorRead	Bool	false	FALSE
8	statusRead	DWord	16#0	16#0000_0000
9	doneRead	Bool	false	FALSE

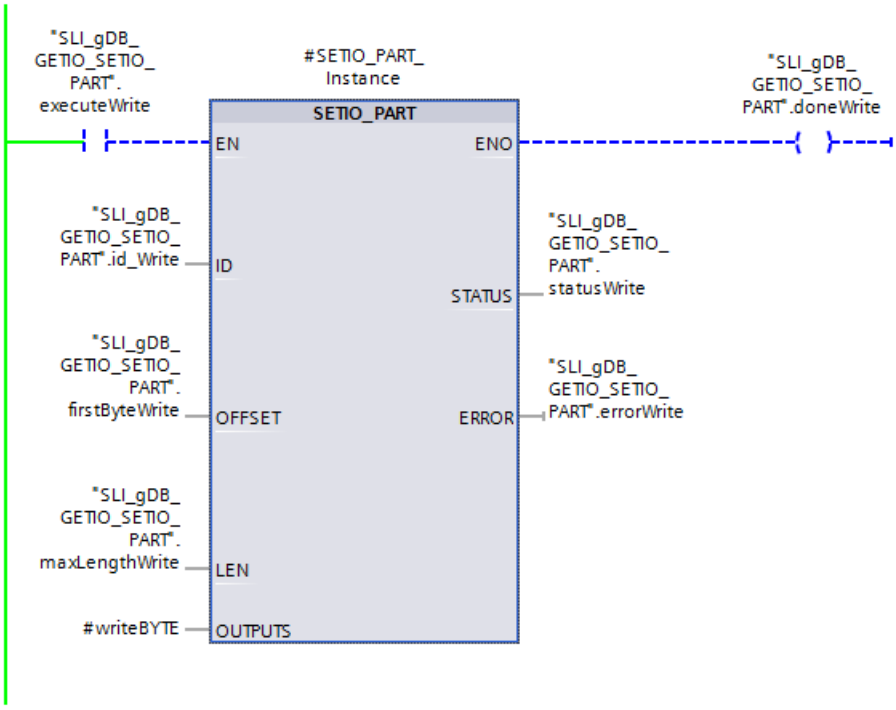
Result of network 3 (GETIO_PART)

Using MOVE instructions and the FC SLI_itemiseByte_gpspIO, the structure "#readBYTE" transfers the values of the tags to the tags of the structure "readInputs". The values of the channels 0 to 7 and 8 to 15 are hereby converted from BYTE to array of BOOL.

To improve understanding, the tags of the "readInputs" structure are represented by descriptive names.

Result of network 4 (SETIO_PART)

Using MOVE instructions and the FC SLI_itemiseByte_gpspIO, the structure "writeOutputs" transfers the values of the tags to the tags of the structure "#writeBYTE". The values of the channels 0 to 7 and 8 to 15 are converted from array of BOOL to BYTE.



To improve understanding, the tags of the "writeOutputs" structure are represented by descriptive names.

Result of network 5 (SETIO_PART)

When the input parameter EN ("executeWrite") returns the signal state "TRUE", the "SETIO_PART" instruction is started. The instruction "SETIO_PART" calls the output module via the input parameter ID ("id_Write"). New values are written to the channels of the output module via the input parameter OUTPUTS ("#writeBYTE").

Through the input parameter OFFSET ("firstByteWrite") with the value "0", the instruction "SETIO_PART" starts to write to channels of the output module starting from the "BYTE 0". Only one BYTE (8 channels) is written according to the value "1" of the input parameter LEN ("maxLengthWrite"). In this example, this value corresponds to the channels 0 to 7. The channel 9 set to the value "TRUE" (see "writeOutputs", "Channel_8-15[1]") is thus not taken into consideration during writing to the channels of the output module.

The block status is displayed at the output parameter STATUS ("statusWrite") and ERROR ("errorWrite"). Processing takes place without errors.

Result of network 6 (SETIO_PART)

When the instruction "SETIO_PART" has been executed, the output parameter ENO ("doneWrite") returns the signal state "TRUE". After this, the resetter sets the tag "executeWrite" to "FALSE" and ends the processing of "SETIO_PART".

10	id_Write	HW_SUBMODULE	258	16#0102
11	executeWrite	Bool	false	FALSE
12	firstByteWrite	Int	0	0
13	maxLengthWrite	Int	1	1
14	writeOutputs	Struct		
15	errorWrite	Bool	false	FALSE
16	statusWrite	DWord	16#0	16#0000_0000
17	doneWrite	Bool	false	FALSE

Result of reprocessing of GETIO_PART

If the tag "executeRead" is reset to "TRUE", the structure "readInputs" shows the new values on the channels of the input module after the execution of GETIO_PART. A change affects only the channels 0 to 7 according to the values of the tags "firstByteWrite" and "maxLengthWrite". The channels 1 and 2 ("Channel_0-7[1]..[2]") now return the signal state "TRUE". The signal state of channel 9 ("Channel_8-15[1]") is unchanged.

6	readInputs	Struct		
7	Channel_0-7	Array[0..7] of Bool		
8	Channel_0-7[0]	Bool	false	FALSE
9	Channel_0-7[1]	Bool	false	TRUE
10	Channel_0-7[2]	Bool	false	TRUE
11	Channel_0-7[3]	Bool	false	FALSE
12	Channel_0-7[4]	Bool	false	FALSE
13	Channel_0-7[5]	Bool	false	FALSE
14	Channel_0-7[6]	Bool	false	FALSE
15	Channel_0-7[7]	Bool	false	FALSE
16	Channel_8-15	Array[0..7] of Bool		
17	Channel_8-15[0]	Bool	false	FALSE
18	Channel_8-15[1]	Bool	false	FALSE

Note

Changing the signal state of a channel

If a value is already assigned to a channel on which a signal state is to be changed (for example by a PLC tag), this pre-assignment can make a change by SETIO_PART invalid. Make sure that the signal state of a channel to be changed is not already determined by other factors.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

GETIO_PART: Read process image area (Page 3624)

SETIO_PART: Transfer process image area (Page 3626)

RALRM: Receive interrupt (S7-1200, S7-1500)

Description RALRM (S7-1200, S7-1500)

Description

The instruction receives an interrupt with all corresponding information from an I/O module (centralized configuration) or from a module of a DP slave or PROFINET IO device. This information is made available at its output parameters.

The information in the output parameters contains the start information of the called OB as well as information of the interrupt source.

The configuration of the data structure of the target range AINFO corresponds to that for a central configuration of the PROFINET IO data structure.

Call "RALRM" only within the interrupt OB started by the CPU operating system as a result of the I/O interrupt that is to be examined.

Note

If you call "RALRM" in an OB whose start event is not an I/O interrupt, the instruction will provide correspondingly reduced information in its outputs.
Make sure to use different instance DBs when you call "RALRM" in different OBs. If you evaluate data resulting from an "RALRM" call outside of the associated interrupt OB, use a separate instance DB per OB start event.

Note

The interface of the "RALRM" instruction is identical to that in the "RALRM" FB defined in the standard "PROFIBUS and PROFINET Guideline Communication Function Blocks on PROFIBUS DP and PROFINET IO".

Calling RALRM

RALRM" can be called in three operating modes (MODE parameter). These are explained in the table below.

MODE	RALRM ...
0	... shows the component that triggered the interrupt in the output parameter ID and sets the output parameter NEW to TRUE.
1	... writes all output parameters, regardless of the component triggering the interrupt.
2	... checks whether the component specified in the F_ID input parameter has triggered the interrupt. • If not, NEW = FALSE • If yes, NEW = TRUE and all other output parameters are written.

Parameters

The following table shows the parameters of the "RALRM" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module. The number is assigned automatically and is stored in the hardware configuration properties of the component or interface.
MLEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the interrupt information to be received in bytes. With MLEN = 0, all data specified at the AINFO parameter are read.
NEW	Output	BOOL	I, Q, M, D, L	A new interrupt was received.
STATUS (Page 3638)	Output	DWORD	I, Q, M, D, L	Error code
ID	Output	HW_IO	I, Q, M, D, L	Hardware identifier of the module from which the interrupt was received.
LEN	Output	UINT	I, Q, M, D, L	Length of the received interrupt information
TINFO (Page 3642)	InOut	VARIANT	D, L	Target range for OB start and management information
AINFO (Page 3659)	InOut	VARIANT	I, Q, M, D, L	Target range for header information and additional interrupt information For AINFO , provide a length of at least MLEN bytes.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

If you select a target range (Page 3667)TINFO or AINFO that is too short, RALRM does not enter the full information.

Diagnostics for Windows applications

It may be possible that Windows can no longer send a signal to the CPU in case of a bluescreen.

For additional information, call the instruction "RALRM" (SFB54) with the diagnostic interrupt (OB82).

The "RALRM" instruction is called with the following input parameters:

Input	Type	Value
MODE	INT	2
F_ID	HW_IO	59 (Host Interface RID)
MLEN	UINT	0
TINFO	VARIANT	Address for each area of 54 bytes
AINFO	VARIANT	Address for each area of 54 bytes

Bytes 50 and 51 can be used by the "AINFO" parameter to receive additional information:

- 0xA1: Bluescreen
- 0xA2: Windows running
- 0xA3: Windows not running

Example

You can find the example here: Program example for RALRM (Page 3668).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

Parameter STATUS (S7-1200, S7-1500)

Description

The STATUS output parameter contains error information. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	• B#16#00, if no error • Function ID from DPV1-PDU: In the event of an error, B#16#80 is output (in the event of an error reading a data record B#16#DE and writing a data record B#16#DF). If no DPV1 protocol element is used, then B#16#C0 will be output.
STATUS[2]	Error_Decode	Location of the error ID
STATUS[3]	Error_Code_1	Error ID
STATUS[4]	Error_Code_2	Manufacturer-specific extension of the error ID

Field element STATUS[2]

STATUS[2] can have the following values:

Error_Decode (B#16#...)	Source	Meaning
00 to 7F	CPU	No error or no warning
80	DPV1	Error according to IEC 61158-6
81 to 8F	CPU	B#16#8x shows an error in the xth call parameter of the instruction.
FE, FF	DP profile	Profile-specific error

Field element STATUS[3]

STATUS[3] can have the following values:

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
00	00		No error, no warning
70	00	reserved, reject	Initial call; no active data record transfer
	01	reserved, reject	Initial call; data record transfer has started
	02	reserved, reject	Intermediate call; data record transfer already active
80	81		The system data type at parameter TINFO does not match the call environment of the instruction. The used system data type must match the organization block in the user program (example: for a time-delay interrupt OB you need the system data type TI_Delay).
	90	reserved, pass	Invalid logical start address
	92	reserved, pass	Illegal type for VARIANT pointer
	93	reserved, pass	The DP component addressed via ID or F_ID is not configured.
	96		The "RALRM (Page 3636)" does not supply the OB start information, management information, header information, or additional interrupt information. For OBs 4x, 55, 56, 57, 82 and 83, you use the "DPNRM_DG (Page 3715)" instruction to read the current diagnostic frame of the relevant DP slave asynchronously (address information from OB start information).
	A0	read error	Negative acknowledgment when reading the module
	A1	write error	Negative acknowledgment when writing to the module
	A2	module failure	DP protocol error at layer 2 (e.g., slave failure or bus problems)
	A3	reserved, pass	• PROFIBUS DP: DP protocol error with Direct-Data-Link-Mapper or User-Interface/User • PROFINET IO: General CM error
	A4	reserved, pass	Communication on PBUS+ disrupted

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
	A5	reserved, pass	–
	A7	reserved, pass	DP slave or module is occupied (temporary error
	A8	version conflict	DP slave or module reports non-compatible versions
	A9	feature not supported	Function is not supported by DP slave or module
	AA to AF	user specific	DP slave or module reports a manufacturer-specific error in its application. Please check the documentation from the manufacturer of the DP slave or module.
	B0	invalid index	Data record not known in module Illegal data record number ≥ 256
	B1	write length error	Error at length specification: • With "RALRM (Page 3636)": length error in AINFO (Page 3659) • With "RDREC (Page 3578)": length error in MLEN • With "WRREC (Page 3596)": length error in LEN
	B2	invalid slot	The configured slot is not occupied.
	B3	type conflict	Actual module type does not match specified module type
	B4	invalid area	DP slave or module reports access to an invalid area
	B5	state conflict	DP slave or module not ready
	B6	access denied	DP slave or module denies access
	B7	invalid range	DP slave or module reports an invalid range for a parameter or value
	B8	invalid parameter	DP slave or module reports an invalid parameter
	B9	invalid type	DP slave or module reports an invalid type With "RDREC (Page 3578)": buffer too small (subsets cannot be read) With "WRREC (Page 3596)": buffer too small (subsets cannot be written)
	BA to BF	user specific	DP slave or module reports a manufacturer-specific error when accessing. Please check the documentation from the manufacturer of the DP slave or module.
	C0	read constrain conflict	With "WRREC (Page 3596)": The data is only written when the CPU is in STOP mode. Note: this means that writing by the user program is not possible. You only write the data online with PG/PC. With "RDREC (Page 3578)": the module routes the data record, but either no data is present or the data can only be read when the CPU is in STOP mode. Note: if data can only be read when the CPU is in STOP mode, then an evaluation by the user program is not possible. Therefore, it is only possible to read the data online with PG/PC.

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
	C1	write constrain conflict	The data of the previous write job on the module for the same data record has not yet been processed by the module.
	C2	resource busy	The module is currently processing the maximum possible number of jobs for a CPU.
	C3	resource unavailable	The required operating resources are currently occupied.
	C4		Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.
	C5		DP slave or module not available.
	C6		Data record transfer was canceled due to priority class cancellation
	C7		Job aborted due to warm or cold restart on the DP master
	C8 to CF		DP slave or module reports a manufacturer-specific resource error. Please check the documentation from the manufacturer of the DP slave or module.
	Dx	user specific	DP slave specific. Refer to the description of the DP slave.
	Ex	user specific	Manufacturer-specific. Please check the documentation of the module.
81	00 to FF		Error in the initial call parameter (with "RALRM (Page 3636)": MODE
	00		Illegal operating mode
82	00 to FF		Error in the second call parameter
:	:		:
88	00 to FF		Error in the eighth call parameter (with "RALRM (Page 3636)": TINFO (Page 3642))
	01		Wrong syntax ID
	23		Configuration limits exceeded or destination area too small
	24		Wrong range ID
	32		DB/DI no. out of user range
	3A		DB/DI no. is NULL for area ID DB/DI or specified DB/DI does not exist
89	00 to FF		Error in the ninth call parameter (with "RALRM (Page 3636)": AINFO (Page 3659))
	01		Wrong syntax ID
	23		Configuration limits exceeded or destination area too small
	24		Wrong range ID
	32		DB/DI no. out of user range
	3A		DB/DI no. is NULL for area ID DB/DI or specified DB/DI does not exist
8A	00 to FF		Error in the 10. Call parameters

Error_Decode (B#16#...)	Error_Code_1 (B#16#...)	Explanation according to DVP1	Meaning
:	:		:
8F	00 to FF		Error in the 15. Call parameters
FE, FF	00 to FF		Profile-specific error

Parameter TINFO (S7-1200, S7-1500)

Data structure of the destination area TINFO

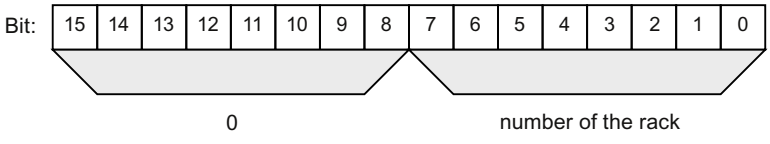
The data structure of the destination area TINFO contains the start information of the organization block in which "RALRM" is currently being called.

The TINFO destination area can contain the start information with standard access or optimized access. The format of the start information in the TINFO destination area must always match the start information of the corresponding organization block.

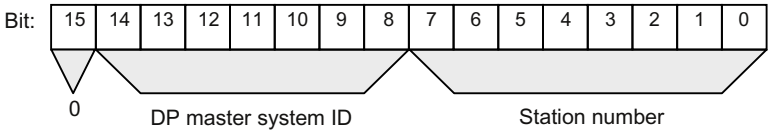
- The start information of an OB with standard access is always stored in the first 20 bytes of the "Temp" section in the block interface. Use the "TI_Classic" data structure for this.
- The start information of an OB with optimized access is always written to the "Input" section. The start information is stored in data structures specific to the organization block. Use the data structure specific to the organization block.

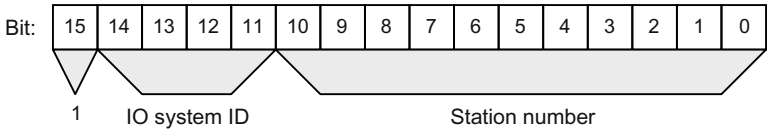
Changing the block access (standard/optimized) also changes the block interface.

The following table provides an overview of the data structures that are used depending on the organization block at the TINFO parameter.



Name of the data structure		S7-1200 CPUs as of version	S7-1500 CPUs as of version	Data structure used for:
Data structure for organization blocks with standard access				
	TI_Classic	-	V1	Organization blocks without optimized block access.
Data structure for organization blocks with optimized block access				





Name of the data structure	S7-1200 CPUs as of version	S7-1500 CPUs as of version	Data structure used for:
TI_ProgramCycle	V2	V1	Cycle OB (program cycle)
TI_Startup	V2	V1	Startup OB (startup)
TI_Delay	V2	V1	Time delay interrupt
TI_Cyclic	V2	V1	Cyclic interrupt OB
TI_HWInterrupt	V2	V1	Hardware interrupt OB
TI_HWInterrupt_Extended	-	V2.0	Hardware interrupt OB
TI_TimeError	V2	V1	Time error OB
TI_DiagnosticInterrupt	V2	V1	Diagnostic error interrupt OB
TI_PlugPullModule	V2	V1	Pull/plug of modules OB
TI_StationFailure	V2	V1	Rack or station failure OB
TI_ProgIOAccessError	V2	V1	• Programming error OB • I/O access error OB
TI_TimeOfDay	V2	V1	Time-of-day interrupt OB
TI_SynchCycle	-	V1	Synchronous cycle interrupt OB
TI_Submodule	V2	V1	• Status interrupt OB • Update interrupt OB • OB for manufacturer or profile-specific interrupt

Data structure for organization blocks with standard access

The following shows the TI_Classic data structure:

Parameter	Data type	Byte	Description
TI_Classic			Data structure for organization blocks without optimized block access.

Parameter	Data type	Byte	Description
Bytes 0 to 19: Start information of the OB in which "RALRM" is currently being called.*			
EV_CLASS	BYTE	0	Event class Example OB1: • Bits 0-3: ID of the event (1 = incoming event) • Bits 4-7: Event class (1 = Event class 1)
EV_NUM	BYTE	1	Event number (depending on OB type) Example OB1 (SCAN_1): • SCAN_1 = 1 for first call • SCAN_1 = 3 for all additional calls
PRIORITY	BYTE	2	Priority class
NUM	BYTE	3	OB number
TYP2_3	BYTE	4	Additional information Different information is stored in the BYTES "TYP2_3" and "TYPE 1" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • TYP2_3: OB1_RESERVED_1 (reserved) • TYP1: OB1_RESERVED_2 (reserved)
TYP1	BYTE	5	
ZI1	WORD	6 to 7	Additional information Different information is stored in "ZI1" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • ZI1: OB1_PREV_CYCLE (runtime of previous cycle in ms)
ZI2_3	DWORD	8 to 11	Additional information Different information is stored in "ZI2_3" depending on the OB type used. What these are is described in the documentation for the organization blocks. Example (OB1): • ZI2: OB1_MIN_CYCLE (minimum cycle time (ms) since the last startup) • ZI3: OB1_MAX_CYCLE (maximum cycle time (ms) since the last startup)
OB_DATE_TIME	DATE_AND_TIME (DT)	12 to 19	Date and time-of-day when the OB was called.
Bytes 20 and 21: Address information			
address	WORD	20 and 21	Address information like S7-300/400 CPUs: • In a central configuration, the rack number (0-31):  • For a distributed configuration with PROFIBUS DP: – DP master system ID (1-31) – Station number (0-127).

Parameter	Data type	Byte	Description
			 • In a distributed configuration with PROFINET IO: – The last two positions in the PROFINET IO system ID (0-15). To obtain the complete PROFINET IO system ID, you must add 100 (decimal) to it. – Station number (0-2047). 
Bytes 22 to 31: Management information			
slv_prfl	BYTE	22	Slave profile like S7-300/400 CPUs: • In a central configuration: 0 (data record 0 or data record 1) • In a distributed configuration: – Bit 0 to 3: Slave type - 0000: DP (structure data record 0) - 0001: DPS7 (structure data record 0 or data record 1) - 0010: DPS7 V1 (structure data record 0 or data record 1) - 0011: DPV1 (structure according to PROFIBUS DP standard) - 0100 – 0111: Reserved - 1000: PROFINET IO (structure according to PROFINET IO standard) - from 1001: Reserved – Bit 4 to 7: Profile type (reserved)
intr_type	BYTE	23	Interrupt info type like S7-300/400 CPUs: • In a central configuration: 0 • In a distributed configuration: – Bit 0 to 3: Interrupt info type - 0000: Interrupt comes from a configured remote module - 0001: Interrupt comes from a non-DPV1 slav / non IO device or a slot that is not configured - 0010: Interrupt generated in the CPU - from 0011: Reserved – Bit 4 to 7: Structure version - 0000: Initial - from 0001: Reserved
flags1	BYTE	24	Flags of the PROFIBUS DP master interface module / PROFINET IO controller interface module like S7-300/400 CPUs: • In a central configuration: 0 • In a distributed configuration: – Bit 0 = 0: Interrupt originating from an integrated interface module (PROFINET IO or PROFIBUS DP)

Parameter	Data type	Byte	Description
			– Bit 0 = 1: Interrupt originating from an external interface module (PROFINET IO or PROFIBUS DP) – Bit 1 to 7: Reserved
flags2	BYTE	25	Flags of the PROFIBUS DP master interface module / PROFINET IO controller interface module like S7-300/400 CPUs: • In a central configuration: 0 • For a distributed configuration with PROFIBUS DP: – Bit 0: EXT_DIAG_FLAG from the diagnostics message frame, or 0 if this bit does not exist in the interrupt The bit is 1 if the DP slave is faulty. – Bit 1 to 7: Reserved • In a distributed configuration with PROFINET IO: – Bit 0: ARDiagnosisState or 0 if there is no information in the interrupt. The bit is 1 if the IO device is faulty. – Bit 1 to 7: Reserved
id	UINT	26 and 27	Management information • In a central configuration: 0 • For a distributed configuration with PROFIBUS DP: PROFIBUS ID number as unique identifier of the PROFIBUS DP slave • In a distributed configuration with PROFINET IO: PROFINET IO device ID number as unique identifier of the PROFINET IO device
manufacturer	UINT	28 and 29	Manufacturer ID (only in a distributed configuration with PROFINET IO).
instance	UINT	30 and 31	Ident number of the instance (only in a distributed configuration with PROFINET IO).
*The start information depends on the OB used. You can find the start information of each OB type at the interface or in the documentation of the OB.			

Data structures for organization blocks with optimized block access

The data structures for organization blocks with optimized block access have the following format:

- Bytes 0 to 3: Format of the start information, class and number of the called OB (same structure for all data structures).
- Bytes 4 to 19: Optimized start information (structure depends on the OB type). The data in bytes 4 to 19 correspond to the structure and content of the corresponding OB interface.
- Bytes 20 to 31: In addition, the address and management information for certain OBs. The data in bytes 20 to 31 correspond to the data of 20 to 31 bytes of the TI_Classic data structure.

The format of the data structures is described in the following tables.

Table 11-26 **Cycle OB: Data structure TI_ProgramCycle**

Parameter		Data type	Byte	Description
TI_ProgramCycle				Data structure for cycle OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=1)
	OB_Nr	UINT	2	OB number (1...32767).
	Initial_Call	BOOL	4	= TRUE in the first call of this OB: • Transition from STOP or HOLD to RUN • After reloading
	Remanence	BOOL	5	= TRUE, if retentive data are available.

Table 11-27 **Startup OB: Data structure TI_Startup**

Parameter		Data type	Byte	Description
TI_Startup				Data structure for startup OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=100)
	OB_Nr	UINT	2	OB number (1...32767).
	LostRetentive	BOOL	4	=TRUE, if the contents of retentive data areas have been lost.
	LostRTC	BOOL	5	=TRUE, if the time-of-day of the real-time clock has been lost.

Table 11-28 **Time delay interrupt OB: Data structure TI_Delay**

Parameter		Data type	Byte	Description
TI_Delay				Data structure for time delay interrupt OB
	SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
	OB_Class	USINT	1	OB class (=20)
	OB_Nr	UINT	2	OB number (1...32767).
	Sign	WORD	4	User ID: Input parameter SIGN from the call of the "SRT_DINT (Page 3830)" instruction.

Table 11-29 **Cyclic interrupt OB: Data structure TI_Cyclic**

Parameter	Data type	Byte	Description
TI_Cyclic			Data structure for cyclic interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=30)
OB_Nr	UINT	2	OB number (1...32767).
Initial_Call	BOOL	4	= TRUE in the first call of this OB • At the transition from STOP or HOLD to RUN • After reloading
Event_Count	INT	6	Number of discarded start events since the last start of this OB.

Table 11-30 **Hardware interrupt OB: Data structure TI_HWInterrupt**

Parameter	Data type	Byte	Description
TI_HWInterrupt			Data structure for hardware interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=40)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware identifier of the module that triggers the hardware interrupt.
USI	WORD	6	Identifier for future extensions (not user-relevant).
IChannel	USINT	8	Number of the channel that triggered the hardware interrupt.
EventType	BYTE	9	Identifier for the event type associated with the event triggering the interrupt (e.g., rising edge). You can find this ID in the description of the respective module.
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UNIT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UNIT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UNIT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-31 **Hardware interrupt OB: Data structure TI_HWInterrupt_Extended**

Parameter	Data type	Byte	Description
TI_HWInterrupt_Extended			Data structure for hardware interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=40)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware identifier of the module that triggers the hardware interrupt.
USI	WORD	6	Identifier for future extensions (not user-relevant).
IChannel	USINT	8	Number of the channel that triggered the hardware interrupt.
EventType	BYTE	9	Identifier for the event type associated with the event triggering the interrupt (e.g., rising edge). You can find this ID in the description of the respective module.
PointAddr	DWORD	12	• In the case of digital modules: Bit array containing the inputs on the module that triggered the hardware interrupt • In the case of analog modules: Bit array with the information as to which channel has exceeded which limit • In the case of CPs or IMs: Interrupt status of the module (not user-relevant)
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UNIT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UNIT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UNIT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-32 **Time error OB: Data structure TI_TimeError**

Parameter	Data type	Byte	Description
TI_TimeError			Data structure for time error OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=80)
OB_Nr	UINT	2	OB number (1...32767).
Csg_OBnr	OB_ANY	4	Number of the OB that was being executed when the time error occurred.
Fault_ID	BYTE	7	Error code. Possible values: • B#16#01: Cycle time exceeded • B#16#02: The requested OB is still being processed. • B#16#05: Expired time-of-day interrupt due to time jump. • B#16#06: Expired time-of-day interrupt upon re-entry into RUN after HOLD. • B#16#07: Overflow of the OB request buffer for the current priority class. • B#16#08: Isochronous mode interrupt - time error. • B#16#09: Interrupt loss due to high interrupt load • B#16#0B: Technology synchronization interrupt - time error
Csg_Prio	UNIT	8	Priority of the OB that was being executed when the time error occurred.

Table 11-33 **Diagnostic interrupt OB: Data structure TI_DiagnosticInterrupt**

Parameter	Data type	Byte	Description
TI_DiagnosticInterrupt			Data structure for diagnostic interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=82)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_ANY	4	Hardware identifier of the hardware object that triggered the diagnostic interrupt.
IO_State	WORD	6	Status of the hardware object: • Bit 0: Good • Bit 1: Disabled • Bit 2: Maintenance required • Bit 3: Maintenance demanded • Bit 4: Error • Bit 5: Not accessible • Bit 6: Qualified • Bit 7: Not available
Channel	UINT	8	Channel number
MultiError	BOOL	10	=TRUE, if there is more than one error.
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-34 **Pull/plug interrupt OB: Data structure** TI_PlugPullModule

Parameter	Data type	Byte	Description
TI_PlugPullModule			Data structure for pull/plug interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=83)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware identifier of the affected module or submodule
Event_Class	BYTE	6	• B#16#38: (Sub)module plugged • B#16#39: (Sub)module pulled or not responding
Fault_ID	BYTE	7	Error code The following table shows the events that cause the start of the pull/plug interrupt OB. • With Event_Class = B#16#38 - module/submodule plugged: – B#16#54: Submodule plugged and matches configured submodule – B#16#55: Submodule plugged, but does not match configured submodule – B#16#56: Submodule plugged, but error in module parameter assignment – B#16#57: Submodule or module plugged, but with a fault or maintenance – B#16#58: Submodule access error corrected – B#16#61: Module inserted • With Event_Class = B#16#39 - module/submodule pulled or not responding: – B#16#51: Module pulled – B#16#54: Submodule pulled – B#16#61: Module pulled or not responding
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-35 **Rack error OB: Data structure TI_StationFailure**

Parameter	Data type	Byte	Description
TI_StationFailure			Data structure for rack error OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=86)
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_Device	4	Hardware identifier of the defective hardware object.
Event_Class	BYTE	6	• B#16#32: Activation of a station with the "D_ACT_DP" instruction • B#16#33: Deactivation of a station with the "D_ACT_DP" instruction • B#16#38: Outgoing event • B#16#39: Incoming event
Fault_ID	BYTE	7	Error code The error code is used to output the event that caused the start of the rack error OB. • Event_Class = B#16#39, FAULT_ID = C3: Distributed I/O: Failure of a DP master system • Event_Class = B#16#38, FAULT_ID = C4: Failure of a DP station • Event_Class = B#16#39, FAULT_ID = CA: PROFINET IO system failure • Event_Class = B#16#39/38, FAULT_ID = CB: PROFINET IO station failure/ station return • Event_Class = B#16#38, FAULT_ID = CC: PROFINET IO station return with problem or maintenance • Event_Class = B#16#38, FAULT_ID = CD: PROFINET IO station return, expected configuration different from actual configuration • Event_Class = B#16#38, FAULT_ID = CE: PROFINET IO station return, error in module parameter assignment • Event_Class = B#16#32/33, FAULT_ID = CF: Activation/deactivation of a PROFINET IO device with the "D_ACT_DP" instruction • Event_Class = B#16#39/38, FAULT_ID = F8: Failure/return of some of the submodules of a PROFINET I-device • Event_Class = B#16#38, FAULT_ID = F9: Return of some of the submodules of a PROFINET I-device with a device configuration difference
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Table 11-36 **Programming error OB / I/O access error OB: Data structure TI_ProgIOAccessError**

Parameter	Data type	Byte	Description*
TI_ProgIOAccessError			Data structure for programming error OB and I/O access error OB

Parameter	Data type	Byte	Description*
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class: • =121 for programming error OB • =122 for I/O access error OB
OB_Nr	UINT	2	OB number (1...32767).
BlockNr	UINT	4	Number of the block in which the programming error occurred.
Reaction	USINT	6	• 0: Ignore error • 1: Substitute bad value • 2: Skip command
Fault_ID	BYTE	7	Error code • B#16#21: BCD conversion error • B#16#22: Area length error when reading • B#16#23: Area length error when writing • B#16#24: Area error when reading • B#16#25: Area error when writing • B#16#26: Error in timer no. • B#16#27: Error in counter no. • B#16#28: Read access to a byte, word or double word with a pointer, the bit address of which is not 0 • B#16#29: Write access to a byte, word or double word with a pointer, the bit address of which is not 0 • B#16#:30: Write access to a write-protected global DB • B#16#31: Write access to a write-protected instance DB • B#16#32: DB number error when accessing a global DB • B#16#33: DB number error when accessing an instance DB • B#16#34: Number error during FC call • B#16#35: Number error during FB call • B#16#42: I/O access error, reading • B#16#43: I/O access error, writing • B#16#3A: Access to a DB that is not loaded; the DB number is located in the permitted area • B#16#3C: Access to an FC that is not loaded; the FC number is within the permissible range • B#16#3D: Access to an instruction (SFC) that is not loaded; the SFC number is within the permissible range • B#16#3E: Access to an FB that is not loaded; the FB number is within the permissible range • B#16#3F: Access to an SFB that is not available; the SFB number is within the permissible range
BlockType	USINT	8	Type of block in which the error has occurred:

Parameter	Data type	Byte	Description*
			• OB: B#16#88 • FC: B#16#8C • FB: B#16#8E
Area	USINT	9	Memory area in which the incorrect access occurred: • Local data: B#16#40 to 4E, 86, 87, 8E, 8F, C0 to CE • Process image input: B#16#01 • Process image output: B#16#02 • Technology DB: B#16#04 • I: B#16#81 • Q: B#16#82 • M: B#16#83 • DB: B#16#84, 85, 8A, 8B
DBNr	DB_ANY	10	DB no. if AREA = DB (global DB or instance DB) Only relevant for programming error OB.
Csg_OBNr	OB_ANY	12	OB number: • 121: Programming error OB • 122: I/O access error OB
Csg_Prio	USINT	14	OB priority
Width	USINT	15	Type of access during which the error occurred: • Bit: B#16#00 • Byte: B#16#01 • Word: B#16#02 • DWord: B#16#03 • LWord: B#16#04
* Only certain output values are possible depending on the OB (I/O access error OB or programming error OB) from which information is read.			

Table 11-37 **Time-of-day interrupt OB: Data structure TI_TimeOfDay**

Parameter	Data type	Byte	Description
TI_TimeOfDay			Data structure for time-of-day interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=10)
OB_Nr	UINT	2	OB number (1...32767).
CaughtUp	BOOL	4	=TRUE if an OB call was executed subsequently because time was adjusted ahead
SecondTime	BOOL	5	=TRUE if an OB was called a second time because time was adjusted back. Note: SecondTime is set only once in situations in which the time is set back.

Table 11-38 **Isochronous mode interrupt OB: Data structure TI_SynchCycle**

Parameter	Data type	Byte	Description
TI_SynchCycle			Data structure for isochronous mode interrupt OB
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class (=61)
OB_Nr	UINT	2	OB number (1...32767).
Initial_Call	BOOL	4	= TRUE in the first call of this OB: • Transition from STOP or HOLD to RUN • After reloading
IO _System	USINT	5	Number of the distributed I/O system triggering the interrupt
Event_Count	INT	6	• = n: Number of lost cycles • = -1: An unknown number of cycles has been lost (e.g., because cycle has changed).
PIP_Input	BOOL	10	=TRUE: The associated process image of the inputs is up-to-date
PIP_Output	BOOL	11	=TRUE: The associated process image of the outputs was transferred to the outputs in good time after the last cycle
SyncCycle-Time	LTIME	16	Calculated cycle time

Table 11-39 **Status interrupt OB / update interrupt OB for manufacturer or profile-specific interrupt: Data structure TI_Submodule**

Parameter	Data type	Byte	Description
TI_Submodule			Data structure for status interrupt OB / update interrupt OB for manufacturer or profile-specific interrupt
SI_Format	USINT	0	Format of the start information: • 16#FF: None • 16#FE: Optimized start information
OB_Class	USINT	1	OB class • =55 for status interrupt OB • =56 for update interrupt OB • =57 for manufacturer or profile-specific interrupt OB
OB_Nr	UINT	2	OB number (1...32767).
LADDR	HW_IO	4	Hardware address of the component triggering the interrupt
Slot	UINT	6	Slot number of the component triggering the interrupt
Specifier	WORD	8	Interrupt specifier from the interrupt frame
address	WORD	20	See "address" parameter for the TI_Cassic. data structure
slv_prfl	BYTE	22	See "slv_prfl" parameter for the TI_Cassic data structure.
intr_type	BYTE	23	See "intr_type" parameter for the TI_Cassic data structure.
flags1	BYTE	24	See "flags1" parameter for the TI_Cassic data structure.
flags2	BYTE	25	See "flags2" parameter for the TI_Cassic data structure.
id	UINT	26	See "id" parameter for the TI_Cassic data structure.
manufacturer	UINT	28	See "manufacturer" parameter for the TI_Cassic data structure.
instance	UINT	30	See "instance" parameter for the TI_Cassic data structure.

Parameter AINFO (S7-1200, S7-1500)

Data structure of the destination area AINFO with interrupts from PROFIBUS DP

Byte	Meaning	
0 to 3	Header information, for exact description, see below	
4 to 63	Additional interrupt information: data for the respective interrupt:	
	Distributed:	ARRAY[0] to ARRAY[59]

Structure of the header information with interrupts from PROFIBUS DP

Byte	Data type	Meaning	
0	BYTE	Length of the received interrupt information in bytes	
		Central:	4 to 224
		Distributed:	4 to 63

Byte	Data type	Meaning		
1	BYTE	Central:	Reserved	
		Distributed:	ID for the interrupt type	
			1: 2: 3: 4: 5: 6: 31	Diagnostics interrupt Process interrupt Pull interrupt Plug interrupt Status interrupt Update interrupt Failure of an expansion device, DP master system or DP station
			32 to 126:	Manufacturer-specific interrupt
2	BYTE	Slot number of the component that triggered the interrupt		
3	BYTE	Central:	Reserved	
		Distributed:	Specifier	
			Bits 0 and 1:	0: No further information; 1: Incoming event, fault at slot 2: Outgoing event, fault at slot cleared 3: Outgoing event, slot still faulty
			Bit 2:	Add_Ack
			Bits 3 to 7:	Sequence number

Data structure of the destination area AINFO with interrupts from PROFINET IO or central I/O devices

Byte	Meaning
0 to 25	Header information, for exact description, see below
26 to 1431	Additional interrupt information: Standardized diagnostics data for the respective interrupt: ARRAY[0] to ARRAY[1405] Note: The additional interrupt information may also be omitted.

Structure of the header information with interrupts from PROFINET IO or central I/O devices

Byte	Data type	Meaning
0 and 1	WORD	• Bits 0 to 7: Block type • Bits 8 to 15: Reserved
2 and 3	WORD	Block length
4 and 5	WORD	Version: • Bits 0 to 7: low byte • Bits 8 to 15: high byte

Byte	Data type	Meaning
6 and 7	WORD	ID for interrupt type: • 1: Diagnostics interrupt (incoming or outgoing) • 2: Process interrupt • 3: Remove module interrupt • 4: Insert module interrupt • 5: Status interrupt • 6: Update interrupt • 7: Redundancy interrupt • 8: Controlled by supervisor • 9: Released by supervisor • 10: Configured module not inserted • 11: Return of the sub-module • 12: Diagnostics interrupt (outgoing) • 13: Slave-to-slave connection alarm • 14: Neighborhood change alarm • 15: Clock synchronization message (bus end) • 16: Clock synchronization alarm (device end) • 17: Network component alarm • 18: Time synchronization alarm (on bus side) • 19 to 31: Reserved • 32 to 127: Manufacturer-specific interrupt • 128 to 65535: Reserved
8 to 11	DWORD	API (Application Process Identifier)
12 to 13	WORD	Slot number of the component triggering the interrupt (value range 0 to 65535)
14 to 15	WORD	Submodule slot number of the component triggering the interrupt (value range 0 to 65535)
16 to 19	DWORD	Module identification; specific information on the source of the interrupt

Byte	Data type	Meaning
20 to 23	DWORD	Submodule identification; specific information on the source of the interrupt
24 to 25	WORD	Interrupt specifier: • Bits 0 to 10: Sequence number (value range 0 to 2047) • Bit 11: Channel diagnostics: 0: No channel diagnostics available 1: Channel diagnostic information exists • Bit 12: Status of manufacturer-specific diagnostics: 0: No manufacturer-specific status information available 1: Manufacturer-specific status information available • Bit 13: Status of diagnostics for sub-module: 0: No status information available, all errors have been corrected 1: At least one item of channel diagnostics and/or status information is available • Bit 14: Reserved • Bit 15: Application relationship diagnosis state: – 0: None of the modules configured within this AR are reporting diagnostic information – 1: At least one of the modules configured in this AR is reporting diagnostic information

Structure of the additional interrupt information for interrupts from PROFINET IO or central I/O

The additional interrupt information for PROFINET IO depends on the format identifier. It can comprise multiple data blocks with the same or different format identifier. The following format identifiers are available:

- W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics

Byte	Data type	Meaning
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics
2 to n	BYTE	See manufacturer's manual.

- W#16#8000: Channel diagnostics
  Channel diagnostics is output in blocks of 6 bytes each. The additional interrupt information (without format identifier) is only output for disrupted channels.

Byte	Data type	Meaning	
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#8000: Channel diagnostics	
2 to 3	WORD	Channel number of the component triggering the interrupt (value range: 0 to 65535): • W#16#0000 to W#16#7FFF: Channel number of the interface module/sub-module • W#16#8000: The generic substitute for the whole sub-module • W#16#8001 to W#16#FFFF: Reserved	
4	BYTE	Bits 0 to 2:	Reserved
		Bits 3 to 4:	Type of error: • 0: Reserved • 1: Incoming error • 2: Outgoing error • 3: Outgoing error, other errors present
		Bits 5 to 7:	Type of channel: • 0: Reserved • 1: Input channel • 2: Output channel • 3: Input/output channel

Byte	Data type	Meaning
5	BYTE	Data format: • B#16#00: Free data format • B#16#01: Bit • B#16#02: 2-bit • B#16#03: 4-bit • B#16#04: Byte • B#16#05: Word • B#16#06: Double word • B#16#07: 2 double words • B#16#08 to B#16#FF: Reserved

Byte	Data type	Meaning
6 to 7	WORD	Type of error: • W#16#0000: Reserved • W#16#0001: Short-circuit • W#16#0002: Undervoltage • W#16#0003: Overvoltage • W#16#0004: Overload • W#16#0005: Overtemperature • W#16#0006: Wire break • W#16#0007: High limit exceeded • W#16#0008: Low limit value exceeded • W#16#0009: Error • W#16#000A: Simulation active • W#16#000B to W#16#000E: Reserved • W#16#000F to W#16#001F: Manufacturer-specific • W#16#0020 to W#16#00FF: Reserved • W#16#0100 to w#16#7FFF: Manufacturer-specific • W#16#8000: Data transfer not possible • W#16#8001: Error at partner • W#16#8002: Media redundancy error • W#16#8003: Synchronization loss • W#16#8004: Isochronous mode error • W#16#8005: Multicast CR error • W#16#8006: Reserved • W#16#8007: Fiber-optic error • W#16#8008: Function failure of network component • W#16#8009: Time error • W#16#800A: DFP problem (DFP: dynamic frame packing) • W#16#800B: MRPD problem (MRPD: media redundancy with planned duplication) • W#16#800C: System redundancy error • W#16#800D to W#16#FFFF: Reserved Not all channels support every error type. For detailed information, refer to the description of the diagnostic data for the specific device.

Note

The section from "channel number" to "error type" can occur from 0 to n times.

- W#16#8001: MULTIPLE (different types of diagnostics information are transmitted). In this case, the additional interrupt information is transmitted as blocks of variable length.

Byte	Data type	Meaning
0 to 1	WORD	Format identifier for the structure of the following data serving as additional interrupt information W#16#8001: Manufacturer-specific diagnostics and/or channel diagnostics
2 to 3	WORD	Block type
4 to 5	WORD	Block length
6	BYTE	Version: high byte
7	BYTE	Version: low byte
8 to 11	DWORD	API (only if low byte of version = 1)
12 to 13	WORD	Slot number
14 to 15	WORD	Subslot number
16 to 17	WORD	Channel number
18 to 19	WORD	Channel properties
20 to 21	WORD	Format identifier: • W#16#0000 to W#16#7FFF: Manufacturer-specific diagnostics • W#16#8000: Channel diagnostics • W#16#8002: Extended channel diagnostics • W#16#8003: Stepped extended channel diagnostics • W#16#8004 to W#16#80FF: Reserved
22 to n	BYTE	Data depend on the format identifier

Note

The section starting from "block type" can occur from 1 to n times.

- W#16#8002: Extended channel diagnostics

Byte	Meaning
0 to 1	Format identifier W#16#8002
2 to 3	Channel number
4 to 5	Channel properties
6 to 7	Error type
8 to 9	Additional error value
10 to 13	Additional error information

- W#16#8003: Stepped extended channel diagnostics

Byte	Meaning
0 to 1	Format identifier W#16#8003
2 to 3	Channel number
4 to 5	Channel properties
6 to 7	Error type
8 to 9	Additional error value
10 to 13	Additional error information
14 to 17	Qualified channel qualifier

- W#16#8100: Maintenance information

Byte	Meaning
0 to 1	Format identifier W#16#8100
2 to 3	Block type
4 to 5	Block length
6 to 7	Block version
8 to 9	Reserved Note: These two bytes are missing with central modules. These exist with distributed modules (according to the PROFINET standard).
10 to 13	Maintenance status

Note

You can find more detailed information about the structure of the additional alarm information in the *Programming Manual SIMATIC PROFINET IO from PROFIBUS DP to PROFINET IO* and the current version of IEC 61158-6-10-1.

Destination area TINFO and AINFO (S7-1200, S7-1500)

Destination area TINFO and AINFO

Depending on the respective OB in which "RALRM (Page 3636)" is called, the destination areas TINFO and AINFO are only partially written. Refer to the table below to find out which information is entered respectively.

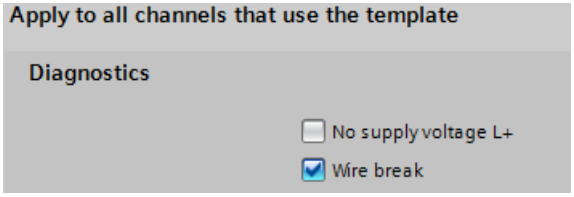
Interrupt type	OB class	TINFO OB start information	TINFO Management information	AINFO Header information	AINFO Additional interrupt information	
Process interrupt	4x	Yes	Yes	Yes	Central:	No
					Distributed:	As supplied by PROFIBUS DP slave/PROFINET IO device
Status interrupt	55	Yes	Yes	Yes	Yes	Yes
Update interrupt	56	Yes	Yes	Yes	Yes	Yes
Manufacturer-specific interrupt	57	Yes	Yes	Yes	Yes	Yes

Interrupt type	OB class	TINFO OB start information	TINFO Management information	AINFO Header information	AINFO Additional interrupt information	
I/O redundancy error	70	Yes	Yes	No	No	No
Diagnostics interrupt	82	Yes	Yes	Yes	Central:	Structure according to PROFINET IO standard
					Distributed:	As supplied by PROFIBUS DP slave/PROFINET IO device
Insert/remove interrupt	83	Yes	Yes	Yes	Central:	No
					Distributed:	As supplied by PROFIBUS DP slave/PROFINET IO device
Special form of the remove module interrupt: Controlled by supervisor	83	Yes	Yes	Yes	PROFINET IO only	
Special form of the insert module interrupt: Enabled by supervisor	83	Yes	Yes	Yes	PROFINET IO only	
Unconfigured module inserted	83	Yes	Yes	Yes	PROFINET IO only	
Rack failure/ station failure	86	Yes	Yes	No	No	
... all other OBs		Yes	No	No	No	

Program example for RALRM (S7-1200, S7-1500)

Introduction

In the following example, you generate a wire break via an input module and receive the interrupt, including associated information. The example applies to PROFINET IO and/or an S7-1500 CPU.



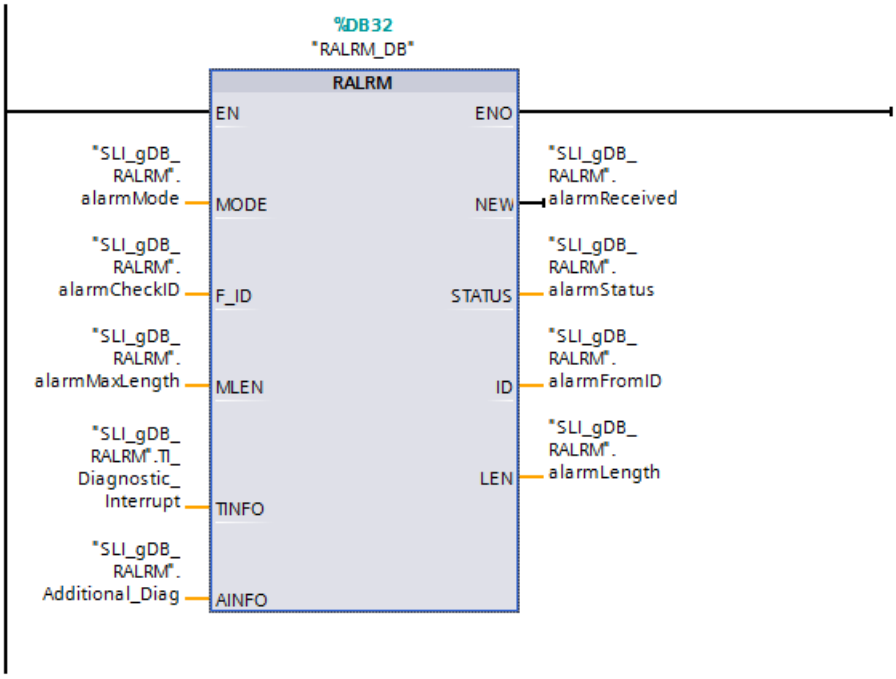
Note

Place the example

The example must be stored in the setup in which the input module is to generate an interrupt (wire break).

Requirements

- An input module is created and the hardware identifier is read out in the properties of the input module. You store the hardware identifier via the input parameter F_ID ("alarmCheckID").
- To generate an interrupt, select the option "Wire break" for the input channels. This option is available under "Module parameters > Channel template > Inputs".



- To store the data, create seven tags and the structures "TI_Diagnostic_Interrupt" and "Additional_Diag" in a global data block. Create the "TI_Diagnostic_Interrupt" structure with the "TI_DiagnosticInterrupt" data type.

SLI_gDB_RALRM

	Name	Data type	Start value
1	Static		
2	alarmMode	Int	2
3	alarmCheckID	HW_IO	257
4	alarmStatus	DWord	16#0
5	alarmFromID	HW_IO	16#0
6	alarmReceived	Bool	false
7	alarmMaxLength	UInt	0
8	alarmLength	UInt	0
9	TI_Diagnostic_Interrupt	TI_DiagnosticInterrupt	
10	Additional_Diag	Struct	
11	header	Struct	
12	BlockType	Word	16#0
13	BlockLength	UInt	0
14	Version	Word	16#0
15	InterruptType	UInt	0
16	API	DWord	16#0
17	SlotNumber	UInt	0
18	SubSlotNumber	UInt	0
19	ModulSpecInfo	DWord	16#0
20	SubmodulSpecInfo	DWord	16#0
21	InterruptSpecifier	Word	16#0
22	addInfo	Struct	
23	FormatIdentifier	Word	16#0
24	ChannelNumber	Word	16#0
25	ChannelErrorType	Byte	16#0
26	DataFormat	Byte	16#0
27	ErrorCode	Word	16#0

Interconnect parameters

Call the instruction "RALRM" in a diagnostic interrupt OB (OB82). Interconnect the parameters of the instruction as follows.

Result of RALRM

Note

Trigger wire break

To trigger the interrupt, pull one of the power cables of the input module's inputs and then reconnect the cable. Alternatively, you can also pull a potential bridge of the input module and reconnect it.

When you generate a wire break, the input module generates an interrupt. The diagnostic interrupt OB is then called and the instruction "RALRM" started.

The instruction "RALRM" calls the input module via the input parameter F_ID ("alarmCheckID"). The instruction "RALRM" checks whether the interrupt originates from the input module according to the value "2" of the input parameter MODE ("alarmMode"). If the interrupt originates from the input module ("alarmCheckID" and "alarmFromID" are identical), the output parameter NEW ("alarmReceived") is set to "TRUE" and the interrupt information is stored via the parameters TINFO ("TI_Diagnostivc_Interrupt") and AINFO ("Additional_Diag"). The hardware identifier of the module generating the interrupt (the input module) is displayed at the output parameter ID ("alarmFromID").

The length of the received interrupt information is recorded at the output parameter LEN ("alarmLength"). According to the value of the input parameter MLEN ("alarmMaxLength" has the value “0"), the information that is to be read for AINFO ("Additional_Diag") is unlimited.

The block status is displayed at the output parameter STATUS ("alarmStatus"). Processing takes place without errors.

SLI_gDB_RALRM

	Name	Data type	Start value	Monitor value
1	Static			
2	alarmMode	Int	2	2
3	alarmCheckID	HW_IO	257	16#0101
4	alarmStatus	DWord	16#0	16#0000_0000
5	alarmFromID	HW_IO	16#0	16#0101
6	alarmReceived	Bool	false	TRUE
7	alarmMaxLength	UInt	0	0
8	alarmLength	UInt	0	76

The following sections contain the evaluation for TINFO and AINFO.

Details about parameter TINFO ("TI_Diagnostivc_Interrupt")

The OB start information and management information are stored at the parameter TINFO ("TI_Diagnostivc_Interrupt").

The generated interrupt includes the following information:

- OB start information: The OB82 uses optimized start information ("SI_Format" with the value "254").
- Management information:
  - The input module (see "LADDR") with the status "Error" (see the value of "IO_State") is read out.
  - An interrupt was recently recorded for the channel "15" (see the value of "Channel").
  - Multiple errors were recorded ("MutliError" with the value "TRUE").
  - An interrupt was recently recorded for station "0" (see the value of "address").
  - A structure was recorded according to the diagnostics data record 0 (see the value of "slv_prfl").
  - The interrupt was triggered by a configured, distributed module (see the value of "intr_type").

9	TI_Diagnostic_Interrupt	TI_DiagnosticInter...		
10	SI_Format	USInt	0	254
11	OB_Class	USInt	82	82
12	OB_Nr	UInt	0	82
13	LADDR	HW_ANY	16#0	16#0101
14	IO_State	Word	16#0	16#0010
15	Channel	UInt	0	15
16	MultiError	Bool	false	TRUE
17	address	Word	16#0	16#0000
18	slv_prfl	Byte	16#0	16#00
19	intr_type	Byte	16#0	16#00
20	flags1	Byte	16#0	16#00
21	flags2	Byte	16#0	16#00
22	id	UInt	0	0
23	manufacturer	UInt	0	0
24	instance	UInt	0	0

Details about parameter AINFO ("Additional_Diag")

The header information and additional information about the interrupt is stored at the parameter AINFO ("Additional_Diag").

Note

Structure and scope of the interrupt information

This example is intended to show reception of a single hardware fault (wire break). Accordingly, only the interrupt information about one of the relevant channels is displayed when a multierror occurs.

- To call the additional information for each channel individually, use a multiple call of RALRM: For each call, query the channel ("TI_Diagnostivc_Interrupt.Channel") and store the information of the tags "ChannelErrorType" to "ErrorCode" for each channel. See also "FAQ for channel diagnostics with RALRM (https://support.industry.siemens.com/cs/ww/en/view/109480387)".
- Depending on the application, note the structure to be stored at the parameter AINFO (Page 3659).

The generated interrupt includes the following information:

- The OB used is a diagnostic interrupt OB ("InterruptType" with the value "1").
- The interrupt is reported for a module at the slot "2" ("SlotNumber") and for the channels 8 to 15 (BYTE 1, "SubSlotNumber").
- At least one item of channel diagnostics and/or status information is available for the submodule ("InterruptSpecifier" with the value "16#2000").
- In this example, the structure of the channel diagnostics is used ("FormatIdentifier" with the value "16#8000").
- The channel number of the component that triggered the interrupt is assigned to the submodule ("ChannelNumber" with the value "16#0008").
- An incoming error for an input channel ("ChannelErrorType" with the value "16#28") is diagnosed.

- The data format used is a bit ("DataFormat" with the value "16#01").
- A wire break was diagnosed ("ErrorCode" with the value "16#0006").

25	Additional_Diag	Struct		
26	header	Struct		
27	BlockType	Word	16#0	16#0002
28	BlockLength	UInt	0	72
29	Version	Word	16#0	16#0100
30	InterruptType	UInt	0	1
31	API	DWord	16#0	16#0000_0000
32	SlotNumber	UInt	0	2
33	SubSlotNumber	UInt	0	1
34	ModulSpecInfo	DWord	16#0	16#0000_0000
35	SubmodulSpecInfo	DWord	16#0	16#0000_0000
36	InterruptSpecifier	Word	16#0	16#2000
37	addInfo	Struct		
38	FormatIdentifier	Word	16#0	16#8000
39	ChannelNumber	Word	16#0	16#0008
40	ChannelErrorType	Byte	16#0	16#28
41	DataFormat	Byte	16#0	16#01
42	ErrorCode	Word	16#0	16#0006

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

Additional example

A more complex example is available here: "FAQ for channel diagnostics with RALRM (https://support.industry.siemens.com/cs/ww/en/view/109480387)".

D_ACT_DP: Enable/disable DP slaves (S7-1200, S7-1500)

Description

With the instruction D_ACT_DP", you can disable and enable configured DP slaves/ PROFINET IO devices in a targeted manner. In addition, you can determine whether each assigned DP slave or PROFINET IO device is currently activated or deactivated.

You cannot disable/enable an IE/PB Link PN IO type of gateway using the instruction "D_ACT_DP". If you nevertheless use "D_ACT_DP" on the gateway named, the CPU returns the value W#16#8093 (there is no hardware object that can be activated or deactivated for the address specified in LADDR).

As of firmware version V1.8 of the S7-1500 CPUs the following applies: You can use the "D_ACT_DP" instruction to disable/enable DP slaves that are connected to an IE/PB Link PN IO type of gateway.

The instruction cannot be used on PROFIBUS PA field devices that are connected by a DP/PA link to a DP master system.

Note

Several runs through the cycle control point are required to perform the disabling or enabling job. Therefore, you do not wait for the end of such a job in a programmed loop.

Functional description

"D_ACT_DP" is an asynchronous instruction. Processing takes place across several calls. You start the job by calling "D_ACT_DP" with REQ = 1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571).

Application

If you configure DP slaves/PROFINET IO devices in a CPU which are not actually present or not currently required, the CPU will nevertheless continue to access these DP slaves/PROFINET IO devices at regular intervals. After the slaves are deactivated, further CPU accessing will stop. With PROFIBUS DP, the fastest possible DP bus cycle can be achieved in this manner. The corresponding error events no longer occur.

Examples

From a machine OEM's point of view, there are numerous device options possible in series production of machines. However, each delivered machine includes only one combination of selected options.

Every one of these possible machine options is configured as a DP slave/PROFINET IO device by the manufacturer in order to create and maintain a common user program having all possible options. Use "D_ACT_DP" to deactivate all DP slaves/PROFINET IO devices not present at machine startup.

A similar situation exists for machine tools having numerous tooling options available but actually using only a few of them at any given time. These tools are implemented as DP slaves/PROFINET IO devices. With "D_ACT_DP", the user program activates the tools currently needed and deactivates those required later.

Identification of a job

If you have started a deactivation or activation job and you call "D_ACT_DP" again before the job is complete, the behavior of the instruction depends on whether or not the new call involves the same job. If the input parameter LADDR matches, the call will be interpreted as follow-on call.

Deactivating DP slaves/PROFINET IO devices

When you deactivate a DP slave/PROFINET IO device with "D_ACT_DP", its process outputs are set to the configured substitute values or to 0 (safe state). The assigned DP master/ PROFINET IO controller does not continue to address this component. Deactivated DP slaves/ PROFINET IO devices are not identified as faulty or missing by the error LEDs on the DP master/PROFINET IO controller or CPU.

The process image inputs of deactivated DP slaves/PROFINET IO devices is updated with 0. Therefore, it is treated just like failed DP slaves/PROFINET IO devices.

If you directly access the user data of a previously deactivated DP slave/PROFINET IO device from your program, the I/O access error OB is called and the corresponding start event is entered in the diagnostics buffer. If you attempt to access a deactivated DP slave/PROFINET IO device via an instruction (such as "RD_REC (Page 3694)"), you will receive the same error information in RET_VAL as for an unavailable DP slave/PROFINET IO device.

Deactivating a DP slave/PROFINET IO device does not start the program error OB, even if its inputs or outputs belong to the system-side process image to be updated.

If a DP station/PNIO station fails after you have deactivated it with "D_ACT_DP", the operating system does not detect the failure.

Applies to PROFIBUS DP: If you wish to deactivate DP slaves functioning as transmitters in slave-to-slave communication, we recommend that you first deactivate the receivers (listeners) that detect which input data the transmitter is transferring to its DP master. Deactivate the transmitter only after you have performed this step.

Activating DP slaves/PROFINET IO devices

When you reactivate a DP slave/PROFINET IO device with "D_ACT_DP", this component is configured and assigned parameters by the associated DP master/PROFINET IO controller (as with the return of a failed DP station/PROFINET IO station). This activation is complete when the component is able to transfer user data.

Activating a DP slave/PROFINET IO device does not start the program error OB, even if its inputs or outputs belong to the system-side process image to be updated.

If you try to activate a DP slave/PROFINET IO device with "D_ACT_DP" that cannot be accessed (for example, because it was physically separated from the bus), the instruction returns the error code W#16#80A7 after expiration of the configured parameter assignment time for distributed I/O. The DP slave/PROFINET IO device is activated and the fact that the activated DP slave/PROFINET IO device cannot be accessed results in a corresponding display in the system diagnostics.

If the DP slave/PROFINET IO device is accessible again afterwards, this results in standard system behavior (for example, a call of the OB configured for this purpose).

Note

Activating a DP slave/PROFINET IO device may be time-consuming. If you want to cancel a currently running activation job, start "D_ACT_DP" with the same value for LADDR and MODE =2. You repeat the call for "D_ACT_DP" with MODE = 2 until the successful cancellation of the activation job is displayed with RET_VAL =0.

If you wish to activate DP slaves which take part in the slave-to-slave communication, we recommend that you first activate the transmitters and then the receivers (listeners).

Parameters

The following table shows the parameters of the "D_ACT_DP" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Level-triggered control parameter REQ=1: Run activation or deactivation
MODE	Input	USINT	I, Q, M, D, L or constant	Job identifier Possible values: • 0: Request information on whether the addressed component is activated or deactivated (output via RET_VAL parameter) • 1: Activate the DP slave/PROFINET IO device • 2: Deactivate the DP slave/PROFINET IO device
LADDR	Input	HW_DEVICE	I, Q, M, D, L or constant	Hardware identifier of the DP slave (HW_DPSlave)/PROFINET IO device (HW_Device) The number can be taken from the properties of the DP slave / PROFINET IO device in the Network view or from the "System constants" tab of the standard tag table. If both the identifier for the device diagnostics as well as the ID for operating state transitions are both specified there, you must use the code for the device diagnostics.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	Active code: • BUSY=1: The job is still active. • BUSY=0: The job was terminated.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	Job completed without error.
0001	The DP slave/PROFINET IO device is active (this error code is possible only with MODE = 0.)
0002	The DP slave/PROFINET IO device is deactivated (this error code is possible only with MODE = 0.)

Error code* (W#16#...)	Explanation
7000	First call with REQ= 0: The job specified with LADDR is not active; BUSY has the value "0".
7001	First call with REQ= 1. The job specified with LADDRwas triggered. BUSY has the value "1".
7002	Intermediate call (REQ irrelevant). The activated job is still active; BUSY has the value "1".
8090	• You have not configured a module with the address specified in LADDR. • You operate your CPU as I-slave / I-device and you have specified an address of this I-slave/I-device in LADDR.
8092	The deactivation of the currently addressed DP slave/PROFINET IO device (MODE=2) cannot be canceled by being activated (MODE=1). Activate the component at a later time.
8093	The address specified in LADDR does not belong to any DP slave/PROFINET IO device that can be activated or deactivated or the MODE parameter is unknown.
8094	You have attempted to activate a device which is potential partner for a tool change port. However, another device is already activated on this tool change port at this time. The activated device will remain activated.
80A0	Error during the communication between the CPU and the IO controller.
80A3	The DP master/PROFINET IO controller concerned does not support this function.
80A4	The CPU does not support this function for external DP masters/PROFINET IO controller.
80A7	A timeout occurred during activation: The remote device is unreachable or you have set the parameter assignment time for central and distributed I/O too short. The status of the remote device is "activated", but it is not reachable.
80AA	Activation with errors in the DP slave/PROFINET IO device: Differences in the configuration
80AB	Activation with errors in the DP slave/PROFINET IO device: Parameter assignment error
80AC	Activation with errors in the DP slave/PROFINET IO device: Maintenance required
80C3	• Temporary resource error: The CPU is currently processing the maximum possible activation and deactivation jobs (8). • The CPU is busy receiving a modified configuration. Currently you can not enable/disable DP slaves/ PROFINET IO devices.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

ReconfigIOSystem: Reconfigure IO system (S7-1200, S7-1500)

ReconfigIOSystem: Reconfigure IO system (S7-1500)

Description

You can use the "ReconfigIOSystem" instruction to transfer a data record to the PROFINET interface of the CPU. This data record ("CTRLREC" parameter) contains the following information for controlling the configuration:

- A list of optional IO devices to be activated
- A list of the partner ports to be specified, if you have set the "Partner is set in the user program" option in the port properties of IO devices

Note

The "ReconfigIOSystem" instruction uses the "D_ACT_DP" instruction internally in MODE 1 and MODE 3 to enable/disable IO devices. Therefore, observe the rules and notes in the description of this instruction.

See also "D_ACT_DP: Disable/enable distributed I/O devices (Page 3673)".

Dependencies between instruction versions

Version V1.1 of instruction "ReconfigIOSystem" requires version V1.1 of the instruction "WRREC".

Version V1.0 of instruction "ReconfigIOSystem" requires version V1.1 of instruction "WRREC".

Functional description

"ReconfigIOSystem" is an asynchronous instruction. Processing takes place across several calls. You start the job by calling "ReconfigIOSystem" with REQ=1.

The output parameters STATUS and BUSY indicate the status of the job.

Parameters

The following table shows the parameters of the "ReconfigIOSystem" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Edge-triggered control parameter REQ=1: Perform data transfer
MODE	Input	UINT	I, Q, M, D, L or constant	You control how the instruction works with the MODE parameter. You can find a detailed functional description in the table below. Possible values: • 1: Disable all IO devices of the IO system for the conversion phase • 2: Reconfigure the IO system according to the data record settings (CTRLREC) • 3: Enable all IO devices of the IO system again after reconfiguration
LADDR	Input	HW_INTERFACE	I, Q, M, D, L or constant	Hardware identifier of the PROFINET interface (IO controller)
CTRLREC	Input	VARIANT	I, Q, M, D, L	Data record for controlling the actual configuration of the IO system
DONE	Output	BOOL	I, Q, M, D, L	0: Instruction not yet completed 1: Instruction completed
BUSY	Output	BOOL	I, Q, M, D, L	Active code: 0: Instruction active 1: Instruction completed

Parameter	Declaration	Data type	Memory area	Description
ERROR	Output	BOOL	I, Q, M, D, L	0: Instruction completed without error 1: Instruction completed with error
STATUS	Output	DWORD	I, Q, M, D, L	Result/error code
ERR_INFO	Output	WORD	I, Q, M, D, L	HW ID of the most recently determined IO device that caused an error.

You can find additional information on valid data types under "Overview of valid data types (Page 2239)".

Parameter MODE

The following values are possible for the MODE input parameter:

MODE	Description
1	All IO devices of the IO system can be disabled by calling the instruction with mode 1. The "ReconfigIOSystem" instruction uses the "D_ACT_DP" instruction internally. "ReconfigIOSystem" returns errors that are detected by D_ACT_DP in the following output parameters: • STATUS (error code) • ERR_INFO (hardware identifier of the IO device causing the error). In STATUS and ERR_INFO, the CPU enters the last determined error/HW identifier and in so doing overwrites an existing error code. For this reason, additional errors can be present besides the entered error.
2	For controlling the actual configuration of the IO system, the instruction transfers the data record to the PROFINET interface, which is addressed with LADDR. See the following section for information on the structure of the data record. See the following section about the STATUS parameter for error analysis.
3	All non-optional IO devices in the IO system and optional IO devices that are listed in the control data record CTRLREC are enabled. The optional IO devices that are **not** listed in the CTRLREC data record remain disabled. If IO devices that are part of docking units are listed in the CTRLREC control data record, the PN IO system reacts as follows: • IO devices of the docking units remain disabled when ReconfigIOSystem is called with Mode 3. This reaction corresponds to the reaction of a configuration without configuration-controlled IO devices. IO devices of docking units are disabled by default and must be enabled in the user program.

Structure of the control data record

You can use the control data record ("CTRLREC" parameter) to inform the PROFINET interface of the CPU which optionally configured IO devices are available in the real IO system configuration and which port interconnections are to be set.

This requires a configuration that allows IO system configuration to be adapted:

- The IO devices listed in the control data record must be enabled as "Optional IO device" (IO device properties: PROFINET interface [X1] > Advanced options > Interface options).
- The port interconnections listed in the control data record are only possible when the partner port is set to "Partner is set by the user program" for the appropriate ports.

The data type of parameter CTRLREC is "VARIANT". The "CTRLREC" control data record must have the following structure:

- Until version V1.1 of ReconfigIOSystem: Array of elements of the Word data type (for numerical addressing)
- As of version V1.2 of ReconfigIOSystem: Array of elements of the UInt data type (for symbolic or numerical addressing) or array of elements of the Word data type (for numerical addressing)

Below, the basic structural composition of "CTRLREC" is described with the Word element data type.

You read the required hardware identifiers directly in the "System constants" tab in the network view or in the device view. To do this, select the object in the network view (IO device) or in the device view (PROFINET interface).

Recommendation: Use the symbolic addressing of the HW identifiers by using the names of the HW identifiers.

Name	Data type	Comment
Version_High, Version_Low	Word	Version of the control data record(High byte: 01 Low byte: 00
Number_of_opt_Devices_used	Word	Number of optional IO devices that are used in the real IO system configuration. Optional IO devices that are not listed below remain disabled.
Activate_opt_Device_1	Word / Hw_Device	The optional IO devices that are present in the real configuration must be listed with their hardware identifiers. Use the system constant of the IO device object. Example: The IO device object has the name "IO-Device_4~IO-Device" and its type is "Hw_Device".
Activate_opt_Device_2	Word / Hw_Device	2nd optional IO device (e.g. with value 262)
...	...	...
Activate_opt_Device_n	Word / Hw_Device	nth optional IO device (e.g. with value 282)
Number_of_Port_Interconnections_used	Word	Number of port interconnections listed below. If you do not specify port interconnections, enter "0". For all the ports for which you have configured "Partner is set by the user program" and that are not listed below, the CPU uses the "Any partner" setting.
Port_Interconnection_1_Local	Word / Hw_Interface	1st port interconnection, HW identifier of local port Use the system constant of the port object. Example: The port object has the name "IO-Device_2~PROFINET_interface~Port_2" and its type is "Hw_Interface".
Port_Interconnection_1_Remote	Word / Hw_Interface	1st port interconnection, HW identifier of partner port
Port_Interconnection_2_Local	Word / Hw_Interface	2nd port interconnection, HW identifier of local port

Name	Data type	Comment
Port_Interconnection_2_Remote	Word / Hw_Interface	2nd port interconnection, HW identifier of partner port
...	...	...
Port_Interconnection_n_Local	Word / Hw_Interface	nth Port interconnection, hardware identifier local port
Port_Interconnectio_n_Remote	Word / Hw_Interface	nth Port interconnection, hardware identifier local port

Parameter STATUS

The STATUS output parameter contains error information. You can find a detailed list of possible error codes in the next section. If STATUS is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	B#16#DF: Error writing data record, otherwise B#16#00.
STATUS[2]	Error_Decode	B#16#80 is output for an error (corresponding to IEC 61158-6 in the context of reading and writing data records).
STATUS[3]	Error_Code_1	B#16#AA in the case of an error in the structure of the data record
STATUS[4]	Error_Code_2	Manufacturer-specific error ID extension: • B#16#00 Error in the data record (e.g. incorrect padding byte values (not equal to 0) • B#16#01 Reserved • B#16#02 At least one station number for an IO device in the data record is invalid (not configured, points to a non-optional IO device or has the value 0 for an IO controller) • B#16#03 At least one partner port specified in the data record is invalid: Examples: – Subslot address of a partner port is not available – Partner port is configured incorrectly (the correct setting is: "Partner is set by the user program") – Partner port belongs to an IO device that is disabled • B#16#10 Version of the CTRLREC control data record invalid (specified version is not supported) • B#16#11 The number of optional IO devices to be activated in the CTRLREC control data record is not supported • B#16#12 The number of specified interconnections ("Partner set in the user program") in the CTRLREC control data record is not supported • B#16#13 Internal conversion of the hardware identifier to device number failed. The ERR_INFO output parameter contains the hardware identifier of the device causing the error. • B#16#14 Consistency error: The length of the CTRLREC control data record does not match the information in the control data record. Example: 20 optional IO devices are specified, but the control data record only has a length of 10 bytes.

Error codes (STATUS parameter)

Error code	Description
16#0000_0000	Job completed without error
16#0070_0000	No job active
16#0070_0100	First call of the instruction
16#0070_0200	Following call of the instruction (instruction is still running, BUSY = 1)
16#0080_8000	MODE is not supported
16#0084_5100	Incorrect data type of CRTLREC data record. Use an array of UInt or an array of Word.
16#0080_9100	The LADDR parameter does not address any PROFINET interface (does not exist or wrong type, e.g. PROFIBUS interface). The PROFINET interface does not support configuration control of IO systems.
16#0080_Cx00	Temporary error, e.g., due to temporary lack of resources.
16#DF80_AAxy	Error in the structure of the data record (MODE 2). For the meaning of "xy", see the definition of STATUS[4] Error_Code_2 above.
16#DF80_B6xy	Configuration control not possible because either no optional IO device was configured or no port was assigned with "Partner is set in the user program". This configuration is a prerequisite for calling the instruction. "xy" is irrelevant.
16#0080_9400 16#0080_A000 16#0080_A700 16#0080_AA00 16#0080_AB00 16#0080_AC00	Forwarded error codes of the internally called D_ACT_DP instruction. For the meaning of these error codes, see "D_ACT_DP (Page 3673)". The hardware identifiers of IO devices causing errors are entered in ERR_INFO (entry is consecutively overwritten by subsequent errors). If more than one IO device is involved, online diagnostics with STEP 7 is recommended. With IRT configuration: The device numbers of the IO devices should follow from the IO controller in ascending order of their topological interconnection, see here.

Example

You will find the example here: Program example for ReconfigIOSystem (Page 3683).

You can find additional information and the program code for the example here: Sample Library for Instructions (Page 2568).

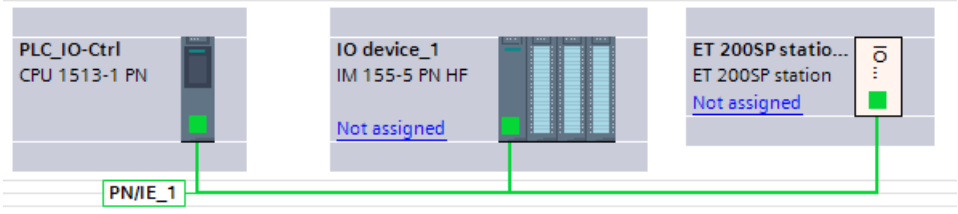
Difference between synchronous and asynchronous instructions (Page 2571)

Program example for ReconfigIOSystem (S7-1200, S7-1500)



Introduction

In the following example, you configure an IO system via the program using the control data record "CTRLREC". The target configuration should consist of an S7-1500 CPU, an IO device (for example ET 200MP) and an optional IO device (for example, ET 200SP). For this purpose, disable an existing IO system, transfer the configuration values to the PROFINET interface of the CPU and enable the IO devices.

You can find additional information on the data records in Overview of the types of data records (Page 3571).

Requirements

- An S7-1500 CPU has been created.
- Two ET 200 have been created.
- A PROFINET connection has been created and the hardware settings have been made:
  - IO device (for example, ET 200MP IM 155-5 PN HF)
  - optional IO device (for example, ET 200SP IM 155-6 PN ST
  - IO system is set up by the program

Note

Hardware settings for an IO system to be set up by the program

Proceed as follows:

1. Connect the two ET 200 via PROFINET with the CPU.
2. Assign the two ET 200 as IO controllers to the CPU. Then open the CPU properties.
3. Open the entry "PROFINET interface [X1] > Advanced options > Port X1 P1 > Port interconnection > Partner port". Select the option "Set Partner by user program". Do the same for "Port X1 P2".
4. Open the properties of ET 200MP (...> Port X1 P1) and select the option "Set Partner by user program" (see step 3).
5. Open the properties of ET 200SP (...> Port X1 P1) and perform the following settings:
   - Select the option "Set Partner by user program" (see step 3).
   - Open "PROFINET interface [X1] > Advanced options > Interface options" and select the option "Optional IO device".

Storage of data

To store the data, create the two structures "operateMode" and "ctrlRec" and 13 additional tags in a global data block.

The structure "ctrlRec" contains the control data record "CTRLREC".

SLI_gDB_ReconfigIOSystem

	Name	Data type	Start value
1	Static		
2	start	Bool	false
3	startDone	Bool	false
4	reset	Bool	false
5	getExecute	Bool	false
6	operateMode	Struct	
7	value	UInt	1
8	Disable_all_IO_devices_done	Bool	false
9	Reconfigure_IO_system_done	Bool	false
10	Enable_all_IO_devices_done	Bool	false
11	laddr_interface	HW_INTERFACE	64
12	ctrlRec	Struct	
13	Version	Word	16#0100
14	Number_of_opt_Devices_used	Word	1
15	Activate_opt_Device_1	HW_DEVICE	264
16	Number_of_Port_Interconnections_used	Word	2
17	Port_Interconnection_1_Local	HW_INTERFACE	65
18	Port_Interconnection_1_Remote	HW_INTERFACE	259
19	Port_Interconnection_2_Local	HW_INTERFACE	66
20	Port_Interconnection_2_Remote	HW_INTERFACE	273
21	status	DWord	16#0
22	busy	Bool	false
23	done	Bool	false
24	error	Bool	false
25	errorDevice	Word	16#0
26	memErr	Bool	false
27	memErrDevice	Word	16#0
28	memErrStatus	DWord	16#0

Note

You have to specify the values of the hardware identifiers ("laddr_interface", "ctrlRec") according to your system.

For example, determine the hardware identifier of the interface of the CPU ("laddr_interface") as follows:

In the CPU, open the entry "PLC tags > Show all tags > System constants" and search for the name <Local~PROFINET-Interface_1> with the data type "Hw_Interface". The associated cell "value" contains the hardware identifier.

Note

Pay attention to the interfaces used.

- The Port X1 P1 of the IO device (ET 200MP/"<IO_device_1>") is connected with the port X1 P1 of the CPU ("<Local>").
- The Port X1 P1 of the optional IO device (ET 200SP/"<IO_device_2>") is connected with the port X1 P2 of the CPU ("<Local>"). You also require the hardware identifier of the device (data type "Hw_Device") from the optional IO device.

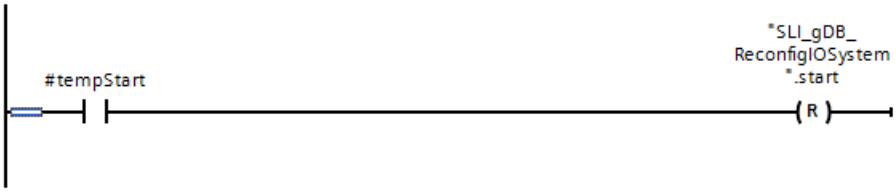
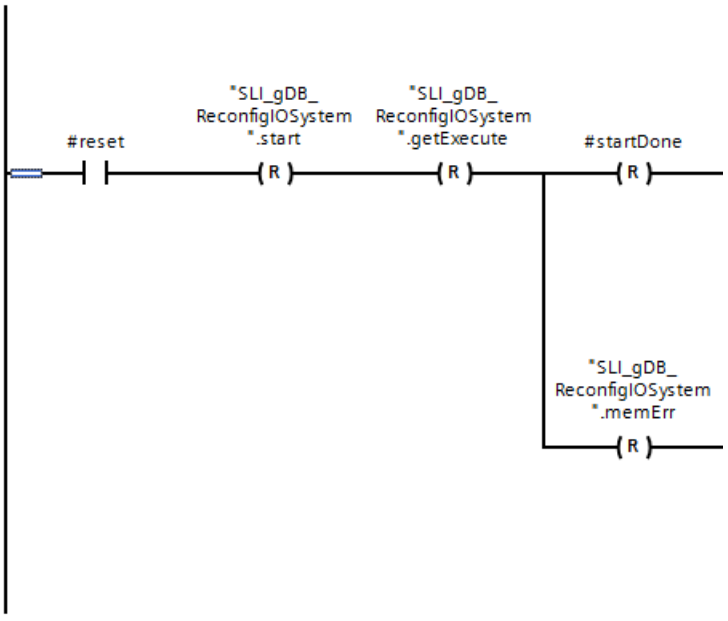
Interconnecting parameters in the FC "SLI_FC_start_reset_ReconfigIOS"

To start or reset the instruction "ReconfigIOSystem", create the FC "SLI_FC_start_reset_ReconfigIOS". To pass on the data, create the following local tags in the FC.

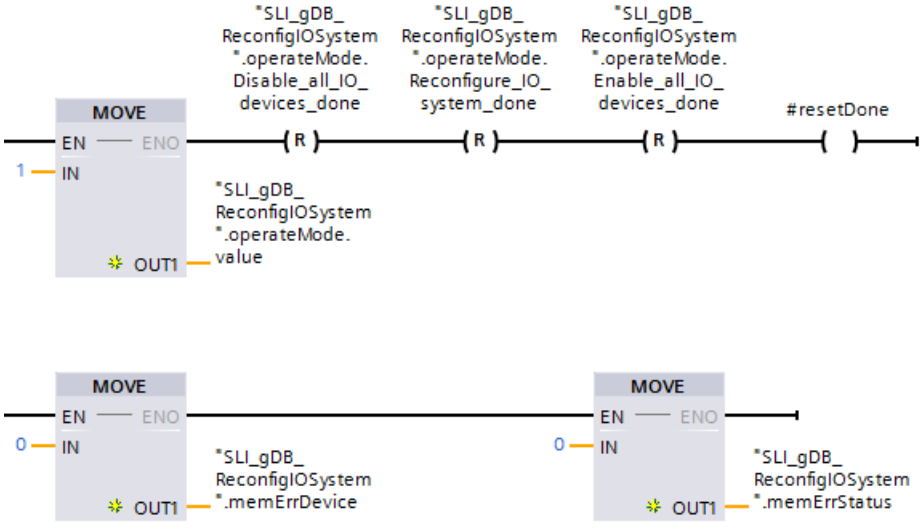


SLI_FC_start_reset_ReconfigIOS

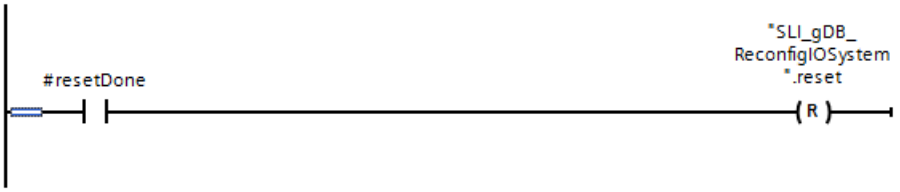
	Name	Data type
1	Input	
2	start	Bool
3	reset	Bool
4	Output	
5	<Add new>	
6	InOut	
7	startDone	Bool
8	Temp	
9	tempStart	Bool
10	resetDone	Bool



Network 1: To set the input parameter REQ ("getExecute"), interconnect the tag "start".

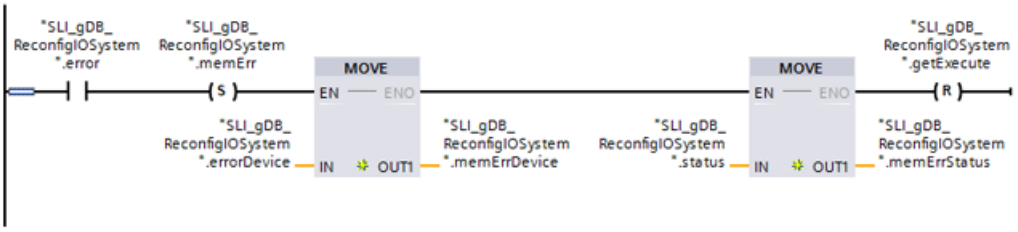


Network 2: To reset "start", create the following interconnections.

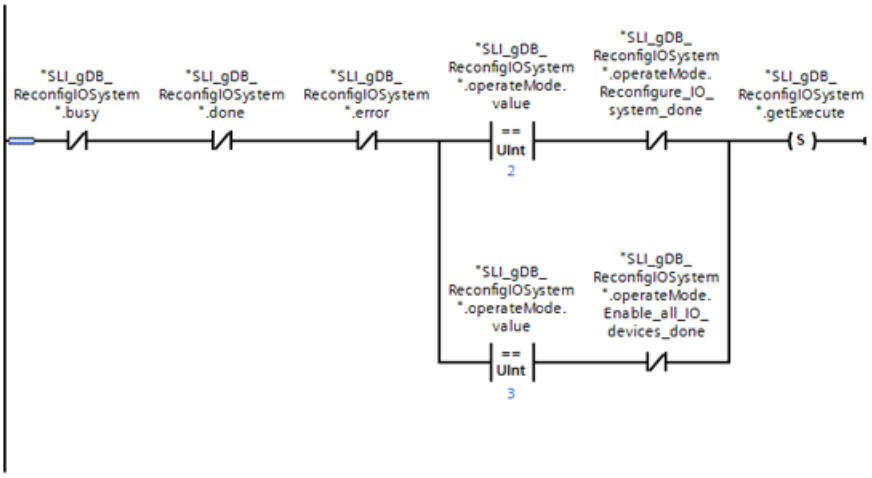


Network 3: To reset all set process values, create the following interconnections. Part 1 of the network:

Part 2 of the network:

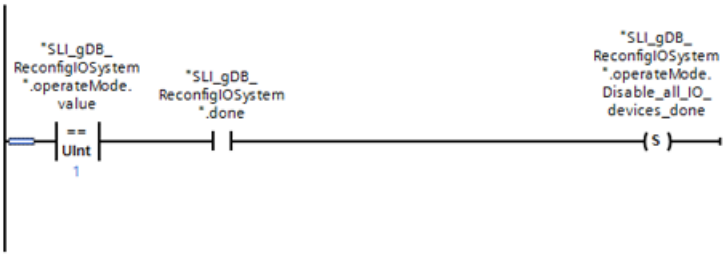


Network 4: To reset "reset", create the following interconnections.

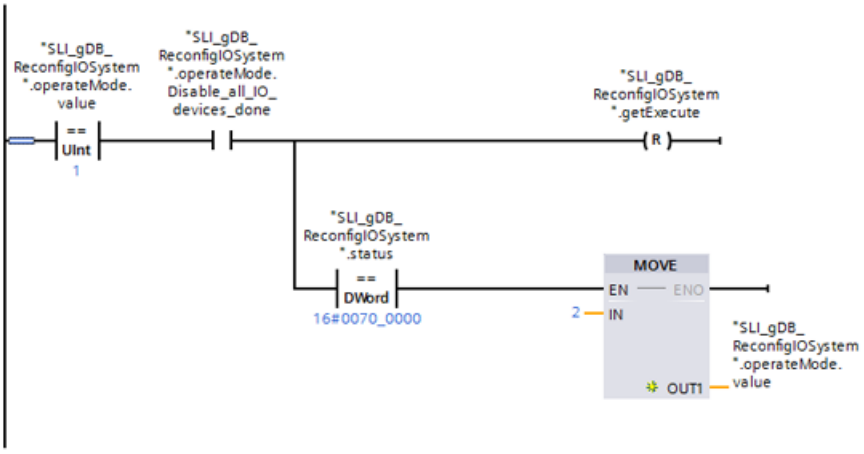


Interconnecting parameters in the FC "SLI_FC_switchMode_ReconfigIOS"

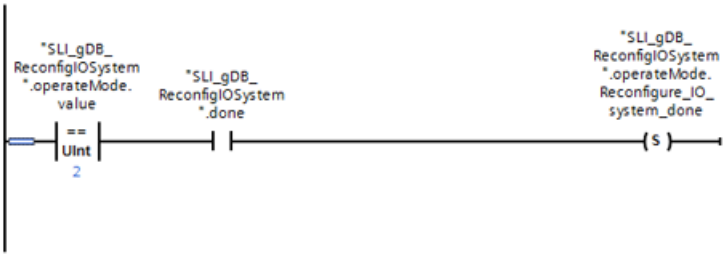
To safely reconfigure the IO system, run through all three modes of "ReconfigIOSystem". You need to set an automatism for mode switchover in the FC "SLI_FC_switchMode_ReconfigIOS" so that you do not have to switch the modes of the "ReconfigIOSystem" instruction yourself.



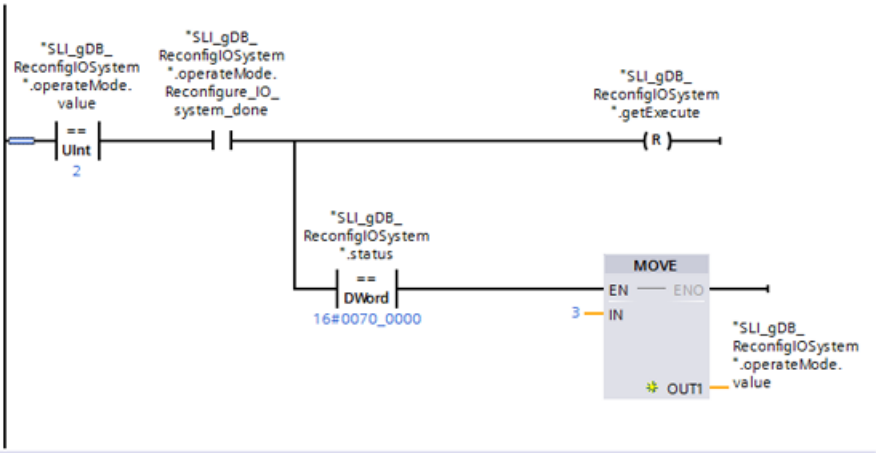
Network 1: To save the information in the case of error, create the following interconnections.



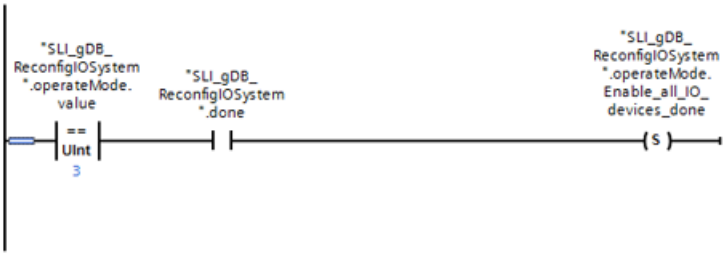
Network 2: To automatically start the instruction "ReconfigIOSystem" in mode 2 or mode 3, create the following interconnections.



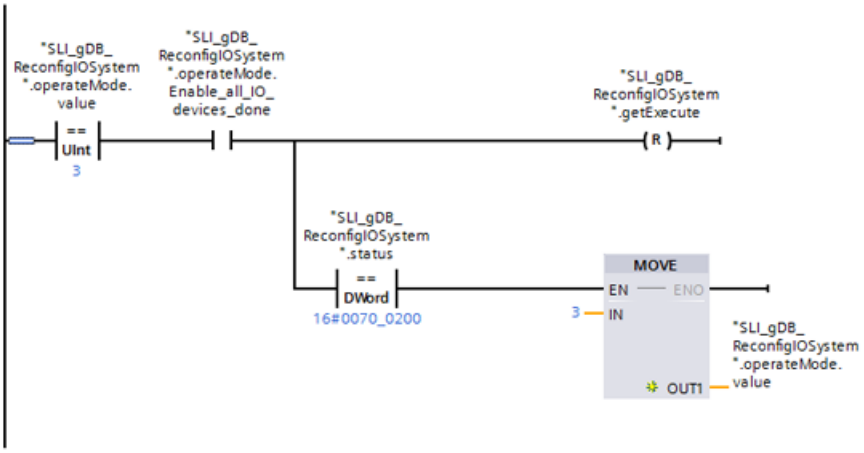
Network 3: Record the success of the processing of ReconfigIOSystem in mode 1 as follows.



Network 4: To safely switch from mode 1 to mode 2, create the following interconnections.



Network 5: Record the success of the processing of ReconfigIOSystem in mode 2 as follows.

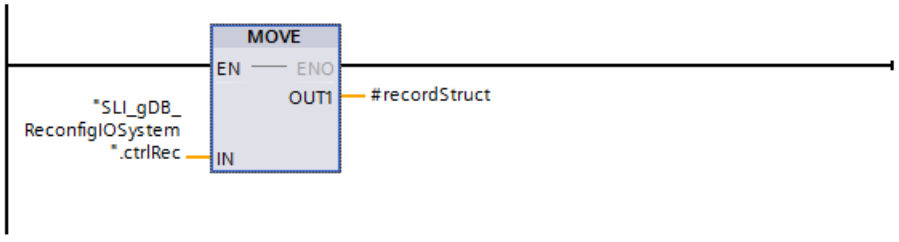


Network 6: To safely switch from mode 2 to mode 3, create the following interconnections.

Network 7: Record the success of the processing of ReconfigIOSystem in mode 3 as follows.

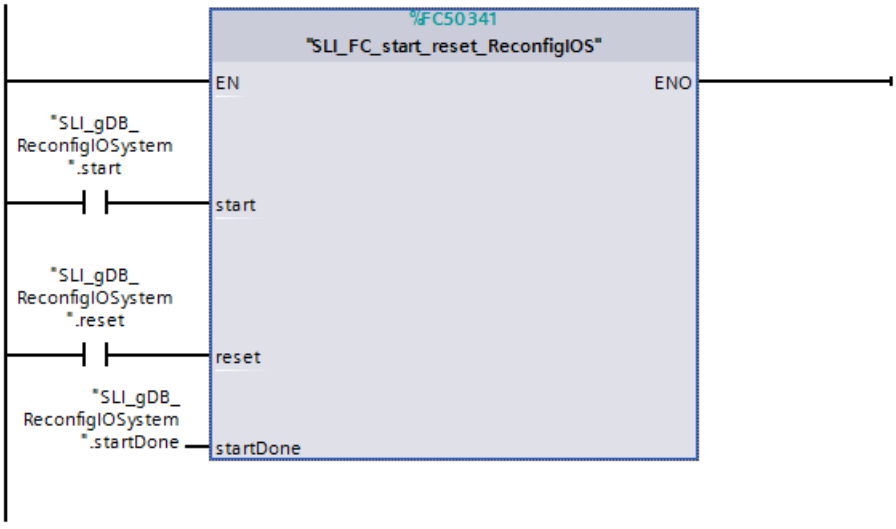
Network 8: To end the processing of ReconfigIOSystem, create the following interconnections.

Note



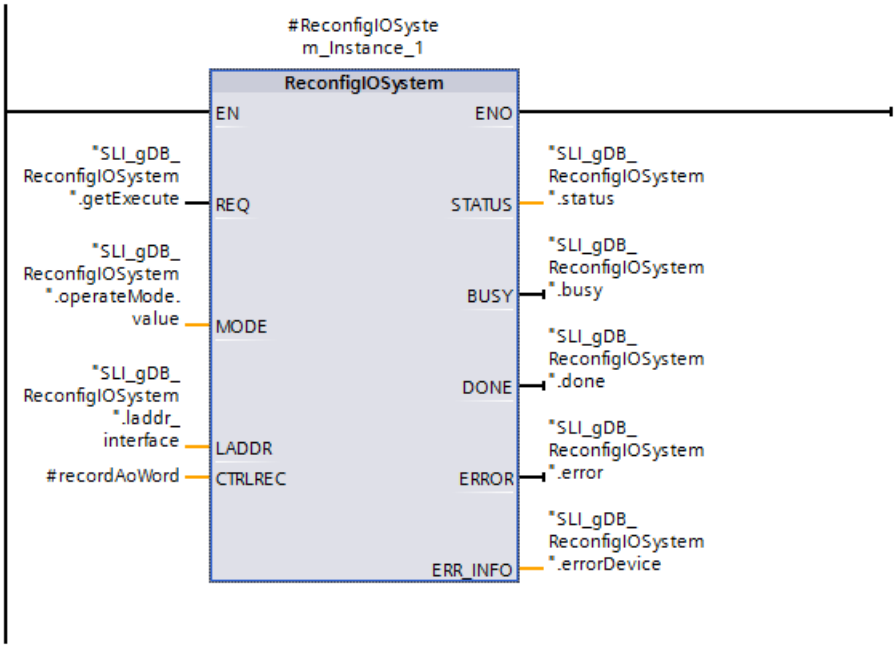
Alternatively, you can switch from mode 3 to mode 1 after processing. For this purpose, enter the value "1" for the instruction "MOVE".

Interconnecting parameters in the FB "SLI_FB_ReconfigIOSystem"

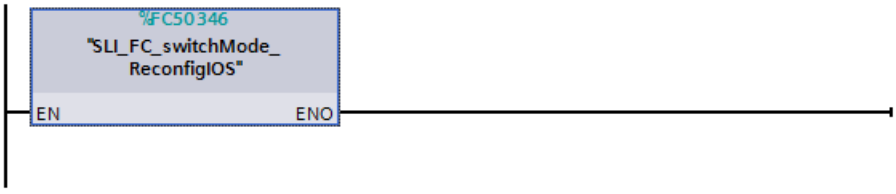


Call the instruction "ReconfigIOSystem" in an FB ("SLI_FB_ReconfigIOSystem"). To pass on the data, create the following local tags in the FB. Create the tags "#recordAoWord" and "#recordStruct" as AT constructs. The tags must be the same size (as "ctrlRec").

7		Static			
8		ReconfigIOSystem_Instance_1	ReconfigIOSyste...		
9		recordAoWord	Array[0..7] of Word		Set in IDB
10		recordStruct AT "recordAoWord"	Struct		Set in IDB
11		Version	Word		Set in IDB
12		Number_of_opt_Devices_used	Word		Set in IDB
13		Activate_opt_Device_1	HW_DEVICE		Set in IDB
14		Number_of_Port_Interconnections_...	Word		Set in IDB
15		Port_Interconnection_1_Local	HW_INTERFACE		Set in IDB
16		Port_Interconnection_1_Remote	HW_INTERFACE		Set in IDB
17		Port_Interconnection_2_Local	HW_INTERFACE		Set in IDB
18		Port_Interconnection_2_Remote	HW_INTERFACE		Set in IDB



Network 1: To transfer the data record ("ctrlRec"), create the following interconnection.



Network 2: Interconnect the FC "SLI_FC_start_reset_ReconfigIOS" as follows.

Network 3: Interconnect the instruction "ReconfigIOSystem" as follows.

Network 4: Interconnect the FC "SLI_FC_switchMode_ReconfigIOS" as follows.

Call the FB ("SLI_FB_ReconfigIOSystem") in an OB1.

Result (FB "SLI_FB_ReconfigIOSystem")

FB Network 1:

The values of the data record ("ctrlRec") are transferred to an Array of WORD ("#recordAoWord") via a MOVE instruction. To improve understanding, the tags of the "ctrlRec" and "#recordStruct" structures are represented by descriptive names.

FB Network 2:

When the input parameter start ("start") returns the signal state "TRUE", the tag "getExecute" and the output parameter startDone ("startDone") are set to "TRUE". The processing of the instruction "ReconfigIOSystem" is started by the tag "getExecute" at "TRUE".

When the input parameter reset ("reset") returns the signal state "TRUE", the start command of "ReconfigIOSystem", the process values of the processing and the information of the fault scenario are reset.

FB Network 3:

When the input parameter REQ ("getExecute") returns the signal state "TRUE", the "ReconfigIOSystem" instruction is started. The instruction "ReconfigIOSystem" calls the interface of the CPU via the input parameter LADDR ("laddr_interface").

The mode for the operating mode is transferred to the instruction "ReconfigIOSystem" via the input parameter MODE ("operateMode.value"). ReconfigIOSystem disables all existing IO systems of the CPU according to the start value "1". The block status is displayed at the output parameter STATUS ("status"). In the example, processing takes place without errors.

The "ReconfigIOSystem" instruction only calls the data record at the input parameter CTRLREC ("#recordAoWord") in mode 2. The configuration values for the IO system of ReconfigIOSystem to be set up are communicated to the CPU (IO controller).

In mode 3, the "ReconfigIOSystem" instruction enables the IO system. The switchover of the input parameters REQ ("getExecute") and MODE ("operateMode.value") is implemented in network 4 ("SLI_FC_switchMode_ReconfigIOS").

SLI_gDB_ReconfigIOSystem

	Name	Data type	Start value	Monitor value
1	Static			
2	start	Bool	false	FALSE
3	startDone	Bool	false	TRUE
4	reset	Bool	false	FALSE
5	getExecute	Bool	false	FALSE
6	operateMode	Struct		
7	value	UInt	1	3
8	Disable_all_IO_devices_done	Bool	false	TRUE
9	Reconfigure_IO_system_done	Bool	false	TRUE
10	Enable_all_IO_devices_done	Bool	false	TRUE
11	laddr_interface	HW_INTERFACE	64	16#0040
12	ctrlRec	Struct		
13	Version	Word	16#0100	16#0100
14	Number_of_opt_Devices_used	Word	1	16#0001
15	Activate_opt_Device_1	HW_DEVICE	264	16#0108
16	Number_of_Port_Interconnections_used	Word	2	16#0002
17	Port_Interconnection_1_Local	HW_INTERFACE	65	16#0041
18	Port_Interconnection_1_Remote	HW_INTERFACE	259	16#0103
19	Port_Interconnection_2_Local	HW_INTERFACE	66	16#0042
20	Port_Interconnection_2_Remote	HW_INTERFACE	273	16#0111
21	status	DWord	16#0	16#0070_0000
22	busy	Bool	false	FALSE
23	done	Bool	false	FALSE
24	error	Bool	false	FALSE
25	errorDevice	Word	16#0	16#0000
26	memErr	Bool	false	FALSE
27	memErrDevice	Word	16#0	16#0000
28	memErrStatus	DWord	16#0	16#0000_0000

FB Network 4:

If the instruction "ReconfigIOSystem" was successfully processed in mode 1 (the tag "done" has the value "TRUE"), the tag "operateMode.Disable_all_IO_devices_done" is set to "TRUE". As a result, the input parameter REQ ("getExecute") is then reset to "FALSE". As soon as ReconfigIOSystem is inactive ("status" has the value "16#0070_0000"), the value "2" is passed to the tag "operateMode.value". ReconfigIOSystem is then in mode 2.

In mode 2, the input parameter REQ ("getExecute") is automatically set to "TRUE" if the following applies to the instruction "ReconfigIOSystem":

- ReconfigIOSystem is inactive ("busy" and "done" is "FALSE").
- No error occurs ("error" is "FALSE").
- The success state of mode 2 is not reached ("operateMode.Reconfigure_IO_system_done" is "FALSE").

If the instruction "ReconfigIOSystem" was successfully processed in mode 2 (the tag "done" has the value "TRUE"), the tag "operateMode.Reconfigure_IO_system_done" is set to "TRUE". Afterwards, the scenario is similar to with mode 1.

- The "getExecute" tag is reset to "FALSE".
- ReconfigIOSystem ("operateMode.value") is set to mode 3.

In mode 3 the input parameter REQ ("getExecute") is automatically set to "TRUE" if the same applies to the "ReconfigIOSystem" instruction as for mode 2 - with one exception:

- The success state of mode 3 is not reached ("operateMode.Enable_all_IO_devices_done" is "FALSE").

The success status in mode 3 (the tag "done" has the value "TRUE") is queried in the same way as for mode 2. After the successful processing ReconfigIOSystem remains in mode 3 ("operateMode.value" retains the value).

After the completed processing of the three modes, the "ReconfigIOSystem" instruction is inactive ("status" has the value "16#0070_0000"). The IO system is set up: An S7-1500 CPU with an IO device and an optional IO device. Both IO devices are activated.

Program code

You can find additional information and the program code for the above-named example here: Sample Library for Instructions (Page 2568).

RD_REC: Read data record from I/O (S7-1500)

Description

Use the instruction to read the data record with the number RECNUM from the addressed module. You start the read process by assigning the value "1" to the input parameter REQ during the call. If the read process is executed immediately, the instruction returns the value "0" at the output parameter BUSY . If BUSY has the value "1", reading is not yet complete.

See also: Difference between synchronous and asynchronous instructions (Page 2571). The data record read is entered in the target range spanned by the RECORD parameter, providing the data transfer was free of errors.

Note

When you read out a data record with a number greater than one from an FM or a CP you have purchased prior to February 1997 (below referred to as "old modules"), "RD_REC" responds differently than it does in new modules. This special situation is covered in the section "Using old S7-300 FMs and CPs with data record numbers >1" (see below).

If a DPV1 slave is configured via GSD file (GSD rev. 3 and higher) and the DP interface of the DP master is set to "S7 compatible", then you may not read any data records from the I/O modules in the user program with "RD_REC". In this case, the DP master addresses the wrong slot (configured slot + 3).

Remedy: Set the interface of the DP master to "DPV1".

Parameters

The following table shows the parameters of the "RD_REC" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number (permitted values: 0 to 240)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. In addition: Length of the actually transferred data record in bytes (possible values: +1 to +240), if the target range is greater than the transferred data record and if no error occurred during the transfer.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.
RECORD	Output	ANY	I, Q, M, D, L	Target range for the data record read. With asynchronous execution of "RD_REC", make sure that the actual parameters of RECORD have the same length information for all calls. Only the BYTE data type is permitted. Note: Note that for S7-300 CPUs, the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 byte 100). The omission of an explicit DB number is illegal for S7-300 CPUs and leads to an error message in the user program.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RECORD

Note

If you want to ensure that the entire data record is always read, select a target range with a length of 241 bytes. If the data transfer is without error, RET_VAL contains the actual data record length.

Using old S7-300 FMs and CPs with data record numbers > 1

If you want to use the instruction "RD_REC" to read out a data record with a number greater than one from an old S7-300 FM or old S7-300 CP, remember the following points:

- If the target range is greater than the actual length of the required data record, no data is entered in RECORD . RET_VAL is written with W#16#80B1.
- If the target range is less than the actual length of the required data record, the CPU reads as many bytes beginning at the start of the record as are specified in the length information of RECORD and enters this number of bytes in RECORD . RET_VAL is written with "0".
- If the length specified in RECORD is the same as the actual length of the required data record, the CPU reads the data record and enters it in RECORD . RET_VAL is written with "0".

Parameter RET_VAL

- If an error occurred while the function was being executed, the return value contains an error code.
- If no error occurred during the transfer, RET_VAL contains the following:
  - 0, if the entire target range was filled with data from the selected data record (the data record can also be incomplete).
  - The length of the actually transferred data record in bytes (possible values: +1 to +240), if the target range is greater than the transferred data record.

Note

If the general error W#16#8745 occurs, this only indicates that access to at least one byte of the process image was blocked. The data record was read by the module correctly and written to the I/O memory area.

When looking at the "real" error information (error codes W#16#8xyz) in the following table, two different cases are described:

- Temporary errors (error codes W#16#80A2 to 80A3, 80Cx):
  It is possible that this type of error is eliminated without user action. For this reason, it is advisable to call the instruction again (multiple calls, if necessary).
  Example of a temporary error: Resources required are currently in use (W#16#80C3).
- Permanent errors (error codes W#16#809x, 80A0, 80A1, 80Bx):
  This type of error does not correct itself. Once you have eliminated the error, the instruction needs to be called again. Example of a permanent error: Wrong length specification in RECORD (W#16#80B1).

Note

If you transfer data records to a DPV1 slave with "WR_REC (Page 3699)" or if you read data records from a DPV1 slave with RD_REC and if this DPV1 slave operates in DPV1 mode, the DP master evaluates the error information it received from the slave as follows:

If the error information lies within the range from W#16#8000 to W#16#80FF or W#16#F000 to W#16#FFFF, the DP master passes the error information to the instruction. If the error information is outside this range, the DP master passes the value W#16#80A2 to the instruction and suspends the slave.

For a description of the error information originating from DPV1 slaves, refer to STATUS[3] Parameter STATUS (Page 3638).

Parameter RET_VAL for WR_REC and RD_REC

Error code* (W#16#...)	Explanation	Restriction
0000	No error	-
7000	First call with REQ=0: No data transfer active; BUSY has the value 0.	-
7001	First call with REQ=1: Data transfer started; BUSY has the value 1.	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value 1.	Distributed I/O
8090	Address specified at parameter ADDR is invalid.	-
8092	A type other than BYTE is specified in the ANY reference.	-
8093	This instruction is not permitted for the module selected by means of LADDR and IOID .	-
80A0	Negative acknowledgment when reading from the module: Module was removed during the reading process or is defective	With "RD_REC" only
80A1	Negative acknowledgment when writing to the module: Module was removed during the writing process or is defective	With "WR_REC (Page 3699)" only
80A2	• DP protocol error at layer 2 (for example, slave failure or bus problems) • For ET 200S, data record cannot be read in DPV0 mode.	Distributed I/O
80A3	DP protocol error with user interface/user	Distributed I/O
80A4	Communication on PROFIBUS disrupted.	-

Error code* (W#16#...)	Explanation	Restriction
80B0	• Instruction not possible for module type. • The module does not recognize the data record. • Data record number 241 not permitted. • With "WR_REC (Page 3699)", data records 0 and 1 are not permitted.	-
80B1	The length specified in parameter RECORD is incorrect.	• With "WR_REC (Page 3699)": Length incorrect • With "RD_REC" (only when using old S7-300 FMs and S7-300 CPs): specified length > data record length • With DPNRM_DG: specified length < data record length
80B2	The configured slot is not occupied.	-
80B3	Actual module type does not match specified module type	-
80B5	DP slave or module is not ready.	-
80B7	DP slave or module reports an invalid range for a parameter or value.	With "RD_REC" only
80C0	With "WR_REC (Page 3699)": The data is only written when the CPU is in STOP mode. Note: this means that writing by the user program is not possible. You can only write the data online with PG/PC. With "RD_REC": the module routes the data record, but either no data is present or the data can only be read when the CPU is in STOP mode. Note: if data can only be read when the CPU is in STOP mode, then an evaluation by the user program is not possible. In this case, you can only read the data online with PG/PC. With "DPNRM_DG (Page 3715)": No diagnostics data available.	With "WR_REC (Page 3699)" or "RD_REC" or "DPNRM_DG (Page 3715)"
80C1	The data of the previous write job on the module for the same data record has not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	-
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available.	Distributed I/O
80C6	Data record transfer stopped due to priority class abort (restart or background)	Distributed I/O
80Ex	Manufacturer-specific. Please check the documentation of the module.	-

Error code* (W#16#...)	Explanation	Restriction
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".		

WR_REC: Write data record to I/O (S7-1500)

Description

Use the instruction "WR_REC" to transfer the data record RECORD to the addressed module.

The data to be transferred are read from the RECORD parameter during the first call. If the transfer of the data record takes longer than the duration of one call, the contents of the RECORD parameter are no longer relevant for the subsequent instruction calls (for the same job).

You start the writing process by assigning the value "1" to the input parameter REQ during the call. If the writing process could be executed immediately, the instruction returns the value "0" at the output parameter BUSY. If BUSY has the value "1", writing is not yet complete.

Parameters

The following table shows the parameters of the instruction "WR_REC":

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, T, C or constant	REQ = 1: Write request
LADDR	Input	HW_IO	I, Q, M, D, L or constant	Hardware identifier of the module.
RECNUM	Input	BYTE	I, Q, M, D, L or constant	Data record number
RECORD	Input	VARIANT	I, Q, M, D, L	Data record
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The writing process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

See also: RD_REC: Read data record from I/O (Page 3694)

Note

If the general error W#16#8544 occurs, it only indicates that access to at least one byte of the I/O memory area containing the data record was denied. The data transfer was continued.

DPRD_DAT: Read consistent data of a DP standard slave (S7-1200, S7-1500)

Description

Use the instruction "DPRD_DAT" to read out consistent data from an I/O module.

The instruction can be used for the central modules as well as for the DP standard slaves and PROFINET IO devices.

You require "DPRD_DAT" because you can only read out a maximum of four continuous bytes using the load commands that access the I/O or the process image input table. If required, you can also read consistent data via the process image of the inputs. Refer to the related documentation to find out if your CPU supports this functionality. For additional information on consistent data of a DP standard slave/PROFINET IO device, refer to Section "Data consistency (Page 4383)".

If necessary, use the instruction "DPRD_DAT" also for a data area of 1 byte or larger. For information on the maximum length of the data, refer to the documentation of your CPU (e.g. 64 bytes for an S7-1214).

- Use the parameter LADDR to select the module of the DP normslave/PROFINET IO device. If an access error occurs, the error code W#16#8090 is output.
- Use the RECORD parameter to define the target range for the read data:
  - The target range has to be at least as long as the inputs of the selected module. If the target range is longer than the inputs of the module, it is written from the front with the values of the inputs; with S7-1200 CPUs the remaining bytes of the target range remain unchanged, with S7-1500 CPUs the remaining bytes are filled with zeros. If you read from a DP standard slave with a modular configuration or with several DP identifiers, you can only access the data of a module of the configured hardware identifier per "DPRD_DAT" call. If the selected target range is too small, the error code RET_VAL is output at the 80B1 parameter.
  - The following data types can be used: BOOL, BYTE, CHAR, WCHAR, WORD, LWORD, DWORD, INT, UINT, USINT, SINT, LINT, ULINT, DINT, UDINT, REAL, LREAL. The use of these data types in a data structure of the type ARRAY or STRUCT is also permissible.
  - The STRING and WSTRING data types are not supported.
  - PLC data types (UDT) and system data types are supported.
- If there was no error during the data transmission, the data that has been read is entered in the target range defined at the RECORD parameter.

Parameters

The following table shows the parameters of the instruction "DPRD_DAT":

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware ID of the module from which the data is to be read. The hardware ID can be found in the properties of the module in the device view or system constants.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
RECORD	Output	VARIANT	I, Q, M, D, L	Target range for the user data that were read.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	• You have not configured a module for the specified hardware identifier or • You have ignored the restriction concerning the length of consistent data, or • you have not specified a hardware identifier as an address at parameter LADDR .
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.
8093	No DP module/PROFINET IO device from which you can read consistent data exists for the hardware identifier specified in LADDR . This error code also occurs if the module addressed by means of LADDR does not have inputs.
80A0	An access error was detected when accessing the I/O.
80B1	The length of the specified target range at parameter RECORD is shorter than the configured user data length.
80C0	The data have not been read yet.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

See also

Parameter STATUS (Page 3638)

DPWR_DAT: Write consistent data of a DP standard slave (S7-1200, S7-1500)

Description

Use the instruction "DPWR_DAT" to transfer the data at the parameters RECORD consistently to the addressed module of the central module or of the DP standard slave/PROFINET IO device and if necessary to the process image (i.e. if the affected address range of the DP standard slaves is projected as consistency range in a process image).

You require "DPWR_DAT" because you can only write a maximum of four continuous bytes using the transfer commands that access the I/O or process image output. If required, also write consistent data via the process image output. Refer to the related documentation to find out if your CPU supports this functionality. Do not use both possibilities concurrently when writing consistent data: Either use "DPWR_DAT" or write via the process image output table. For additional information on consistent data of a DP standard slave/PROFINET IO device, refer to Section "Data consistency (Page 4383)". If the DP standard slave has a modular design, you only access one module of the DP slave.

⚠ CAUTION

I/O access

When using "DPWR_DAT", avoid accessing I/O areas that have process image partitions with OB6x connections (isochronous mode interrupts) assigned to them.

If necessary, the instruction "DPRD_DAT" can also be used for a data area of 1 byte or larger. For information on the maximum length of the data, refer to the documentation of your CPU (e.g. 64 bytes for an S7-1214).

- Use the LADDR parameter to select the DP standard slave / PROFINET IO device. If an access error occurs on the addressed module, the error code 8090 is output.
- Use the RECORD parameter to define the source range of the data to be written:
  - The source range has to be at least as long as the outputs of the selected module. Only the outputs are transferred, the other bytes are not considered. If the source area at parameter RECORD is longer than the outputs of the configured module, only the data up to the maximum length of the outputs is transferred. If the source area at parameter RECORD is shorter than the outputs of the configured module, the error code 80B1 is output.
  - The following data types can be used: BOOL, BYTE, CHAR, WCHAR, WORD, LWORD, DWORD, INT, UINT, USINT, SINT, LINT, ULINT, DINT, UDINT, REAL, LREAL. The use of these data types in a data structure of the type ARRAY or STRUCT is also permissible.
  - The STRING and WSTRING data types are not supported.
  - PLC data types (UDT) and system data types are supported.

The data transfer is synchronous. Once the instruction is finished, the write process is completed.

Parameters

The following table shows the parameters of the instruction "DPWR_DAT":

Parameter	Declaration	Data type	Memory area	Description
LADDR	Input	HW_IO	I, Q, M, L or constant	Hardware ID of the module to which the data is to be written. The hardware ID can be found in the properties of the module in the device view or system constants.
RECORD	Input	VARIANT	I, Q, M, D, L	Source area for the user data to be written.
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Error code* (W#16#...)	Explanation
0000	No error occurred.
8090	• You have not configured a module for the specified hardware identifier or • You have ignored the restriction concerning the length of consistent data, or • you have not specified a hardware identifier at parameter LADDR .
8092	A data type other than (Array of) bit string or integer was specified at the RECORD parameter.
8093	No DP module /PROFINET IO device to which you can write consistent data exists at the HW ID specified in LADDR . This error code also occurs if the DP standard slave / PROFINET IO device addressed via LADDR does not have outputs.
80A1	Access error detected while I/O devices were being accessed.
80B1	The length of the specified source range at the RECORD parameter is shorter than the outputs of the configured DP standard slave / PROFINET IO device.
80C1	The data of the previous write job have not yet been processed by the DP standard slave / PROFINET IO device.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Parameter STATUS (Page 3638)

iDevice / iSlave (S7-1200, S7-1500)

RCVREC: Receive data record (S7-1200, S7-1500)

Description

An I-device can receive a data record from a superordinate controller. The receipt takes place in the user program with the instruction "RCVREC" (receive record).

The instruction has the following operating modes:

- Check whether the I-device has a request for a data record receipt.
- Make the data record available to the output parameters.
- Sending an answer to the superordinate controller.

You can determine the operating mode executed by the instruction using the input parameter MODE (see below).

The I-device must be in the RUN or STARTUP mode.

With MLEN, you specify the maximum number of bytes you want to receive. Select the destination area RECORD at least MLEN bytes long.

If a data record was received (MODE=1 or MODE=2), the output parameter NEW will indicate that the data record was stored in RECORD. Note that RECORD has a sufficient length. The output parameter LEN contains the actual length of the data record received in bytes.

Set CODE1 and CODE2 to zero for the positive answer to the superordinate controller. If the received data record is rejected, enter Error Code 1 in CODE1 and Error Code 2 in CODE2 of the negative answer at the superordinate controller.

Note

If the I-device has received a request for a data record receipt, you must recognize the delivery of this request within a certain duration. After recognition, you must send an answer to the superordinate controller within this time period. Otherwise the I-device will experience a timeout error which causes the operating system of the I-device to send a negative answer to the superordinate controller. For information on the value for the time period, refer to the specifications of your CPU.

The output parameter STATUS receives the error information after the occurrence of an error.

Operating modes

You can determine the operating mode of the instruction "RCVREC" with the input parameter MODE. This step will be explained in the following table.

MODE	Meaning
0	Check whether a request for a data record receipt exists If a data record from a higher-level controller exists on the I-device, the instruction will only write the output parameters NEW, SLOT, SUBSLOT, INDEX and LEN. If you call the instruction several times with MODE=0, then the output parameter will only refer to one and the same request.
1	Receiving a data record for any subslot of the I-device If a data record from a superordinate controller exists on the I-device for any subslot of the I-device, the instruction will write the output parameter and transfer the data record to the parameter RECORD.
2	Receiving a data record for a specific subslot of the I-device If a data record from a superordinate controller exists on the I-device for a specific subslot of the I-device, the instruction will write the output parameter and transfer the data record to the parameter RECORD.
3	Sending a positive answer to the superordinate controller The instruction checks the request of the superordinate controller to receive a data record, accepts the existing data record and sends a positive acknowledgment to the superordinate controller.
4	Sending a negative answer to the superordinate controller The instruction checks the request of the superordinate controller to receive a data record, rejects the existing data record and sends a negative acknowledgment to the superordinate controller. Enter the reason for the rejection in the input parameters CODE1 and CODE2.

Note

After the receipt of a data record (NEW=1) you must call "RCVREC" twice to ensure complete processing. You must do this in the following order:

- First call with MODE=1 or MODE=2
- Second call with MODE=3 or MODE=4

Parameters

The following table shows the parameters of the "RCVREC" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Subslot in the transfer area of the I-device for the data record to be received (only relevant for MODE=2). The high word is always set to zero.
MLEN	Input	INT*	I, Q, M, D, L or constant	Maximum length of the data record to be received in bytes
CODE1	Input	BYTE	I, Q, M, D, L or constant	"0" (for MODE=3) and/or Error Code 1 (for MODE=4)
CODE2	Input	BYTE	I, Q, M, D, L or constant	"0" (for MODE=3) and/or Error Code 2 (for MODE=4)

Parameter	Declaration	Data type	Memory area	Description
NEW	Output	BOOL	I, Q, M, D, L	• MODE=0: New data record was received • MODE=1 or 2: Data record was transferred to RECORD
STATUS	Output	DWORD	I, Q, M, D, L	Error information
SLOT	Output	HW_SUB-MODULE	I, Q, M, D, L	Identical to F_ID
SUBSLOT	Output	HW_SUB-MODULE	I, Q, M, D, L	Identical to F_ID
INDEX	Output	UINT	I, Q, M, D, L	Number of the data record received
LEN	Output	UINT	I, Q, M, D, L	Length of the data record received
RECORD	InOut	VARIANT	I, Q, M, D, L	Destination area for the data record received. Note: Note that for S7-300 CPUs, the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 Byte 100) The omission of an explicit DB number is illegal for S7-300 CPUs and leads to an error message in the user program.
* Use the data type UINT in the STL programming language.				

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

For interpretation of the STATUS parameter, refer to section: Parameter STATUS (Page 3638)

PRVREC: Make data record available (S7-1200, S7-1500)

Description

An I-device can receive a request from a superordinate controller to make a data record available. The I-device makes the data record available in the user program with the instruction "PRVREC" (provide record).

The instruction has the following operating modes:

- Check whether the I-device has a request for making a data record available.
- Transfer the requested data record to the superordinate controller.
- Sending an answer to the superordinate controller.

You can determine the operating mode executed by the instruction using the input parameter MODE (see below).

The I-device must be in the RUN or STARTUP mode.

Enter the maximum number of bytes the data record to be sent should have with LEN. Select the destination area RECORD at least LEN bytes long.

If a request to make a data record available exists, (MODE=0), the output parameter NEW will be set to TRUE.

If the request for making a data record available is accepted, write RECORD for the positive answer to the superordinate controller with the requested data record and write zero for CODE1 and CODE2. If the request for making a data record available is to be rejected, enter the negative answer to the superordinate controller in Error Code 1 of the CODE1 and in Error Code 2 of theCODE2.

Note

If the I-device has received a request for making a data record available, you must recognize the delivery of this request within a certain time period. After recognition, you must send an answer to the superordinate controller within this time period. Otherwise the I-device will experience a timeout error which causes the operating system of the I-device to send a negative answer to the superordinate controller. For information on the value for the time period, refer to the specifications of your CPU.

The output parameter STATUS receives the error information after the occurrence of an error.

Operating modes

You can determine the operating mode of the instruction "PRVREC" with the input parameter MODE. This step will be explained in the following table.

MODE	Meaning
0	Check whether a request for making a data record available exists If a request from a higher-level controller for making a data record available exists on the I-device, the instruction will only write the output parameters NEW, SLOT, SUBSLOT, INDEX and RLEN. If you call the instruction several times with MODE=0, then the output parameter will only refer to one and the same request.
1	Receiving a request for making a data record available for any subslot of the I-device If such a request from a superordinate controller for any subslot of the I-device exists on the I-device, the instruction will write the output parameter.
2	Receiving a request for making a data record available for a specific subslot of the I-device If such a request from a superordinate controller for a specific subslot of the I-device exists on the I-device, the instruction will write the output parameter.
3	Make the data record available and send a positive answer to the superordinate controller The instruction checks the request of the superordinate controller to make a data record available, makes the request data record available to RECORD and sends a positive acknowledgement to the superordinate controller.
4	Sending a negative answer to the superordinate controller The instruction checks the request of the superordinate controller to make a data record available, rejects this request and sends a negative acknowledgement to the superordinate controller. Enter the reason for the rejection in the input parameters CODE1 and CODE2.

Note

After the receipt of a request (NEW=1) you must call the instruction twice to ensure complete processing. You must do this in the following order:

- First call with MODE=1 or MODE=2
- Second call with MODE=3 or MODE=4

Parameters

The following table shows the parameters of the "PRVREC" instruction:

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	INT	I, Q, M, D, L or constant	Mode
F_ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Subslot in the transfer area of the I-device for the data record to be sent (only relevant for MODE=2). The high word is always set to zero.
CODE1	Input	BYTE	I, Q, M, D, L or constant	"0" (for MODE=3) and/or Error Code 1 (for MODE=4)
CODE2	Input	BYTE	I, Q, M, D, L or constant	"0" (for MODE=3) and/or Error Code 2 (for MODE=4)
LEN	Input	UINT	I, Q, M, D, L or constant	Maximum length of the data record to be sent in bytes
NEW	Output	BOOL	I, Q, M, D, L	The new data record was requested by the superordinate controller.
STATUS	Output	DWORD	I, Q, M, D, L	Error information
SLOT	Output	HW_SUBMODULE	I, Q, M, D, L	Identical to F_ID
SUBSLOT	Output	HW_SUBMODULE	I, Q, M, D, L	Identical to F_ID
INDEX	Output	UINT	I, Q, M, D, L	Number of the data record to be sent
RLEN	Output	UINT	I, Q, M, D, L	Length of the data record to be sent
RECORD	InOut	VARIANT	I, Q, M, D, L	Data record made available Note: Note that for S7-300 CPUs, the parameter RECORD always requires the full specification of the DB parameters (for example, P#DB13.DBX0.0 Byte 100) The omission of an explicit DB number is illegal for S7-300 CPUs and leads to an error message in the user program.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter STATUS

For interpretation of the STATUS parameter, refer to section: Parameter STATUS (Page 3638)

PROFIBUS (S7-1200, S7-1500)

DPSYC_FR: Synchronize DP slaves / Freeze inputs (S7-1500)

Description

You use the instruction to synchronize one or more groups of DP slaves.

The function involves sending one of the control commands below, or a combination of them, to the relevant groups:

- SYNC (simultaneous output and freezing of output states on the DP slaves)
- UNSYNC (cancels the SYNC control command)
- FREEZE (freeze the input states on the DP slaves and read in the frozen inputs)
- UNFREEZE (cancels the FREEZE control command)

Before you send the control commands listed above, you must assign the DP slaves to groups per configuration. You must know which DP slave is assigned to which group, with which number and know the reactions of the various groups to SYNC/FREEZE.

Note

Note that the control commands SYNC and FREEZE also remain valid when you perform a warm/cold restart.

Please note also that you may initiate only one SYNC/UNSYNC job or only one FREEZE/ UNFREEZE job at a time.

Functional description

"DPSYC_FR" is an asynchronous instruction. Processing takes place across several calls. You start the job by calling "DPSYC_FR" with REQ=1.

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571).

Identification of a job

If you have triggered a SYNC/FREEZE job and called "DPSYC_FR" again before the first job was completed, the response of the instruction depends on whether the new call is for the same job. If the input parameters LADDR, GROUP and MODE match, the call is interpreted as a follow-on call.

Writing outputs of DP modules

The writing of outputs of DP modules is triggered as follows:

- By transfer commands to the DP I/O
- By writing the process image of the outputs to the modules (by the operating system at the end of OB 1 or by calling the instruction "UPDAT_PO (Page 3565)")
- Calling the "DPWR_DAT (Page 3702)" instruction.

In normal operation, the DP master transfers the output bytes cyclically (within the cycle of the PROFIBUS DP bus) to the outputs of the DP slaves.

If you want to have certain output data (possibly distributed over several slaves) applied to the outputs to the process at exactly the same time, you can send the SYNC control command to the relevant DP master using the "DPSYC_FR" instruction.

What are the effects of SYNC?

With the SYNC control command, the DP slaves of the selected groups are switched to Sync mode. The DP master transfers the current output data and instructs the DP slaves involved to freeze their outputs. With the following output message frames, the DP slaves enter the output data in an internal buffer and the state of the outputs remains unchanged.

Following each SYNC control command, the DP slaves of the selected groups apply the output data of their internal buffer to the outputs on the process.

The outputs are only updated cyclically again when you send the UNSYNC control command using the "DPSYC_FR" instruction.

Note

If the DP slaves of the selected group(s) are not currently connected to the network or have failed when the control command was sent, they will not be switched to SYNC mode. This information will not be communicated in the return value of the instruction.

Reading input data of DP modules

The input data of the DP modules are read as follows:

- Using load commands to the DP I/O
- When the process image of the inputs is updated (by the operating system at the start of OB 1 or by calling the "UPDAT_PI (Page 3562)" instruction)
- By calling the "DPRD_DAT (Page 3700)" instruction.

In normal operation, the DP master receives this input data cyclically (within the cycle of the PROFIBUS DP bus) from its DP slaves and makes them available to the CPU.

If you want to have certain input data (possibly distributed over several slaves) to be read from the process at exactly the same time, send the FREEZE control command to the relevant DP master using the "DPSYC_FR" instruction.

What are the effects of FREEZE?

With the FREEZE control command, the DP slaves involved are switched to Freeze mode. The DP master instructs the DP slaves involved to freeze the current state of the inputs. It then transfers the frozen data to the input area of the CPU.

Following each FREEZE control command, the DP slaves freeze the state of their inputs again.

The DP master receives the current state of the inputs cyclically again after you have sent the UNFREEZE control command with the "DPSYC_FR" instruction.

Note

If the DP slaves of the selected group(s) are not currently connected to the network or have failed when the control command has been sent, they will not be switched to FREEZE mode. This information will not be communicated in the return value of the instruction.

Data consistency

Because the DPSYC_FR functions are asynchronous and can be interrupted by higher priority classes, you should make sure that the process images are consistent with the actual inputs and outputs of the I/O when using the "DPSYC_FR" instruction.

This is guaranteed if you comply with the following consistency rules:

- Define suitable process image partitions for the "SYNC outputs" and the "FREEZE inputs" (only possible on the S7-400). Call the "UPDAT_PO (Page 3565)" instruction immediately before each first call of a SYNC job. Call the "UPDAT_PI (Page 3562)" instruction immediately after the respective last call of a FREEZE job.
- As an alternative: Use only direct I/O access for outputs involved in a SYNC job and for inputs involved in a FREEZE job. Do not write to these outputs when a SYNC job is active and do not read in these inputs when a FREEZE job is active.

Use of DPWR_DAT and DPRD_DAT

If you use the "DPWR_DAT (Page 3702)" instruction, it must be complete before you send a SYNC job for the outputs involved.

If you use the "DPRD_DAT (Page 3700)" instruction, it must be complete before you send a FREEZE job for the inputs involved.

Startup and "DPSYC_FR"

The user alone must take responsibility for sending the SYNC and FREEZE control commands in the startup OBs.

If you want the outputs of one or more groups to be in SYNC mode when the user program starts, you must initialize these outputs during startup and completely execute the "DPSYC_FR" instruction with the SYNC control command.

If you want the inputs of one or more groups to be in FREEZE mode when the user program starts, you must execute the "DPSYC_FR" instruction with the FREEZE control command completely for these inputs during startup.

Parameters

The following table shows the parameters of the "DPSYC_FR" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	Level-triggered control parameter REQ = 1: Triggering of the SYNC/FREEZE job
LADDR	Input	HW_INTERFACE	I, Q, M, D, L or constant	Hardware identifier of the DP master interface The number can be taken from the properties of the DP master interface in the Network view or from the "System constants" tab of the standard tag table.
GROUP	Input	BYTE	I, Q, M, D, L or constant	Group selection Bit 0 = 1: group 1 selected Bit 1 = 1: group 2 selected : Bit 7 = 1: group 8 selected You can select several groups per job. The value B#16#0 is invalid.

Parameter	Declaration	Data type	Memory area	Description
MODE	Input	BYTE	I, Q, M, D, L or constant	Job ID (coding complies with EN 50 170 Volume 2, PROFIBUS) Bit 0: reserved (value 0) Bit 1: reserved (value 0) Bit 2: • = 1: UNFREEZE will be executed • = 0: no meaning Bit 3: • = 1: FREEZE will be executed • = 0: no meaning Bit 4: • = 1: UNSYNC will be executed • = 0: no meaning Bit 5: • = 1: SYNC will be executed • = 0: no meaning Bit 6: reserved (value 0) Bit 7: reserved (value 0) Possible values: • with exactly one ID per job: – B#16#04 (UNFREEZE) – B#16#08 (FREEZE) – B#16#10 (UNSYNC) – B#16#20 (SYNC) • with more than one ID per job: – B#16#14 (UNSYNC, UNFREEZE) – B#16#18 (UNSYNC, FREEZE) – B#16#24 (SYNC, UNFREEZE) – B#16#28 (SYNC, FREEZE)
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. Make sure that you evaluate RET_VAL each time the block has been executed.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY=1: The SYNC/FREEZE job is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

Note

If you access DPV1 slaves, error information of these slaves can be forwarded from the DP master to the instruction. For a description of this error information, refer to STATUS[3], STATUS (Page 3638) parameter.

Error code* (W#16#...)	Explanation
0000	Job completed without error.
7000	First call with REQ= 0: The job specified with LADDR , GROUP and MODE is not active; BUSY has the value "0".
7001	First call with REQ= 1. The job specified with LADDR , GROUP and MODE was triggered; BUSY has the value "1".
7002	Intermediate call (REQ irrelevant). The activated SYNC/FREEZE job is still running; BUSY has the value 1.
8090	The module selected with LADDR is not a DP master.
8093	This instruction is not permitted for the module selected with LADDR (configuration or version of the DP master).
8094	GROUP parameter is incorrect
8095	MODE parameter is incorrect
80A4	Communication on PROFIBUS disrupted.
80B0	The group selected with GROUP is not configured.
80B1	The group selected with GROUP is not assigned to this CPU.
80B2	The SYNC job specified with MODE is not permitted on the group selected with GROUP.
80B3	The FREEZE job specified with MODE is not permitted on the group selected with GROUP .
80C2	Temporary shortage of resources on the DP master: The DP master is currently processing the maximum number of jobs for a CPU.
80C3	This SYNC/UNSYNC job cannot be activated at present because only one SYNC/UNSYNC job can be triggered at a time. Check your user program.
80C4	This FREEZE/UNFREEZE job cannot be activated at present because only one FREEZE/UNFREEZE job can be triggered at a time. Check your user program.
80C5	Short circuit directly at DP interface
80C6	Job aborted due to I/O disconnection by CPU
80C7	Job aborted due to warm or cold restart on the DP master
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

DPNRM_DG: Read diagnostics data from a DP slave (S7-1200, S7-1500)

Description

You use the "DPNRM_DG" instruction to read the current diagnostic data of a DP slave in the form specified in EN 50 170 Volume 2, PROFIBUS.

Refer to the following table for the basic structure of the slave diagnostic data and to the manuals of the DP slaves for further information.

Byte	Meaning
0	Station status 1
1	Station status 2
2	Station status 3
3	Master station number
4	Vendor ID (high byte)
5	Vendor ID (low byte)
6 ...	Additional slave-specific diagnostic information

The data that has been read is entered in the destination area indicated by RECORD following without error data transfer. You start the read process by assigning the value "1" to the REQ input parameter when the "DPNRM_DG" instruction is called.

Functional description

The read process is executed asynchronously. It can span several calls. The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Parameters

The following table shows the parameters of the "DPNRM_DG" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ = 1: Read request
LADDR	Input	HW_DPSLAVE	I, Q, M, D, L or constant	Hardware identifier of the DP slave Note: The identifier must be specified in hexadecimal form. For example, hardware identifier 1022 means: LADDR:=W#16#3FE.
RET_VAL	Return	DINT, INT, LREAL, REAL	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code. If no error has occurred, the length of the data actually transferred is entered in RET_VAL.

Parameter	Declaration	Data type	Memory area	Description
RECORD	Output	VARIANT	I, Q, M, D, L	Destination area for the diagnostic data that were read. Only the data type BYTE is valid. The minimum length of the data record to be read or the destination area is 6. The maximum length of the data record to be read is 240. For standard slaves, which have a diagnostic data length of more than 240 bytes up to a maximum of 244 bytes, the first 240 bytes are transferred to the destination area. Then, the corresponding overflow bit is set in the data.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = 1: The reading process is not yet complete.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

You can find information on data type conversion in the different programming languages under "Overview of data type conversions (Page 2531)".

Parameter RECORD

The CPU evaluates the actual length of the read diagnostic data:

If the length specified for RECORD

- is less than the number of data bytes supplied, the data is discarded. The corresponding error code is entered in RET_VAL.
- is greater than or equal to the number of data bytes supplied, the data is accepted in the destination area and the actual length is entered in RET_VAL as a positive value.

Note

You must ensure that the actual parameters of RECORD correspond in all calls belonging to a job.

A job is uniquely identified by the LADDR input parameter.

Standard slaves with more than 240 bytes of diagnostic data

With standard slaves on which the number of standard diagnostic data is between 241 and 244 bytes, note the following points:

If the length specified for RECORD

- is less than 240 bytes, the data is discarded and the corresponding error code is entered in RET_VAL.
- is greater than or equal to 240 bytes, the first 240 bytes of the standard diagnostic data is transferred to the destination area and the overflow bit is set in the data.

Parameter RET_VAL

- If an error occurred while the function was being executed, the return value contains an error code.
- If no errors have occurred during data transfer, RET_VAL contains the length of the data read in bytes as a positive number.

Note

The amount of data read in a DP slave depends on its diagnostics status.

For the evaluation of the error information of the RET_VAL parameter, refer to the following table.

Error code (W#16#...)	Explanation	Restriction
7000	First call with REQ = 0: No data transfer active; BUSY has the value "0".	-
7001	First call with REQ = 1: Data transfer triggered; BUSY has the value "1".	Distributed I/O
7002	Intermediate call (REQ irrelevant): Data transfer already active; BUSY has the value "1".	Distributed I/O
8090	Address specified at parameter LADDR is invalid.	-
8093	This instruction is not permitted for the module selected by means of LADDR and IOID.	-
80A2	• DP protocol error at layer 2 (for example, slave failure or bus problems) • For ET 200S, data record cannot be read in DPV0 mode.	Distributed I/O
80A3	DP protocol error with user interface/user	Distributed I/O
80A4	Communication on PROFIBUS disrupted.	Distributed I/O
80B0	• Instruction not possible for module type. • The module does not recognize the data record. • Data record number 241 not permitted. • With "WR_REC (Page 3596)", data records 0 and 1 are not permitted.	-
80B1	The length specified in parameter RECORD is incorrect.	specified length < data record length
80B2	The configured slot is not occupied.	-
80B3	Actual module type does not match specified module type	-
80C0	There are no diagnostic data available.	-
80C1	The data of the previous write job on the module for the same data record has not yet been processed by the module.	-
80C2	The module is currently processing the maximum possible number of jobs for a CPU.	-
80C3	The required resources (memory, etc.) are currently occupied.	-

Error code (W#16#...)	Explanation	Restriction
80C4	Internal temporary error. Job could not be executed. Repeat the job. If this error occurs often, check your installation for sources of electrical interference.	-
80C5	Distributed I/O not available.	Distributed I/O
80C6	Data record transfer stopped due to priority class abort (restart or background)	Distributed I/O
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)	-
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".

Overview of data type conversions (Page 2531)

DP_TOPOL: Determine topology for DP master system (S7-1500)

Description

You use the instruction to trigger the topology determination for a selected DP master system. Calling the instruction will address all diagnostics repeaters on a DP master system.

Note

The topology can only be determined for one DP master system at a time.

Topology determination is the prerequisite for the detailed display of the error location if line errors occur. After configuration and after every change to the physical configuration of a DP master system, you must repeat the topology determination with "DP_TOPOL".

Changes to the physical configuration are:

- Changes in line lengths
- Adding or removing stations or components with repeater function
- Changing station addresses

If an error is reported by a diagnostics repeater, "DP_TOPOL" writes the DPR and DPRI outputs for the duration of one "DP_TOPOL pass. If errors are reported by multiple diagnostics repeaters of the selected DP master system, "DP_TOPOL" writes information on the first error-reporting diagnostics repeater to DPR and DPRI . You can read out the entire diagnostic information on the programming device or using the "DPNRM_DG (Page 3715)" instruction. If no diagnostics repeater reports an error, the DPR and DPRI outputs have the value "0".

If you want to repeat a topology determination after an error occurs, you must first reset "DP_TOPOL". This is done by calling "DP_TOPOL" with REQ=0 and R=1.

Functional description

"DP_TOPOL" is an asynchronous instruction. Processing takes place across several calls. You start determining the bus topology by calling "DP_TOPOL" with REQ=1 . If you want to cancel the process, call "DP_TOPOL" with R=1 .

The output parameters RET_VAL and BUSY indicate the status of the job.

See also: Difference between synchronous and asynchronous instructions (Page 2571)

Note

Determining the topology may take several minutes.

Identification of a job

The input parameter DP_ID uniquely specifies a job.

If you call "DP_TOPOL" again before the topology is discovered, the manner in which the instruction reacts depends on whether the new call involves the same job: If the DP_ID parameter matches a job that has not yet been completed, then the call is interpreted as a follow-up call. The value W#16#7002 is entered in RET_VAL. On the other hand, if another job is involved, the CPU rejects it.

Parameters

The following table shows the parameters of the "DP_TOPOL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L or constant	REQ=1: Trigger topology determination
R	Input	BOOL	I, Q, M, D, L or constant	R=1: Cancel topology determination
DP_ID	Input	HW_IOSYSTEM	I, Q, M, D, L or constant	DP master system ID of those master systems for which the topology will be determined
RET_VAL	Return	INT	I, Q, M, D, L	If an error occurs while the instruction is being executed, the return value contains an error code.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY=1: Topology determination is not yet complete.
DPR	Output	BYTE	I, Q, M, D, L	PROFIBUS address of the diagnostics repeater reporting the error.
DPRI	Output	BYTE	I, Q, M, D, L	Measuring segment diagnostics repeater reporting the error: • Bit 0 = 1: Temporary faults on segment DP2 • Bit 1 = 1: Permanent faults on segment DP2 • Bit 4 = 1: Temporary faults on segment DP3 • Bit 5 = 1: Permanent faults on segment DP3

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter RET_VAL

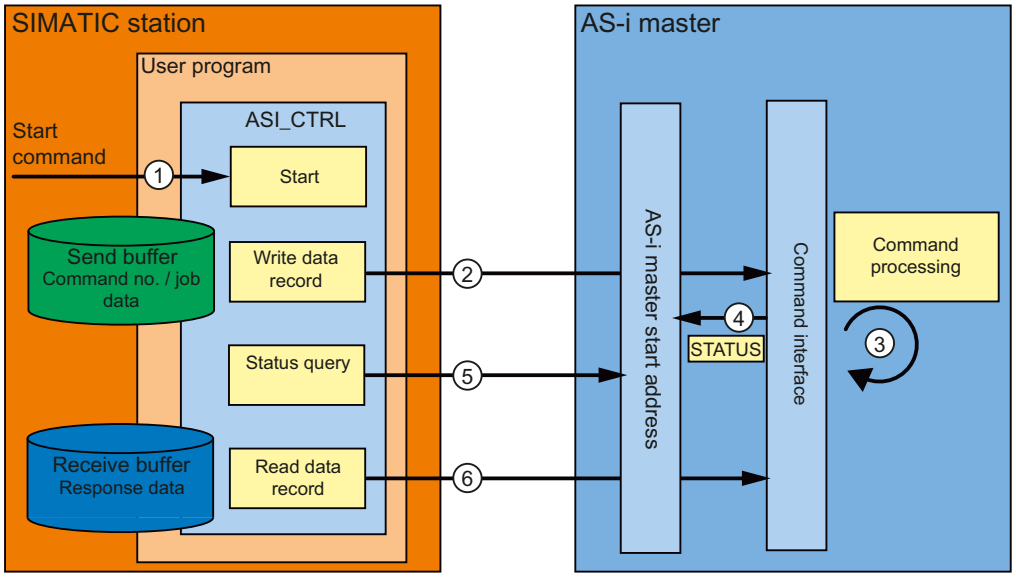
The "real" error information (error codes W#16#8xyz) can be divided into two classes:

- Temporary errors (error codes W#16#80A2 to 80A4, 80C3, 80C5):
  It is possible that this type of error is eliminated without user action. It is advisable to call "DP_TOPOL" again (multiple calls, if necessary).
  Example of a temporary error: Resources required are currently in use (W#16#80C3).
- Permanent errors (error codes W#16#8082, 80B0, 80B2):
  With this error type, you must resolve the error. A new call of "DP_TOPOL" is required once you have eliminated the error. Example of a permanent error: The DP master/CPU does not support this service. (W#16#80B0).

Error code* (W#16#...)	Explanation
0000	Job completed without error.
7000	First call with REQ=0. Topology determination is not triggered. BUSY has the value "0".
7001	First call with REQ=1. The request to execute topology determination was sent. BUSY has the value "1".
7002	Intermediate call (REQ irrelevant): Topology determination is not yet complete. BUSY has the value "1".
7010	You have attempted to cancel topology determination. But there is no running job with the specified DP_ID. BUSY has the value "0".
7011	First call with R=1. The cancellation of the topology determination was triggered. BUSY has the value "1".
7012	Intermediate call: The cancellation of the topology determination is not yet complete. BUSY has the value "1".
7013	Final call: The topology determination was cancelled. BUSY has the value "0".
8082	No DP master system is configured with the specified DP_ID.
80A2	Error during topology determination; for more detailed information, refer to output parameters DPR and DPRI.
80A3	Error during topology determination: Monitoring time has elapsed (timeout).
80A4	Communication on PROFIBUS disrupted.
80B0	The DP master/CPU does not support this service.
80B2	Error during topology determination: No diagnostics repeater was found at the selected DP master system.
80C3	Resources required are currently in use. Possible cause: You have initiated a second topology determination (only one topology determination is permitted at one time).
80C5	The DP master system is currently not available.
General error information	See also: GET_ERR_ID: Get error ID locally (Page 2840)
* The error codes in the program editor are displayed as integer or hexadecimal values. For information on switching the display formats, refer to "See also".	

ASi (S7-1500)

ASI_CTRL: Control AS-i master behavior (S7-1500)



Description of ASI_CTRL (S7-1500)

Description

Using the instruction "ASI_CTRL", the behavior of the AS-i master is controlled from the user program of the PLC. The instruction processes the command protocol automatically. It also enables parameter assignment on SIMATIC AS-i masters and reading out information data. The functions and operation of the command interface are detailed in the manual for the AS-i master.

Both centrally inserted AS-i masters and distributed AS-i masters via PROFIBUS DP are supported. Combinations with PROFINET IO (e.g. IE/PB Link PN IO) are also possible.

The schematic diagram below shows the functions of the "ASI_CTRL" instruction:

① Start of processing at the REQ parameter.

② The program sends the required command to the AS-i master via the instruction "RDREC".

③ The AS-i master processes the command.

④ The current status of the AS-i master is stored in the input area of the binary data (logical start address).

⑤ The instruction "ASI_CTRL" cyclically queries and evaluates the 4 status bits.

⑥ Once command processing is complete, the command job is completed with "RDREC". Depending on the command, the data field of "RDREC" may contain the response data for the command or additional status information.

Dependencies between instruction versions

Version V1.3 of instruction "ASI_CTRL" requires version V1.1 of instruction "WRREC".

Version V1.2 of instruction "ASI_CTRL" requires version V1.1 of instruction "WRREC".

Differences in the command call between IE/ AS-i Link and DP/AS-i Links

There are significant differences in how a controller exchanges commands with an AS-i master.

- **IE/AS-i Link** (PROFINET) used the data record interface. The different commands are called with either "Write data record" ("WRREC" instruction) or "Read data record" ("RDREC" instruction) by various data record numbers.
- **DP/AS-i Links** (PROFIBUS) use the command interface. All commands are called by data record number 2 with "Write data record" ("WRREC" instruction) plus "Read data record" ("RDREC" instruction). The type of command is defined by the data content in the write job.

Operation of the "ASI_CTRL" instruction

The instruction "ASI_CTRL" is an asynchronous function block. Processing takes place across several calls.

- A job is started with REQ = TRUE.
- The job status is displayed via the BUSY output parameters and the two central bytes of the output parameter STATUS.
- The BUSY parameter is set during job processing. Upon the first call, STATUS is assigned the value 00700100_H. Upon all subsequent calls for this job, it is assigned the value 00700200_H. When the job is complete, the result is output at the parameters DONE or ERROR.
  - If no errors have occurred, DONE is set. For jobs with response data from the AS-i master, this data is provided in the specified receive buffer. In such cases, the STATUS parameter also displays the volume of data supplied in bytes. For jobs without response data, the value 00000000_H is entered in STATUS.
  - If an error occurs during job processing, ERROR is set. The content of the receive buffer is invalid in such a case. An error code is entered in the STATUS parameter for a more detailed description of the error which has occurred.

Number of command calls

If you use the instruction "ASI_CTRL" to send commands, you may not simultaneously send other commands to the same AS-i master with "RDREC (Page 3578)" or "WRREC (Page 3596)". This also applies to multiple calls of the instruction for the same AS-i master.

The instruction "ASI_CTRL" cannot be run with interruptions. Calls therefore must not be programmed in program priority classes which interrupt each other (for example with calls in OB 1 and in OB 35).

Parameters

The following table shows the parameters of the "ASI_CTRL" instruction:

Parameter	Declaration	Data type	Memory area	Description
REQ	Input	BOOL	I, Q, M, D, L, constant	REQ = TRUE starts a new job unless a job is already in progress. No edge evaluation takes place.
LADDR	Input	HW_IO	I, Q, M, D, L, constant	Hardware identifier of the AS-i master. You can obtain the address from the module properties.
SD	Input	VARIANT	I, Q, M, D, L	Send buffer The parameter refers to a memory area in which the command is to be specified (see "ASi commands (Page 3725)").
RD	Input	VARIANT	I, Q, M, D, L	Receive buffer This buffer is only relevant for commands which deliver answer data. The parameter refers to a memory area in which a command response is stored (see "ASi commands (Page 3725)").
DONE	Output	BOOL	I, Q, M, D, L	DONE = TRUE: Job completed without errors.
BUSY	Output	BOOL	I, Q, M, D, L	BUSY = TRUE: Job in process.
ERROR	Output	BOOL	I, Q, M, D, L	ERROR = TRUE: Job aborted with error.
STATUS	Output	DWORD	I, Q, M, D, L	Job status / error code See the "STATUS parameter" description.

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Note

LADDR, SD and RD parameters

The parameters LADDR, SD and RD must not be changed in any block cycle when a job is in progress: they must remain constant.

Parameter STATUS

The following table shows the possible STATUS displays dependent upon DONE and ERROR.

DONE	BUSY	ERROR	STATUS	Meaning
0	0	0	00700000_H	First call with REQ = FALSE; no active job.
0	1	0	00700100_H	First call with REQ = TRUE; job has started.
0	1	0	00700200_H	Subsequent call (REQ irrelevant); job is still in progress.
1	0	0	00000000_H	Job completed without errors. No response data.
1	0	0	$0000xx00_H$	Job completed without errors. Number of xx bytes of response data.
0	0	1	$C0818400_H$	Data type of formal operand RD invalid.

DONE	BUSY	ERROR	STATUS	Meaning
0	0	1	C0818500 H	Error in communication with AS-i master (incorrect address configured at the LADDR parameter).
0	0	1	C0838100 H	Incorrect AS-i slave address.
0	0	1	C0838200 H	AS-i slave is not enabled (not in LAS).
0	0	1	C0838300 H	Error at the AS interface (the SD parameter may have been set too small).
0	0	1	C0838400 H	The command is not valid with the current AS-i master status.
0	0	1	C0838500 H	There is an AS-i slave with the address "0".
0	0	1	C0838600 H	The AS-i slave has invalid configuration data (I/O or ID codes).
0	0	1	C083A100 H	The AS-i slave addressed has not been found at the AS interface.
0	0	1	C083A200 H	There is an AS-i slave with the address "0".
0	0	1	C083A300 H	There is already an AS-i slave with the new address at the AS interface.
0	0	1	C083A400 H	The AS-i slave address cannot be deleted.
0	0	1	C083A500 H	The AS-i slave address cannot be set.
0	0	1	C083A600 H	The AS-i slave address cannot be permanently saved.
0	0	1	C083A700 H	Error during reading of the extended ID1 code.
0	0	1	C083A800 H	The target address is not plausible (e.g. a B slave address has been used for a standard slave).
0	0	1	C083B100 H	A length error has occurred during string transfer.
0	0	1	C083B200 H	A protocol error has occurred during string transfer.
0	0	1	C083F800 H	Unknown job number or job parameter.
0	0	1	C083F900 H	The AS-i master has detected an EEPROM error.

ASi commands (S7-1500)

Description

The command interface allows the controller and AS-i master to exchange parameter assignment and information data.

These commands

- provide the complete functionality of the M4 master profile of the AS-i master specifications.
- enable the AS-i master to be completely configured from the controller.

Note

AS-i commands supported

Please see the manual of the relevant AS-i master for the AS-i commands supported and a detailed description.

General structure of the send buffer

The general structure of the send buffer for commands and job data is set out in the table below. The area for the command number must always be filled. The number of bytes for the job data can be found in the description of the command (see AS-i master documentation). In this case, "q" refers to the start address of the send buffer.

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	Meaning							
q + 0	Command number							
q + 1	Job data							
q + 2	Job data							
q + ...	Job data							

General structure of the receive buffer

The general structure of the receive buffer for the command response data is set out in the table below. The number of bytes for the response data depends on the command. Some commands do not return response data, and therefore only require the definition of a virtual receive buffer which is not filled with data. In this case, "n" refers to the start address of the receive buffer.

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	Meaning							
n + 0	Response data							
n + 1	Response data							
n + 2	Response data							
n + ...	Response data							

NOTICE
Memory areas can be overwritten If the receive buffer of the "ASI_CTRL" instruction is too short, neighboring memory areas may be overwritten. The length specified in the ANY pointer of the RD parameter when the instruction "ASI_CTRL" is called is irrelevant. The required length for the receive buffer can be found in the description of the command. The following applies for command numbers 39_H, 41_H, 42_H, 43_H and 44_H: The receive buffer must be 221 bytes long (bytes 0 to 220), even if the command returns less data. Depending on the command, the highest bytes in the receive buffer may be overwritten with zero values by the AS-i master.

AS-i commands

A selection of possible AS-i commands is set out in the table below.

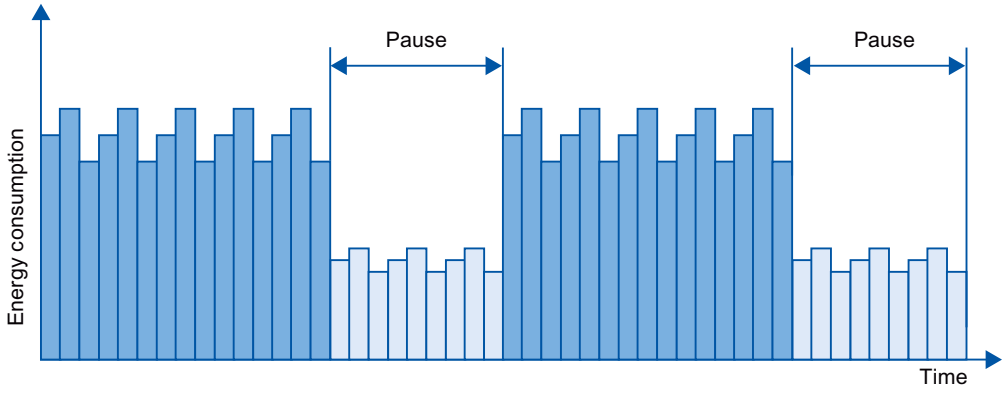
Name	Parameter	Return	Coding
Set_permanent_parameter (Set_Permanent_Parameter)	Slave address, parameter		00_H
Get_permanent_parameter (Get_Permanent_Parameter)	Slave address	Parameter	01_H
Write_parameter (Write_Parameter)	Slave address, parameter	Parameter echo	02_H
Read_parameter (Read_Parameter)	Slave address	Parameter value	03_H
Store_actual_parameters (Store_Actual_Parameters)			04 H
Set_configuration_data	Slave address, configuration		25 H
Get_configuration_data	Slave address	Set configuration data	26 H
Store_actual_configuration (Store_Actual_Configuration)			07_H
Get_actual_configuration	Slave address	Actual configuration data	28_H
Configure_LPS	LPS		29_H
Set_offline_mode	Mode		$0A_H$
Select_auto-program	Mode		$0B_H$
Set_mode	Mode		$0C_H$
Change_AS–iSlave_address (Change_AS–iSlave_Address)	Address1, Address2		$0D_H$
Get_AS-iSlave_status	Slave address	Error record of the AS-i slave	$0F_H$
Read_lists_and_flags		LDS, LAS, LPS, flags	30_H

Name	Parameter	Return	Coding
Get_overall_configuration		Actual configuration data, current parameters, LAS, flags	39 $_H$
Set_overall_configuration	Overall configuration		3A $_H$
Write_parameter_list	Parameter list		3C $_H$
Read_parameter_echo_list		Parameter echo list	33 $_H$
Write_CTT2_request	Slave address CTT2 string	CTT2 string	44 $_H$
Read_version_identifier		Version string	14 $_H$
Read_AS-i_slave	Slave address	ID code	17 $_H$
Read_AS-i_slave_extended_ID1	Slave address	Extended ID1 code	37 $_H$
Write_AS-iSlave_extended_ID1	Extended ID1 code		3F $_H$
Read_AS-iSlave_extended_ID2	Slave address	Extended ID2 code	38 $_H$
Read_AS-iSlave_IO	Slave address	I/O configuration	18 $_H$
Read_I/O_error_list		LPF	3E $_H$
Write_AS–i-slave_parameter_string	Slave address, parameter string		40 $_H$
Read_AS–iSlave_parameter_string	Slave address	Parameter string	41 $_H$
Read_AS-iSlave_ID_string	Slave address	ID string	42 $_H$
Read_AS-iSlave_diagnostic_string	Slave address	Diagnostic string	43 $_H$
Read_AS-i_line_error_counter			4A $_H$
Read_and_clear_AS-i_line_error_counter			4B $_H$
Read_AS-iSlave_error_counter	Slave address		4C $_H$
Read_and_clear_AS-iSlave_error_counter	Slave address		4D $_H$
Additional command for DP/ AS-i F-Link:			
AS–i_status/diag_of_F_slaves		Status/diagnostics of all AS-i safe slaves	51 $_H$

Note

Re-initializing the AS-i master command interface

Another command which is not mentioned in the table is command 77 $_H$. This call serves to re-initialize the command interface of the AS-i master. Any command which the AS-i master specified is currently processing will be terminated.



As of version V2.1.20 of DP/AS-i LINK Advanced, command 0E $_H$ is also available. This call is used to release or block the ground fault monitoring function for a line.

11.4.4.5 PROFIenergy (S7-1200, S7-1500)

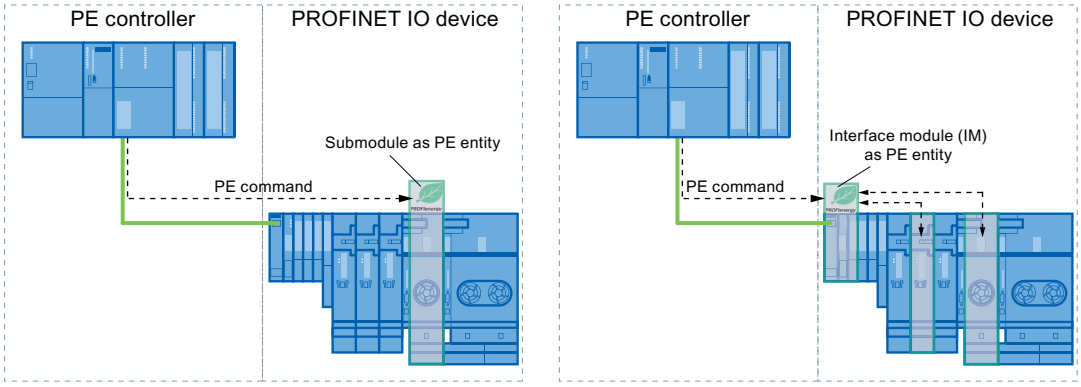
Description of PROFIenergy (S7-1200, S7-1500)

PROFIenergy

PROFIenergy is a manufacturer- and device-neutral profile for energy management with PROFINET. To reduce electricity consumption during breaks in production and unplanned interruptions, it is possible to shut down equipment in a coordinated and centralized manner using PROFIenergy.

The PROFINET devices/power modules are switched off via special commands in the user program of the PROFINET IO controller. No additional hardware is required. The PROFINET devices interpret the PROFIenergy commands directly.

PROFIenergy controller (PE controller)



The PE controller is a PLC that activates or deactivates the idle state of lower-level devices. Specific production components or complete production lines are deactivated and reactivated via the user program. Commands (e.g. "Start_Pause" and "End_Pause") are sent to the lower-level device using corresponding instructions (function blocks). The commands are sent via the PROFINET communication protocol.

PROFIenergy entity (PE entity)

The PE entity receives the PROFIenergy commands of the PE controller and executes these accordingly (for example, by returning a measured value or activating an energy saving mode). Implementation of the PE entity in a PROFIenergy-capable device is device- and manufacturer-specific.

The PE entity can, for example, be executed:

- Within the proxy of a submodule: The PE commands are valid for the addressed submodule and any existing lower-level submodules.
- Within the proxy of a module: The PE commands are valid for different submodules within the module.

- For networked submodules without a proxy function: The PE commands in this case are only valid for the respective submodule.

PROFIenergy instructions

- Instructions for IO controller
  - The "PE_START_END (Page 3730)" instruction represents the simplest way to activate or deactivate the idle state of the PROFINET devices (PROFIenergy commands "Start_Pause" and "End_Pause"). This is done using a positive and negative signal edge in the instruction.
  - The "PE_CMD (Page 3735)" instruction allows you to transmit all PROFIenergy commands, including "Start_Pause" and "End_Pause". With other commands, you can query the current status of the PROFINET devices or the behavior during breaks, for example.
  - The instruction "PE_DS3_Write_ET200S (Page 3740)" is used to define the switching characteristic of up to 8 slots of ET 200S. The instruction is not a PROFIenergy instruction; however, it supplements the PROFIenergy functions for an ET 200S.
- Instruction for iDevices
  The "PE_I_DEV (Page 3765)" instruction allows you to implement PROFIenergy on iDevices as well. The instruction receives PROFIenergy commands on the iDevice and forwards these to the user program for processing. After processing the command, the user program calls the "PE_I_DEV (Page 3765)" instruction again in order to send the acknowledgement to the IO controller. For these replies, each command offers you a corresponding auxiliary block that supplies the response data to the instruction "PE_I_DEV (Page 3765)".

PROFIenergy commands (PE commands)

The PE controller transmits PE commands to the PE entity. The PE command can be either a control command to switch a PE entity to the energy-saving mode, or a command to read a status or measured value:

- PI commands for control
  PROFIenergy supports two control commands that can be executed using either the "PE_Start_End (Page 3730)" instruction or the "PE_CMD (Page 3735)" instruction:
  - Start_Pause: Starting a suitable energy-saving mode (PE Energy-saving mode)
  - End_Pause: Exiting the energy-saving mode (switch to PE_ready_to_operate mode)
- PI commands for reading a status or measured value
  Certain condition information can be read by the control system using the following status commands with the instruction "PE_CMD (Page 3735)":
  - PE_Identify: Reading the list of PE commands supported by the PE entity.
  - PEM_Status: Reading the currently active mode of a PE entity (e.g. PE_ready_to_operate).
  - Query_Modes: Output of an overview of all supported energy-saving modes, including the time and energy information
  - Query_Measurement: Output of the measured values of a PE entity

Example applications

Examples for use of PROFIenergy instructions can be found in the Industry Online Support in the entry "PROFIenergy - Saving Energy with SIMATIC S7 (http://support.automation.siemens.com/WW/view/en/41986454)".

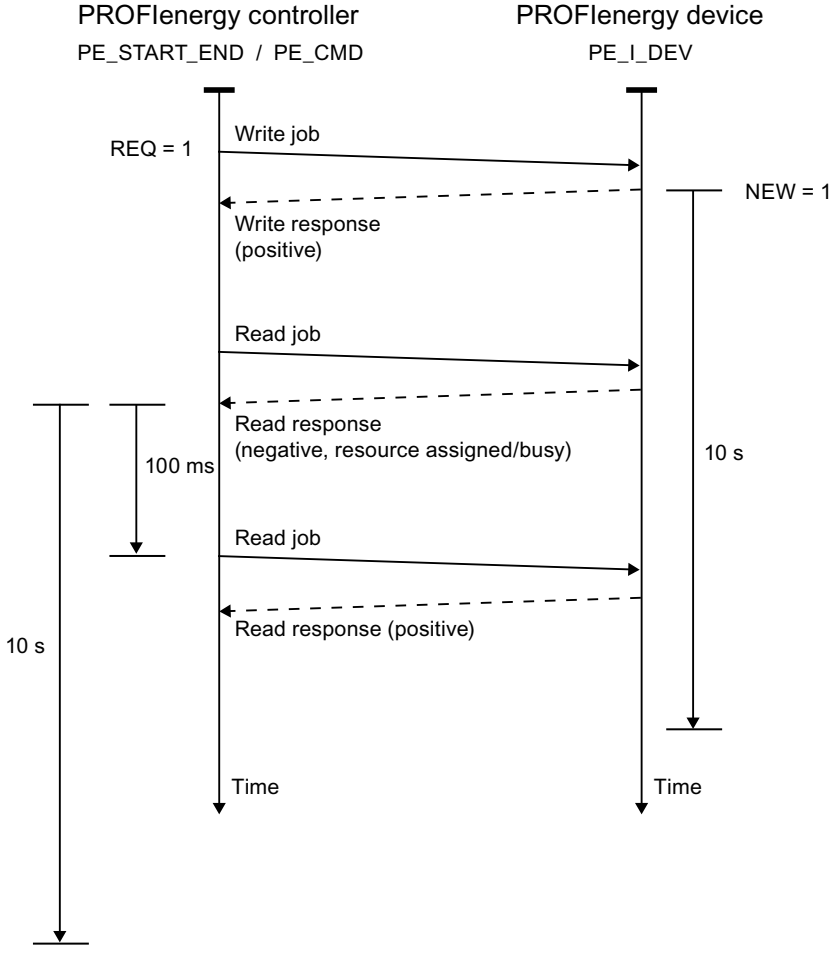
IO controller (S7-1200, S7-1500)

PE_START_END: Start and exit energy-saving mode (S7-1200, S7-1500)

Description

The instruction "PE_START_END" is used to start and exit the energy-saving mode of a specified PE entity (e.g. ET 200S).



The instruction "PE_START_END" is used in the PE controller, preferably when only field devices from which energy data does not need to be read out are connected to the corresponding PE devices. Alternatively, the instruction "PE_CMD (Page 3735)" can be used to read energy data.

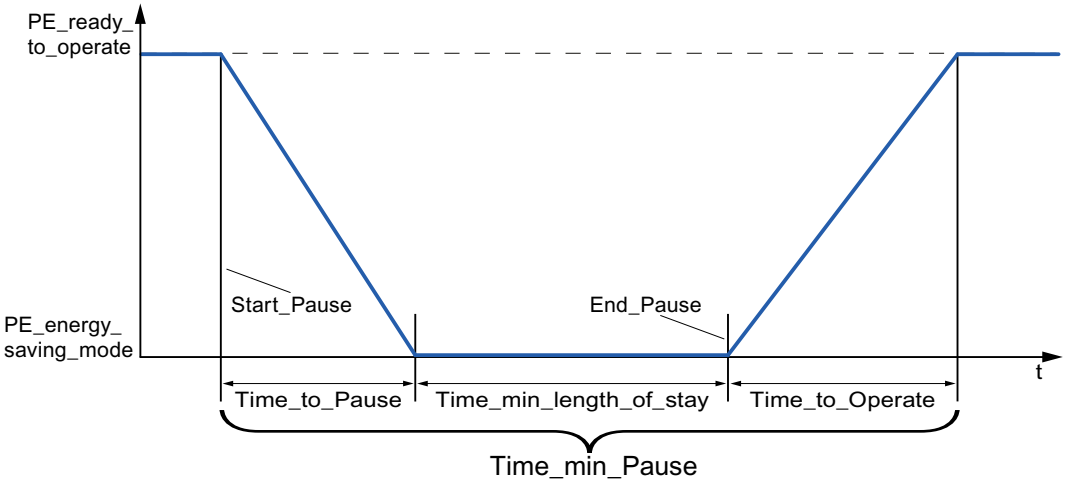
The energy-saving modes are configured in the user program of the PE controller. On completion of the "PE_START_END" instruction, the PE entity reports its current energy-saving mode and outputs this data at parameter PE_MODE_ID.

Write and read jobs of the "PE_START_END" instruction.

The instruction "PE_START_END" sends a PROFIenergy command internally as a write job to the PE entity using "WRREC (Page 3596)". "PE_START_END" then waits for acknowledgment from the PE entity. The acknowledgment data record is read with the instruction "RDREC (Page 3578)" every 100 milliseconds. Until acknowledgment is received from the PE entity, the function repeats the read job for 10 seconds at intervals of 100 milliseconds. The response data of the PE entity is also read with the instruction "RDREC (Page 3578)".

Below is a flowchart of the write and read jobs:

Parameter



The following table shows the parameters of the "PE_START_END" instruction:

Parameter	Declaration	Data type	Memory area	Description
START	Input	BOOL	I, Q, M, D, L or constant	Transmitting the PE command "Start_Pause" to the PE entity with the address set at parameter ID.
END	Input	BOOL	I, Q, M, D, L or constant	Transmitting the PE command "End_Pause" to the PE entity with the address set at parameter ID.
ID	Input	HW_SUBMODULE	I, Q, M, D, L or constant	Address of the PE entity Use the hardware ID of the head module for a PROFINET IO device. Refer to the system constants of the assigned IO controller for the hardware ID. The name of the head module is composed of the name of the IO device and the suffix [Head] (example: "IO_Device_1[Head]"). If the PE entity is an I-device, use the hardware identifier of a transfer area instead.
PAUSE_TIME	Input	TIME	I, Q, M, D, L, P or constant	Planned pause duration. • Range: T#1MS to T#24D20H31M23S647MS • Start value: T#0MS
VALID	Output	BOOL	I, Q, M, D, L	PE command successfully sent.
BUSY	Output	BOOL	I, Q, M, D, L	PE command still being processed.
ERROR	Output	BOOL	I, Q, M, D, L	Error occurred during processing. The error message is output at the STATUS parameter.
STATUS	Output	DWORD	I, Q, M, D, L, P	Block status / error number (see "STATUS parameter")
PE_MODE_ID	Output	BYTE	I, Q, M, D, L, P	Identification number of energy-saving mode (energy-saving level for the duration of the pause).

You can find additional information on valid data types under "Overview of the valid data types (Page 2239)".

Parameter PAUSE_TIME

The parameter PAUSE_TIME is used to set the default duration of the energy-saving period at the PE entity. The PE entity checks whether the pause period is of sufficient length and whether it can be implemented. The minimum pause duration (Time_min_Pause) must be greater than the sum of the times the device needs to switch to energy-saving mode (Time_to_Pause) and to switch back to operating mode (Time_to_Operate).

ET 200S checks whether the scheduled pause duration is greater than or equal to the minimum pause duration (PM-E_Pause_Min) saved on the ET 200S. This is fixed at 10 seconds. If a shorter pause is used, the power modules (PM-E) of the ET 200S will remain on.

The module does not switch back on automatically at the end of the pause; it remains in OFF mode until the "END" command is sent. This prevents uncoordinated switch-on, which can cause undesired peak loads.

Parameter STATUS

Error information is output at the STATUS output parameter. If it is interpreted as ARRAY[1...4] of BYTE, the error information has the following structure:

Field element	Name	Meaning
STATUS[1]	Function_Num	Cause of the error • B#16#**00**: No error • B#16#**DE**: Error while reading the data record • B#16#**DF**: Error while writing the data record • B#16#**C0**: Error message caused by the instruction or the communication instructions "RDREC (Page 3578)" and "WRREC (Page 3596)" used internally.
STATUS[2]	Error_Decode	Location of the error ID • **80**: DPV1 error as defined in IEC 61158-6 or application-specific • **FE**: DP/PNIO profiles - PROFIenergy-specific error

Field element	Name	Meaning
